Comment 1.6.1. This comment, which is about the "average highway conditions" along potential spent nuclear fuel shipping routes, has been largely resolved by incorporating the Sprung et al. (DIRS 152476-2000) accident model into the transportation impact analysis. The analysts evaluated shipping cask performance under 190-kilometer (120-mile)-per-hour impact conditions onto an unyielding surface. A shipping cask would need to free-fall a great distance to strike a surface at 190 kilometers (120 miles) per hour. Finite element analyses of the truck cask designs did not predict with certainty that a 190-kilometer impact onto an unyielding surface would produce seal leakage. For rail cask designs, Sprung et al. (2000) predicted seal leakage to occur for 97-kilometer (60-mile)-per-hour impact events onto unyielding surfaces, equivalent to a freefall from about 37 meters (120 feet). When "real-world" surfaces are assumed, the impact velocities (and thus the approximate freefall distances) that are required to cause cask seal leakage increase substantially. For this reason, the probability that such impact velocities are achieved is extremely small leading to the conclusion that the occurrence of such an accident is not reasonably foreseeable.

Comment 1.6.2. This comment is similar to 1.6.1 above except it addresses rail casks falling from high bridges. The same response applies.

Comment 1.6.3. The National Environmental Policy Act requires assessment of reasonably foreseeable impacts from proposed agency actions. In its various EISs, DOE has defined a reasonably foreseeable accident as one that has a frequency of occurrence of at least once in 10 million years (1×10^{-7} per year).

Consistent with the National Environmental Policy Act and DOE practice, the EIS conducts two analyses of transportation accident impacts, the maximum reasonably foreseeable accident assessment and the probabilistic risk assessment. The probabilistic risk assessment, conducted using the RADTRAN 5 computer code, considers the entire spectrum of accidents, including those worst-case accidents that are less likely than once in 10 million years. The computer code evaluates the probabilities of accidents and their consequences, combines the probability and consequence information to calculate risk values, and then sums the risk values across the entire spectrum. In the probabilistic risk assessment, the once-per-10-million-year frequency criterion is not employed to truncate the analysis, as the commenter suggests. However, it is true that the extremely unlikely accident scenarios (that is, those with frequencies less than once per 10 million years, do not contribute significantly to the total integrated risk. Although the consequences of these extremely unlikely accidents would be large, their frequencies would be so small that their risk values, which are the products of their frequencies and consequences, would be small in relation to the risk of more frequent but less severe accidents.

The probabilistic risk assessment is different than the maximum reasonably foreseeable accident analysis. In the analysis of the consequences of the maximum reasonably foreseeable accident, the results are presented in terms of the maximum consequences to the population and maximally exposed individual potentially affected by the accident. Only the consequences of such accidents are presented; that is, the combining of the frequency and consequence terms to develop a risk value is not performed in the maximum reasonably foreseeable accident analysis.

In the analysis of the maximum reasonably foreseeable accident, the EIS considered accident scenarios with frequencies less than once per 10 million years. These accidents are not reasonably foreseeable, but the consequences of these accidents are listed in Tables J-22 and J-23 of the EIS.

Comment 1.6.4. DOE is aware that there are uncertainties associated with the transportation impact results presented in the EIS. There are uncertainties associated with route characteristics, demographics, weather, atmospheric dispersion models, spent nuclear fuel characteristics, accident rates, release fractions, and many other elements of the risk assessments. Because one of DOE's goals is to choose between alternatives, the consistent consideration of uncertainty among alternatives means that the relative differences in impact estimates among alternatives should not be affected. To account for uncertainties in the data, conservative assumptions were made so the impacts reported in the EIS would bound the potential impacts; would produce results that are higher than the true risk. However, DOE has chosen not to use conservative assumptions in all cases, as this practice tends to produce unrealistic and improbable results. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing environmental impacts. Such practices mask the real differences and would not produce suitable results to support choices among the alternatives. Similarly, presenting ranges of impacts, as the commenter suggests, would also mask the true differences between alternatives. It would provide misleading information and lend credibility to accident scenarios that are clearly insignificant contributors to the true risks of transporting spent nuclear fuel and high-level to the proposed repository. Presentation of ranges of impacts would require complex and confusing explanations of how the ranges were calculated and their significance. This would be contrary to one purpose of an EIS, which is to provide clear and concise information to the public about the environmental impacts of proposed agency actions. Therefore, the EIS concentrates on developing point estimates with approximately equal levels of conservatism and uncertainty so valid comparisons among alternatives can be made.

Comment 1.6.5. The transportation impact analysis in the EIS, including the analysis of maximum reasonably foreseeable accidents, is consistent with National Environmental Policy Act requirements, Council on Environmental Quality Guidelines, and DOE policies and procedures. The analysis of reasonably foreseeable accidents is based on the best data available to DOE, considers the designs of current generation shipping casks, uses appropriate accident probability distributions and estimation techniques, and is more comprehensive in scope and level of detail than the transportation impact analyses in most other EISs prepared by Federal agencies. The analysis in the EIS has been revised to reflect the recently published reanalysis of spent nuclear fuel shipment risks (see DIRS 152476-Sprung et al. 2000), which updates the accident risk model developed in Fischer et al. (DIRS 101828-2000). The methods used to calculate transportation impacts are state-of-the-art. As a consequence, DOE believes the scope, level of detail, and basis for the transportation impact analysis are consistent with all National Environmental Policy Act-related requirments and that the EIS adequately analyzes potential impacts of the Proposed Action and certain aspects of transportation.

Comment - EIS000306 / 0006
Your estimates do not suggest the temperature that a diesel fire causes, and it would burn more than the half hour that you suggest.

Response
As discussed in Appendixes J and M, most real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask into a river, and similar extreme accident conditions, would not likely result in release of radioactive materials from the shipping casks. The performance standards for the casks prescribed by the Nuclear Regulatory Commission were selected to ensure that less than one percent of real-world accidents would result in loss of cask integrity and release of radioactivity from the cask. These standards ensure that the casks would be extremely robust.

As stated in Section J.1.4.2.1 of the EIS, the temperature of the fully engulfing fire was assumed to range from 750ºC (1,350ºF) to 1,000ºC (1,800ºF). Truck fires were assumed to burn for up to 8 hours and train fires were assumed to burn for up to 11 hours. More details on fire duration and temperature can be found in the Nuclear Regulatory Commission study *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000).

8.10 (8471)
Comment - EIS000817 / 0143
P. 6-29. You are basing some of this on a 1987 study by Fischer. That is just too outdated. The Nuclear Waste Project comments are valid. It's not up to them to do your studies for you, only to comment on what you do. There should be tests to benchmark computer models. All too often this is not done correctly.

Response
The EIS has been revised to use the release fractions and conditional probabilities from *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Benchmarking of the finite element code used in the analysis is discussed in Section 5.1.5 of that study. The changes from using the data from Sprung et al. (2000) are that radiation risk for rail and truck accidents are lower, radiation impacts for incident-free truck transportation are lower, and consequences of severe accidents are higher. These results are included in Chapter 6 of the EIS.

8.10 (8607)
Comment - EIS001837 / 0009
What if the narrow railroad bridge across the Colorado River adjacent to the Federal Wildlife Preserve, collapses under the weight of the heavy high level nuclear waste shipments? Your DEIS is inadequate and deficient because it does not address the issue of reinforcing that bridge or cleaning up potential spills into the Colorado River, or how to prevent attacks on that bridge. What is the contingency plan if the train derails on the bridge or the casks fall into the Colorado River and destroys the drinking water of millions of people?

Response
Adequate national highways, rail lines, crossings, bridges, and tunnels exist to support the transportation of materials described in the EIS. The shipment of radioactive materials requires no special transportation infrastructure that is not necessary for safe transport of commodities in the United States today. The U.S. Department of Transportation is the regulatory agency responsible for establishing and enforcing the standards for the transportation infrastructure.

The precise location, timing, prevailing weather conditions, and other circumstances surrounding a transportation accident cannot be predicted. In addition, it would not be practical for the EIS to attempt to analyze accident consequences for every location along the shipping route. Instead, maximum consequences are analyzed for three types of population zones: urban, suburban, and rural. For example, an accident in the Las Vegas area would be characterized by the analysis for an urban area. Table J-24 shows consequences of maximum reasonably foreseeable truck and rail accidents in urbanized and rural areas.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

The EIS does not specifically analyze a transportation accident involving contamination of surface water or groundwater. Analyses performed in previous EISs (see Section 1.5.3 and Table 1-1 of this EIS) have consistently shown that the airborne pathway has the greatest potential for exposing large numbers of people to radioactive material in the event of a release of radioactive materials during a severe transportation accident. An analysis of the potential importance of water pathway contamination for spent nuclear fuel transportation accident risk using a worst-case water contamination scenario (DIRS 157052-Ostmeyer 1986) showed that the impacts of the water contamination scenario were about one-fiftieth of the impacts of a comparable accident in an urban area.

8.10 (8746)

Comment - EIS001907 / 0008

One area of concern in nuclear waste transportation is the exposure of waste handlers, drivers and the general public to radiation even during routine (non-accident) conditions. Even though shipping containers are shielded and designed to reduce exposures to radiation being emitted by the spent fuel or high-level waste, federal regulations allow a low level of radiation to emanate from the casks. As we all know, even low-levels of radiation have adverse health effects.

Even after ten years of cooling, spent nuclear fuel emits dangerous levels of gamma and neutron radiation. A person standing one yard away from an unshielded spent fuel assembly could receive a lethal dose of radiation in less than three minutes. The surface dose rate of spent fuel is so great (10,000 rem/hour or more), that shipping containers with enough shielding to completely contain all emissions would be too heavy to transport economically.

Federal regulations allow shipping casks to nuke the public at about 10 millirems/hour at 2 meters from the cask. What happens to the driver? Does a standard driver then get 100 millirems per ten hours driving? Routine exposures become especially problematic in situations where the transport vehicle is caught in heavy traffic with cars and other vehicles in close proximity for extended periods. Routine exposures also are of concern when the cask vehicle is stopped for repair, fueling, inspections, etc. Were the cumulative health impacts to toll booth workers taken into effect? What about gas station attendants? Were these people even notified about this hazard passing through their work areas? Does that violate Occupational Safety and Health Standards?

Response

Chapter 6 of the EIS presents DOE's evaluation of public health and safety consequences of routine, incident-free transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. The analyses used the RADTRAN 5 computer program in estimating exposure of members of the public who would live near shipment routes to low-level ionizing radiation from the shipments. The estimates include impacts to maximally exposed individuals who are postulated to live or work along or near routes where shipments would pass, including a person stuck in a traffic jam next to a shipment, person at a service station, railyard crew members, inspectors, and escorts. The results of these analyses are presented in Tables 6-9 and 6-12 for the national mostly legal-weight truck and mostly rail scenarios, respectively.

The impacts to maximally exposed individuals in the general public would be very low. For comparison purposes, the rate of exposure for a chest X-ray would be about 10,000 times greater than the rate of exposure of a maximally exposed individual 6 meters (20 feet) from a cask. This individual would need to be 6 meters from a shipment for 3 hours to receive the same dose from a chest X-ray that occurs in about 1 second. These radiation doses are low and would not be expected to result in any health effects and are well within regulations promulgated by the Nuclear Regulatory Commission. The Occupational Health and Safety Administration does not have jurisdiction over radiation safety. To the maximum practical extent, DOE would ensure that transport operations were conducted to reduce dose to members of the public to levels below those permitted by regulations.

The commenter was concerned about the radiation doses to truck drivers. U.S. Department of Transportation regulations limit the radiation dose rate in normally occupied areas of the vehicles to 2 millirem per hour (see 49 CFR 173.441) unless the carriers operate under an approved radiation protection program and crews wear personal radiation dosimeters. This regulation has been in force for decades and has provided adequate protection to truck drivers from the very low levels of radiation emitted by the shipping casks. In addition, annual exposure limits are applicable to truck drivers. As stated in Table 6-6 of the EIS, crew members were assumed to be limited to an 800-millirem radiation dose. Over 24 years, this would result in an individual exposure of 12 rem, which represents a slightly increased probability (0.005) of latent cancer fatality.

With respect to the comment that low levels of radiation have adverse health effects, on average, members of the public are exposed to approximately 360 millirem per year from natural and manmade radiation sources. This amounts to about 8,640 millirem (8.6 rem) for the 24 years of operation for the proposed shipments. Approximately 80 percent of this is a result of natural sources, such as radon in homes and buildings and terrestrial radiation from rocks and soil. Figure F-1 of the EIS shows the relative contributions by radiation sources to people living in the United States. The maximum individual resident along the route of the proposed shipments would receive about 5.4 millirem (0.0054 rem) over the 24 years of operation. Thus, the increase in exposure to radiation for this person as a result of the proposed shipments would be about 0.0625 percent. This small exposure would not be expected to result in life-shortening or any other detrimental health effect. Additional background information on human health effects from exposures to radioactive and toxic materials is presented in Appendix F of the EIS.

8.10 (8822)

Comment - EIS002082 / 0003

And one thing, too with Yucca Mountain, and there's all the garbage, garbage going up to Yucca Mountain and the truck spills some kind of dirt over. They stopped the truck right there. I don't know what they done after that.

Response

DOE does not plan on shipping radiologically contaminated dirt to the proposed Yucca Mountain Repository. Chapter 6 and Appendix J of the EIS discuss accidents involving spent nuclear fuel, which does not resemble dirt.

8.10 (8956)

Comment - EIS001040 / 0005

According to DOE Document DE-ACO4-84A-25747 "These Wastes Have a Potential for Causing Great Harm." They are thermally hot (250,000 BTUS/Hour) and highly radioactive. A ruptured cask either in transport or in the dump would be a major environmental disaster that could contaminate a large area. The recent disaster in Japan would be nothing compared to a breach of containment.

Response

An accident that could rupture a cask during transport and contaminate a large area is an extremely unlikely occurrence. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there could be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

8.10 (8957)

Comment - EIS001040 / 0006

In the NRC's [Nuclear Regulatory Commission's] Final Environmental Statement for the Callaway Plant NUREG-75/011 Section 5-11 states that during normal transport (without an accident 601,100 people would be exposed to gamma radiation due to transport of one shipment.

Response

The exposed populations from truck and rail shipments of spent nuclear fuel and high-level radioactive waste are discussed in Sections 6.2.3.1 and 6.2.3.2 of the EIS. For legal-weight truck shipments, the exposed population within 0.8 kilometer (0.5 mile) of the roads was about 10 million and for rail shipments, the exposed population within 0.8 kilometer of the railroads was about 16 million over the 24 years of operation.

8.10 (9057)

Comment - EIS001866 / 0009

All existing casks for the transport of waste emit some level of radiation. Casks can be licensed and used if they pass required tests and do not exceed emission limits when inspected. It is assumed that exposures to individuals, at these allowable levels, will not be harmful. When dose and exposure limits are analyzed, and justification for safety decisions explained, the implication is that the exposures are single incidents. There is no consensus regarding health effects and other adverse consequences of single low dose of radiation. However it is increasingly evident that multiple exposures pose multiple risks and that cumulative exposures increase the risk burden.

Response

In the EIS transportation analyses, the typical assumption is that radiation doses are for multiple exposures, not single exposures. For example, in Table 6-9 in Section 6.2.3.1 of the EIS, the radiation dose to residents along the route, a person at a service station, and a resident near a rail stop are for exposures to multiple shipments. For cases such as exposure of a person in a traffic jam, it is unlikely that a person would be exposed more than once and the radiation dose is based on exposure to a single shipment.

DOE recognizes that, although studied extensively for over 75 years, there is still much that is not understood about effects related to exposure to low level radiation. However, the Department is not aware of any substantial, peer-reviewed literature that indicates disproportionate harm associated with exposure to low-level radiation.

Because of uncertainties in the low-dose/dose-region of the dose effect curve, DOE has selected, for use in the EIS, dose-to-risk factors recommended by the National Council on Radiation Protection and Measurements (DIRS 101856-NCRP 1993) and the International Commission on Radiological Protection (DIRS 101836-ICRP 1991) for estimating the risk of latent cancer fatality from exposure to ionizing radiation. These factors were developed based on the linear no-threshold hypothesis, which assumes that adverse health effects could occur from exposure to ionizing radiation regardless of how small the dose.

DOE, as well as national and international scientific advisory organizations such as the Federal Radiation Council, the International Commission on Radiation Protection (DIRS 147927-ICRP 1966), the National Council on Radiation Protection and Measurements (DIRS 101857-NCRP 1993), the National Academy of Sciences/National Research Council Committee on the Biological Effects of Ionizing Radiation (BEIR V) (DIRS 100473-National Research Council, 1990), and the National Academy of Sciences/National Research Council Committee on an Assessment of Centers for Disease Control Radiation Studies (DIRS 154539-National Research Council 1995), have recognized for many years that the use of dose-to-risk conversion factors based on the linear no-threshold hypothesis to estimate stochastic effects (such as latent cancer fatalities) from very low exposures to ionizing radiation can overestimate the actual risk. These organizations have been careful to point out over the years that the use of the risk factors derived using the linear no-threshold hypothesis will provide reasonable assurance the actual effect will not be underestimated. For these reasons, the linear no-threshold hypothesis has been accepted for use by Federal agencies—including DOE, the Environmental Protection Agency, and the Nuclear Regulatory Commission—for radiation protection and for estimating risk from exposure to ionizing radiation. Until such time as these advisory committees change their acceptance of the linear no-threshold hypothesis and the Federal agencies agree that these changes should be incorporated, DOE will continue to use risk factors recommended by the national and international advisory groups that are based on the linear no-threshold hypothesis.

Comment - EIS001641 / 0004
Shipments by rail are more dangerous as there have been several catastrophic train accidents in the Cajon Pass in recent years.

Response
Chapter 6 of the EIS discusses the transportation impacts of shipping spent nuclear fuel and high-level radioactive waste to the repository. Over a 24-year shipping campaign, the EIS estimates that there could be about 17 fatalities if mostly trucks were used and about 10 fatalities if mostly trains were used. The analyses in the EIS show that the impacts of transporting spent nuclear fuel and high-level radioactive waste are low for both modes and do not provide a distinguishing basis for choosing a transport mode.

8.10 (9538)
Comment - EIS001888 / 0199
[Summary of comments noted by Clark County Nuclear Waste Division staff at various citizens' meetings.]

Hopeful that DOE would consider trucking impacts that were not really considered - "there will be accidents."

Response
The comment was not specific about trucking impacts the EIS did not consider. Chapter 6 and Appendix J of the EIS evaluate the impacts of shipping spent nuclear fuel and high-level radioactive waste by truck. Impacts of routine truck shipments would include radiological impacts from low-level radiation outside the shipping casks and nonradiological impacts from normal vehicle emissions. The EIS evaluates transportation accidents in terms of (1) radiological impacts from accidental releases of radioactivity, and (2) traffic fatalities.

8.10 (9580)
Comment - EIS001888 / 0254
This unprecedented high level of handling activity has never taken place before. Handling at an intermodal facility is just as problematic. There is no accident or incident data describing likely accidents handling spent fuel at intermodal facilities. A major cause of concern is the use of historical accident rates to describe the risks of a roadway not yet constructed. The DEIS assumes that the mostly truck alternative will use Clark County's northern and western beltways to transport spent fuel. These roads have not yet been constructed and there is no empirical data about accidents on these roadways.

Response
Appendix J of the EIS documents the methodology used for analysis of accidents that could occur during handling of spent nuclear fuel shipping casks at intermodal facilities. The analysis considered external initiating events (for example, seismic events, aircraft crash) and internal initiating events (for example, dropping a cask during transfer). Extensive empirical data exists regarding the design standards of the casks and the ability of the casks to maintain their integrity under a variety of accident conditions. The analyses performed for the EIS found no credible accidents with the potential for radioactive release at an intermodal transfer station.

The EIS uses accident rates for roadways based on state-specific rates of accidents involving interstate-registered combination trucks for 1994, 1995, and 1996. As the commenter points out, accident rates for new roadways that have not yet been constructed cannot be used in the analysis. However, new roadways would be constructed in accordance to state and U.S. Department of Transportation standards, and the accident rates for new roadways would not be expected to be greater than the rates for existing roadways.

8.10 (9722)
Comment - EIS002149 / 0002
Another issue I'd like to address is the transportation one very briefly. There are three things that are really important in this transportation problem. There's the testing we've heard about. There's real live accident scenarios, which we don't hear about too much and you don't really hear about them very much in this thing at all, and then there's the models which we hear a lot about. These three are three pieces that have to be connected, and to me and to Citizen Alert that the analysis, the risk analysis in this document, the transportation analysis is not complete unless those three concepts are connected.

How do the tests that we keep hearing about connect to real world accidents? That needs to be connected for people to understand. How do the models connect to real world accidents and the tests? That needs to be connected for people to understand the impacts. That is the responsibility of our federal agencies, the DOE and the NRC [Nuclear Regulatory Commission], and though that connection has not been made.

Response
Regulatory test conditions for Type B packages, such as spent nuclear fuel shipping casks, were developed about 40 years ago. The intent was to establish a set of laboratory test conditions that would provide consistent and reproducible results for package testing. Although they were originally derived from examining stresses from various types of severe accidents, they are not intended to simulate actual transportation accident scenarios. Rather, the package tests are intended to represent the actual stresses that could be imposed on a package during a severe accident. The logic behind this approach is that if a package is capable of withstanding the Type B package tests (see the hypothetical accident conditions defined in 10 CFR 71.73 and described in the EIS, Section M.4) without serious leakage, they could withstand most real accidents without major rupture or large release of the contents.

Part of the difficulty in designing the Type B package tests was reproducibility. The developers recognized they could not design tests that simulate real accidents because of large variability in the environment in which the accidents could occur. For example, they could have specified a test consisting of a 97-kilometer (60-mile)-per-hour impact into a real surface, such as rock or soil. However, the physical properties of rock and soil are variable from location to location, so the energy-absorbing characteristics of the surface affected by the shipping cask had to be specified for the tests to be reproducible. The test developers decided to specify an "unyielding" surface, which is easily modeled even though it does not exist in nature. The use of an unyielding surface means that all of the mechanical energy of a collision is absorbed by the shipping cask; that is, none of the energy is absorbed by the affected surface. The use of an unyielding surface results in greater package damage than a real surface, such as other vehicles, rocks, etc., because real surfaces crush and thus absorb some of the impact energy. The test developers followed similar processes to arrive at puncture, thermal, and immersion test specifications. Based on information available to the test developers, they were confident that the Type B package tests they specified would encompass the vast majority of real accidents.

Licensing (or certification) of Type B shipping casks requires the approval of the Nuclear Regulatory Commission. An applicant submits detailed designs and safety analyses of the shipping cask to the Commission in a Safety Analysis Report for Packaging (SARP). The SARP contains, among other things, an evaluation of the effects of the Type B package tests on the shipping cask. The performance of the shipping cask under the Type B package test conditions can be evaluated using detailed computer codes and models that have been developed and improved over many years. Full-scale and half- or quarter-scale testing has been conducted to validate the predictions made by the computer models. In other words, predictions of package damage made by the computer codes have been compared to the actual damage produced in scale model testing and the computer codes have been determined to accurately predict package performance. Based on this experience, DOE and the Nuclear Regulatory Commission are confident that the computer codes and models used to demonstrate compliance with the Type B packaging requirements effectively and accurately predict the performance of the shipping casks when subjected to the Type B test conditions. Furthermore, successful demonstration of package performance under the Type B test conditions provides assurance that the package is capable of withstanding the vast majority of real transportation accidents.

8.10 (9936)
Comment - EIS001732 / 0010
During the Three Mile Island shipments there was an accident on the very same highly-inspected and maintained train tracks. Luckily, the accident did not involve the TMI shipment. The accident sticks in my mind because it was in a very hard to reach area that was also close to highly populated communities. The accident involved train cars hanging suspended off of a train trestle over a river. We do have rivers in Missouri. How many hours they hung there while [a] high-intensity, long-duration fire blazed beneath them while the emergency personnel struggled to get there, which severely delayed their response time.

What dangers would this type of accident present if the train cars were carrying casks containing high-level radioactive waste from nuclear reactors nation-wide?

Response
In the severe transportation accidents analyzed in the EIS, fully engulfing fires were analyzed. This means that the cask was assumed to be at the center of the fire, were the amount of heat transferred to the cask would be the greatest. At other locations, such as the cask dangling above the fire, the amount of heat transferred to the cask would be less and therefore, the amount of damage to the cask would also be less. Therefore, the consequences of the type of accident described by the commenter would be less than the consequences of the severe transportation accidents presented in the EIS.

The consequences of these severe accidents are presented in Sections 6.2.4.2.1 and 6.2.4.2.2 of the EIS, for truck and rail transportation, respectively. For a maximum reasonably foreseeable truck accident analyzed in the EIS, the estimated probability is about 2.3 in 10 million per year. The consequences of these accidents are presented in Section 6.2.4.2.

Comment - EIS001888 / 0516
[Clark County summary of comments it has received from the public.]

Collateral Risk is sum of risks posed by activities effecting shipment. Example, 8% of County roads undergoing construction at any one time. Accidents go up significantly around construction. Some routes have high frequency of construction must include.

Response
DOE is aware of the U.S. Department of Transportation and state transportation agencies current emphasis on reducing traffic accidents in highway work zones. A review of work zone crash data available from the U.S. Department of Transportation indicated that the number of fatalities in work zone accidents nationally have

been relatively stable since 1980. In addition, fatalities in work zones were included in the accident data used in the EIS.

Use of accident data specific to work zones such as the commenter suggests would not materially affect the comparisons of alternatives and decisions to be made with regard to construction and operation of the proposed repository. The requested information could provide useful information for identifying and quantifying differences between alternative routes; however, DOE does not intend to designate preferred routes based on the EIS. Rather, this would occur in the future, and would be conducted in accordance with U.S. Department of Transportation routing guidelines. The preferred routes would be submitted to the U.S. Nuclear Regulatory Commission for approval. DOE would consider location-specific accident data during the route selection process. Furthermore, preshipment planning activities described in Section M.3.2 of the EIS would identify work zones on preferred highway routes and they would be avoided entirely by using an alternative preferred route, if possible, be accessed at times when traffic volumes are low, or wait in a safe parking area until heavy traffic clears. This would not always be possible due to the limited routing options available but would reduce the potential for accidents in work zones involving spent nuclear fuel and high-level radioactive waste shipments to the proposed repository.

Comment - EIS001888 / 0536
[Clark County summary of comments it has received from the public.]

Clark County is in early stages of 10 year transportation improvement project. This results in increased accident risk this must be considered.

Response
The commenter appears to be concerned about potential transportation accidents in work zones. DOE is aware of the U.S. Department of Transportation and state transportation agencies current emphasis on reducing traffic accidents in highway work zones. A review of work zone crash data available from the Department of Transportation indicated that the number of fatalities in work zone accidents nationally have been relatively stable since 1980. In addition, fatalities in work zones were included in the accident data used in the EIS.

Use of accident data specific to work zones such as the commenter suggests would not materially affect the comparisons of alternatives and decisions to be made with regard to construction and operation of the proposed repository. The requested information could provide useful information for identifying and quantifying differences between alternative routes; however, DOE does not intend to designate preferred routes based on the EIS. Rather, this would occur in the future, and would be conducted in accordance with U.S. Department of Transportation routing guidelines. The preferred routes would be submitted to the U.S. Nuclear Regulatory Commission for approval. DOE would consider location-specific accident data during the route selection process. Furthermore, preshipment planning activities described in Section M.3.2 of the EIS would identify work zones on preferred highway routes and they would be avoided entirely by using an alternative preferred route, if possible, be accessed at times when traffic volumes were low, or wait in a safe parking area until heavy traffic cleared. This would not always be possible due to the limited routing options available but would reduce the potential for accidents in work zones involving spent nuclear fuel and high-level radioactive waste shipments to the proposed repository.

The routing of shipments of spent nuclear fuel by legal-weight truck would be in accordance with U.S. Department of Transportation regulations. These regulations limit shipments of highway route controlled quantities of radioactive materials such as spent nuclear fuel to Interstate System highways whenever possible. These regulations allow a state or tribe to designate alternate routes in accordance with Department of Transportation guidelines. In the absence of the identification of an alternate route by the State of Nevada, in the EIS DOE analyzed the routes that satisfied the Department of Transportation regulations. In the Las Vegas area, use of Interstate-15 to U.S. 95 to Yucca Mountain is the only existing Interstate Highway System route. The only current alignment of Interstate-15 is through the "Spaghetti Bowl," and transportation of nuclear waste along this segment was analyzed in the EIS. However, the Beltway around Las Vegas would avoid this area. The impacts of using the Beltway were analyzed in the EIS.

Comment - EIS001371 / 0010
The investigation into Amtrak's deadliest crash focused Thursday on a towboat operator who - 12 minutes before the crash - radioed that he was having a problem with a runaway barge.

The barge struck a railroad trestle over the foggy backwater of Bayou Canot early Wednesday just before the train plunged off the bridge into the water and exploded, killing at least 44 of the 210 people on board.

"The fact is, he was lost," said Coast Guard Capt. Michael Perkins, speaking of the pilot of the towboat Mauvilla. "While he was trying to gather up his barges, the train came along and the accident occurred."

Response
As discussed in Section J.1.4.2.3, the analyses in the EIS used current data to estimate the risks and consequences of rail and barge accidents. These data included accidents of all causes, including accidents of the type discussed by the commenter. As discussed in Appendixes J and M, most real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask into a river, and similar extreme accident conditions, would not likely result in releases of radioactive materials from the shipping casks. The performance standards for the casks prescribed by the Nuclear Regulatory Commission were selected to ensure that less than 1 percent of real-world accidents would result in loss of cask integrity and release of radioactivity from the cask. These standards ensure that the casks would be extremely robust.

8.10 (10746)
Comment - EIS002101 / 0008
So those rods are hanging in the air on the cranes. They got what they call hot cells. That's very dangerous work. They're lowering it into the dry casks. One of those welds could be wrong. Who knows what's going to happen? We're not talking about one time, five times. We're talking about 30,000 shipments. Nobody talks about how many rods that is.

Response
The characteristics of the spent nuclear fuel to be shipped to the proposed repository are described in Section 1.2 and Appendix A of the EIS. Nearly all of the spent nuclear fuel to be transported to the repository would be in the form of intact fuel assemblies, which consist of an array of fuel rods (for example, a 7-by-7 array) held together by structural components. If loose rods were shipped, for example loose rods generated during fuel consolidation demonstrations in the 1980s and early 1990s or postirradiation examinations, they would be overpacked.

In addition, canisters of vitrified high-level radioactive waste and various categories of DOE spent nuclear fuel would be shipped to the repository. DOE estimates that, for the proposed action, approximately 53,000 shipments of spent nuclear fuel and high-level radioactive waste would occur under the national mostly legal-weight truck scenario and 13,000 shipments would occur under the mostly rail scenario.

Hot cells exist at many nuclear-industry related research and operations facilities across the country. The hot cells and equipment are designed to be operated remotely using a variety of means, including remotely operated cranes, manipulators, and conveyances. Hot cells are typically heavily shielded rooms that use steel or concrete shielding and leaded glass windows to control the radiation dose rates outside the cells. In addition, the hot cells are provided with controlled ventilation and filtration systems to prevent the flow of contamination to occupied areas, contain airborne radioactive materials, and filter radioactive materials from the exhaust air prior to its discharge to the environment. A large amount of experience has been gained since the 1940s on how best to design hot cells and conduct remote operations. In addition, a large experience base exists for handling spent nuclear fuel assemblies, including both underwater and dry handling operations, that has been factored into the designs of shipping casks and development of shipping cask and fuel handling operations. Based on this experience, DOE is confident that hot cell operations, spent nuclear fuel handling, and transportation of spent nuclear fuel would be conducted safely and within regulatory limits and adequate public and worker protection would be provided.

DOE recognizes that human errors cannot be totally eliminated during the fabrication and operation of the shipping casks. Section J.1.4.2.1 of the EIS presents a discussion of the potential effects of human error, including undetected defects such as bad welds, on accident impacts. To minimize the impacts of human errors, the shipping casks would be fabricated under Nuclear Regulatory Commission-approved quality assurance programs. As indicated in the GA4/9 shipping cask Certification of Compliance, each shipping cask would be extensively tested prior to its first use, including radiographic and ultrasonic inspections of welds, load testing of lifting trunnions, pressure testing of the cask containment boundary, gamma scans of the depleted uranium shield, and other tests. Trained and qualified personnel would conduct all testing. The shipping casks would be subjected to periodic in-service testing and maintenance, such as seal replacement, visual inspections of seals and sealing surfaces, and leakage testing. In addition, all shipping cask handling, loading, unloading, testing, and maintenance operations would be conducted in accordance with detailed written procedures and by trained and qualified personnel. DOE believes these testing, maintenance, procedural, and personnel training requirements would minimize the likelihood and consequences of human errors during cask fabrication and operation.

Comment - EIS000357 / 0024
Could corridors be designated as heavy-haul nuclear freight as a mitigating measure in order to alleviate concerns of motorists who wanted to avoid worse case scenario nuclear accidents? Wouldn't such a measure also reduce the possibility of exposure, if there was a highway accident causing a leak?

Response
Section J.3 of the EIS analyzes the impacts associated with using heavy-haul trucks. Potential heavy-haul truck routes in Nevada are highways identified by the Nevada Department of Transportation for shipments of overweight and overdimension loads. Permits that specify approved routing for heavy-haul truck shipments on Nevada highways would be issued by the Nevada Department of Transportation. Alternate routes could be designated by the State of Nevada as specified in 49 CFR 397.103. There are no regulations regarding the exclusive designation of a highway for "heavy-haul nuclear freight."

8.10 (11063)
Comment - EIS000610 / 0022
Page 6-17, 18, Section 6.21 national transportation. I understand the probability, and if one goes back and examines the train wreck that spilled thousands of gallons of toxic material into the Sacramento River, it probably is outside the limits for the model used by DOE. It only takes one to do significant damage.

The difference between all the past accidents and one that could occur transporting nuclear waste is that past accidents were cured in one lifetime, but the nuclear accident time to cure could extend over many lifetimes. The reference section is again laced with adjectives that do not belong in an engineering document.

If you can state it is not likely or very unlikely, state the probability.

Response
Probabilities of severe spent nuclear fuel accidents are presented in Section J.1.4.2.1 of the EIS. Over 24 years of truck shipments to Yucca Mountain there would be less than a 1-percent chance of an accident that could result in a release of radioactive material from a cask. The chance of a rail accident that would cause release from a cask would be even lower. The chance that such an accident would occur in any locale would be much less than 1 percent. Therefore, an accident such as the train derailment near the Sacramento River would not be likely to release radioactive materials from the casks into the river.

8.10 (11067)
Comment - EIS000610 / 0025
6-28, block at the bottom of the page. DOE uses the argument that if an accident is not reasonable, it is not analyzed. This is defined by the conditions that occur more often than one in ten million times a year. They eliminate any conditions that occurs less than that number.

The public should be told of what can happen because if it can, it will in the years that material is being transported. In other words, don't use that. I want to know outside of that, because I maintain if it can happen, it will happen during the time that you are transporting materials in this country.

Response
Environmental Impact Statements are not required to analyze worst-case accidents but they are required to analyze reasonably foreseeable accidents. DOE guidelines (DIRS 104601-DOE 1993) suggest that these include accidents with probabilities in the range of 1 in a million to 1 in 10 million per year. As discussed in Section 6.2.4.2 and J.1.4.2.1 of the EIS, the accident analyses in the EIS include these "maximum reasonably foreseeable accidents." In addition to accidents with a probability greater than 1×10^{-7} per year, the EIS presented the consequences from all accident severity categories presented in Sprung et al. (DIRS 152476-2000).

8.10 (11271)
Comment - EIS001814 / 0006
6.2 National Transportation

The potential accident scenarios detailed in the National Transportation analysis grossly underestimate the environmental and health effects that may be associated with accidents by truck or rail because it assumes that probability of any particular accident occurring is low. See 6.2.4.2. First, the DEIS merely assumes that "[r]adiological impacts of accidents on biological resources would be very small." 6.2 at 6-18. Such conclusory statements are inadequate to fulfill the agency's duties under NEPA [National Environmental Policy Act]. The project envisions nuclear waste being shipped from throughout the United States, the possibility of an accident in an area of high rainfall or at a railroad crossing over a river is wholly unexamined. Such accidents may be statistically "rare" but even a single occurrence could irreparably damage biological resources in the area in which it does occur.

Response
The EIS does not assume that the probability of any particular accident occurring is low. Rather, the EIS evaluates the probabilities and consequences for a complete spectrum of accidents, ranging from accidents with high probabilities and low consequences to accidents with low probabilities and high consequences. Generally, plants and animals are no more sensitive to radiation than are humans. Both acute and chronic radiation doses that do not adversely affect humans are not known to affect terrestrial species of plants and animals. *Effects of Ionizing Radiation on Plants and Animals at Levels Implied by Current Radiation Standards* (DIRS 103277-IAEA 1992) reports that there is no convincing evidence that indicates that the current radiological dose standards for humans would harm animal or plant populations. In other words, if humans are adequately protected, plants and animals are likely to be adequately protected. For these reasons, DOE has concluded that there would be not be significant impacts on terrestrial species of plants and animals located along the transportation corridors.

8.10 (11364)
Comment - EIS002278 / 0001
I too would like to address some of my transportation concerns. Number one is that using the 85 mile-an-hour car running into the 20 cubic-foot block wall, or whatever it was, sounds great, but that wouldn't even be close to the amount of impact that you would have running head-on to another, say, cement truck or something coming at you from a two-lane road, say along the I-20 or U.S. 27 going towards Tecopa, or whatever highway is where you have head-on collisions with two vehicles traveling maybe 65 miles an hour apiece.

Response
In the analysis of accidents, severe collisions leading to mechanical damage and functional failure of a spent nuclear fuel shipping cask are termed "initiating events." A large number of specific initiating events can be identified by review of historic transportation accidents or by the imagination. Any initiating event, including a collision with a cement truck or other vehicle as suggested by the commenter, can be characterized in terms of its mechanical forces and heat. The event can then be categorized according to the matrix shown in Figure J-9 of the EIS, which was taken from a recent study conducted by the Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000). As a consequence, it is not necessary to analyze every possible initiating event individually because the range of accidents included in Sprung et al. (2000) encompasses all credible initiating events.

Regardless of the specific initiating event, the severity of a transportation accident can be characterized by the combination of mechanical forces and heat involved in the accident. Mechanical forces account for the severity of the crash itself, while heat accounts for the severity of a fire that could be involved in the accident. Sprung et al. (DIRS 152476-2000) concluded that only a tiny fraction of all accidents, less than one in 10,000, would be severe enough to fail a spent nuclear fuel shipping cask. The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. This study reaffirmed that the spent nuclear fuel transportation regulations provide adequate protection of public health and safety.

8.10 (11405)
Comment - EIS002251 / 0003
A one-in-ten-million chance of an accident is too many for me to even fathom how somebody can come up with these kind of numbers. It is unbelievable. Okay, what happens if the transportation is interrupted? If you have a bridge that fails, and you have to reroute it? I see nothing about the added effects from extended length of transportation time.

Response
The EIS acknowledges that transportation accidents could occur during the transport of radioactive materials to the proposed Yucca Mountain Repository. In Section J.1.4.2.3.2, the EIS estimates that there could be as many as 66 accidents under the mostly legal-weight truck shipping scenario and 8 accidents could occur under the mostly rail scenario. A study recently conducted by the Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000) concluded that only a tiny fraction of all accidents, less than 1 in 10,000, would be severe enough to fail a spent nuclear fuel shipping cask. The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. Based on these statistics, DOE does not expect an accident to occur that would result in a radiological release and subsequent environmental cleanup.

The methods and data used to estimate the 1 in 10 million per year probability are discussed in Section J.1.4.2 of the EIS. Rerouting of shipments because of adverse weather and road conditions is discussed in Section M.3.2.1.4.

8.10 (11432)
Comment - EIS002277 / 0003
I believe that the DEIS should look at the conditions in the Cajon Pass under high-wind conditions and not under stable wind conditions.

On J-70 a small fraction -- a small fraction, whatever that means, of the accidents could generate forces capable of damaging the casks.

Let me say this: If it can happen, it will happen in 30 years. So when you use adjectives of "small fractions may have," it will happen. As the gentleman said, the Titanic wasn't supposed to sink. It was man made. We are not God, and I think we can't build things that are that positive.

[Page] J-58 atmospheric conditions called neutral or average conditions. The reason I keep raising this condition question is I keep getting the fact that it is – I don't want to see "average" when we talk about conditions in certain areas of California which have very radical atmospheric conditions compared to the rest of the country.

Atmospheric conditions called "neutral average conditions likely to prevail during a severe accident or an act of sabotage." Now, what makes people think that they won't do it under a Santa Ana wind condition? I don't understand why that – in the wintertime we have a lot of Santa Anas. So I think these are things that have to be relooked at in the transportation area. More specific figures, not adjectives.

Response
The EIS acknowledges that transportation accidents could occur during the transport of radioactive materials to the proposed Yucca Mountain Repository. In Section J.1.4.2.3.2, the EIS estimates that there could be as many as 66 accidents under the mostly legal-weight truck shipping scenario and 8 accidents could occur under the mostly rail scenario. A study recently conducted by the Nuclear Regulatory Commission (DIRS 152476-Sprung et al., 2000) concluded that only a tiny fraction of all accidents, less than 1 in 10,000, would be severe enough to fail a spent nuclear fuel shipping cask. This is the "small fraction" referred to by the commenter. The main reason that only a small fraction of accidents are severe enough to result in failure of the shipping casks is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste

shipping casks. Based on these statistics, DOE does not expect an accident to occur that would involve radiological consequences.

Two sets of atmospheric conditions were used in the transportation impact analysis. These are referred to in Section J.1.4.2.1 of the EIS as “neutral or average” and “stable.” Neutral or average conditions are those that would not be exceeded more than 50 percent of the time and stable refers to conditions that would not be exceeded more than 95 percent of the time. Under stable conditions, wind speeds are usually very low [on the order 1 meter (3.3 feet) per hour]. Stable atmospheric conditions and low wind speeds result in minimal dispersion of the radioactive materials released from a potential transportation accident; that is, the plume of radioactive material would slowly move downwind and would be dispersed slowly. This means that the concentrations of radioactive material in the plume, and thus the consequences to individuals and populations in the area through which the plume passes, would be higher under stable conditions than they would be under less stable conditions with high winds. Under unstable or neutral atmospheric conditions, the plumes of released material spread out further and more rapidly than under stable, low-wind conditions. Thus, if an accidental release occurred under Santa Ana wind conditions, a lower radiation dose would be predicted than the EIS predicted in using the two sets of atmospheric conditions described above.

Comment - EIS002253 / 0003
There has to be, I believe, almost a mile-by-mile, half-mile-by-half-mile evaluation of the tracks all the way to Yucca Mountain. And if they find these tracks deficient, in cooperation with the railroad, get them fixed. Put them at such a level that they never will be afraid of putting those casks on those trains, because they know that track won’t fail.

The failures of coming down Cajon Pass, by the way, were trains coming down. You remember the one ten years ago that ran right into a neighborhood, an out-of Control train. It was because of the train, it wasn’t the track. And it ran right into a neighborhood and obliterated a neighborhood and buried it in soda ash. And it was because it was coming down, not up.

Response
The U.S. Department of Transportation is the Federal agency responsible for establishing and enforcing the standards for the transportation infrastructure. The Department of Transportation’s Federal Railroad Administration is responsible for safety of the rail system, including track, locomotives, highway crossings, incident reporting, brake systems, etc. (see 49 CFR Parts 200 to 266). The Federal Railroad Administration provides funds to states for track and train inspectors. The Federal Railroad Administration and state inspectors conduct the track inspections suggested by the commenter. Owners of track and rights-of-way continuously perform maintenance and upgrade activities to keep railroads safe. The Federal Government would own the tracks and the rights-of-way for the branch rail line in Nevada and would be responsible for conducting maintenance and repair. Nationally, the rail companies own their tracks and rights-of-way. The rail companies are responsible for maintenance and repair of their own tracks and rights-of-way. DOE and private rail lines would conduct inspection, maintenance, and repair activities as required by the Federal Railroad Administration and the states.

In general, adequate rail lines, crossings, bridges, and tunnels exist to support the transportation of materials described in the EIS. The shipment of radioactive materials requires no special transportation infrastructure that is not necessary for safe transport of commodities in the United States today.

In spite of all the precautions to be taken to prevent accidents such as the out-of-control train mentioned by the commenter, the EIS acknowledges that transportation accidents could occur during the transport of radioactive materials to the proposed Yucca Mountain Repository. In Section J.1.4.2.3.2, the EIS estimates that there could be as many as 66 accidents under the mostly legal-weight truck shipping scenario and 8 accidents could occur under the mostly rail scenario. A study recently conducted by the Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000) concluded that only a tiny fraction of all accidents, less than 1 in 10,000, would be severe enough to fail a spent nuclear fuel shipping cask. The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level waste radioactive shipping casks. Based on these statistics, DOE does not expect an accident to occur that would involve radiological consequences.

8.10 (11493)
Comment - EIS002254 / 0006
We had a big accident three weeks ago through our community, a dripping waste truck came through. So don't tell me that that's not what's going on every day here in this country. Don't tell me that lie again.

Response
DOE would not use defective or leaking casks to ship spent nuclear fuel and high-level radioactive waste. The Nuclear Regulatory Commission and the U.S. Department of Transportation regulate the design, manufacture, maintenance, and use of these casks. Specific controls include (1) independent Nuclear Regulatory Commission review of designs to ensure compliance with requirements in 10 CFR Part 71, and (2) Nuclear Regulatory Commission-approved and audited quality assurance programs for design, manufacturing, maintenance, and use of transportation packages.

8.10 (11571)
Comment - EIS002281 / 0001
The routes going through San Bernardino and Riverside counties, Inyo County – I lived in Inyo County for two years, and I can attest to what was described about Route 127 as being a paved-over wagon trail, as that is exactly what it is. I have driven that many times. It is a two-lane road, definitely not made for heavy trucks of any stretch of the imagination, yet I do know they pass over it.

If a nuclear accident happened, if something happened on that stretch of highway, who would know about it? It is not traveled that extensively, except maybe when they have the dune races out at Dumont Dunes.

It is dangerous. It crosses sacred Indian land. Any time the government decides that it's just empty land and it's just a few people out there, it smacks of environmental racism. Poor people, people of color, are always the ones who get impacted with this the most. This cannot be allowed.

It's dangerous, and again I cannot emphasize more than has already been said, coming through Cajon Pass, an accident there is catastrophic. An accident coming through Los Angeles between Orange County and San Bernardino, you can hardly tell where one city stops and the other one begins. Anything through there – and how many times do you see or hear of accidents that involve big-rig trucks? For whatever reason, somebody cuts it off, some little foreign car cuts it off, or just traveling a bit too fast and losing control on a wet highway.

Response
Presently, State Route 127 is not a preferred highway and thus could not be used for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. However, should the State of Nevada or California designate this highway as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states and local jurisdictions would be necessary. The affected routing authorities would consider the conditions of State Route 127, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

The EIS examines the issue of environmental justice in Section 6.3.4. DOE believes that there would be no disproportionately high and adverse impacts to minority or low-income populations as a result of the Proposed Action.

As discussed in Section J.1.4 of the EIS, the release of radioactive materials during an accident is an extremely unlikely event (an annual probability of 0.01 percent. Transportation safety related to potential release of radioactive materials is primarily based on the integrity of shipping casks. The leaking of a transportation cask could only occur if mechanical forces (impact) and heat (fire) exceeded the design limits of the transportation cask structures and materials. Additional information on the safety and testing of transportation casks is provided in Section M.4. Information on human behavior is included in the accident rates and discussed in Section J.1.4.2.1.

8.10 (11581)
Comment - EIS002235 / 0004
As you have heard stated previously today, last week we focused our attention on the top of the Cajon Pass with 58 cars, five big rigs, and a massive pile-up that it took hours to untangle. Not uncommon here. What many of us didn't see was that at about two o'clock on the same day a county fire employee was first on scene on Interstate 10 at another massive accident and began rendering aid to victims, our citizens, as cars continued to crash -- literally crash around him.

What that brings up is that under even DOT (sic) predictions, with an unopened cask one may receive 10 millirems per hour at 10 meters, which is approximately 5 percent of the annual average dose that one would expect naturally.

In the event of an accidental release, particulates would be borne by desert and Santa Ana wind conditions for many, many miles, and the inhalation hazard would be catastrophic.

The DOE itself claims that in an accidental release, a 42-square-mile area would be contaminated and require 460 days to decontaminate it, and cost over 620 million dollars.

Response
Sections 6.2.4.2 and J.1.4.2 of the EIS evaluate severe transportation accidents such as the one described by the commenter. A severe truck accident is an extremely unlikely event (an annual probability of 1.9 in 10 million) per year. The consequences of this accident were estimated to be 18 latent cancer fatalities. The dose to the maximally exposed individual would be about 4 rem. These consequences include the radiation doses from inhaling radioactive material released during the accident. In addition, DOE assumed that emergency response activities such as evacuation would not take place, which provides conservative estimate of potential impacts.

The allowable dose from a closed, loaded cask is 10 millirem at 2 meters (6.6 feet).

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

Comment - EIS000996 / 0001
The Mississippi River provides 70 percent of the Nation's water resources and its boundaries as a water resource begin in the East in Appalachian Mountains and in the West in the Rocky Mountain Range. Drainage to the Mississippi River to the north and south is defined within the entire range of the United States and all the way North into Canada as well. Along the drainage system are 76 and 103 operating commercial reactors. Most of the shipments of radioactive materials are designed for storage in the Yucca Mountains will pass through this water resource area. The potential devastating effects of the gases released from the fission processes of radioactive nucleotides within these used cells being transported is unknown. What is known is that these gases will get into water resources of the Mississippi River drainage system and will affect our food, our water, and that for the billions of plants and animals that depend on this water. What would happen if an accident occurred and one of the shipments might fall into the water and affect 70 percent of the nation's water resource could be even more devastating. I question the validity of the casks, which are storing radioactive materials capable of keeping fission products from escaping. What is the capacity, should these casks fall from trucks or trains carrying them to withstand physical destruction?

Response
The EIS does not specifically analyze a transportation accident involving contamination of surface water such as the Mississippi River. Analyses performed in previous EISs (see Section 1.5.3 of the EIS) have consistently shown that the airborne pathway has the greatest potential for exposing large numbers of people to radioactive material in the

event of a severe transportation accident. A paper that analyzed the potential importance of water pathway contamination for spent nuclear fuel transportation accidents using a worst-case water contamination scenario (DIRS 157052-Ostmeyer 1986) showed that the impacts of the water contamination scenario were about one-fiftieth of the impacts of a comparable accident in an urban area. Therefore, if an accident occurred and one of the shipments fell into the water, the impacts would be much less than the impacts presented for the severe transportation accidents analyzed in Chapter 6 and Appendix J of the EIS. Many studies have shown that when people are protected, animals and plants are protected.

The casks used to transport spent nuclear fuel must meet stringent standards established by the Nuclear Regulatory Commission (10 CFR Part 71). These standards include requirements for keeping fission products from escaping during normal transportation and during severe accidents. The consequences of severe transportation accidents are presented in Section 6.2.4.2 and Appendix J of the EIS. Though a severe accident that releases radioactive materials is not expected to occur during the 24-year campaign, DOE has performed an analysis of a maximum reasonably foreseeable accident. Section 6.2.4.2 presents the results of the analysis. Section J.1.4.2 presents details on the data, methods, and assumptions used to estimate these consequences. Section M.4 contains more information on the safety and testing of transportation casks.

<u>Comment</u> - EIS001879 / 0055
A careful review of the Draft EIS was unable to identify any evaluations of the consequences of an avalanche related transportation accident or [an] accident scenario whereby a cask plummets down a steep rocky slope. While the probability of such an event is apparently included within the analyses presented in the Draft EIS (in terms of reportable traffic incidents which would include these types of events), it does not appear that the severity is accounted for adequately.

There are numerous avalanche detection monitors and rock fall fences located along the Union Pacific Railroad lines in Clover Valley, immediately east of Caliente, Nevada. Discussions with railroad employees indicate that rock falls and avalanches are a common occurrence, that train cars are often hit, and that in some cases, boulders as large as boxcars have fallen onto the railroad tracks. Other portions of rail routes through mountainous terrain probably also have similar occurrences. The Draft EIS does not contain any evaluation of the consequences of a rock fall or avalanche along transportation routes (both rail and truck) or how such events would rank in the probability/severity matrix given in Figure J-8. The EIS must be revised to include an evaluation of the consequences of a rock fall or avalanche.

The Draft EIS does not evaluate the scenario of a traffic accident that results in a cask falling down a steep rocky slope. A review of the source documentation (NUREG/CR4829, Fischer et al. 1987) indicates that only single impact scenarios were evaluated and that one of the key factors is the maximum effective strain on the containment shell of the cask. No evaluations were made of multiple impact scenarios such as a cask falling down a slope. Under a multiple impact scenario, numerous breaches could occur and much more severe breaches are likely; as a result, the release fractions from the fuel rods to the casks could be much higher than those originally estimated by Oak Ridge National Laboratory (see Lorenz et al. Fission Product Release from Highly Irradiated LWR Fuel, NUREG/CR-0722 as referenced in Fischer et al. Shipping Container Response to Severe Highway and Railway Accident Conditions, NUREG/CR-4829). The EIS must be revised to include an evaluation of multiple-impact scenarios especially with regard to release fractions from multiple impact and cask breach scenarios.

<u>Response</u>
The commenter requested analyses of specific accident scenarios involving avalanche-related accidents and shipping casks falling down a steep rocky slope. In the analysis of accidents, these events are termed “initiating events.” A large number of specific initiating events can be identified by review of historic transportation accidents or by the imagination. These include collisions with fixed objects (bridge abutments, walls, barriers, etc.); collisions with other vehicles and animals; rollovers; jackknife; derailments; and collisions at grade Crossings. Any initiating event can be characterized in terms of its mechanical forces and heat, and the event can then be categorized according to the matrix shown in Figure J-9 of the EIS, which is the transportation accident risk model used in the EIS. This model was taken from a recent study conducted by the Nuclear Regulatory Commission, *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). As a consequence, it is not necessary to analyze

every possible initiating event individually because the range of accidents included in Sprung et al. (2000) encompasses all credible initiating events.

Regardless of the specific initiating event, the severity of a transportation accident can be characterized by the combination of mechanical forces and heat involved in the accident. Mechanical forces account for the severity of the crash itself, while heat accounts for the severity of fire that could be involved in the accident. Sprung et al. (DIRS 152476-2000) concluded that only a tiny fraction of all accidents, less than 1 in 10,000, would be severe enough to fail a spent nuclear fuel shipping cask. The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. This study reaffirmed that the spent nuclear fuel transportation regulations provide adequate protection of public health and safety.

The massive shipping casks are designed to sustain severe damage without resulting in functional failure. In addition, the shipping casks are protected by crushable impact limiters that absorb impact energy that would otherwise be applied to the shipping cask. Furthermore, the shipping casks are attached to trailers and railcars that would absorb additional impact energy as long as the shipping casks remain attached. Finally, the actual surfaces that the shipping cask would strike in a collision event, such as the ground, rocks, or other vehicles, would absorb some of the impact energy. Therefore, although the specific initiating events suggested by the commenter might not be explicitly evaluated in the EIS or in Sprung et al. (DIRS 152476-2000), the damage to the shipping cask and its cargo is included in the accident model shown in Figures J-9 of the EIS.

<u>Comment</u> - EIS001879 / 0056
The Draft EIS does not include information on how the judgments regarding the release fractions were made. As noted by Lorenz et al. (as cited above, page 9-23), "...the ORNL [Oak Ridge National Laboratory] test data may or may not overestimate the actual releases under high-impact conditions," and on page 9-29,..." The results of this study depend primarily on the quality of the cask response models, the radiation release models, and the probability models and distributions used in the analysis.... If the objective of this study is to precisely define spent fuel transportation risk, many improvements need to be made to these models to calculate the probability and radioactive release estimates and to quantify the uncertainties in the estimates." The EIS should state that the maximum release scenario is based upon limited tests, mathematical models that incorporate a number of simplifying assumptions, and professional judgment.

<u>Response</u>
The EIS has been revised to use the release fractions from the U.S. Nuclear Regulatory Commission study *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000) to estimate the risks and consequences of transportation accidents. The methods and data used to estimate these release fractions are summarized in Section J.1.4.2 of the EIS and are discussed in more depth in Section 7 of Sprung et al. (2000).

8.10 (12093)
<u>Comment</u> - EIS002307 / 0007
Section 6 of the DEIS is incorrect in the assessment of train accident risks because the DEIS, assuming that the highway and rail conditions will be similar, relies on data from highway conditions to compute train accident risks.

<u>Response</u>
As discussed in Section J.1.4.2.3, the EIS uses train accident data to estimate train accident risks, and does not use highway accident data to estimate train accident risks.

8.10 (12135)
<u>Comment</u> - EIS001887 / 0437
Inputs to computer models predicting exposure levels

3.1. Use of temperature and strain as independent variables
Refer to Resnikoff, 1993. In many severe accidents, high impacts are coupled with vehicle fires. In predicting probabilities of accidents of a given severity, the probability of fire of a certain severity is multiplied by the

probability of an impact of a given strain. This tends to underestimate the "true probability" of strain-fire accidents, as these two variables are not independent. This is another artifact of the Modal study needing revision.

3.2. Inconsistent assumptions made in RADTRAN4 and RISKIND

3.2.1. DOE employs RADTRAN4 for total risk, summing individual accident probabilities multiplied by consequences. RISKIND is employed to assess the maximum accident consequences. The assumptions employed should be identical, but they are not. RADTRAN4 assumes ingestion of contaminated food after an accident in rural areas in determining collective population dose; RISKIND assumes no radiological dose to populations from ingestion of contaminated food after an accident in determining maximum accident scenarios. It is unclear why these two inputs are different.

3.2.2. In calculating effects to the maximally exposed individual in an accident scenario, the EIS assumes that this person is located 360 meters (~1200 ft) from the site. In calculating effects to the maximally exposed individual in sabotage scenario, the EIS assumes this person is 140 meters (~460 ft) from the site. It is unclear where these distances came from, or why they are different.

3.3. Incident-free exposure assumptions

3.3.1. Escorts
DOE based its estimates of annual dose to escorts on regulations that we believe are insufficient to ensure the safety of the transportation vehicles. We recommend that these requirements be increased so that there is always at least one armed escort traveling in a separate vehicle from all truck shipments, and in separate rail cars for all train shipments. This will increase the estimated dose to escorts.

3.3.2. Individuals stuck in traffic
DOE assumes that individuals exposed to radiation dose due to being stuck in traffic near a transportation vehicle will occur only once per individual. However, personal driving patterns are not random, since people (especially commuters) tend to be on the same road at the same time of day. Therefore, persons being stuck in traffic near a transportation vehicle once are likely to be stuck multiple times.

3.4. Population density

The EIS uses average population densities from the 1990 Census to estimate the "worst case" accident and sabotage scenarios. This ignores time-dependent, such as daytime population densities in cities due to worker commuting (Manhattan's population doubles every day), tourist population densities, special-event and localized densities. The maximum population densities used in the RISKIND code should reflect these factors.

3.5. Characteristics of spent fuel used in accident consequence estimates

3.5.1. Age of spent fuel

Simply put, the longer a given type of fuel is removed from a reactor prior to shipment, the less radioactive it is. Fuel which has cooled for a long time has had the time to undergo decay reactions, reducing its level of radioactivity. The DOE assumes in its estimates a spent fuel age of 25.8 years, even though fuel is only required to be cooled for 5 years prior to transportation. This results in a reduced estimate of hazard. Unless the DOE can show through legal requirements that spent fuel will be aged 25.8 years prior to shipment, it is not appropriate to use this age in its exposure assessments for incident-free and accident scenarios.

A more likely scenario is that older fuel, already stored in storage casks at reactor sites or at the proposed PFS [Private Fuel Storage] storage facility in Utah, will remain stored while newer fuel, stored in fuel pools, but aged more than five years, will first be transported off the reactor site so that reactors can be decommissioned more rapidly. DOE has established an acceptance quota for reactor fuel; for utilities, the most advantageous use is to further reactor decommissioning. Further, DOE would have to pay the cost of casks and transportation of this newer fuel. Older fuel would then be shipped at a much later date.

In a 25.8–year period, important radioactive contaminants in irradiated fuel will have decayed away. For example, Co^{60}, a main contributor to radiation dose from crud spallation, has a half-life on the order of 5 years. Concentrating on 25.8-year fuel decreases the amount of Co^{60} modeled by a factor of 2^5, seriously reducing possible radiological effects in the event of a release.

Response

3.1 At the time the Draft EIS was published, DOE considered *Shipping Container Response to Severe Highway and Railway Accident Conditions* (DIRS 101828-Fischer et al. 1987; also called the Modal Study) to contain the best available information regarding spent nuclear fuel transportation accidents. However, the U.S. Nuclear Regulatory Commission has recently published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000), which contains additional information regarding spent nuclear fuel transportation accidents, including the use of different shipping cask designs than the representative steel-lead-steel cask used in the Modal Study. Because Sprung et al. (2000) provides more recent information and is based on the most recent shipping cask designs, DOE has conducted an analysis using the information from that document. The results of this analysis are presented in Appendix J of the EIS and show that the impacts estimated in the EIS using the Modal Study exceed the impacts estimated using Sprung et al. (2000). As a consequence, the Draft EIS overestimated the impacts of spent nuclear fuel transportation accidents and the Final EIS contains more realistic estimates of spent nuclear fuel transportation accident impacts.

DOE agrees with the commenter that impact and thermal conditions in transportation accidents are not independent of each other. For example, one would expect that fires are more likely to occur in high-speed impacts than in low-speed impacts. In essence, Sprung et al. (DIRS 152476-2000) assumes three general sequences of events could lead to a release. These are (1) severe collision events without fires, (2) collisions followed by fires, and (3) fire only. These variables are not treated independently, as indicated in Section 7.2.8.1 of Sprung et al. (2000), but rather the probabilities of fires are dependent on the particular accident scenario that occurs (truck accident scenarios are depicted in Figure 7-3 of that document).

3.2.1 The commenter is correct in that the integrated population risk calculation included doses from ingestion of contaminated foods for accidents in rural areas only, whereas the analysis of maximum reasonably foreseeable accidents did not include ingestion. DOE's experience with this and other EISs as well as many other radiation dose studies is that ingestion doses are small in relation to inhalation and direct external exposures. In general, the population doses from the maximum reasonably foreseeable transportation accidents would be highest in urban areas where population densities are highest. Since little agricultural production occurs in urbanized areas, ingestion of crops that have become contaminated by a release of radioactive materials would not occur. In other words, the assumed population densities have a much stronger effect on population dose consequences than does including/excluding ingestion doses. In this context, the absolute magnitudes of the results are less important than the consistent treatment of assumptions and uncertainties. Since the integrated population risks calculated by RADTRAN are not compared to the consequences of maximum reasonably foreseeable transportation accidents, differing assumptions about ingestion would not affect the comparisons among alternatives in this EIS. Therefore, DOE believes the effects of these differing assumptions are small and, in addition, would have no effect on the decisions to be made in this EIS.

3.2.2 The distance to the maximum exposed individual is a function of the prevailing atmospheric conditions at the time of a release of radioactive material and the height of the release. For example, consider an accident that involves a serious fire. If material was released from a shipping cask, the fire would initially cause the released material to be transported upward. We have all seen large fires on television news in which the cloud of smoke rises directly up from the source of the fire. As the released material gets farther from the fire, the released particles cool and the forces of gravity would begin to bring the particles back to the ground. The effects of wind and weather would cause the particles to be transported downwind. Because of the initial upward movement of the plume, the location of the highest concentrations of released material would be at some distance downwind of the accident scene, depending on the severity of the fire, wind speed, and atmospheric stability. If a release occurs that is not accompanied by a fire, the initial vertical (upward) movement does not occur or is relatively weak and the plume of released material remains close to the ground. Therefore, the maximum concentration of particles would be closer to the accident scene for a nonfire scenario than it would be for an accident that involves a fire. In a sabotage event, the released material does not have the same vertical driving force that a long-duration fire produces. Thus, the particles remain near ground level and the maximum concentrations are nearer to the release point than they would for a fire-driven release.

3.3.1 The Nuclear Regulatory Commission's regulations in 10 CFR Part 73 prescribe safeguards and security requirements for spent nuclear fuel shipments. These safeguards, which include armed escorts in urban areas, should be effective in reducing the likelihood of a successful attack to low levels. In addition to armed escorts in urban areas, the requirements include tracking, reporting, route planning and prenotification. Prenotification of the timing and routes used for shipments would be held in confidence as a matter of security, but state governors' offices would be made aware of schedules. These operational actions would be supplemented by the robust nature of the cask itself, which would make an attack that was not thwarted by the safeguards measures even more unlikely of success.

Application of the urban escorting requirements in all areas would have drawbacks without any significant increase in overall security. The drawbacks would relate to the additional radiological exposure, as stated by the commenter, and increased potential for accidents involving the escort vehicles. Armed guards would be required in heavily populated areas because the total radiological impact in such areas would be higher than in less populated areas. In neither area is it expected that doses to individuals would be markedly different or above levels that could have health effects. Thus, individuals in high, medium, and low population areas are treated equally.

DOE sees no particular need for additional security measures over and above those that would be provided as a result of applying the Nuclear Regulatory Commission safeguards requirements in place at the time of the shipments. As stated in the EIS, escorts are required in heavily populated areas. These areas are defined in a list that is provided by the Commission as part of its requirements for safeguarding spent nuclear fuel in transportation. Section M.7 of the EIS provides additional information on physical protection of spent nuclear fuel in transport.

3.3.2 A defensible basis for estimating the number of times that a person could be stuck in traffic next to a spent nuclear fuel shipment could not be established. It is extremely unlikely that even one occurrence would be experienced, given the number of vehicles on the highways in relation to the number of spent nuclear fuel shipments occurring at a given time. Approximately six shipments per day would be received at the repository over the 24-year operating period of the repository under the national mostly legal-weight truck scenario. As stated in Section 3.2.2 of the EIS, legal-weight truck shipments would represent less than 0.5 percent of commercial vehicle traffic on U.S. 95 (and an even smaller fraction of total commercial plus private vehicle traffic). Although certain people are more likely to be on a highway at a given time (for example, commuters during rush hour), the likelihood of any individual being stuck next to a shipment even one time is approximately random due to the great number of vehicles that would also be on the highway in relation to the number of spent nuclear fuel and high-level radioactive waste shipments. As stated in Section M.3.2, during preshipment planning, the Regional Servicing Contractors should consider preferred time of day travel through urban areas as part of routing determinations. The intent is to schedule departures so avoid traveling through urban areas during rush-hour periods. Real-time tracking and communications systems provide the capability to relay information to drivers on upcoming road and weather conditions. Preshipment planning and real-time tracking and communications would therefore reduce the likelihood of such an event.

3.4 The precise timing, location, and other circumstances surrounding a transportation accident cannot be predicted. In addition, it would not be practical for the EIS to attempt to analyze accident consequences for every location along the shipping route. Instead, maximum consequences were analyzed for three types of population zones: urban, suburban, and rural. For example, an accident in the Las Vegas area would be characterized by the analysis for an urban area. Tables 6-14 and 6-15 of the EIS provide the estimated impacts of the maximum reasonably foreseeable accident in an urbanized area for truck and rail, respectively. Table J-24 shows consequences of maximum reasonably foreseeable accidents in urbanized and rural areas.

The EIS does not analyze a worst-case accident, as the commenter suggests. Rather, the EIS used the concept of a maximum reasonably foreseeable accident, which is sometimes misinterpreted as being a worst-case accident. An example of a worst-case transportation accident would involve a shipment containing the highest possible quantity of spent nuclear fuel or high-level radioactive waste, in a highly populated area, with catastrophic failure of the shipping container, an engulfing fire lasting many hours, and stable weather conditions (very low atmospheric dispersion of plume). However, this worst-case accident scenario would not be reasonably foreseeable because it requires the simultaneous occurrence of a series of unlikely events, which, compounded, result in a likelihood of occurrence that is less than once in 10 million years. Council on Environmental Quality regulations (40 CFR 1502.22) state that analysis of accidents should avoid scenarios that are based on pure conjecture and avoid compounding conservatisms. The practice of compounding conservatisms produces unrealistic results that mask the real differences between alternatives and would not produce suitable results to support choices among the alternatives.

3.5 The commenter pointed out that the assumptions used in the EIS for the age and radiological characteristics of spent nuclear fuel in the maximum reasonably foreseeable accident scenarios could understate the transportation risks. It is true that DOE could ship some spent nuclear fuel that is more radioactive than the 26-year-old pressurized-water reactor spent nuclear fuel analyzed in the scenario. Based on comments received and DOE's additional review of technical documents and conduct of hazard analyses, the basis for the transportation impact analysis has been revised to consider commercial spent nuclear fuel that has median hazard. Spent nuclear fuel having median hazard would be discharged from a reactor approximately 14 years before shipment to Yucca Mountain. If any 5-year-old or 10-year-old spent nuclear fuel was to be shipped to the repository, it would be a small fraction of the total shipments. This is a case in which "average" data is used in the EIS as opposed to bounding assumptions. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing accident scenarios. Other elements of the impact analyses (for example, radiation dose rates, atmospheric dispersion modeling, release fractions) are bounding such that the transportation impact results presented in the EIS are bounding, yet not so conservative that the results mask the true differences between the alternatives.

8.10 (12136)
Comment - EIS001887 / 0438
Improper attention to Intermodal Transfer Station

4.1. Crash scenarios analyzed

4.1.1. Airplane crash scenario

The airplane crash scenario assumes that the crash velocities will be those typical of takeoff and landing operations. As a worst case scenario, the potential impact of a crashing military jet traveling at 600 mph should be considered. This is likely to cause release of some radioactive material.

Response
The methodology employed in the EIS to estimate penetration characteristics of large aircraft projectiles into shipping casks was based on extensive research that is summarized in DOE-STD-3014-96, *Accident Analysis for Aircraft Crash into Hazardous Facilities* (DIRS 101810-DOE 1996). This document and its supporting studies contain the best available information on aircraft crash probabilities and the effects of aircraft crashes on systems, structures, and components. The studies include this information for commercial, general aviation, and military aircraft crashes. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing environmental impacts. Such practices would provide misleading information and lend credibility to accident scenarios that are clearly insignificant contributors to the true risks of an intermodal transfer facility. If DOE decided to construct an intermodal transfer facility in Nevada, it would conduct additional aircraft hazard analyses to support nuclear facility safety analyses and designs of structures, systems, and components important to safety. DOE believes the aircraft hazard analysis summarized in the EIS would probably not be adequate to support detailed design and safety analyses of an intermodal transfer facility but is adequate for its intended purpose of informing the reader about the potential likelihood and consequences of accidents related to transportation of spent nuclear fuel and high-level radioactive waste to the proposed repository.

Bechtel-SAIC Company (DIRS 157210-BSC 2001) estimated the potential releases of radioactive materials that could result from the crash of a commercial jet airliner into a shipping cask containing spent nuclear fuel. According to the analysis, the release from a rail cask struck by a jet engine traveling 640 kilometers (400 miles) per hour and exposed to the ensuing jet-fuel fire would be no greater than the releases in a severe rail transportation accident in which the cask impacted a hard rock surface at between 48 and 97 kilometers (30 and 60 miles) per hour and was engulfed by fire for 0.5 hour. The consequences of this accident–1,300 person-rem or 0.67 latent cancer fatality–are presented in Section J.1.4.2 of the EIS. The consequences for an event in which the commercial airliner impacted a legal-weight truck cask would be about the same–1,100 person rem or 0.57 latent cancer fatality. A truck cask event that would have similar consequences would involve impact into a hard rock surface at a speed greater than 190 kilometers (120 miles) per hour followed by an engulfing fire for up to 0.5 hour.

8.10 (12193)
Comment - EIS000096 / 0006
Fourth, the Draft EIS underestimates the consequences of severe accidents and terrorist/sabotage incidents involving HHT [heavy-haul truck] shipments through Tonopah, Goldfield, and Beatty. The close proximity of the highway to hotels, casinos, retail businesses, schools, churches, and residences would increase human health effects in the event of an accident or incident involving loss of cask containment or shielding. Proximity to the route would increase the economic consequences of a HHT accident or incident, even one involving no loss of cask integrity.

Response
While a specific analysis of a severe accident or terrorist attack in the vicinity of Tonopah, Goldfield, and Beatty was not conducted, maximum reasonably foreseeable accidents were analyzed for national transportation. These results are reported in Section 6.2.4.2 and Appendix J of the EIS. The EIS analysis assumed that an accident determined to be reasonably foreseeable for national transportation could occur in Nevada with similar results. The consequences in both urbanized and rural areas were considered in determining the maximum reasonably foreseeable accident impacts.

8.10 (12262)
Comment - EIS001888 / 0598
The DEIS indicates that the DOE prepared a description of the Maximum Reasonably Foreseeable Accident (MRFA) that describes the most severe accident liable to occur to a cask being transported from a reactor to Yucca Mountain. However, none of that information is provided in the DEIS. Emergency management impacts are a critical component of the EIS. The DEIS must provide an unambiguous description of the Maximum Reasonably Foreseeable Accident as well as the likely continuum of lesser accidents that may require local emergency response assets.

Response
Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). DOE has concluded that the models used for analysis in the Draft EIS relied on assumptions about spent nuclear fuel and cask response to accident conditions that caused an overestimation of the resulting impacts. Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there could be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Figure J-9 of the EIS provides a description of transportation accidents in terms of cask temperature and impact speed. Section J.1.4.2.1 presents consequences for accidents that could release radioactive materials.

8.10 (12419)
Comment - EIS001888 / 0558
[Clark County summary of comments it has received from the public.]

Commenters stated that a full range of transportation accidents, especially low probability/high consequence accidents should be evaluated in the EIS. Other commentators stated that the EIS should evaluate a severe, but credible, transportation accident. Some commenters offered specific transportation accidents for analysis.

Response
The transportation accident risk analysis in the EIS encompasses the full range of transportation accidents. As noted in the comment, several commenters requested analysis of specific accident scenarios, such as a crash between a

railcar and a herd of cattle, a crash involving two trucks, a crash involving a truck and a train, etc. The accident analysis referred to such events as "initiating events." A large number of specific initiating events can be identified by review of historic transportation accidents or by the imagination.

Regardless of the specific initiating event, the severity of a transportation accident can be characterized by the combination of mechanical forces and heat involved in the accident. Mechanical forces account for the severity of the crash itself, while heat accounts for the severity of fire that might be involved. The risk model used in the EIS evaluated the full range of transportation accidents based on the severity of the mechanical forces and heat. Figure J-9 of the EIS shows the range of transportation accidents based on this model. An initiating event can be characterized in terms of its mechanical forces and heat, and then according to the matrix shown in Figures J-9. As a consequence, it is not necessary to analyze every possible initiating event individually because the range of accidents encompasses all credible initiating events.

Because of the rigorous design standards for shipping casks, most accidents (more than 99 percent) would not generate forces capable of causing functional damage to the cask. Therefore, most accidents would have no radiological consequences. Although it is not likely that an accident would result in functional damage to the cask and a release of radioactivity, the EIS evaluates the consequences of such an accident if it occurred. For example, Table 6-14 lists estimated impacts of the maximum reasonably foreseeable accident for truck transportation. The highest consequences would occur in an urbanized area resulting in about five latent cancer fatalities. The likelihood of such an accident is very small, about 2 in 10 million years.

8.10 (12734)
Comment - EIS001873 / 0060
P. 6-2. The statistical presentation in this section on the incident-free and accident scenario impacts of transporting high-level waste nationally and in Nevada is probably incomprehensible to the average resident of, say, Caliente, Nevada. This chapter should be rewritten in plain English. The various tables in this section alternate between expressing risk in terms of individual doses, collective doses, numbers of cancer deaths, and probabilities of cancer death. While the information appears fairly complete, the tables are not presented in a logical order that allows the risk of the various alternatives to be compared.

This kind of statistical approach, absorbing definite risk to actual people in large, vaguely defined population numbers results in statements which are simply not credible to an ordinary person.

By analogy, it is not considered safe by anyone to discharge a shotgun on the streets of a city of a million people, even though the statistical probability that a particular individual will be hurt may be negligible. To continue the analogy, if someone were actually proposing to fire the gun anyway, it would be important to know on which street and whether it would be pointed horizontally or vertically. The DEIS totally avoids the question of who is being targeted for potentially deadly radiation bombardment. The DEIS also ignores the fact that individuals in some communities will receive a significantly higher exposure. For example residents of communities on a transportation route in Nevada, Utah, or Arizona will likely be exposed to more shipments than people on a route in California or New England.

Response
DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

8.10 (12895)
Comment - EIS010314 / 0003
Of particular concern would be a collision that would result in a long-duration (longer than 30 minutes), high-temperature (hotter than 1475°) fire. Or a head-on or sideways collision that would result in a puncture of the cask.

Response
The Type B shipping casks DOE would use to transport spent nuclear fuel and high-level radioactive waste to the proposed Yucca Mountain Repository would be designed to withstand severe hypothetical accident conditions. The hypothetical accident conditions are described in Nuclear Regulatory Commission regulations (see 10 CFR 71.73), and include free drop, puncture, thermal, and immersion conditions. These tests are intended to simulate the effects of severe impact and long-duration fires on the shipping cask.

In the analysis of accidents, long-duration fires or punctures of the cask leading to damage and functional failure of a spent nuclear fuel shipping cask are termed "initiating events." A large number of specific initiating events can be identified by review of historic transportation accidents or by the imagination. These include collisions with fixed objects (bridge abutments, walls, barriers, etc.), collisions with other vehicles and animals, rollovers, jackknifes, derailments, and collisions at grade crossings. Any initiating event can be characterized in terms of its mechanical forces and heat, and the event can then be categorized according to the matrix shown in Figure J-9 of the EIS, which is the transportation accident risk model used in the EIS. DOE took this model from a recent Nuclear Regulatory Commission study, *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). As a consequence, it is not necessary to analyze every possible initiating event individually because the range of accidents included in the document encompasses all credible initiating events. Regardless of the specific initiating event, the severity of a transportation accident can be characterized by the combination of mechanical forces and heat involved in the accident. Mechanical forces account for the severity of the crash itself, while heat accounts for the severity of fire that might be involved in the accident. The Nuclear Regulatory Commission concludes that only a tiny fraction of all accidents, less than 1 in 10,000, would be severe enough to cause a spent nuclear fuel shipping cask to fail (Sprung et al. 2000). The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. This study reaffirmed that the spent nuclear fuel transportation regulations provide adequate protection of public health and safety.

8.10 (12896)
Comment - EIS010314 / 0004
Taking note of the fact that seventy-six commercial nuclear power reactors are currently operating to the east of the Mississippi River (and twenty-seven to the west), it would be highly plausible that a train or truck carrying spent fuel could derail on a Mississippi River bridge, resulting in the fuel cask's underwater submersion in the river. Or perhaps there could be an accident on a bridge over the Missouri, Meramec or other river in our state. Having watched the problems that faced the large crew of emergency workers here in St. Louis County (Webster Groves) when 14 coal cars derailed and dumped their freight on May 31, I absolutely cannot imagine how an immersed spent fuel cask could be removed from the river after falling from one of our high, heavily traveled bridges. It would seem that enough water in leakage could occur to make the fissile material in the cask subject to a criticality accident. (I would refer you to the Code of Federal Regulations, Title 10, Part 51 -- Section 52 (Table S-4) and Part 71 regarding the packaging and transport of radioactive materials.)

Response
As discussed in Appendixes J and M of the EIS, most real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask into a river, and similar extreme accident conditions, would not be likely to result in release of radioactive materials from the shipping casks. Spent nuclear fuel casks are much more robust than the coal cars. If a spent nuclear fuel rail cask had been on the train that derailed and crashed into the river, the accident conditions would not have been more severe than the design standards for the cask. No release of radioactive materials from the cask would have been expected. The performance standards for the casks prescribed by the Nuclear Regulatory Commission were selected to ensure that the chance that a real-world accident would result in loss of cask integrity and release of radioactivity from the cask is extremely remote. These standards ensure that the casks would be extremely robust.

Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there could be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low.

8.10.1 SABOTAGE

Comment - 16 comments summarized
A number of commenters expressed concern over terrorism and sabotage against shipments of spent nuclear fuel and high-level radioactive waste. Commenters summarized the State of Nevada's petition to the Nuclear Regulatory Commission to modify 10 CFR Part 73 to increase the level of security for these shipments. One commenter noted that neither the Draft EIS nor the supporting Sandia National Laboratories report acknowledges Nevada's petition for rulemaking. The commenters asked if spent nuclear fuel and high-level radioactive waste shipments would have armed escorts along the entire shipment route rather than just while they were in urban or high-population areas. The commenters recommended that armed escorts be required for the entire route and that DOE go beyond Commission regulations that prescribe safeguards for fuel shipments. Several commenters mentioned the shipment of plutonium and commented that this material would be a particularly attractive target for terrorists.

Response
Nuclear Regulatory Commission regulations (10 CFR Part 73) prescribe safeguards and security measures for spent nuclear fuel shipments. These measures are required to reduce the likelihood of a successful sabotage attack. DOE shipments to a repository would comply with these safeguards and security regulations.

Regulations in 10 CFR Part 73 require armed guards in heavily populated areas. Escorts, but not armed guards, are required in areas not considered heavily populated. The State of Nevada's petition to the Nuclear Regulatory Commission (PRM-73-10) requests that such a distinction based on population density be eliminated from the regulations. DOE is aware of the petition and, in its January 27, 2000, comments to the Commission, expressed the opinion that the current performance-based regulations are more than sufficient to permit consideration of all appropriate threat scenarios. However, if the regulations for safeguards and security measures that apply to spent nuclear fuel transportation were revised, DOE would comply with the revised regulations for shipments to a repository. Similarly, for shipments other than spent nuclear fuel, which are addressed in 10 CFR 73.37, DOE would comply with all applicable Nuclear Regulatory Commission safeguards and security requirements.

Recent terrorist attacks have involved high-profile symbols of the United States and produced a large number of immediate fatalities. Sabotage of a spent nuclear fuel shipment would not achieve this result. Even a successful sabotage attempt would not likely release significant quantities of radioactive materials. Casks would be designed and built to prevent release of their contents in all but the most severe accidents.

8.10.1 (133)
Comment - 40 comments summarized
Several commenters expressed concern that the shipments of spent nuclear fuel and high-level radioactive waste would present an attractive target for saboteurs and terrorist actions. Media stories related to terrorism events frequently were cited for the concern. In addition, the fact that shipments would be frequent and would involve a known destination is seen as suggesting that they would be an attractive target. Commenters questioned protecting shipments at stopping points in the transportation cycle. The assertion was made that protection is likely to be inadequate compared to in-transit safeguards. Specifically, commenters stated that the Draft EIS does not address potential acts of sabotage at intermodal transfer stations. Concern was expressed about the increased risk of sabotage in Utah because of the large number of shipments going through the state and the Private Fuel Storage facility proposed in Skull Valley. In addition, one commenter requested DOE maintain efforts to test the latest potential sabotage devices against casks.

Response
Recent terrorist attacks have involved high-profile symbols of the United States and produced a number of immediate fatalities. Sabotage of a spent nuclear fuel shipment would not achieve this result. Even a successful sabotage attempt would not be likely to release significant quantities of radioactive materials. Nevertheless, the

Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection and safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the physical protection and safeguards regulation are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. The cask safety features that provide containment, shielding, and thermal protection also provide protection against sabotage. The casks would be massive. The spent nuclear fuel in a cask would typically be only about 10 percent of the gross weight; the remaining 90 percent would be shielding and structure. Additional information on the physical protection of spent nuclear fuel and high-level radioactive waste during transportation can be found in Section M.7 of the EIS.

It is not possible to predict whether sabotage events would occur, and if they did the nature of such events, nevertheless, DOE examined various accidents, including an aircraft crash into a transportation cask. The consequences of both the maximum reasonably foreseeable accident and the aircraft crash are presented in the EIS for the mostly truck and mostly rail transportation scenarios and can provide an approximation of the types of consequences that could occur from a sabotage event. In addition, DOE analyzed the potential consequences of sabotage on a truck or rail cask (see Section 6.2.4.2.3 of the EIS). The results of this analysis indicate that the risk of the maximally exposed individual incurring a fatal cancer would increase from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the terrorist attack of September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

As suggested in some comments, some types of anti-armor weapons can penetrate a cask (as shown in Section 6.2.4.2.3 of the EIS), but it should not be assumed that an attack would be easy or that a significant release would result even if a cask was penetrated. Sandia National Laboratories conducted an analysis that estimated maximum releases of radioactive material from the action of a high-energy density device when used against a shipping cask containing spent nuclear fuel (DIRS 104918-Luna, Neuhauser, and Vigil 1999). The devices evaluated by Sandia for analysis were chosen because they represent devices that are potentially available, could be carried by a person, and are highly effective at producing damage for their device category. The results of potential sabotage are discussed in Section 6.2.4.2.3.

8.10.1 (166)
Comment - 20 comments summarized
A number of comments reflected a disbelief of the Draft EIS projected sabotage consequence saying it was at least a factor of 10 too small. The commenters traced this underestimate to a recent Sandia study (DIRS 104918-Luna, Neuhauser, and Vigil 1999). The critique of the Sandia study centered on a number of aspects of the analysis which include failure to consider multiple devices, incendiary devices, modern attack devices, commercial devices or modern military anti-armor weapons. Other criticism included failure to assume full penetration, use of the “swept volume” method, failure to consider fuel oxidation, lack of testing, the use of the SCAP computer program for penetration prediction, and the use of RADTRAN and RISKIND for risk and consequence analysis. A commenter stated that the Draft EIS is silent on any impacts other than human health effects from sabotage.

Response
The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection and safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the physical protection and safeguards regulation are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. The cask safety features that provide containment, shielding, and thermal protection also provide protection against sabotage. The casks would be massive. The spent nuclear fuel in a cask would typically be only about 10 percent of the gross weight; the remaining 90 percent would be shielding and structure. Additional information on the physical protection of spent nuclear fuel and high-level radioactive waste during transportation can be found in Section M.7 of the EIS.

It is not possible to predict whether sabotage events would occur, and if they did the nature of such events, nevertheless, DOE examined various accidents, including an aircraft crash into a transportation cask. The consequences of both the maximum reasonably foreseeable accident and the aircraft crash are presented in the EIS for the mostly truck and mostly rail transportation scenarios and can provide an approximation of the types of consequences that could occur from a sabotage event. In addition, DOE analyzed the potential consequences of sabotage on a truck or rail cask (see Section 6.2.4.2.3 of the EIS). The results of this analysis indicate that the risk of the maximally exposed individual incurring a fatal cancer would increase from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the terrorist attack of September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

The Sandia analysis estimated maximum releases of radioactive material from sabotage against a shipping cask containing spent nuclear fuel. Sandia considered 15 devices and chose two for detailed analyses. Incendiary devices, which are most effective when there are combustibles present, were not considered because there would be no combustibles in a cask. Therefore, the effect of an incendiary device on a cask or its contents would be small compared to an initial release caused by the action of a high-energy density device. Fuel oxidation was not considered as a mechanism to create more particulates for release because it takes considerable time to occur and would not be a contributor to the direct release of spent nuclear fuel materials.

The Sandia scientists used the SCAP computer program, which has been benchmarked against experiments for estimating depth of penetration produced by the action of high-energy density devices. As indicated in the Sandia report (DIRS 104918-Luna, Neuhauser, and Vigil 1999), SCAP was tested against several experiments involving device interactions with material configurations not unlike spent nuclear fuel casks. Although the SCAP program's ability to estimate the depth of penetration through dense materials was demonstrated by benchmarks, the program underestimates the volumes of materials that would be destroyed by the action of a high-energy density device. Recognizing this, Sandia scientists developed a method for correcting the estimates provided by SCAP of destructed, or swept, volume. Although incorrectly described in an equation in the analysis report, swept volume was explicitly defined in the Sandia analysis.

DOE used the RISKIND computer program and the results of the Sandia analysis to estimate the human health consequences of releases of radioactive materials that could result from an act of sabotage. The RISKIND code has been used widely and is generally accepted as appropriate for estimating the consequences of radioactive material transportation accidents that could release radioactive materials. Releases of radioactive materials in a sabotage event would be comparable to releases in maximum reasonably foreseeable accidents analyzed in the EIS using RISKIND. DOE did not use the RADTRAN computer program in estimating consequences of an act of sabotage.

DOE believes the analysis provides realistic, but conservative, estimates of releases of radioactive material that could result from sabotage against a cask transporting spent nuclear fuel, and the consequences of these releases.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $9.4 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

8.10.1 (167)

Comment - 4 comments summarized

Several commenters stated that, based on state policy, law enforcement agencies would provide armed escorts while the spent nuclear fuel and high-level radioactive waste shipments were within the state's boundaries. The commenters questioned who would pay for the escorts and emergency management equipment. The commenters stated that the costs of security measures should have been delineated, along with the responsible parties, in the EIS. One commenter asked for the definition of "heavy-populated" areas in the context of armed security requirements.

Response
DOE would comply with the Nuclear Regulatory Commission safeguards requirements in place at the time of the shipments. The costs associated with meeting the safeguards requirements, including those for escorts, would be borne by DOE. If states or tribes determined that they wished to provide escorts in addition to those provided by DOE, the cost of these additional escorts would have to be borne by the state or tribe. As stated in the EIS, armed escorts would be required in heavily populated areas. A heavily populated area is defined by the Nuclear Regulatory Commission as follows: "Certain areas within United States territory are designated as heavily populated for the purposes of regulation of spent nuclear fuel shipments. Heavily populated areas are characterized in terms of urbanized areas, as defined by the Bureau of the Census, having total populations of one hundred thousand persons or more" (DIRS 154766-NRC 1980). Response to an emergency that could occur involving a shipment of spent nuclear fuel would come initially from local response personnel, as it would for a shipment of any other commodity.

In response to public comments, DOE added Appendix M to the EIS, which describes Section 180(c) of the NWPA (see Section M.6). Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. DOE published a Notice of Revised Proposed Policy and Procedures (63 *FR* 23753, April 30, 1998) that sets forth the proposed mechanisms for implementing the requirements of Section 180(c). As part of this program, eligible jurisdictions would receive a one-time planning grant to assess their training needs. In accordance with the Draft Policy and Procedures, jurisdictions may use a certain percentage of their financial assistance to purchase equipment that can be used for training and for emergency response.

8.10.1 (1028)
Comment - EIS000209 / 0003
At present time, Nevada believes the DEIS sabotage analysis before the end of the formal comment period. The [A] Sandia report significantly underestimates the amount of spent nuclear fuel released from the cask(s) and they may also underestimate the fraction of the release, which is a respirable aerosol. The DEIS failed to consider any impacts other than direct human health effects. Nevada will also evaluate the adequacy of the RISKIND model for this type of analysis, particularly RISKIND's ability to accurately simulate near field (within 100 to 1,000 meters of the attack site) particulate dispersal and deposition, with and without fire effects.

Response
The Sandia report (DIRS 104918-Luna, Neuhauser, and Vigil 1999) estimated the average and maximum releases of radioactive material from sabotage against a shipping cask containing spent nuclear fuel. Luna, Neuhauser, and Vigil considered 15 devices and chose two for detailed analyses. Incendiary devices, which are most effective when there are combustibles present, were not considered because there are no combustibles within a cask. Therefore, the effect of an incendiary device on a cask or its contents would be small compared to an initial release caused by the action of a high-energy density device.

The SCAP computer code was used to estimate the depth of penetration produced by the action of the high-energy-density-devices. SCAP was benchmarked against several experiments involving device interactions with material configurations not unlike spent nuclear fuel casks (DIRS 104918-Luna, Neuhauser, and Vigil 1999).

DOE used the RISKIND computer code and the results from Luna, Neuhauser, and Vigil (DIRS 101836-1999) to estimate the human health consequences of releases of radioactive materials that might result from an act of sabotage. The RISKIND computer code has been used widely and is generally accepted within the health physics community as appropriate for estimating the consequences of radioactive material transportation accidents that could release radioactive materials. Releases of radioactive materials in a sabotage event would be comparable to releases in maximum reasonably foreseeable accidents analyzed in the EIS using RISKIND. DOE did not use the RADTRAN computer program in estimating consequences of an act of sabotage.

DOE believes the EIS analysis provides realistic, but conservative, estimates of releases of radioactive material that could result from sabotage against a cask transporting spent nuclear fuel or high-level radioactive waste, and the consequences of these releases.

The EIS uses the risk of a latent cancer fatality as its primary measure of radiological impact. However, other radiation-related impacts such as the incidence of nonfatal cancers and severe genetic effects are discussed in Section F.1.1.5 of the EIS. All radiation effects are linear with latent cancer fatalities and including these other radiation-related impacts would increase the total detriment from radiation exposures by about 50 percent.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. Section J.1.4.2.5 discusses ecological restoration after a release of radioactive material.

8.10.1 (1035)
Comment - EIS000209 / 0005
Increased vulnerability of shipping casks results from changes in the capabilities and availability of high-energy explosive devices and from changes in cask designs. Portable antitank weapons have become more powerful, more reliable, and more available worldwide since the early1980s. Many of these weapons are capable of penetrating 20 to 40 inches of armor plate steel. Commercial shaped charges and detonation systems developed for applications in the construction and petroleum industries are widely available. Numerous “off the shelf” military and commercial shaped charges weighing around one kilogram are capable of penetrating 10 to 20 inches of steel. It is probable that even more powerful and efficient explosives will become available during the next four decades when repository shipments are under way.

The new shipping casks assumed in the DEIS appear to be highly vulnerable to attacks using currently available high-energy explosive devices. The new General Atomics GA-4 and GA-9 legal-weight truck casks have a side-to-side width of 35 to 37 inches, with walls containing about 2 inches of stainless steel and 2.6 inches of depleted uranium. The DEIS provides less specific details about the new rail cask designs. The largest new rail casks will likely have designs similar to the Nuclear Assurance Corporation NAC-TSC, the Holtec HI-STAR 100, or DOE large MPC Rail Transporter. These casks have diameters of 85 to 96 inches, with walls containing 4 to 7 inches of stainless steel and 2 to 4 inches of carbon steel or lead and depleted uranium.

Response
Luna, Neuhauser, and Vigil (DIRS 104918-1999) estimated the average and maximum releases of radioactive material from the action of sabotage against a shipping cask containing spent nuclear fuel. Luna, Neuhauser, and Vigil considered 15 devices and chose two for detailed analyses. Incendiary devices, which are most effective when there are combustibles present, were not considered because there are no combustibles within a cask. See Section 6.2.4.2.3 of the EIS for additional information.

Comment - EIS000605 / 0001
Now item 1, security. Nowhere have I seen any document stating truck drivers and railroad personnel are required to have [a] special government clearance. Not in the RFP, request for proposal draft dated 1998, nor in the EIS or even in the DOT regulations.

Actually, imagine 70,000 tons of high level nuclear hazardous waste has arrived at Yucca Mountain. The entire world has been watching and waiting. After all, we are making history. Various tragedies have occurred as this material traveled through 43 states to its final destination.

According to Volume 1, paragraph 1.2.4, 55 tons of weapons usable plutonium has arrived. According to geologist John T. Rosenthal, he works for [Booz] Allen and Hamilton, he says about security:

"If Yucca Mountain becomes a high level waste storage site, Energy Department plans call for either closing it up as early as 10 years after the last waste canisters are buried, or keeping it open for hundreds of years. If the Department elects to close the mountain it would seal all the shafts, ramps, exploratory bore holes and other underground openings to further discourage any intruders."

We're like a bunch of idiots here.

"Permanent warning markers and monuments would be put up around the site."

Now this is what Rosenthal says.

"The Department is not worried about sabotage. In its recent Environmental Impact Statement, it says that the site's remote location and the area's low population density makes it an unattractive target. In addition, it tends to have extra security measures in place. At one of the alcoves a fixed spaghetti of cable snakes from the walls to an array of sophisticated monitoring equipment and electronic board the size of a large screen TV records the total power used, as well as the total power cost and the current rock temperature."

Now, my final statement. Hypothetically, 70,000 tons -- did I read this already? Okay. Now please close your eyes just for two minutes and imagine, 75 to a hundred miles away, nowhere near the security measures referred to by John Rosenthal. Instead, John Q. Tourist trained by Kadafy is about to launch one missile using his sophisticated electronic equipment. Or this same scenario could happen somewhere on route to Yucca Mountain.

Response
The EIS discusses sabotage during transportation in Section 6.2.4.2.3. Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (1922)
Comment - EIS000477 / 0002
Another issue I have is the transportation of the waste. If as the DOE studies demonstrate, an accident during the shipment process (1:343 ratio) happens in a populated area, who will accept personal responsibility, you? I've seen the infocommercials back in 1991 showing a locomotive smashing into the stainless steel waste container -- I wasn't convinced. If the waste travels by rail, it makes sense that it will pass through the heart of Las Vegas and North Las Vegas, not to mention Nellis Air Force Base. What additional safeguards are being discussed to prevent any accidental leakage of radioactivity. It would be very easy for local governments or individuals to block rail routes. Remember the Shoshone-Bannock Tribe in Fort Hall, Idaho, using their police force to prevent a nuclear shipment in 1995? What if a terrorist group did that? How secure are these shipments going to be?

Response
The safety and security of spent nuclear fuel shipments is the responsibility of DOE. DOE would ensure that the contractors making the shipments followed DOE and Nuclear Regulatory Commission safeguards requirements. In response to comments, additional information on safeguards requirements is included in Section M.7 of the EIS.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

Comment - EIS000440 / 0001
But, today we address the vulnerability of repository shipments to terrorism and sabotage, specifically the consequences of attacks on shipping cask utilizing high-energy explosive devices. You are not going to hear much applause from the State of Nevada for the Draft EIS by the DOE, but there is one issue on which we will applaud them this morning, and that is their decision to address the issues of terrorism and the consequences of sabotage, radiologic sabotage, forthrightly in this document.

We're heartened to see that for the first time in the 20 years that I have been reviewing Department of Energy EIS there's at least a willingness on their part to acknowledge the vulnerability of shipping casks to such attacks.

Response

8.10.1 (2732)
Comment - EIS000709 / 0006
The DOE, in No Action Scenario 1, states that storage at the present sites has the disadvantage of increased risks of sabotage and materials diversion. They do not, however, use that same reasoning when it comes to the 49,500 shipments from across the country to Yucca Mountain. Even without detailed analysis, it is obvious that a shipment of radioactive material, even under military guard, is much more vulnerable to attack than that same material in a secured storage area within a secured nuclear power facility.

Response

8.10.1 (3251)
Comment - EIS000949 / 0002
On transportation, a terrorist attack on high level nuclear waste carriers is potentially the most serious. The federal government should fund engineers during the next ten to twenty years to design the protective shipping containers to withstand any terrorist attack, including bombing the trucks and trains with high explosive bombs. The Department of Energy must assure us that the containers will not break open and let nuclear waste escape, even in the worst conditions. It is further suggested that sabotage and terrorism should be addressed in the Nuclear Regulatory Commission design study that is responsive to these concerns.

Response
Cask safety features that provide containment, shielding, and thermal protection also provide protection against sabotage. The casks would be massive. The spent nuclear fuel in a cask would typically be only about 10 percent of the gross weight; the remaining 90 percent would be shielding and structure.

Comment - EIS000973 / 0001
I would like to know the explosive power in TNT [tri-nitro toluene, or dynamite] units that a [cask] carrying nuclear waste can tolerate.

Response
The details of the results of specific tests related to sabotage of spent nuclear fuel casks are not provided in public documents such as this EIS.

8.10.1 (3645)
Comment - EIS000816 / 0002
No type of packaging will be entirely safe from structural damage if an accident or an event involving an act of sabotage occurs. Each of these scenarios foresees breach of cask and an insuring radiation release. Depending on type of material being transported and location of the release, this could result in not only immediate and numerous losses of life, but latent ongoing health concerns and unspecified danger for the immediate environment and all its inhabitants in perpetuity.

Response

Comment - EIS000980 / 0002

How about sabotage or terrorist attacks? Terrorist would love to steal our plutonium to manufacture their own bombs. Or they might just want to demand millions of dollars or other terrorist" release from jail in exchange for not blowing up a high-level radioactive waste transport. With such frequency of shipment, it couldn't be too hard for terrorists to figure out when and where these materials are enroute. If a bomb landed on one of these vehicles, or a suicide bomber decided to ram one, we're talking about life-threatening pollution, not just to the surrounding area, but to the entire city. In the DOE's Draft Summary Environmental Impact Statement, in a chart of Estimated National Transportation Impacts for 24 years of operations (p. S-53), latent cancer fatalities from maximum reasonably foreseeable accidents are 5 for mostly truck scenarios and 31 for mostly rail scenarios. These estimates could not possibly have included potential terrorist attacks. Apparently, there is some concern about such attacks, as the Nuclear Regulatory Commission will require two armed escorts for every shipment of irradiated fuel rods. Such guards might have been able to save the stagecoaches of days past, but I have little hope that they could overpower modern terrorists.

Response

Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health.

Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

Comment - EIS001474 / 0004

The question of terrorism as a danger for these shipments, it's been said that these shipments are not. If you listen to the Department of Energy and as well to the Nuclear Regulatory Commission, these shipments are very safe, nothing could ever go wrong with these shipments. But they contain some of the deadliest materials on earth. If they're breached and the materials are released into the environment, that is a catastrophe to that local environment. And it's very difficult to clean up radionuclides that get into the environment, and Chernobyl shows that. A huge percentage of the national budget of the countries over there is being devoted to Chernobyl cleanup. And right at the reactor itself, which was the showcase of the cleanup efforts, the readings are still very high right there. So it's very difficult to clean the stuff up once it gets out.

And it's interesting that we just had a court case in Kalamazoo where we were trying to get an injunction against a Department of Energy shipment of plutonium experimental fuel through Michigan, and we had a person who's worked for the State of Nevada who's done reports of danger of terrorism to high-level waste shipments, and he was one of the expert witnesses who testified that this plutonium shipment was a high-profile federal project, that there was concern, and that it hadn't been addressed by the Department of Energy in its environmental assessment for that project.

And one of the arguments that the U.S. attorneys representing the Department of Energy made was that this single shipment of plutonium was not equal to Yucca Mountain and all those shipments, so how could we ask the judge to put an injunction on this one shipment when Yucca Mountain just dwarfed it.

So I thought that was really interesting that that argument was floated. And I imagine they didn't think that anybody involved with Yucca Mountain would ever hear those words. So it was an admission that terrorism is a significant situation that wasn't addressed adequately at all in this document.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health.

The EIS discusses sabotage in Section 6.2.4.2.3. Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. Section J.1.4.2.5 discusses ecological restoration after a release of radioactive material.

Comment - EIS001209 / 0002
The Commonwealth of Virginia also reviewed the *Federal Register* Notice published by the Nuclear Regulatory Commission pertaining to a petition filed by the State of Nevada to amend NRC's [Nuclear Regulatory Commission's] regulations governing safeguards for shipment of spent nuclear fuel against sabotage and terrorism. As stated in our November 29, 1999 response to the NRC, Virginia is supportive of any precautionary measures, which serve to protect its citizens, environment, and natural resources against potential danger associated with spent nuclear fuel shipment and storage. Therefore, the Department of Emergency Services, Brian Iverson at (804) 674-2400, and the appropriate localities should be notified prior to the transportation of hazardous materials from or through Virginia. Also, we agree with the recommendation of reviewers that a periodic review of threat levels and an evaluation of tactical response measures may be appropriate.

Response
DOE would follow the Nuclear Regulatory Commission requirements on prenotification in effect at the time of shipment. Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

Comment - EIS000992 / 0002

One specific issue that has been raised in recent years by those in opposition to nuclear power is terrorist assault or acts of sabotage directed against used nuclear fuel and high-level radioactive waste shipments. Although this country has been sensitized to the terrorist potential ever since the World Trade Center bombing, I am convinced that used nuclear fuel and high-level waste shipments are a remote target for such acts. Having said that, if for some rare reason a shipment might be singled out for assault I am confident that the design basis of the package (cask) and the nature of the contained radioactive material would make the attack either unsuccessful or in the worst case a limited, manageable event. Clearly not one postulated by the preposterous “Mobile Chernobyl” term that the anti-nuclear factions have incorrectly used to characterize the shipping of these materials.

From the design point of view, the Federally mandated accident conditions bound the conditions that would be expected in an assault such as those in Oklahoma City, New York City, Atlanta, and a few other locations. These have been “homemade” large explosive devices that are effective against structures such as buildings, or against people. However, the blast effects and even the objects propelled by such blasts may dislocate a cask and its transporter (e.g., overturn) but in my judgment are bounded by the design conditions for the package. That is, package integrity will be maintained.

Our opponents cite high-energy weapons such as anti-tank missiles as having the ability to penetrate a cask wall. I cannot quarrel with this, since such was demonstrated by the NRC [Nuclear Regulatory Commission] and the DOE in the 70’s and 80’s in a comprehensive testing program. [It is worth noting that there have been no terrorist assaults in this country where such weaponry has been used.] But the significance of the earlier testing program and the update of that program performed by Sandia in support of the YMP [Yucca Mountain Project]/EIS (SAND99-0963) is that even with a penetration of the cask the amount of material released is a small fraction of the total cask contents. Estimates range from 0.0003% to 0.01% depending on the size of the cask. Of this amount roughly 0.5% of it is estimated to be of aerosol size capable of being dispersed beyond the immediate vicinity. Regardless of cask size, this is a small amount of material. It will result in a highly localized contamination event with limited effects outside the immediate area. Both are quite manageable.

Of course the radiological consequences, as manageable as they are projected to be, can only occur if one accepts the assertion of the anti-nuclear activists that these shipments are a likely target. I am convinced that just the opposite is true.

Those dedicated to terrorism are making a statement through their acts. Such a statement demands a successful outcome of the assault, something that is highly unlikely when used nuclear fuel or high-level radioactive waste shipments are the target. Indeed, a failed attempt is essentially a confirmation of the safety that is inherent in the cask design and the shipment of these commodities, a strong deterrent in itself. There are many factors that make attempts likely to fail.

Initially, there are Federal regulations in 10 CFR 73 that address in-transit security. These speak to the security of shipping information, transport personnel qualifications, escort requirements, communications requirements, and transportation equipment features. Shipments will be continuously tracked via satellite thus assuring constant monitoring of shipment parameters.

Additionally, there is the issue of a successful assault. As stated previously, a large explosive device is not going to be successful in disrupting cask integrity, even though it may result in dislocation of the transport system. An attack using some form of high-energy penetrating weapon has a number of associated problems as outlined in the recent Sandia report. These include: weapon portability, training, targeting, weapon functioning, cask construction features, transporter speed, and meteorological conditions. These all contribute to the high likelihood of an unsuccessful attempt.

Realistically there are countless targets through which a terrorist can make a statement with reasonable confidence of a successful assault. A used nuclear fuel or high-level radioactive waste shipment, in my opinion, is not one of them. Even an anti-nuclear terrorist would select a target with greater assurance of success.

Federal regulations and the planned operations of the transportation system together with the rugged design of the shipping casks and the success uncertainty of any assault makes terrorist attacks or acts of sabotage against used fuel or high-level waste shipments extremely unlikely. And, in the event of a successful, assault, the effects are projected to be acceptable low.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

It is the Department's opinion that the EIS adequately analyzes the potential environmental impacts of spent nuclear fuel and high-level radioactive waste accidents, including sabotage.

Comment - EIS000968 / 0010
The State [of Nevada] is responsible for providing for the security and safety of the proposed shipments. The DEIS dos not address minimum security requirements, proper escort staffing, or inspection of vehicles entering the State.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. More detailed information is provided in Section M.7 of the EIS.

8.10.1 (5307)
Comment - EIS001887 / 0043
The Draft underestimates the consequences of severe accidents and terrorism/sabotage incidents, especially with respect to heavy-haul transportation. The Draft EIS fails to appropriately recognize human initiated events as risk factors associated with the loading, transportation, and unloading of radioactive waste shipments. The Draft reflects an overriding "denial" philosophy that is evidenced in the lack of critical or even anecdotal discussion of sabotage and terrorism within Section 6 and Appendix J of the Draft EIS.

The Draft EIS must acknowledge the existence of credible and realistic risks from sabotage and terrorism. The symbolic value of repository shipments as targets and the regularity, frequency, and duration of shipments substantially increase the risks of human initiated events.

Spent fuel loading, transfer, and unloading activities should have been recognized as vulnerable to sabotage and terrorism attacks. These risks should have been addressed in the Draft EIS together with the implications of new regulations needed to limit the effects of human initiated events on the overall repository shipment program.

The complete point-to-point shipment process needs to be re-analyzed using updated assumptions about terrorist/ sabotage technology and more realistic expectations of the potential for sabotage and terrorism attacks. The State of Nevada has begun this process by publishing several relevant documents on target types and risks associated with potential adversaries. Recognition of these concerns and an adequate analysis of the risks associated with potential terrorism/sabotage must be incorporated within the final EIS.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear

fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. Because the heavy-haul truck implementing alternative would be like moving a rail cask on a truck, the analysis of the consequences of an accident to a rail cask is applicable. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Spent nuclear fuel loading, transfer, and unloading activities would occur in fixed facilities. These facilities would have to meet the requirements in U.S. Nuclear Regulatory Commission physical protection or safeguards regulations. For example, 10 CFR 63.21 requires a repository at Yucca Mountain to have physical protection consistent with 10 CFR 73.51. This regulation specifies a performance objective, which provides “high assurance that activities involving spent nuclear fuel and high-level radioactive waste do not constitute an unreasonable risk to public health and safety.” The regulation requires that spent nuclear fuel and high-level radioactive waste be stored in a protected area such that:

- Access to the material would require passage through or penetration of two physical barriers. The outer barrier would have isolation zones on each side to facilitate observation and threat assessment, would be continually monitored, and would be protected by an active alarm system.

- Adequate illumination would be provided for observation and threat assessment.

- The area would be monitored by random patrol.

- Access would be controlled by a lock system and personnel identification would be used to limit access to authorized persons.

A trained, equipped, and qualified security force would be required to conduct surveillance, assessment, access control, and communications to ensure adequate response to any security threat. Liaison with a response force would be required to permit timely response to unauthorized entry or activities.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments and key facilities. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

<u>Comment</u> - EIS001660 / 0015
The DEIS inadequately provides information about terrorist/extremist threats, and used old data to provide this information. The DEIS must use current data and involve new experiments concerning modem cask response to sabotage events. The Memo to Mr. R. Halstead from “Radioactive Waste Management Associates” which has been included in Mineral County’s comments for record are referenced - “2. Deficient Treatment of Sabotage”. pp. 6-19, see Attachment G. [Following is text of reference.]

Deficient Treatment of Sabotage

There are a number of points of contention with the current treatment of sabotage by the DOE in the Draft Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada (DOE/EIS-0250D, 1999) and referenced documents. In order to establish the need for a reevaluation of the analysis of sabotage used by DOE in preparation of the EIS most clearly, only the most significant problems will be addressed. The final conclusion of this section is that the

DOE does not adequately address the threat of sabotage, nor does it prove that concerns about the affects of such an event are unwarranted.

Inadequate selection of Reference Weapons and Reference Cask

The type of shaped charge used in the Sandoval experiments and cited in Luna as the device offering the maximum impact of a sabotage attack is the M3A1 military shaped charge. This charge, when tested against a full-scale GE IF-200 cask, was capable of penetrating one cask wall, penetrating 42 cm (16.5 inches) into the cask, damaging 50% of the spent fuel rods, and releasing more than 1% of the total fuel. Sandoval also says that a survey of attack devices was performed in this study, with the devices selected based on their availability to the perpetrator and their potential to breach truck casks. The details of this evaluation are classified.

In order to better understand exactly what devices were considered for possible use as the reference weapon, it is necessary to understand the restrictions placed on this analysis. In 10 CFR 73.1.a.1, "radiological sabotage" is defined as:

(i): a determined violent external assault, attack by stealth, or deceptive actions, of several persons with the following attributes, assistance, and equipment:

a. well-trained (including military) and dedicated individuals

b. inside assistance, passive or active

c. suitable weapons, up to and including hand-held automatic weapons, equipped with silencers and having effective long-range accuracy

d. hand carried equipment, including incapacitating agents and explosives for use as tools of entry or for otherwise destroying reactor, facility, transporter, or container integrity or features of the safeguard system.

e. four-wheel drive land vehicle used for transporting personnel and their hand Carried equipment to the proximity of vital areas

(ii): an internal threat of an insider, including an employee

(iii): a four-wheel drive land vehicle bomb

This provides the parameters by which the assessment of possible weapons was made. The definition of "hand Carried equipment" is unclear. It appears that such anti-tank artillery as the Milan Anti-Tank Missile and the US TOW 2 Anti- Tank missile, reported to have armor-penetrating capabilities of greater than 1000mm (39.4 inches) and greater than 700mm (28.5 inches), respectively, have not been considered as plausible sabotage weapons. In contrast, the M3A1 is reported as having armor-penetrating capabilities of at least 20 inches. This means that either of the anti-tank missiles will penetrate deeper into a spent fuel cask, likely completely through, drastically increasing the amount of material released. Anti-tank missiles of this sort must be analyzed in a credible sabotage analysis. Both devices can be transported by a few persons, or a vehicle, and thus should be considered "hand Carried."

Failure to consider arson coupled with missile strike as credible reference weapon and reference attack

A very significant factor to note when analyzing the results of the Luna report is that missile strikes accompanied by fires have not been considered. In section 3, the following statement is made:

"[U]nlike tanks and other typical targets of armor-piercing weapons, nuclear waste casks contain no explosive or combustible materials that could be touched off by the HEDD penetration, so little secondary damage is expected. In other words, only penetration and swept volume of spent fuel disrupted determine the magnitude of the damage that can be inflicted by an attack on a cask, not penetration depth per se."

This shows a hidden assumption in the assessment of sabotage. The Luna study assumes that there will be no fire coupled to a missile strike in the event of sabotage. Luna makes this assumption noting that the casks themselves are not combustible. However, this does not account for the potential of saboteurs to deliberately set a fire, or for the fact that the casks will be in proximity to combustible materials while being transported. Shipping casks are designed for transport on trucks or trains that are powered by highly flammable, combustible materials. These casks are also very likely to spend a significant portion of their travel in proximity to other trucks, rail cars, pipelines, etc. containing combustible or explosive materials. Further, potential saboteurs must be assumed to have knowledge that engulfing a target in flames in addition to striking it with a missile will be very likely to cause extensive damage. All of these factors lead to the conclusion that "secondary damage" cannot be ignored, as it has in this study.

Heat input to a cask will weaken the areal density of the metal shielding layers. If potential saboteurs were to first weaken the shipping casks via thermal input before missile strike, this could significantly increase the damage caused by such an event. In a series of experiments testing resistance of shipping containers to puncture conducted for the NRC by Lawrence Livermore National Laboratory and published in 1980, the impact of increasing temperature on cask strength was addressed (NUREG/CR-0930). One experiment in this study concentrated on the effect of temperature on the ultimate "punch force" required to completely penetrate a shipping cask wall. From this test it was determined that "the force at failure decreases with increasing temperature," (NUREG/CR0930, p. 32). This study used three temperatures for this determination: room temperature, 200°F, and 400°F. Since this study shows there is a correlation between the force required to penetrate a shipping cask wall and the temperature of the cask, it is very important that these effects be considered in a proper evaluation of sabotage scenarios. Further, the temperatures involved in deliberately set, engulfing fires will be able to raise the cask outer wall temperature to levels much beyond this range. In the Modal Study, it is commented that the rail and truck casks used in their analysis "can be exposed to a regulatory fire (1475°F, engulfing) for over 1 hour" (6-43) before the temperature at the mid-lead thickness of the cask wall reaches 500°F. ... What this statement does show is an acknowledgement that the regulatory fire will raise the temperature of a shipping cask wall over the 400°F temperature estimate used in NUREG/CR-0930. This leads to the conclusion that in extreme fire situations, such as those deliberately set as part of a sabotage attempt, the temperature of the shipping cask will rise. This will lessen the force required to completely penetrate the shipping cask wall, as was discovered in NUREG/CR-0930, resulting in greater damage to a fuel cask in the event of a subsequent missile attack.

In addition, not addressing the effects of heat input on spent fuel respirable release in the event of a breach ignores the ability of temperature to increase the percentage of spent fuel released in respirable form. For example, the conversion of $U0_2$ to U_30_8 is exothermic at slightly elevated temperatures, and results in the formation of a fine powder of respirable size (Aronson). Coupling a fire with a cask breach will expose the spent fuel inside the cask to elevated temperatures, resulting in thermodynamically favorable conditions for the above reaction. The importance of this term needs to be addressed in an assessment of sabotage consequences.

By failing to include thermal effects in its assessment of sabotage, the DOE has provided an insufficient treatment of sabotage consequences in the Yucca Mountain EIS. This needs to be remedied before the true impact of a successful event can be analyzed.

Improper extrapolation of previous experiments to current cask designs

Swept Volume

In the Luna report, it is acknowledged that the cask design used in the 1980-1981 tests examined in the Sandoval report is outdated, and an attempt is made then to correlate the data collected in these experiments to a computer simulation of a newer-design cask impact by two HEDD devices. In particular, Luna suggests an "alternative" means of analyzing the test results in the Sandoval report which "enables evaluation of the magnitude of the potential source term in other situations based on calculated hole volumes." (Luna 2.2.6)

To do this, Luna attempts to correlate the experimentally determined ratio of respirable aerosol produced to the mass of fuel released in an event to a calculated ratio based on the mass of swept fuel. The equation is (Luna 2.2.6):

MS =(π/) x NP x NL x NR x PL x PD

NP:
An estimate of the amount of fuel assumed to be affected longitudinally in the pin at the center of the hole. Assumed to be the number of pellets in the missing length rounded up to the next whole pellet. Operationally defined as L/L_p, the missing length of pin divided by the pellet length [unitless].

NL:
An estimate of the affected number of pins laterally. Assumed to be the number of pins within the hole diameter rounded up to the next integer. Operationally defined as L/PP, rounded to the next integer, giving it units of [length^2]

NR:
Defined by Luna as "number of rows of pins along the disruption path/PP," thereby giving it units of [length].

PL:
Depth of penetration of pin disruption. Operationally defined by Luna as NR/PP, giving it units of [length^2]

PD = pellet density, giving it units of [mass/length^3]

Thus according to Luna, the equation works out to be:

MS[mass] =(π/4)[unitless] x NP [unitless] x NL [length^2] x NR [length] x PL [length^2] x PD [mass/length^3],

[mass] = [mass*length^2]

The inconsistent units definitely need explanation by the Sandia researchers responsible for the report. The numerical values obtained using this equation were duplicated by independent calculations, assuming that the number of rows of pins along the disruption path was 6 for the full-scale test... This suggests that either the units are listed incorrectly in the document, or that the equation used to estimate swept mass is invalid. Until this discrepancy is addressed, the DOE's use of the Luna report in the Yucca Mountain EIS is suspect.

Even if the unit discrepancy is a mere typographical error, equating the mass of swept fuel with the respirable release fraction fails to consider such factors as number of holes of penetration (2 for full penetration) and differences in thermal properties of HEDD devices. First, it was assumed that, because the Sandoval full-scale test and the computer modeled test in Luna predicted shaped charges to penetrate only one side of a shipping container, the amount of released respirable material could be described as proportional to the "swept volume" of the fuel pins. However, it was also acknowledged that having multiple holes (for example, an exit and entry hole, or multiple entry holes caused by multiple device strikes) would significantly increase the fraction of respirable material released, since multiple holes will allow outside air to flow through the cask. Because the DOE assumes that a terrorist strike will result in only one hole into a shipping container, it is assumed that this air flow will not be generated, thus leading to the correlation between affected mass and respirable release.

However, it is necessary to consider the event of a full cask penetration (or multiplehole penetration) event. Under these circumstances, there will be a continual supply of oxygen provided to the inner core of the cask. This oxygen will then react with the uranium dioxide spent fuel, oxidizing it to U_30_8. This process is exothermic at slightly elevated temperatures, and results in the formation of a fine powder of respirable size. Further, this air flow, when coupled with elevated temperatures resulting from fire (as would be reasonable in the event of a crash or deliberate arson) would heat the core of the cask without having to first heat its surrounding shields. This will result in a quick elevation of the spent fuel temperature, providing more oxidation and thus more respirable aerosol production. Because the DOE assumed that all sabotage events would at most penetrate a shipping cask with one hole, this mechanism was ignored.

In review of the testing performed at Sandia and Batelle laboratories in the 1980s, it is stated that the M3A1 charge used would completely penetrate certain shipping casks such as the NFS-4 (Dietrich & Walters, 1983 pg. 5). If this type of cask were used in destructive testing, the benchmark forming the basis for the Luna results could be drastically different. This shows the need to consider the effects of a complete penetration event. In the case of a complete penetration, according to the review cited above, "the entrainment of particles in the jet's wake would enhance release at the jet exit hole. Further, two holes should vent more rapidly than one and perhaps capture higher initial concentrations in the efflux" (5). By referencing a flawed computer evaluation of cask resistance to HEDD impact, the EIS has improperly limited the discussion of impacts associated with sabotage events to single-hole, incomplete penetrations. This results in an incomplete estimate of the true effects of a successful sabotage event.

The Luna report acknowledges that the existence of multiple holes results in significant increases in aerosol release fractions. In section 2.2.5, the report states that "the total effect of a full penetration event may be to increase aerosol release by approximately 10 times the aerosol release fraction from partial penetration." If we use this factor of 10 to figure out a new % respirable release and account for the difference between spent fuel and surrogate fuel, the % respirable release is greater than 1%. Below is outlined the % respirable release fractions assuming 10x greater release than was estimated in the Sandoval tests. Also, three different spent fuel-surrogate fuel correction factors are used (see section 2.2.3) to show how they affect the results.

	Release fraction from Sandoval test	**New release fraction, assuming 10x Sandoval result**
Aerosolized fraction of surrogate fuel mass released from pins	0.000537	0.00531
% aerosolized fraction of spent fuel mass released from pins, using SRF of 3	0.1611%	1.611 %
% aerosolized fraction of spent fuel mass released from ph% using SFR of 5.6	0.300%	3.00%
% aerosolized fraction of spent fuel mass released from pins, using SFR of 12	0.644%	6.44%

More analysis needs to be performed before a swept fuel mass can be used as a correlation factor predicting masses of respirable fuel released in the event of a high-energy impact.

In using Swept Volume as a surrogate for respirable release, the analysis is making the assumption that all potential devices used in a terrorist attack will behave the same as the M3A1 charge. Its conclusion rests on the assumption that, given a certain swept volume size, a certain respirable mass fraction will be released, regardless of other factors, such as differences in thermal heat evolution. Further, the computer code used to estimate release fractions of other casks was calibrated using only two test results. When it was found that the code underestimated the hole size by a factor of two, the calibration simply multiplied by 2 to obtain a correlation. Without an, experimental validation of the ability of the SCAP code to effectively model the newer-generation casks, this approach is unacceptable.

Respirable Aerosol Production

Luna addressed a mechanism for additional respirable aerosol release due to the pressurized nature of actual spent fuel rods which was not addressed by the Sandoval tests using unpressurized rods. The report states that in the Sandoval experiments there was a "significant amount of surrogate fuel aerosol created within the cask by the HEDD that remained inside and was ultimately deposited on the inner surfaces of the cask." Some or all of the unaccounted material in the Sandoval tests (which Sandoval concluded "could not have been respirable") is likely to be made up of this material. Luna states that, given a mechanism to create flow of gas out of the cask, this could become an additional respirable aerosol source.

The Luna study addresses the fact that real fuel rods are pressurized, and that rupture of these rods allows gas to escape, producing a flow that will carry aerosol into the environment. In every test subjecting shipping casks (real or modeled) to a HEDD explosion, the fuel rods used were not pressurized, and there was never a direct measurement of the actual quantity of respirable aerosol within the cask that would comprise this contribution from "blowdown." Luna then attempts to estimate the amount of respirable material generated via this pathway by using a brittle fracture study conducted at Argonne National Laboratory (Jardine et al, 1982. "Final Report of Experimental Laboratory-Scale Brittle Fracture Studies of Glasses and Ceramics," Report No. ANL-82-39, Argonne National Laboratory, Argonne, IL.)

Jardine developed experimental data on the amount and size distribution of particulate material produced by calibrated hammer impacts on brittle materials. His work developed a linear relationship between energy density in the material from the impact of a calibrated hammer on brittle materials and the mass of particulate material with geometric diameter less than 10µM over 2 orders of magnitude in energy. Important to note is that Jardine used materials that were sufficiently refractory to ensure that melting and vaporization were not a factor. Thus, one problem with correlating this study for use in tests involving high density devices is that thermal properties are not considered. This is incorrect for missile penetrations, especially when they are coupled with fire (deliberate or otherwise).

Next, Luna takes the relationship found by Jardine for particles of 10µm geometric size and says that this analysis is not interested in these particles. Luna states that "of interest to this study is the quantity of particles that are of respirable sizes. For uranium dioxide pellets with a density of 10.5 g/cm^3, this corresponds to a geometric size of about 3µm." The use of 3µm particle size is unsubstantiated, since particles of size 10µm are airborne and will contribute to overall dose in the event of an explosion. Further, 10µm particles are generally considered the maximum size for respirable aerosols. Therefore, this is the size that should be used in determining the aerosol fraction released in sabotage tests.

Particles of size in the range of 10µm are small enough to be dispersed quite far from an implosion scene. In addition, they can be deposited in the nasal region of the respiratory tract. While it is rare that particles of this size penetrate into the lungs, they will contribute to overall radiological dose. In addition, many of the particles deposited in the nasal region will be ingested, contributing to continued dose inside of the body. Ignoring particles greater than 3µm thus leads to an underestimate of the true radiological health effects of a postulated terrorist event.

To estimate the impact energies expected from HEDD1, Luna takes the estimated HEDD1 kinetic energy and divides it by the estimated swept volume of the disrupted fuel. Luna then makes two estimates: "the highest energy represents no attenuation of the HEDD energy by penetrating the wall. Since the HEDD action penetrated about equal amounts of mass per unit area passing through the wall and passing through the fuel, the residual energy deposited in the fuel is likely to be one-half to one-third of the initial energy density. This is shown by the low end of the range indicated on the plot." In fact, the lower energy is 1/3 of the higher energy. Luna then states that the correlation, using a particle diameter of 3µm and an energy density of 1/3 the estimated initial energy density, approximates that 5% of the unaccounted mass will be respirable.

There are a number of things seriously wrong with this conclusion. First, the Jardine study that the entire relationship is based on does not take into account thermal effects when estimating the correlation between energy density and respirable aerosol production. The correlation used was obtained from a test involving a calibrated hammer, not a high-temperature explosive device. As was mentioned earlier, Luna comments that "all materials were sufficiently refractory to assure that melting and vaporization were not a factor in the tests." (22) This suggests that the correlation is leaving out the importance of temperature in creating additional respirable particles, which if included would certainly increase the fraction of respirable aerosol production.

Second, the $U0_2$ and spent fuel data points obtained from other studies (MacDougall et al, 1987. "Site Characterization Plan Conceptual Design Report, Volume 4, Appendices F-O," Report No. SAND94-2641, Sandia National Laboratories, Albuquerque, New Mexico), (Alvarez et al, 1982. "Waste Forms Response Project Correlation Testing," Report No. EGG-PR-5590, Idaho National Engineering Laboratory, Idaho Falls, Idaho), which Luna states act to validate the use of the Jardine results for spent fuel, are inconclusive. The data from the MacDougall study is in the very low energy density range, and they cannot be used to demonstrate any correlation without more data points taken in the higher energy density range. The Alvarez study appears (the graph in Luna is hard to read) to provide respirable percents from 2% - 40% at an energy density approximately 7 times smaller than the density estimated for the HEDD. Regardless of any of these uncertainties, the Luna study assumes one value for the respirable fraction produced and places no uncertainty boundaries on it.

Third, Luna assumes that the HEDD will have an energy density of 1/3 that estimated based on the swept volume and kinetic energy of the device. It is argued in the Luna study that since the device penetrated about equal amounts of mass per unit area penetrating the wall of the cask as it did penetrating the fuel rods, the energy available for action on the fuel rods is likely "to be 1/2 to 1/3 of the initial energy density." However, this assumes that the HEDD action on the cask wall does not impart an energy to the fuel rods. Because of this fact, Luna's use of 1/3 of the initial assumed energy density is an underestimate (using 1/3 instead of 1/2 is an underestimate in itself). Without actual knowledge of the amount of respirable aerosol produced (as in a properly sampled test), the energy density should be assumed to be 100% of the initial.

In order to check the effect of the assumptions made by Luna in correlating the Jardine data to the sabotage benchmark, we calculated the likely aerosol release ignoring all of the objections raised here except for the use of 3µm particles (see attached spreadsheet). Instead, we used Figure 2 from the Luna report to obtain a % respirable production in the energy range given by Luna for the HEDD penetration assuming l0µm-sized particles. Using this, the Jardine correlation estimates that 50-100% of the fuel impacted by the HEDD will be respirable, as opposed to the 5% assumed by Luna. This changes the respirable surrogate fuel aerosol produced estimate from .19kg (Luna) to 1.91-3.82 kg.

Without any direct measurement of the respirable aerosol produced by HEDD penetration, the 5% assumption used is neither conservative nor grounded in reality. Unless experimental studies are conducted that specifically measure this term, a more conservative approximation of 50-100% respirable production must be used.

Spent Fuel to Surrogate Fuel Aerosol Ratio

The Luna report also proposes a reduction in the spent fuel to surrogate fuel aerosol ratio used to estimate spent fuel releases using data obtained with $DU0_2$. Luna lists several experimental estimates of the (spent fuel release/ surrogate fuel release) which vary over two orders of magnitude: .53, 5.6, .71, .42, 3, 2.8, 2.5, 3, 12. The Sandoval report used the value of 5.6, obtained for the analysis using a wet sieve technique. However, Luna questioned the validity of this technique, and concluded that a value of 3 was a more valid ratio, largely based on the only spent fuel aerosol point obtained from any experiments. Again, it is difficult to see how this can be substantiated. For the most conservative approach, the ratio should be the highest one experimentally estimated, which is 12.

In order to determine the effect of using different ratios on the estimation of the source term for a spent fuel release, we recalculated the estimated amount and percentage of fuel released from the truck cask used in the Sandoval experiments in the manner done by Luna in table A-1. We calculated this term while varying this ratio from 3 to 12, in addition to varying the estimated respirable aerosol production from 5%-100%. The results are summarized below.

Respirable aerosol production percentage	**Spent fuel-surrogate fuel correction factor**	**Respirable spent fuel produced (kg)**	**Percentage of total spent fuel in cask**
5	3	0.574	0.29%
50	3	1.071	0.53%
100	3	2.294	1.14%
5	5.6	5.736	2.85%
50	5.6	10.708	5.33%
100	5.6	22.945	11.41%
5	12	11.472	5.71%
50	12	21.415	10.65%
100	12	45.890	22.82%

Clearly, the 0.29% release calculated by Luna is not conservative. This is important because the same assumptions about spent fuel-surrogate fuel ratios and respirable aerosol productions are used when estimating the effects of HEDD impact on newer-generation casks. As is shown above, these assumptions are incorrect and lead to highly incorrect results. Because of this, it is recommended that experimental tests be performed subjecting new generation shipping casks to HEDD impact, rather than to rely on an incorrect computer simulation.

SCAP computer code used without sufficient benchmarking

The Luna study attempts to utilize a computer model as a replacement for actual experimentation in order to determine the possible damage caused by two HEDD's on state-of-the-art shipping casks. However, the code that they use admittedly does not model multi-layered targets well. The Luna study "benchmarks" the SCAP code against the Sandoval full-scale test and determines that the code predicts penetration depth well, but underestimates the size of the hole created by the penetration. In an attempt to remedy this, the Luna report multiplies the predicted hole size by a factor of 2.0 to obtain "correct" results, then proceeds to do the same when modeling other cask designs. This approach is seriously incorrect. It assumes that the code will consistently model all cask layer or shell arrangements, including different numbers of layers, which is incorrect. Important to this analysis is understanding the reasons why the SCAP code underpredicts the hole diameter. According to Luna, "underestimation is believed to be a result of some secondary effects, such as the dispersive layered nature of the targets, the relatively unfocused nature of the HEDD1, and the near one-dimensional nature of the flow dynamic of the code." (23) The SCAP user's manual addresses the problems in applying the model to predict penetration characteristics on multi-layered targets, stating that "there may exist interface phenomena not modeled by the code which could result in serious difficulties in comparing SCAP modeling output and experimental data. For a *limited number of interfaces* the code should still be useful." (27, emphasis added).

Below is a table comparing the cask used in the Sandoval study with the casks used in the Luna model.

Cask used in Sandoval:		**Truck Cask used in Luna**		**Rail Cask used in Luna**	
Steel-lead-steel Weight (ton)	25	steel-uranium-steel weight (ton)	25	steel-uranium-lead-steel weight (ton)	125
Inner cavity diameter (cm)	69.86	Inner cavity diameter (cm)		Inner cavity diameter (cm)	162.56
Length (cm)	490.22	Length (cm)	406	length (cm)	
Steel outer shell thickness (cm)	3.175	Steel outer shell thickness (cm)	3.81	steel outer shelf thickness (cm)	4.60375
Lead Wide thickness (cm)	16.84	Uranium middle thickness (cm)	7	lead middle thickness (cm)	1.27
Steel inner shell thickness (cm)	0.79	Steel inner shelf thickness (cm)	0.9525	uranium middle thickness (cm)	5.55625
Neutron Shield: water jacket, empty (cm)	1143	Neutron Shield: steel outer layer (cm)	0.3175	steel inner shell thickness (cm)	3.81
		Neutron shield: polypropylene layer (cm)	11.43	neutron shield: steel outer layer (cm)	0.635
				neutron shield: water jacket layer (cm)	15.24
1 PWR assembly		4 PWR assemblies		26 PWR assemblies	

Looking at the above table, it becomes apparent how different the three casks actually are from each other. They consist of different materials in different proportions, can carry different numbers of fuel assemblies, and have different sizes and weights. Regardless of these factors, the analysis carried out in the Luna report assumes that the correction of "2.0" to the predicted hole diameter is appropriate for all of the casks above.

As is shown on Table 1 of the Luna report (p. 34), the casks are broken down into different layers to be used as input into the SCAP code. What is important to note is that with every different layer, there exists an interface which is not modeled by the SCAP code. For the cask used in "benchmarking" the code, these interfaces were air-steel, steel-lead, and steel-PWR assembly, along with the various interactions in the assembly itself A factor of 2 difference between the predicted hole size and the larger experimental hole was attributed to difficulties in modeling these interface phenomena, among other things. This factor of 2 was then assumed to account for the interface phenomena in the other casks listed above, even though these casks have different interfaces and different numbers of layers. There is no justification of this step.

The use of the SCAP code to model cask response to shaped charge attack without having an appropriate experimental model to calibrate with is unacceptable. The SCAP code consistently underpredicts the diameter of the hole created by the explosion of the M3A1 device against the outdated cask used in the Sandoval report. The only justification that has been given for using a factor of two to correct this underprediction is that this makes the code correlate with experimental results. Therefore, it seems necessary to conduct new experiments using the newer casks to determine how to correlate the SCAP code with these experimental results. Since the newer casks have different numbers and types of layers, and since new HEDD devices are modeled by the code, it is likely that the deviations from experiment will be significantly different from those in the Sandoval case. Therefore, the Sandoval test results must not be used to calibrate the SCAP code for new casks and HEDD's.

Further, it appears that the PWR assemblies were modeled as having a single, uniform density which was taken as an average of the densities of the fuel rods, the uranium, and air. This leads to the false assumption that the penetration of the HEDD will be consistently impeded by dense material, rather than using the reality that the HEDD will find a very mixed environment with respect to density inside the cask cores.

In summary, the SCAP code simply cannot be used to provide a reliable or conservative estimate of the amount of damage expected to be caused by a HEDD on a multi-layered, modem cask. Unless there is experimental evidence that confirms the estimations presented in the Luna report, they should not be used as credible indicators of the effects of a successful sabotage event. The admitted shortcomings of the SCAP code - namely that it does not accurately predict penetration phenomena into multi-layered targets- prevents this code from offering useful information, especially since there have been no actual experiments to back these predictions up. It is not sufficient to benchmark the code against experiments performed on an outdated cask having fewer and different layers. Actual experiments must be performed with potential HEDD's in order to assess the validity of the SCAP predictions. Until this is done, the results remain irrelevant.

Omission of important sabotage scenarios

Intermodal transfer station sabotage event

The EIS, on pg. J-95, states that section J.1.5 evaluates the effects of sabotage on intermodal transfer stations. However, there is no section J.1.5, and there is no mention of this potential sabotage event again. It is essential to perform an analysis of the likely effects of a successful sabotage event on an intermodal transfer station because of its unique conditions. For one, shipping casks at an intermodal station will be stationary. This eliminates some of the problems associated with striking a pivoting target optimally that were presented in the EIS. Also, this makes the possibility of a multiple Cask release possible. Third, the appeal among potential saboteurs of attacking a station rather than a truck or train must be addressed. Intermodal transfer will also occur at reactor sites without rail access. All of these factors suggest that the potential for sabotage at an intermodal station must be addressed in a comprehensive manner.

Barge transport sabotage event

The EIS does not consider the consequences of a possible sabotage event on a barge shipment of spent nuclear fuel. As this is one of the transportation options being considered, it is important to consider the effects of a successful sabotage event, including the breach of shipping casks and release of radioactive material into the air and water, especially near populated areas, water supplies, or natural environments. It is essential to address this concern, especially since there was no discussion of the consequences of severe barge accidents, which were determined by the EIS to be not reasonably foreseeable.

Failure to identify/profile potential "Threat Groups"

It would be helpful to provide some general profiles of potential "Threat Groups" in terms of characterizing exactly what these groups are capable of doing, and the relative likelihood of each group performing a sabotage act. This would help in determining what types of weapons, forces, expertise, etc can be expected to be utilized by different groups, providing the DOE with a better estimate of what safeguards must be put in place. The Final Environmental Impact Statement: U.S. Spent Fuel Policy Storage of Foreign Spent Power Reactor Fuel (1980: DOE/EIS-0015) provides a list of "Threat Groups" to nuclear fuel storage and transportation; a similar, but updated, list would be helpful.

Improper dismissal of considering the probabi1ity of terrorist events

The EIS and the Luna report both consistently state that, since sabotage events are not randomly occurring, no estimation of their probability can be made, other than assuming they are "extremely rare." However, some comment should be made concerning the increase in large-scale terrorist attacks and how this relates to the need for sufficient safeguards against such attacks. Even though attacks are not random events, some effort should be made to identify trends, such as the increase in attacks on American soil over the last few years. This provides a proper foundation through which to analyze the level of protection required from terrorist attacks.

Failure to present a true "worst case scenario" for consequence analysis

Use of "averaged" wind conditions instead of wind blowing in one direction

The inputs used by the DOE in determining health effects of a successful sabotage scenario assume generalized wind conditions. For a true worst Case scenario, the impact of a radiological release directly downwind from a large population center, such as an office building, prison, stadium, etc. must be addressed. The use of wind conditions averaged over all directions dilutes the effect of a single-direction wind event.

Use of "average" (neutral) weather conditions, instead of worst Case conditions
The EIS states that, because the time and place of a sabotage event cannot be predicted, average weather conditions for the entire United States must be used. However, it seems likely that potential saboteurs will, to the degree feasible, plan sabotage events around those weather conditions that are the most damaging. Thus, for a true "worst case" sabotage scenario, weather conditions leading to the greatest consequences should be used.

"One bullet assumption"

As has been previously discussed, the consideration of only a single HEDD strike in the simulation of a sabotage event is unrealistic. Terrorists who are serious about causing a significant release of radioactive material, and who have the means of obtaining armor-penetrating weaponry, will likely bring a complete arsenal, including several armor-penetrating devices, incendiary devices, etc. Therefore, cask response to multiple missile penetrations, especially if they are fired in succession such that missiles strike an already damaged cask, must be addressed. It is extremely likely that the damage done to an already-penetrated cask will be substantial. This has not been assessed by the DOE and must be in order for the sabotage portion of the EIS to be considered complete.
Failure to assess social, psychological, environmental, or economic costs

In order to be able to assess the consequences of a successful sabotage event satisfactorily, the full scale of effects must be studied. The DOE has commissioned studies addressing the psychological impacts of radiation accidents on the public, but similar studies have not been performed for this EIS. In addition, no consideration of the cost of cleanup of such an event is given. Below is a skeleton outline of the various factors not considered by the EIS that need considerable attention.

Social/psychological costs not addressed
  Increased fear of nuclear energy, and nuclear industry
  Fear of vulnerability to attack (see Oklahoma City bombing)
  Susceptibility of foreign-born citizens to discrimination
  Distrust of government that transports materials capable of such destruction

Environmental costs not addressed
  Groundwater and/or surface water contamination more human costs
  Loss of land use near site for significant amount of time

Economic costs not addressed
  Cleanup costs
  Decontamination costs
  Lost workdays due to radioactive contamination of roads, buildings, etc

Loss of tourism in Las Vegas, e.g., due to contamination or fear
Evacuation costs
Relocation costs

Response
This comment has two main components. The first deals with a critique of the Sandia study (DIRS 104918- Luna, Neuhauser, and Vigil 1999); the second with aspects of the Draft EIS. The critique of the Sandia study has five major sections, to which DOE has responded in order. The part of the comment that deals with problems in the Draft EIS has four major sections.

Criticisms of Luna, Neuhauser, and Vigil (1999):

1. Inadequate Selection of Reference Weapons and Reference Cask. For security reasons DOE cannot state specifically which high-energy density devices (HEDDs) were considered. The analysis provided is expected to envelop the damage that might be produced by modern weapons in a successful sabotage event. The cask tested in Sandoval et al. (DIRS 156313-1983) to produce the data used as the basis for the analysis was not modern, but the use of the SCAP computer code allowed the results from that steel/lead/steel cask to be applied to modern cask wall designs using depleted uranium or lead shielding.

   It is possible that a sabotage attack could involve a fire. Whether the fire could enhance the consequences would depend on their location in relation to the cask and duration. A fire collocated with the cask could cause a greater release of material, but that material would be transported aloft in the plume of smoke and become unavailable for causing radiological impacts near the cask. The additional dispersion from fire-generated turbulence would mean that radiological doses a kilometer or so downwind of the cask would be only slightly higher. The net effect would not be proportional to the increased release.

2. Improper Extrapolation of Previous Experiments to Current Cask Designs. The commenter makes a valid comment with regard to the equation in the report for swept volume. It is incorrect as printed; the number of rows of pins along the disruption path should not be divided by the pin pitch, and the disruption path should therefore be unitless. The actual calculations in the report were rechecked and found to be correct.

   The tests discussed in Sandoval et al. (DIRS 156313-1983) provided both full penetration (two-wall) and one wall penetration results for subsequent use.

   The mass of respirable aerosol exterior to the cask from Sandoval et al. (DIRS 156313-1983) were restated in terms of a fraction of swept volume to use the release fraction results for other HEDDs which might produce a different diameter and length of damaged fuel. The release fraction for a single entry hole case was used as the basis of the calculation of release fraction because the SCAP computer code did not project that either of the HEDDs considered would penetrate both walls of the two representative cask designs considered. Were a through hole produced, a higher release fraction would have been used, but that was not the case. Thus, the increase in release fraction of a factor of 10 as suggested by the commenter is not warranted.

   The thermal properties of shielding material have little effect on the predicted geometry of penetration from use of a HEDD. Penetration is unrelated to thermal effects; it is related to density, depth, and, to some extent, strength of the materials with which the device would interact.

   While multiple holes could lead to an increased release fraction, as suggested by the commenter, the result is unlikely to be additive. This results because the driving pressure from rod pressurization that was postulated to enhance the release fraction over that measured by Sandoval et al. (DIRS 156313-1983) would be lower for each successive hole as the number of undamaged fuel pins get smaller. Without a mechanism for producing a strong flow out of the cask, respirable material within the cask is likely to plate out on the huge surface area within the cask. Thus, DOE believes that it has adequately bounded the sabotage consequence scenario.

   The commenter suggested that multiple holes would allow a flow of air into the cask that would enable exposed UO_2 to oxidize to U_3O_8 [when temperatures exceeded 250ºC (482ºF)], which is asserted to be a fine powdery material. While the oxidation process could occur, achieving temperatures of 250ºC to make the process occur quickly could not occur easily. Penetration by the weapon would not increase temperature noticeably inside the cask, and fires would take some time to get enough heat into the cask to raise temperatures above 250ºC. Moreover, conversion to U_3O_8 in the cask does not mean that particles would escape from the cask or that they would be small enough to become a significant health hazard. Because this scenario requires even more aspects of the sabotage event to proceed perfectly, it becomes increasingly unlikely.

The commenter suggests that more analysis is needed before the swept mass can be used as a correlation factor and that all HEDDs may not produce the same aerosol fraction related to swept mass. Since the publication of the Draft EIS and Luna, Neuhauser, and Vigil (1999), additional data has become available in a paper by Luna (DIRS 157201-2000). This paper describes with three experiments in which an unspecified HEDD penetrated a ductile cast-iron CASTOR cask containing nine mocked-up pressurized-water reactor fuel assemblies. Each assembly was made up of pressurized fuel rods filled with unirradiated fuel pellets. Two experiments were substantially the same. Each yielded a respirable release exterior to the cask of about 1 gram of aerosol. A third experiment was done with the cask interior at a pressure of 0.8 atmosphere, which yielded a release of about 0.3 gram of respirable aerosol. These releases include the cask purging effect of the release of rod plenum gases. The experiment described in Sandoval et al. (DIRS 156313-1983) yielded a respirable release of 3 grams but included no rod pressurization to create a purging flow that would force additional respirable material out of the cask. The two results are close, but the conditions for each were different.

Luna (DIRS 157201-2000) used the swept mass concept to relate these experiments. The respirable release fraction scaled to swept mass for the first two experiments was about a factor of 2 smaller (DIRS 156313-Sandoval et al. 1983). Based on the CASTOR experiments, which suggested that little of the aerosol in assemblies behind the first one penetrated was likely to find its way to the entry hole and be released, the fractional respirable aerosol release fraction was found to be quite close to the value for the Sandoval et al. (1983) experiment. This value includes the effect of releasing rod pressurization gas. This suggests that scaling the release to swept mass is a workable concept for translating experimental results to other situations.

Scaling the diameter of the cavity predicted by the SCAP computer code by comparing its predicted diameter to that observed in two experiments is an approximation that is believed to give reasonable results. What was most important in the SCAP results was the penetration depth prediction that was key in selecting the appropriate scaling factor to swept mass (full penetration versus one wall). As indicated in Luna, Neuhauser, and Vigil (DIRS 104918-1999), SCAP predicted penetration depth closely in two very different configurations. This provides confidence in the overall validity of the estimate of the swept mass from Luna, Neuhauser, and Vigil (1999).

3. Respirable Aerosol. Estimating the total quantity of respirable aerosol in the cask was needed to account for the purging effect of rod plenum gas release that was not simulated in the tests described in Sandoval et al. (DIRS 156313-1983). The commenter takes issue with several aspects of the analysis and concludes that instead of 5-percent respirable the result should have been 50 to 100 percent. Several issues were raised in support of that contention.

3.1 Respirable Particle Diameter. One of the first issues is what constitutes a respirable aerosol. The International Commission on Radiological Protection lung model suggests that the aerodynamic diameter of particles must be smaller than 10 micrometers to reach the lung in significant quantity. To convert aerodynamic diameter to geometric diameter, divide by the square root of the particle density. Thus, uranium oxide particles with a density 10.5 grams per cubic meter must have a diameter of 3.1 micrometers or smaller to be inhalable. Uranium oxide particles with a geometric diameter smaller than 10 micrometers, suggested by the commenter as being respirable, have an aerodynamic diameter of 32 micrometers that is well out of the respirable range. Using that assumption together and accepting other aspects of the Luna, Neuhauser, and Vigil (DIRS 104918-1999) analysis yielded the 50- to 100-percent respirable estimate made by the commenter. This is clearly not a reasonable value for respirable aerosol.

3.2 Thermal Effects. The commenter states that there could be thermal effects in the experiments described in Sandoval et al. (DIRS 156313-1983) that were not accounted for in Jardine's experiments. Sandoval et al. (1983) saw no evidence of thermally generated uranium oxide aerosols in the experiments; therefore, the

Jardine experimental relationship between aerosol production and impact energy density was used to estimate respirable aerosol production.

3.3 Extrapolation of Jardine's Relationship. Jardine's work included energy densities to 140 Joules per kilogram but the estimated energy range for the Sandoval et al. (DIRS 156313-1983) experiment was between 1,000 and 10,000 Joules per kilogram. The commenter criticizes using results of an experiment at the Idaho National Engineering and Environmental Laboratory together with the Jardine relationship to obtain an estimate of the respirable fraction at the high energy density of the original experiments from Sandoval et al. (1983). As discussed in Luna, Neuhauser, and Vigil (DIRS 104918-1999), the Idaho National Engineering and Environmental Laboratory data are within the likely confidence range for the Jardine data, which gives confidence to the extrapolation.

3.4 Energy Density Estimate. The commenter suggests that the end point of the extrapolation should have been at the full energy of the HEDD before the cask wall was penetrated. This suggestion is contrary to reality. It takes energy to penetrate the wall and the penetrated material flows back and away from the direction of HEDD action. Little of this energy expenditure imparted to the wall material could be directed at the surrogate fuel rods as suggested.

Based on the above, the estimate of 5-percent respirable aerosol production is reasonable based on the analysis presented by Luna, Neuhauser, and Vigil (DIRS 104918-1999), however, the experiments discussed in Luna (DIRS 157201-2000) suggest that even the 5-percent value is too high or that there is more significant deposition of the material in the cask before it is released.

4. Spent Nuclear Fuel-to-Surrogate Fuel Ratio. The commenter suggests that the largest observed value of the ratio (12) should be used rather than the value of 3 used in Luna, Neuhauser, and Vigil (DIRS 104918-1999) or the value of 5.6 used in Sandoval et al. (DIRS 156313-1983). Sandoval et al. used 5.6 as an upper limit, which might have been appropriate for the purpose of the analysis. That document indicated that the appropriate value was about 1. For Luna, Neuhauser, and Vigil (1999), it was judged that a realistic, but conservative, value should be used. Looking at the range of experimental values, a value of three was in the middle of the range and reflected 2 of the possible values. This made it a realistically conservative choice for the analysis.

5. SCAP Computer Code Used Without Sufficient Benchmarking. The commenter overlooked the three benchmarking calculations that were completed on a variety of cask and cask-like configurations. These included the same averaging of surrogate fuel and open space to represent fuel assemblies. The prediction of depth of penetration, which is a key issue in the analysis, was correct. The need to adjust the SCAP-predicted diameter by a factor of 2 was preferable to using the predicted diameter and is not likely to introduce significant error in the analysis.

Criticisms of EIS:

1. Omission of Important Sabotage Scenarios. The commenter identifies two additional scenarios, involving an intermodal transfer station and barge transport. Spent nuclear fuel casks at an intermodal transfer facility would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR Part 73), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

   Barge transport sabotage scenarios were considered in Appendix J of the EIS. While there could be the opportunity for a radiation dose from releases to surface water as a result of a barge accident or sabotage, the consequences would be likely to be much less than releases to the atmosphere (DIRS 157052-Ostmeyer 1986).

2. Failure to Identify/Profile Threat Groups and Improper Dismissal of the Probability of Terrorist Acts. The threats against which spent nuclear fuel shipments must be protected are known as "design-basis threats," and are defined in 10 CFR Part 73. Profiling threat groups is beyond the scope of this EIS. With regard to the

probability of terrorist acts, because of the attacks on September 11, 2001, DOE and other agencies are reexamining the protections built into their physical security and safeguards systems. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

3. Failure to Present a True Worst-Case Scenario for Consequence Analysis. The Council on Environmental Quality rescinded the requirement to perform a worst case analysis in an EIS in 1986 (51 *FR* 15618, April 25).

3.1 Use of Averaged Wind Conditions Instead of Wind Blowing in One Direction. The atmospheric data used in the sabotage analysis was a joint frequency of wind speed and stability class. As suggested by this comment, the wind was assumed to blow toward the population, and consequences were estimated for an urban area.

3.2 Use of Average (Neutral) Wind Conditions, Instead of Worst-Case Conditions. The Council on Environmental Quality rescinded the requirement to perform a worst case analysis in an EIS in 1986 (51 *FR* 15618, April 25).

3.3 One-Bullet Assumption. As discussed above, while multiple holes would probably lead to an increased release fraction, as suggested by the commenter, the result would be unlikely to be additive. This results because the driving pressure from rod pressurization that was postulated to enhance the release fraction over that measured in Sandoval et al. (DIRS 156313-1983) would be lower for each successive hole as the number of undamaged fuel pins got smaller. Without a mechanism for producing a strong flow out of the cask, respirable material inside the cask would be likely to plate out on the huge surface area inside the cask. DOE believes that it has adequately bounded the sabotage consequence scenario.

4. Failure to Assess Social, Psychological, Environmental or Economic Costs. In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. Section J.1.4.2.5 discusses environmental restoration after a release of radioactive material. Social and psychological issues are discussed in Appendix N.

8.10.1 (5620)
<u>Comment</u> - EIS001887 / 0246
Page 4-65; Section 4.1.8.3 - Sabotage
The Draft EIS examines a scenario involving low-level exposures in the waste-handling building which can contain radionuclides but not a more serious incident outside of a building, such as a breached cask/container in Caliente. (See Appendix A, section A 2.2/A 2.3) The assumption made in the Draft EIS that "rural targets" for terrorists are non-desirable has recently been proven wrong with the Amtrack derailment in Arizona. The proposed intermodal transfer station would make an attractive and potentially vulnerable target secluded in a canyon with clear overhead shots available.

<u>Response</u>
Spent nuclear fuel casks at an intermodal transfer facility would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR Part 73), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health.

Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments and key facilities. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (6127)

Comment - EIS001654 / 0016

Perhaps it has been studied previously by DOE, but we are unsure whether sabotage threats have been analyzed and compared for shipment of nuclear waste by the various modes. It is possible that one of the attributes of rail shipment that may be advantageous for accident risk exposure may also be a disadvantage in terms of vulnerability to terrorism or other willful attempts to interfere with the shipments. We are not experts in such analyses, but we recommend that the transportation mode selection decision criteria be identified and views of various experts and perspectives be considered in making the optimum mode selection based on a comprehensive risk assessment.

Response

The radiological accident risks estimated in Chapter 6 of the EIS would be sufficiently small so that there is no rationale for using radiological accident risk as reason for selecting a transportation mode.

Both truck and rail spent nuclear fuel shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (6372)

Comment - EIS001587 / 0002

So we proceeded to embark upon a study of terrorism. We used eight different methodologies in attempts to breach these casks. I am not going to tell you what those were. I am not going to provide you with a cookbook. But I will tell you one that didn't work. This was long before the Alfred P. Murrah Building in Oklahoma City, and we used 5,000 instead of 4,000 pounds of ammonium nitrate fuel oil, 10 feet away from a simulated cask. We bent it like a banana and hurled it a hundred feet, but if it had been a real cask, it would not have released any material. That was an unsuccessful method.

We found, indeed, there are ways to open these casks using explosives. We consulted terrorism experts and we were told that terrorists need basically four things. They need the expertise, and there are those people with the expertise. They need the tools, and there are those people who have the tools. They need access to the cask, and we strive hard to prevent that access.

For one thing, each one of these shipments has a transmitter on it and we know within a hundred feet where it is at all times, and if it's diverted we know it immediately. And, fourthly, they need time. The less time you can give them, the lower the probability of a successful attack, and, again, part of our system is to reduce that available time. So, given that, even so, we did find that there are ways to breach the cask.

What we did find is of interest to the terrorists as much as is to you. We selected one method and we conducted an experiment on a shipping cask that had seen service and was retired from service, and we put this thing in a giant bottle and then we attacked it explosively, and we poked a hole in the cask, and we collected all of the material that came out of the cask, and we weighed it and we weighed all the material that was still in the cask, so we knew exactly how much material came out.

We, furthermore, screened the material so we knew what the respirable sizes were, or what the particle sizes were and we could, therefore, infer how much of that cask came out respirable material. All of this done in a bottle.

Now, prior to doing this, we had estimated that an attack of this sort would release one percent of the contents of the cask. And our finding was that it released one ten-thousandth of that amount, .0001 percent.

Now, if you look at that kind of an attack and you conduct it in Manhattan at rush hour on an intersection, the explosion would kill about 400 to 500 people. The release of radioactive materials from the cask, would result in two-tenths of one latent cancer. So the problem is not the release of material. The problem is the explosives and the terrorists know that and so this becomes an unattractive target.

Response
This comment is basically correct as it relates to the experiments carried out at Sandia National Laboratories in the early 1980s. Later analyses reinterpreted that data and extended the estimate of release to current cask designs and spent nuclear fuel loads. While there is a modest increase in expected consequences resulting from cask loading and design, the basic conclusion given in the comment is correct.

8.10.1 (7084)
Comment - EIS000995 / 0006
Once the high-level radioactive waste leaves the reactor sites, how will you avoid accidents or sabotage all along the shipping route? Will emergency management personnel all along the route be fully trained and equipped for a "criticality" accident? What can they really do other than cordon off the area?

Response
Section 6.2.4.2 of the EIS provides information on the data and methods used to analyze transportation accidents. Additional information provided in Section J.1.4.2.1 discusses actuarial data and potential effects of human error on accident impacts. Avoidance of accidents and getting a shipment of spent nuclear fuel or high-level radioactive waste (or any other material) from origin to destination safely would primarily be the responsibility of the management and crews operating the vehicles. The DOE Regional Servicing Contractor would ensure that crews were appropriately trained as required in U.S. Department of Transportation regulations (49 CFR Part 171) and that all operational requirements on the shipments would be met. Section M.3.2 provides some additional information on the operational procedures and protocols required by DOE for shipments. Section M.5 provides additional information on emergency response requirements and responsibilities among state, Federal, and local organizations. As discussed in Chapter 2 of the EIS, the Department would be responsible for implementing the requirements of Section 180(c) of the NWPA by providing funds for determining need for and training state, tribal, and local authorities for the safe transport and response to potential emergencies involving these shipments.

Additional information on stipulations of Section 180(c) is provided in Section M.6 of the EIS. Dealing with a criticality event in an accident is not a goal of the emergency response function. The Nuclear Regulatory Commission certification requirements for casks effectively prevent such an occurrence in transport. DOE expects that emergency response personnel would recover and treat those injured from the physical events of the accident, and control crowds, fires, and dispersal of hydrocarbon fuels at the scene. While emergency response crews would be trained to function in a radiological release situation, it is very unlikely that radioactive material would ever be released from an accident involving a cask. Section M.4 provides additional information on cask safety and testing. Section M.7 provides an overview of procedures used to provide physical protection of shipments.

8.10.1 (7295)
Comment - EIS001832 / 0032
We [The Nuclear Energy Institute] endorse DOE's treatment of sabotage and security risks in this EIS.

A system of safeguards and regulations exist to ensure the safety of the public, handling personnel, and the environment before transport, during transport, and upon arrival of the transport package at its end destination.

NRC [Nuclear Regulatory Commission] will be the lead agency in assessing spent nuclear fuel shipment safety, safeguards, and security. Some of the measures that will ensure safeguarding of spent fuel shipments include:

Periodic updating of route conditions to facilitate use of alternative itineraries en route as conditions warrant.

Route approval and security arrangements for each shipment that must be approved by NRC

Use of armed escorts in urban areas.

Requirements that State and local authorities be notified of shipments.

Vehicle design features that would prevent the unauthorized movement of trucks carrying spent nuclear fuel (locking devices on trucks used to transport SNF [spent nuclear fuel]).

Response
As pointed out by the commenter, transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (7447)
Comment - EIS001969 / 0006
That there are devices already in existence that can penetrate the truck shipping casks (page 6-33 of the EIS) if used by saboteurs, must not be taken lightly. That the trains and trucks will be guarded solves part of the problem, but not entirely. It is presumed that the guards will be armed, but would that protect against an intentional derailment? If the act of sabotage is successful, how would DOE address response and cleanup or control?

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

Cask safety features that provide containment, shielding, and thermal protection also provide protection against sabotage. The casks would be massive. The spent nuclear fuel in a cask would typically be only about 10 percent of the gross weight; the remaining 90 percent would be shielding and structure.

Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. Section J.1.4.2.5 discusses environmental restoration after a release of radioactive material.

8.10.1 (7449)
Comment - EIS001969 / 0007
We could find no mention, in the EIS, of the possibility of one of the trucks being hijacked. A hijacked truck could be driven anywhere and used as a threat. A hijacked trucks would be most vulnerable when they are stopped so that the guards and drivers can eat or sleep. How does DOE plan to address this situation?

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

8.10.1 (7548)
Comment - EIS000544 / 0003
There was very little about sabotage. We found in fact that the sabotage, the only thing that really related to it was in terms of what could happen at the waste handling building, and it really didn't relate to anything outside in the rural areas in canyons or any of the choke points that occur along these routes.

Lastly, we're finding numerical differences basically in looking at turning radii for operating heavy-haul vehicles on our system as it is now. There are certain summits and curves on routes that are listed that we don't think even a double articulated multi-tractored vehicle can actually traverse and legally stay within its loads.

With that I would like to end my comments by saying that we're not here to really say pro or con on the whole project, but we are adamantly against any heavy-haul option.

Response
The EIS discusses sabotage during transportation in Section 6.2.4.2.3. Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Heavy-haul vehicles do make more demands than other vehicles on the geometry and construction of roadways on which they might be used. DOE has identified mostly rail as its preferred mode of transportation both nationally and in Nevada.

DOE has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved, DOE would issue at some future date a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would then identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada.

It is the Department's opinion that the EIS adequately analyzes the potential impacts of Nevada heavy-haul implementing alternatives for transporting spent nuclear fuel and high-level radioactive waste.

8.10.1 (7811)
Comment - EIS001756 / 0002
I would like to start by repeating one statement that I think is extremely important, even though it's been said.

It is estimated that a mixture of approximately 6,000 train and truck shipments would pass through the St. Louis area over the 30 years shipping campaign, or on average one every other day, thus creating the potential for innumerable accidents and terrorist attacks. Terrorists would love to steal our plutonium to manufacture their own bombs or they might just want to demand millions of dollars or other terrorists' release from jail in exchange for not blowing up a high-level radioactive waste transport. With such frequency of shipment, it couldn't be too hard for terrorists to figure out where and when these materials are on route.

If a bomb landed on one of these vehicles or a suicide bomber decided to ram one, we're talking about life-threatening pollution, not just to the surrounding area, but to the entire city. In the DOE's Draft Summary Environmental Impact Statement in a chart of estimated national transportation impacts for 24 years of operation, latent cancer fatalities from maximum reasonably foreseeable accidents are five for mostly truck scenarios and 31 for mostly rail scenarios. These estimates could not possibly have included potential terrorist attacks. Apparently there is some concern about such attacks, as the Nuclear Regulatory Commission will require two armed escorts for every shipment of irradiated fuel rods. Such guards might have been able to save the stagecoaches of days past, but I have little hope that they could overpower modern terrorists.

While I am deeply disturbed about the danger to citizens from these transportation risks, the situation at the Yucca Mountain site itself could be described as a terrorist's dream. If the plan is approved, shipments could begin as early as 2004, but they'll have no safe place to go. Supposedly nuclear wastes can begin to be loaded into the new facility when it is 10 percent completed, but until that time they will be huddled together like a flock of sitting ducks on a parking lot, a perfect target even for an air attack.

While our Department of Energy may not fully acknowledge the peril in transporting high-level nuclear wastes, we don't have to look far to find others around the world who do. Last Saturday's New York Times reported the following: "Bowing to renewed concerns about terrorist attacks, Panama authorities said today that they were beefing up security to protect a British ship carrying radioactive cargo through the Panama Canal this weekend. 'The vessel is a visible target for any group that wants to make a statement,' Jorge Quijano, director of maritime operations for the Panama Canal Authority, said in an interview today. Environmental groups fear that the ship carrying high-level waste to Japan from France is vulnerable to terrorists who could board and dislodge or rupture the casks with the waste, threatening a potentially catastrophic release of radioactivity." Paul Leventhal, a representative from the Nuclear Control Institute in Washington commented, "The consequence of a release of radioactive waste would be long-lived. It would be very hard to clean up, and it could render the canal inoperable and the surrounding areas uninhabitable."

The very thought of submitting countless numbers of our citizens to the possible disasters herein described is incomprehensible.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

In addition, 10 CFR 63.21 requires a repository at Yucca Mountain to have physical protection consistent with 10 CFR 73.51. This regulation specifies a performance objective, which provides "high assurance that activities involving spent nuclear fuel and high-level radioactive waste do not constitute an unreasonable risk to public health and safety." The regulation requires that spent nuclear fuel and high-level radioactive waste be stored in a protected area such that:

- Access to the material would require passage through or penetration of two physical barriers. The outer barrier would have isolation zones on each side to facilitate observation and threat assessment, would be continually monitored, and would be protected by an active alarm system.

- Adequate illumination would be provided for observation and threat assessment.

- The area would be monitored by random patrol.

- Access would be controlled by a lock system and personnel identification would be used to limit access to authorized persons.

A trained, equipped, and qualified security force would be required to conduct surveillance, assessment, access control, and communications to ensure adequate response to any security threat. Liaison with a response force would be required to permit timely response to unauthorized entry or activities.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments and key facilities. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (8472)
Comment - EIS000817 / 0144
P. 6-33. If this Sandia study is anything like the "sanitized" one I studied for our hearing on the VSC-24 cask, I distrust it. You can't analyze a cask using only a part of a rod or an aimed missile, or balloons (that mostly burst) to test radiation in the air -- the whole thing was a mess and unrelated to the real thing as I saw it. I have not seen this Luna Neuhauser 1999 study, but if it relies on a General Atomics cask holding only 4 assemblies -- I say get real! You are planning on using casks for 21 assemblies, aren't you? And dual purpose casks aren't even certified or used yet.

Response
The Sandia study (DIRS 104918-Luna, Neuhauser, and Vigil 1999) estimated the radioactive material release fraction for a truck cask (4 pressurized-water reactor assemblies) and rail cask (26 pressurized-water reactor assemblies) that might result from optimal attacks using two different high-energy density devices. DOE used those release fractions in its analysis and is confident that the results from that study are realistically conservative based on information currently available. Similar analyses can be applied to other cask designs as they become available, but it is not expected that results would be markedly different.

8.10.1 (8503)
Comment - EIS001737 / 0002
We aren't even allowed the liberty of buying milk that is labeled non-hormone treated or other food stuffs labeled non-genetically fiddled with. Haul the stuff by rail -- no. Haul it by highway -- no. Today's trucks can't even turn a corner without getting over into the other person's lane. Not only do we have normal accidents and human error involved, but we have now the threat of deliberate terrorism. What happens when a terrorist plot or some other more common occurrence causes a nuclear-loaded truck or train to go off a bridge on I-44, either on the highway I-44 or railroad bridge over the Gasconade River near Waynesville. The water is subsequently flowing into the Missouri River, then into the Mississippi just above St. Louis.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The

objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

It is the Department's opinion that the EIS adequately analyzes the potential impacts of sabotage.

8.10.1 (8612)
Comment - EIS001837 / 0010
What about the crossing of the vast East Mojave wilderness managed by the Bureau of Land Management and the National Park Service? The DEIS fails to address the issue of terrorist attacks in the East Mojave, the impact of spills in the East Mojave National Preserve.

What alternative routes would be used that would impact operations in the East Mojave National Preserve? How are agencies prepared to manage nuclear waste spills and accidents and cleanups? How will they manage visitors in the area?

Response
Shipments of spent nuclear fuel and high-level radioactive waste would occur primarily on Interstate System highways and mainline railroads. As a result, in the event of an accident, there would probably be relatively good access to the accident site without additional disturbance of the wilderness. In the unlikely event of an accident, cleanup, recovery, or access limitation actions would have to balance the impact on the wilderness with future safety of people in the area.

Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

8.10.1 (8733)
Comment - EIS001317 / 0001
Recently our local Citizens Advisory Panel to the chemical industry was denied risk management plan information on a worst case scenario basis due to FBI [Federal Bureau of Investigation] concerns for terrorist activities. This covered Fixed chemical plants of different sizes and relative risks. No thought was considered to the shipment of materials and no cumulative risk was considered due to the number of plants in the area.

With all the variables to consider in the shipment of nuclear waste no such concern for terrorism has been expressed in today's presentation by DOE.

Response
The EIS discusses sabotage in Section 6.2.4.2.3. Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting

the environment and public health. Section M.7 provides additional information on the physical protection of spent nuclear fuel during transportation.

8.10.1 (9184)
Comment - EIS002123 / 0003
Here's the picture and they've got the cask here and it says: "Armed guards and radiation experts escort a truck transporting a nuclear waste cask from an indoor storage pool at Calvert Cliffs nuclear power plant to a new outdoor storage bunker nearby," and they've got guns and they've got masks on their faces and they've got this cask surrounded, and it's just going to a grove of trees. I wonder what they'd -- what terrorist would do with it if it takes -- for one cask for all these people to guard it to this extent?

Response
The security requirements of nuclear power stations are such that armed guards are required whenever the exterior access doors to the spent nuclear fuel pool (or other sensitive areas) are open. The crew charged with the loading of the cask would be in full protective clothing with masks as they completed the cask loading operation.

8.10.1 (9269)
Comment - EIS001618 / 0004
I did find a fascinating section called the impacts of acts of sabotage on page 6-33, which considered the impacts of successful sabotage attempts on a cask, the casks that most of us have never gotten to see and don't really know how they'll work. We certainly don't know in what ways they've been tested. But don't worry because for the ones that are being shipped on trucks, and the analysis estimated that a sabotage event occurring in an urbanized area could result in the population dose of 31,000 person REM, which would cause an estimated 15 fatal cancers among the population of exposed individuals.

This number is so farcical that the idea that a successful -- I mean, these are casks made out of uranium. So we can look at research that is going on into servicemen as well as native populations in Iraq that have been dealing with depleted uranium shells and probably find higher cancers than that. But the idea that a successful sabotage event in a city like Chicago might cause 15 cancers is the sort of disinformation that one really associates with the Soviet Union denying any of the deaths from Chernobyl, rather than an actual seriously peer reviewed government document on the environmental impact of transportation problems.

And it goes down to 2.4 fatal cancers if it happens out in a rural area, so the farmers should feel totally at ease that the food they sell, I assume that's been irradiated, won't in any way cause cancers.

Not only actually interim during the time its transiting, but any one of these casks could stop, break open, in many other ways be breached. And I like the way this section actually talks about a sabotage event cannot be characterized as a random event. So we are pretty much assuming they are going to happen.

Response
Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area. The fact that some casks contain uranium shielding does not mean that a sabotage attack on such a cask would produce a significant additional radiological or environmental impact compared with the result of the sabotage attack itself.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (9422)
Comment - EIS001584 / 0002
I would like to refer to these casks. In 1976, Hunt Spatza, one of our prominent post Manhattan project physicists at Cornell, was promoting these casks being used on railroad cars. Now, at that time, 15-year-olds were pranking, sending freight trains off to Coventry, as the British would say, off to remote areas….

So that no matter how good your casks are, you're stuck with a time in our life that creates problems more in the area of the Nevada people, their focus on things outside of the technical.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage, and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. For these reasons, deliberate misrouting of spent nuclear fuel shipments is unlikely.

However, because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (9566)
Comment - EIS001888 / 0239
The DEIS failed to credibly address problems of security and terrorism. Security problems should have been prominently discussed. The only discussion of the issue was confined to the cursory refutation of arguments made by the State of Nevada. No discussion of eco-terrorism, civil disobedience, or the diversion of military equipment was included.

Response
The repository and spent nuclear fuel shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of nuclear facilities and spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR Part 73), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health.

In response to comments, additional information is provided in Appendix M of the EIS on safeguards and security requirements that would be imposed by DOE and the Nuclear Regulatory Commission. Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (9597)
Comment - EIS001888 / 0271
Security/Escort

The State of Nevada has successfully argued that the Nuclear Regulatory Commission (NRC) should reconsider the security requirements for handling SNF [spent nuclear fuel]. The DEIS presents no information on the contribution security arrangements will make on the transportation of SNF. This is unfortunate because many responsible trucking companies have developed sophisticated systems for handling sensitive materials that would assist public understanding of the safety systems that can confound potential attackers. The DEIS should have included a description of the contribution to risk made by security and escort programs for each of the modal and implementing alternative options.

Response
The Nuclear Regulatory Commission has not ruled on the State of Nevada petition to reconsider security requirements for spent nuclear fuel but, if the Commission should change its requirements, DOE will incorporate those changes in its procedures. Section M.7 of the EIS contains information on safeguards and security requirements that would be imposed by DOE and the Nuclear Regulatory Commission.

8.10.1 (9631)
Comment - EIS001888 / 0300
The DEIS does not provide a credible analysis of the potential consequences of effects of terrorist activity. In June of 1999, the State of Nevada petitioned the Nuclear Regulatory Commission (NRC) to perform a comprehensive assessment of the security requirements for shipping radioactive waste. This much-needed assessment could establish that there is a definite terrorist threat to shipments of Spent Nuclear Fuel (SNF) and that shipments of high-level waste through Clark County, Nevada en route to Yucca Mountain could be especially vulnerable. The threat of terrorist activity is not trivial and should be taken seriously in the DEIS. The DEIS should be considered insufficient until a credible estimate of the likelihood and consequences of terrorist activity is completed. The DEIS is insufficient because it fails to consider the threat to shipments posed by a wide array of terrorists. The threat should be considered for each of the implementing alternatives considered by the DEIS.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (9633)
Comment - EIS001888 / 0301
To date, two threats against spent fuel shipments have been reported in the United States since 1984. In November 1984, Northern States Power (NSP) shipped spent fuel from the Monticello reactor in northern Minnesota to a storage facility at Morris, Illinois. On February 4, 1985, NSP received a telephone threat warning that a group of anti-nuclear protesters would use a small airplane to stop a train carrying spent fuel from Monticello to Morris. On October 27, 1986, an unknown party removed a 39-foot long section of rail along the Burlington Northern route used for these shipments in Golden Valley, Minnesota. Authorities found a sign reading “Stop RadWaste Shipments” near the tracks. This incident did not result in damage to the train transporting spent fuel. However, a Burlington Northern train hauling lumber, scheduled immediately prior to a train transporting spent fuel from Monticello, derailed at the site of the sabotage.

Clark County believes that the threat of a terrorist attack on a spent fuel shipment capable of causing radiological sabotage should be considered credible and should be evaluated in the DEIS. History clearly suggests that although the terrorist threat may be low, it is not so low that it can be ignored.

The FBI found that the major determinants of the character of a terrorist attack are: 1) the technological means, 2) the political motivation behind the attack, and 3) the weaknesses of the target. The FBI believes that changes will occur in the motivations and goals of terrorist groups. Traditional motivations for terrorism (ethnic, tribal, and religious animosities) will continue and intensify. The disintegration of the Soviet Union and Yugoslavia have fostered entirely new groups that are both well-equipped and well-schooled in terrorist activity. As the World Trade Center bombing demonstrates, terrorists activities span the globe.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (9634)
Comment - EIS001888 / 0302
Clark County presents terrorists with an attractive target for a number of reasons. Each of these reasons, taken individually provides a sound rationale for concern about a terrorist threat. When viewed together, they present a compelling argument in favor of anticipating a terrorist event of some sort. These reasons, visitors, operational consideration, infrastructure, military facilities, and symbolic value are discussed below.

Visitors

“Major events taking place inside the United States may be seen as attractive targets for terrorism.”

Clark County’s population is an attractive target for terrorists. The sheer number of visitors to Clark County (31 million visitors in 1998) provides terrorists with an attractive target. The concentration of people created by Clark County’s mega resorts make it possible for terrorists to craft an attack that would contaminate a large number of people. An example of this concentration is easily exemplified by the intersection of Tropicana and Las Vegas Boulevards. On the comers of this intersection, are 16,500 hotels rooms-more than are in the entire City of San Francisco. Clark County’s hotels are usually 91% occupied. This inflames the problems faced by emergency services should an evacuation be necessary. A terrorist attack on a spent fuel shipment in the valley could create an accident that would overwhelm the ability of local emergency management agencies to provide protection and evacuation.

Exacerbating the problems faced by the County is the large number of special events of all types and sizes. Perhaps the largest of these is COMDEX, the world’s largest computer exposition. Special events can draw up to 250,000 people to the city from all over the world. It is likely that terrorists would schedule an attack to coincide with a well-known event in order to amplify the effects of their attack through media exposure. This occurred at the Munich Olympic Games, the Atlanta Olympic Games and several others. As the FBI report notes, terrorists select targets with care and sophistication. Terrorist activities have a ready-made target in Clark County. The DEIS should present a worst Case terrorism scenario that coincides with an important local event.

Symbolic Value

The number of tourists present in Clark County has value from a terrorists’ perspective not only because of the increased number of potential victims. Terrorist select targets based on their symbolic and political value. One prominent author paraphrases Clausewitz by characterizing terrorism as “politics by other means.” Targets with symbolic significance like government buildings and special events are particularly attractive. This was demonstrated by the Oklahoma City bombing, the Munich Olympic Games, and the Atlanta Olympic Games. Terrorists wish to get immediate publicity for their cause. Any attack in Las Vegas, the world’s center for tourism, would receive extensive media coverage. This problem will increase in the future as Las Vegas adds new events, such as race tracks, major sports teams and so on.

Other aspects of the region deserve mention in any discussion of the symbolic value of examining terrorist activity. The first aspect is the nature of the Nevada Test Site (NTS), which partly contains Yucca Mountain. The DOE conducted approximately 1,000 nuclear tests at the site from the 1950’s to the late 1980’s. These tests became extremely controversial and incited protest marches and acts of civil disobedience. Even without nuclear testing, the NTS remains a lightning rod for opponents of nuclear power as well as nuclear energy. It provides antinuclear groups with a powerful raison d’Etre and ensures the likelihood of an ecoterrorist attack on shipments through the regional remains a real possibility.

The second aspect of Clark County’s symbolic value is due to the controversial nature of its economy. The symbolism of killing Americans in their most famous tourist community makes Clark County a much more attractive target. The Las Vegas Convention and Visitors Authority (LVCA) has surveyed peasants in India and found that they were aware of two cities in the US New York and Las Vegas. Las Vegas may be regarded as anathema by fundamentalist regimes in the Muslim world because it represents everything that is corrupt and sinful about the West. Clark County’s symbolism is an important characteristic that should be examined by the DEIS.

Military Facilities

Nellis Air Force Base, its auxiliary facilities, and the Nevada National Guard armored cavalry squadron (1” Squadron/221st Cavalry) provide options for a terrorist group to distract local law enforcement, or to divert weapons useful in an attack on a shipment.

The close proximity of these facilities to several of the implementing alternatives for transporting the waste increases the likelihood that a terrorist group would favorably view this area for a coordinated series of terrorist events. These facilities also assist in the response to and the mitigation of a terrorist attack. The benefits of these facilities should be assessed. In that assessment should be some analysis of how well they have been integrated into local emergency response planning.

Methods and operational Considerations

The DEIS’ treatment of terrorism relies on incomplete analysis of the ways in which terrorists are likely to attack. Both the methods and the operational characteristics of a terrorist attack should be examined.

Methods

The weapon used by terrorists to attack a shipment of nuclear waste is an important issue that the NRC has agreed to reconsider. The NRC [Nuclear Regulatory Commission] has rightly concluded that it must reexamine the threat defined in its 1984 rulemaking. The DEIS accepted the Sandia National Laboratory’s 1984 and 1999 reports that evaluated the damage to a canister using a military MW demolition charge. The State of Nevada has argued that more sophisticated anti-tank weapons should be considered potential threats. Clark County agrees with this and recommends the NRC examine a terrorist scenario in which the terrorists are equipped with a TOW II or Milan antitank missile or a car bomb as their primary weapon. As the FBI’s 1996 report stated:

“The threat at the lower end of the spectrum is likely to grow as well. The M-16, M-10, Uzi and AK-47 assault rifles will be supplemented by standoff weapons like Stinger antiaircraft missiles, LAWs and RPG-7s, already available on the world weapons market. Just because a weapon is relatively unsophisticated does not mean it cannot cause massive casualties. A stinger missile aimed at a jumbo jet as it takes off or as it approaches a large metropolitan airport could cause tremendous casualties. A LAW or RPG round lobbed into the right area of a nuclear power plant could produce catastrophic consequences.”

These standoff weapons provide the opportunity for highly flexible hit and run attacks. Either of these types of weapons would be more realistic than the cratering charge in the current scenario. A review of terrorist activities reveals that the antitank missile and car bomb are favorite weapons of terrorists and are likely to impose greater strains on the canisters than the M3AI cratering charge currently being considered.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

Cask safety features that provide containment, shielding and thermal protection also provide protection against sabotage. The casks would be massive. The spent nuclear fuel in a cask would typically be only about 10 percent of the gross weight; the remaining 90 percent would be shielding and structure.

Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of a saboteur using a high-energy density device on a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (9635)
Comment - EIS001888 / 0303
Civil Disobedience

As a subset of terrorism, the problem of Civil disobedience is another area in which the DEIS should have made some statement. The transportation of spent nuclear fuel to the Gorleben facility in Germany has touched off numerous annual riots. These riots have resulted in the destruction of infrastructure and deliberate efforts to prevent the transportation of waste. The Nevada experience with civil disobedience is long and centered on opposition to the Nevada Test Site. To date, the protestors have refrained from acts of violence; however, the decision to store HLW [high-level radioactive waste] in Yucca Mountain could be viewed by some radical groups as illegitimate. It is possible that an ecoterrorist group could, while “monkeywrenching” the transportation of spent fuel, inadvertently cause a more severe accident to occur. Certainly, the DEIS must consider the possibility of civil disobedience as an impact.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

DOE relies on local authorities to maintain order and DOE anticipates that the safeguards and security plans for the shipments would include whatever measures necessary to protect the shipments from any threat and ensure that they reach their destination. Appendix M of the EIS provides additional information on transportation safeguards and security requirements.

8.10.1 (9636)
Comment - EIS001888 / 0304
In order for the DEIS to be regarded as a credible document, it is important that certain modifications be made that will ensure the DEIS has properly addressed the problem of terrorist attacks on HLW [high-level radioactive waste] casks. These are:

The DEIS should contain a safety assessment that discusses the relative security of shipping waste via dedicated trains and general freight. The safety assessment should also compare the safety of transporting the waste via dedicated train and truck.

The DEIS should examine the implications of advance approval of truck and rail routes. Security considerations should be incorporated into rail and truck routes selection and RADTRAN modeling should be performed for alternative security scenarios to assess the relative benefits of security considerations.
The DEIS should examine the safety implications escort requirements to include more than a single driver as a possible escort.

The DEIS should discuss the types and character of the terrorist threat likely to effect the proposed action. Civil disobedience should also be included in that discussion.

The DEIS should report on the vulnerability and utility of local military facilities to likely terrorists.

The DEIS should relate the security of waste shipments to the demonstrated and published techniques used by terrorists.

The DEIS should report the results of a full-scale test of the effects of a TOW II missile impacting obliquely on a GA-4 cask from a range of 1,000 meters.

Response
Transportation shipments by dedicated trains, general rail freight, and truck would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

The safeguards requirements for general freight and dedicated train shipments are the same. Dedicated train and truck requirements are generally the same, with the exception of escort requirements, which acknowledge the difference between the transport modes. In response to comments, DOE has added information on transportation safeguards and security measures in Section M.7 of the EIS.

8.10.1 (9758)
Comment - EIS001888 / 0342
[Clark County summary of comments it has received from the public.]

Several commenters requested that the EIS evaluate the implications of transport and disposal of SNF [spent nuclear fuel] and HLW [high-level radioactive waste] on national security, terrorism, and proliferation of nuclear weapons in the U.S. and abroad. Mechanisms that preclude terrorism and proliferation also should be addressed by the EIS.

Response
DOE prepared the EIS to complete the mandate of Congress. Part of the reason to develop a repository would be to dispose of these materials permanently to protect the public health and safety and the environment, including to remove the material from potential diversion and terrorist acts.

8.10.1 (9942)
Comment - EIS001732 / 0011
What safeguards will be in place during the shipping and storage process in case of failed equipment; for instance, O-ring failure as in the TMI [Three Mile Island] case, human error as when a buffer car with a TMI fuel train was labeled as containing calcium carbide, an explosive compound, vehicular accidents such as the accident involving a citizen's car which stalled on the tracks here in St. Louis and was hit by the TMI train, or sabotage? Unfortunately, terrorism is an increasing reality in today's society and must not be ignored, and let me say here, terrorists are very innovative people.

Response
Quality assurance procedures would be in place to minimize the kind of errors cited in this comment, but there is still a chance that errors could occur. However, errors of this sort would require another accident or incident to occur to trigger any effect. The likelihood of a simultaneously occurring event is very low, but even if that occurred, the casks are extremely robust and would survive very severe events.

Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (10021)
Comment - EIS001888 / 0515
[Clark County summary of comments it has received from the pubic.]

DOE's Developing the Transportation Plan is now in EIS and has no focus on security (i.e., guards) for shipments.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. One of the specific requirements in 10 CFR 73.37 is that armed escorts would be required in heavily populated areas that are generally defined as urban areas with a population of 100,000 or greater. Additional information on physical protection of shipments can be found in Appendix M of the EIS.

8.10.1 (10032)
Comment - EIS000657 / 0002
Another thing that bothers me is this transportation thing. We've dwelt on that a great length.

One that I think that boggles my mind, if one of those trains goes through a big city like Denver, Salt Lake City, or Las Vegas and some terrorist dropped a missile on that thing, ain't no way in the world you're going to clean that thing. It's impossible.

Response
The EIS discusses sabotage during transportation in Section 6.2.4.2.3. Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the

maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (10033)
Comment - EIS000809 / 0004
Transportation Security-From the data presented in the EIS, it appears that acts of sabotage greatly increase the risk of concentrated releases of nuclear material. Our concern in this area emanates from the number of stated shipping points. All told, there are a total of 77 separate shipping points. We know that transportation security is fairly consistent within the DOE. However, we would like to have the assurance that transportation security will be treated uniformly from all 77 shipping points and that the DOE will have ultimate responsibility for the security of all such shipments.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. Because DOE would conduct the shipments according to Nuclear Regulatory Commission requirements and Departmental directives, there would be little variation in the process for shipments from the 77 sites.

Although it is not possible to predict the types of potential sabotage events with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of sabotage against a truck or rail cask. The results of this analysis indicate that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (10053)
Comment - EIS001877 / 0009
DOE should incorporate terrorism/sabotage risk management and countermeasures in all DOE transportation plans relating to operation of a repository, interim storage facility, and/or intermodal transfer facility, including liability for costs and damages resulting from terrorism/sabotage against nuclear waste shipments.

To date, DOE has said that it would rely on regulations and the security oversight of the Nuclear Regulatory Commission to ensure the safety of its OCRWM [DOE Office of Civilian Radioactive Waste Management] shipments. No commitments to extra-regulatory measures have been made.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

In addition, 10 CFR 63.21 requires a repository at Yucca Mountain to have physical protection consistent with 10 CFR 73.51. This regulation specifies a performance objective, which provides “high assurance that activities involving spent nuclear fuel and high-level radioactive waste do not constitute an unreasonable risk to public health and safety.” The regulation requires that spent nuclear fuel and high-level radioactive waste be stored in a protected area such that:

- Access to the material would require passage through or penetration of two physical barriers. The outer barrier would have isolation zones on each side to facilitate observation and threat assessment, would be continually monitored, and would be protected by an active alarm system.

- Adequate illumination would be provided for observation and threat assessment.

The area would be monitored by random patrol.

- Access would be controlled by a lock system and personnel identification would be used to limit access to authorized persons.

A trained, equipped, and qualified security force would be required to conduct surveillance, assessment, access control, and communications to ensure adequate response to any security threat. Liaison with a response force would be required to permit timely response to unauthorized entry or activities.

Because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments and key facilities. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.1 (10918)
Comment - EIS000241 / 0005
In a recent study in which they took the early experimental results and applied them to modern casks, and again, as I said, we have calculation tools to do this now as a result of the scale model and full-scale testing we’ve done, you apply these to the existing casks today.

It turns out that the result of a sabotage event is still well within the kinds of environmental impacts, including impact to the public, that you would find acceptable. The latent cancer fatalities are somewhat less than 1 in 100, or 1/100th of one latent cancer fatality.

The other thing that isn’t factored into those kinds of considerations is the fact that these munitions are not easy to use. And two things determine the effectiveness of these munitions. They’re shaped charges. They’re the kind of things the Army uses as bazookas. One of these factors is called obliquity, which means that the shaped charge has to hit the surface of the cask at 90°. If it hits as little deflection as 10°, then the jet is deflected off, and it doesn’t penetrate.

Now, in both cases, the rail cask and the concrete cask, the sides of the cask are such that that area of the cask that you can hit and be successful in poking a hole in it is quite small.

Furthermore, these weapons, if you’re going to use a launcher to fire them, it’s incredible. The closer you are, the more likely you are to miss, because the flight of the projectile is very erratic when it first comes out of the launch tube. It’s only at ranges of about 100 yards that the flight becomes predictable, where the person firing it can actually aim it at something and have a fair chance of hitting it.

But at 100 yards you’re trying to hit a band on a cask that’s maybe four inches wide, maybe six inches wide at the most. And so the likelihood of satisfying the obliquity requirements are very, very low.

Secondly, there is a requirement for this kind of munition to be detonated at a precise distance from the surface it’s trying to penetrate. In these shoulder-launch devices there is a nose cone on there that provides you with that standoff distance, and the fuse is in the nose cone. So when it touches the surface, everything goes off.

The only problem is that these have personnel barriers around them, and so that is what the nose cone is going to hit, and you have defeated the munition simply because of standoff distance.

Now, there is a possibility, if you want to entertain it, that that person's intent on causing this damage could gain physical control of the unit and, in fact, set the system up so it is optimal in its capability for destroying the cask.

Understand, though, that there is a button in the truck, in the cab of the truck, so that if the driver senses any sort of interdiction, he presses the button and red lights go off in all of these control centers all over, and response to the system is quite good, quite quick.

So it takes time for the saboteur to set up the conditions he wants and to detonate his device. And in the meantime, you've got all the resources that we've got coming down on him, and that does not make it a very attractive target for a saboteur.

Response
The EIS discusses sabotage during transportation in Section 6.2.4.2.3. Although it is not possible to predict the types of potential sabotage event with certainty, DOE has examined various accident scenarios, which can provide a sense of the consequences that could occur in such events. In addition, DOE has specifically analyzed the potential consequences of a saboteur against a truck or rail cask. The results of this analysis indicated that the maximally exposed individual would increase the risk of incurring a fatal cancer from approximately 23 percent (the current risk of incurring a fatal cancer from all causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

However, because of the attacks on September 11, 2001, DOE and other agencies ar reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

Comment - EIS001207 / 0009
Although DOE Yucca Mountain Site office cannot intervene in local political manipulation of democratic process, it must acknowledge that trusting local levels to implement NEPA [National Environmental Policy Act] and democratic process is, at times, trust misplaced. Unethical actions and illegal actions have recently been subject of criminal and civil investigations within the region of Ohio and Kentucky considered by DOE as transport corridors for HLRW [high-level radioactive waste] (and surplus nuclear weapons arsenal materials). DOE must consider recent regional examples of conduct (and lack of concern) which could potentially place the general public at considerable risk during transport of nuclear materials through regional transportation corridors.

Lewis County of Kentucky Grand Jury recently indicted an individual believed to be connected to a multi-state, semi-trailer theft ring. The man was from Lucasville, Ohio. Further investigation is continuing with charges expected against a man from Piketon, Ohio (location of the Portsmouth Gaseous Diffusion Plant). See Attachment V, "First Charges Brought in Theft Ring Investigation," THE LEDGER INDEPENDENT, January 25, 2000, pg. A-1. The point here is rather obvious, transport of materials to the Yucca Mountain Site may not be as "secure" as DOE would seem to believe in agency calculations regarding risk assessment from accident, "incident" or theft.

Response
The safety and security of spent nuclear fuel shipments is the responsibility of DOE. DOE would ensure that the contractors making the shipments follow all DOE and Nuclear Regulatory Commission safeguards requirements.

Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

Comment - EIS001729 / 0002
With respect to terrorist assault, I find that the casks are adequately designed to protect against what I would call any expected terrorist assault, but quite frankly, I believe that these packages are not even on the list of anyone who's interested in sabotage or terrorism. They are a target of low opportunity with a very low probability of having any effect and there are far more targets of opportunity, and no one in St. Louis or any other place in the country ought to be worried about it, that particular aspect of the movement of fuel. We've done it. We've been there, done that, as the expression goes. We know what we're doing and we will continue to do it safely in the future.

Response
The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection and safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the physical protection and safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. The cask safety features that provide containment, shielding, and thermal protection also provide protection against sabotage. The casks would be massive. The spent nuclear fuel in a cask would typically be only about 10 percent of the gross weight; the remaining 90 percent would be shielding and structure. Additional information on the physical protection of spent nuclear fuel and high-level radioactive waste during transportation can be found in Section M.7 of the EIS.

It is not possible to predict whether sabotage events would occur, and if they did the nature of such events. Nevertheless, DOE examined various accidents, including an aircraft crash into a transportation cask. The consequences of both the maximum reasonably foreseeable accident and the aircraft crash are presented in the EIS for the mostly truck and mostly rail transportation scenarios and can provide an approximation of the types of consequences that could occur from a sabotage event. In addition, DOE analyzed the potential consequences of sabotage against a truck or rail cask (see Section 6.2.4.2.3 of the EIS). The results of this analysis indicate that the risk of the maximally exposed individual incurring a fatal cancer would increase from approximately 23 percent (the current risk of incurring a fatal cancer from all causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the terrorist attack of September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

Comment - EIS002137 / 0004
We talk about terrorism. Somebody mentioned terrorism. Why would you want to attack a -- a cask full of spent fuel rods? Right out here at Nellis Air Force Base, we have 1,450 nuclear devices. If you want to shoot a missile at something, that ought to light our fire. We don't see anybody saying, "How long are they going to last, 10,000 years?" They got there. They got there on B-52s, they got there with trucks.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. Assessing the vulnerability of military bases to terrorist attacks is not within the scope of this EIS.

Comment - EIS001887 / 0436
Improper Attention to Sabotage and Terrorism Scenarios

2.1 Inadequate Selection of "Reference Weapons"

2.1.1 The 1999 Sandia Study (Luna et al) needs to be more specific on what type of device it selected for computer simulation. Although the report claims that the vagueness was necessary to prevent the document from being classified, it is necessary to provide more details so a thorough analysis of its findings can be performed. This is the only way to test the validity of the computer simulations used in the report.

2.1.2 The DOE needs to make clear exactly what range of devices is available for consideration as "reference devices." It is our belief that devices such as the Milan Anti-Tank Missile and the US TOW 2 Anti-Tank missile, reported to have armor-penetrating capabilities of great than 1000mm (39.4 inches) and greater than 700mm (28.5 inches), respectively, must be considered (Norris).

2.1.3 All Sandia reports considering sabotage implicitly assume that a terrorist attack will involve a single strike using a single charge or missile. However, some devices can be fired multiple times in quick succession: the US TOW 2 can be fired up to three times in 90 seconds (Norris, Halstead & Ballard). The DOE needs to address the potential for a multiple-strike terrorist attack, which is likely to cause significantly more damage then the scenario modeled in the Sandoval and Luna reports.

2.2. Improper extrapolation of previous experiments to current cask designs

2.2.1. Use of "Swept Volume" as a surrogate for fraction or respirable material released

2.2.1.1. The equation listed in the Luna report which attempts to define a "swept mass" solely in terms of the geometric properties of the hole left by the charge does not balance its units. This will be analyzed in detail in the Review Comments. If this equation turns out to be invalid, the entire analysis performed in the Luna report and cited in the EIS becomes irrelevant, requiring a completely new analysis. Until this is addressed the results correlating swept volume and respirable aerosol production cannot be trusted.

2.2.1.2. The relationship assumes that there is only one hole into the fuel cask (i.e., an entry hole but no exit hole). Multiple holes will significantly increase the amount of respirable material released (Luna estimated it to be by a factor of 10). Due to the possibility that certain weapons can completely penetrate a cask, or that a cask will be penetrated by multiple shots, any relationships relying on a single hole entry into the cask is not credible as a worst Case scenario.

2.2.1.3. The "one hole assumption" results in another underestimation of the fraction of respirable aerosol produced by the oxidation of UO_2. Assuming a cask is fully penetrated, this will create a flow of oxygen into the cask, which will result in the oxidation of UO_2 to $U_3 O_8$, a fine powder of mostly respirable particles. This oxidation rate is increased significantly at temperatures above 250ºC (Aronson). Temperatures this high will be likely in the event of a missile strike coupled with a fire. This significant source of respirable aerosols was not accounted for in the Luna correlation exercises.

2.2.1.4. Using a geometric correlation assumes that all casks, and all devices used in an attack, will exhibit the same thermal properties as the cask in the Sandoval experiments. Since the thermal properties of uranium are very different from lead, this will not be the case. Because of this, it is not enough to simply assume a relationship between aerosol released and swept volume, and use this to estimate releases in unrelated casks. This ignores thermal mechanisms of aerosol generation, such as oxidation of UO_2 under elevated temperatures. Further, different attack devices will impart a different amount of heat into the cask, resulting in different aerosol production rates as a function of thermal input. This will be likely to change to relationship between swept volume and aerosol released, making any correlation attempt between different casks or different devices trivial.

2.2.2. Estimation of respirable aerosol produced due to breach of pressurized rods

Luna cited irrelevant data to estimate the amount of surrogate fuel aerosol that could be created within the cask and released in the event of breach. The cited experiment showed a linear relationship between the energy density in the material from the impact of a calibrated hammer on brittle objects and mass of particulate material having diameter smaller than 10µm. However, the materials chosen were refractory to ensure that melting and vaporization were not observed. In the event of a missile strike, temperature effects are likely to be extremely significant. Therefore, any study that tries to estimate aerosol production as a function of energy density, but does not include temperature effects, is irrelevant and should not be used. Because of this, the estimate of 5% aerosol production due to HEDD [high-energy density device] impact is not accurate or conservative. It may do better to assume that all of the uranium mass not accounted for in the Sandoval studies (assumed to be inside the cask and deposited on its walls) was of respirable size and able to be expelled in the event of cask compromise. This will significantly alter the consequence analysis, since about 1% of the total UO_2 mass, and 37% of the mass released from the pins, was "unaccounted for" in the Sandoval full-scale experiment. A direct measurement of the amount of material deposited inside the cask walls is necessary to estimate how much aerosol is produced due to HEDD action. Therefore, a new study is recommended with more complete sampling procedures in order to obtain an experimental value for the respirable aerosol production due to the HEDD. The 5% value assumed is likely to be low.

2.2.3. Unsubstantiated reduction in the spent fuel-surrogate fuel ratio

Luna attempts to reduce the value used by Sandoval which accounts for the fact that spent fuel will produce more respirable aerosols then the surrogate fuel used in most experiments. Luna quotes the following experimental estimations of this ratio: .53, 5.6, .71, .42, 3, 2.8, 2.5, 3, 12. From this, it is estimated that 3 is the most appropriate ratio, even though the range of experimentally-determined ratios differs over 3 orders of magnitude. Further, after Luna (correctly) dismisses all values less than 1.0 as implausible, it would make sense to use the largest cited value for a conservative approximation. Alternately, the geometric mean of a large distribution of numbers is often used for estimation purposes (a value of 4 in this case), so long as a range based on the standard deviation about the mean is given as well.

However, more likely is that the large distribution of estimated ratios suggests that there is no clear, reproducible relationship between the amount of spent fuel and surrogate fuel aerosols produced from a blast of given intensity. Thus, it is argued that no ratio is acceptable. Rather, the inconsistent data suggest that the only way to determine spent fuel response to a detonation is to detonate a cask containing spent fuel and analyze the results. Short of doing this, the correlation used by Luna is arbitrary, non conservative, and unacceptable.

2.3 SCAP computer code used without sufficient benchmarking

The Luna study attempts to utilize a computer model as a replacement for actual experimentation in order to determine the possible damage caused by two HEDD's on state-of-the-art shipping casks. However, the code that they use admittedly does not model multi-layered targets well. The Luna study "benchmarks" the SCAP code against the Sandoval full-scale test and determines that the code predicts penetration depth well, but underestimates the size of the hole created by the penetration. In an attempt to remedy this, the Luna report multiplies the predicted hole size by a factor of 2.0 to obtain "correct" results, then proceeds to do the same when modeling other cask designs. This approach is seriously incorrect. It assumes that the code will consistently model all cask layer or shell arrangements, including different numbers of layers, which is incorrect. With no experimental data to prove this, this assertion is unacceptable. It cannot be assumed that a computer code which, when used to model multi-layered targets could result in "serious difficulties in comparing SCAP modeling output and experimental data" (Robinson), would be expected to model, for example, a lead-steel interface with the same degree of incorrectness as a lead-uranium interface. Therefore, until an experimental proof of the merits of using the SCAP code to model the behavior of a shaped charge strike on a uranium-shielded cask is performed, the code cannot be considered validated. Further, since the code underestimated the true size of the hole in the Sandoval experiments, it cannot be assumed that this code will provide a conservative approximation of penetration damage. This leads to the call for a full set of experiments designed to determine the true effect of a HEDD explosion on cask integrity.

2.4. Omission of two important sabotage scenarios

2.4.1. Nevada intermodal transfer station sabotage event

The EIS, on pg. J-95, states that section J.1.5 evaluates the effects of sabotage on intermodal transfer stations. However, there is no section J.1.5, and there is no mention of this potential sabotage event again. It is essential to perform an analysis of the likely effects of a successful sabotage event on an intermodal transfer station because of its unique conditions. For one, shipping casks at an intermodal station will be stationary. This eliminates some of the problems associated with striking a moving target optimally that were presented in the EIS. Also, this makes the possibility of a multiple Cask release possible. Third, the appeal among potential saboteurs of attacking a station rather than a truck or train must be addressed. Intermodal transfer will also occur at reactor sites without rail access. All of these factors suggest that the potential for sabotage at an intermodal station must be addressed in a comprehensive manner.

2.4.2. Barge transport sabotage event

The EIS does not consider the consequences of a possible sabotage event on a barge shipment of spent nuclear fuel. As this is one of the transportation options being considered, it is important to consider the effects of a successful sabotage event, including the breach of shipping casks and release of radioactive material into the air and water, especially near populated areas, water supplies, or natural environments. It is essential to address this concern, especially since there was no discussion of the consequences of severe barge accidents, which were determined by the EIS to be not reasonably foreseeable.

2.5. Failure to identify/profile potential “Threat Groups”

It would be helpful to provide some general profiles of potential “Threat Groups” in terms of characterizing exactly what these groups are capable of doing, and the relative likelihood of each group performing a sabotage act. This would help in determining what types of weapons, forces, expertise, etc can be expected to be utilized by different groups, providing the DOE with a better estimate of what safeguards must be put in place. The Final Environmental Impact Statement: *U.S. Spent Fuel Policy, Storage of Foreign Spent Power Reactor Fuel* (1980: DOE/EIS-0015) provides a list of “Threat Groups” to nuclear fuel storage and transportation; a similar, but updated list would be helpful.

2.6. Improper dismissal of considering the probability of terrorist events

The EIS and the Luna report both consistently state that, since sabotage events are not randomly occurring, no estimation of their probability can be made, other than assuming they are “extremely rare.” However, some comment should be made concerning the increase in large-scale terrorist attacks and how this relates to the need for sufficient safeguards against such attacks. Even though attacks are not random events, some effort should be made to identify trends, such as the increase in attacks on American soil over the last few years. This provides a proper foundation through which to analyze the level of protection required from terrorist attacks.

2.7. Failure to present a true “worst case scenario” for consequence analysis

2.7.1. Use of “averaged” wind conditions instead of wind blowing in one direction

The inputs used by the DOE in determining health effects of a successful sabotage scenario assume generalized wind conditions. For a true worst Case scenario, the impact of a radiological release directly downwind from a large population center, such as an office building, prison, stadium, etc. must be addressed. The use of wind conditions averaged over all directions dilutes the effect of a single-direction wind event.

2.7.2. Use of “average” (neutral) weather conditions, instead of worst Case conditions

The EIS states that, because the time and place of a sabotage event cannot be predicted, average weather conditions for the entire United States must be used. However, it seems likely that potential saboteurs will, to the degree feasible, plan sabotage events around those weather conditions that are the most damaging. Thus, for a true "worst case" sabotage scenario, weather conditions leading to the greatest consequences should be used.

2.7.3. "One bullet assumption"

As has been previously discussed, the consideration of only a single HEDD strike in the simulation of a sabotage event is unrealistic. Terrorists who are serious about causing a significant release of radioactive material, and who have the means of obtaining armor-penetrating weaponry, will likely bring a complete arsenal, including several armor-penetrating devices, incendiary devices, etc. Therefore, cask response to multiple missile penetrations, especially if they are fired in succession such that missiles strike an already damaged cask, must be addressed. It is extremely likely that the damage done to an already-penetrated cask will be substantial. This has not been assessed by the DOE and must be in order for the sabotage portion of the EIS to be considered complete.

2.7.4. Failure to consider effects of breached cask coupled with long-duration fire

The EIS assumes that there will be no significant secondary effects on the cask after missile impact, since the casks themselves are not flammable. However, the trucks and trains carrying them are flammable. Further, there is the possibility of deliberately causing a fire, either by truck bomb or other method, to intensify the damage from a penetrated cask. This scenario must be taken into account.

2.8. Failure to assess social, psychological, environmental, or economic costs

In order to be able to truly assess the consequences of a successful sabotage event, the full scale of effects must be studied. The DOE has commissioned studies addressing the psychological impacts of radiation accidents on the public, but similar studies have not been performed for this EIS. In addition, no consideration of the cost of cleanup of such an event is given. Below is a skeleton outline of the various factors not considered by the EIS that need considerable attention.

2.8.1. Social/psychological costs not addressed
2.8.1.1. Increased fear of nuclear energy, and nuclear industry
2.8.1.2. Fear of vulnerability to attack (see Oklahoma City bombing)
2.8.1.3. Susceptibility of foreign-born citizens to discrimination
2.8.1.4. Distrust of government that transports materials capable of such destruction

2.8.2. Environmental costs not addressed
2.8.2.1. Groundwater and/or surface water contamination →more human costs
2.8.2.2. Loss of land use near site for significant amount of time

2.8.3. Economic costs not addressed
2.8.3.1. Cleanup costs
2.8.3.2. Decontamination costs
2.8.3.3. Lost workdays due to radioactive contamination of roads, buildings, etc.
2.8.3.4. Loss of tourism in Las Vegas, for example, due to contamination or fear
2.8.3.5. Evacuation costs
2.8.3.6. Relocation costs

Response
This response answers each point using the paragraph numbers from the comment.

2.1 Inadequate Selection of Reference Weapons

2.1.1. Within the scope of its classification policy, DOE can offer no more specific information about the devices considered in Luna, Neuhauser, and Vigil (DIRS 104918-1999).

2.1.2. Within the scope of its classification policy, DOE cannot state specifically which devices the analysis considered. However, the analysis enveloped the damage that modern weapons might produce in an optimally successful sabotage event.

2.1.3. DOE believes that its analysis adequately bounds the sabotage consequence scenario.

2.2 Improper Extrapolation of Previous Experiments to Current Cask Designs.

2.2.1.1. The commenter makes a valid comment with regard to the equation in the report for swept volume. It is incorrect as printed; the number of rows of pins along the disruption path (NR) should not be divided by the pin pitch (PP), and NR should therefore be unitless. The actual calculations in the report were rechecked and found to be correct.

2.2.1.2. While multiple holes could lead to an increased release fraction, as suggested by this comment, the result is unlikely to be additive of the results for a single hole presented in Luna, Neuhauser, and Vigil (DIRS 104918-1999). This is because the driving pressure from rod pressurization postulated to enhance the release fraction over that measured by Sandoval et al. (DIRS 156313-1983) would be lower for each successive attack as the number of undamaged fuel pins became smaller. Without a mechanism for producing a strong gas flow out of the cask, respirable material probably would plate out on the huge surface area in the cask.

The assertion that modern weapons can produce full penetration of both cask walls is not confirmed by calculations from Luna, Neuhauser, and Vigil (DIRS 104918-1999).

2.2.1.3. This comment suggests that multiple holes would allow a flow of air into the cask that would enable exposed UO_2 to oxidize to U_3O_8, which is asserted to be a fine powdery material, when temperatures exceeded 250ºC (482ºF),. While the oxidation process could occur, achieving temperatures of 250ºC to make the process occur quickly could not occur easily. Penetration by the weapon would not increase temperature noticeably inside the cask, and fires would take some time to produce enough heat into the cask to raise temperatures above 250ºC. Moreover, conversion to U_3O_8 in the cask does not mean that particles would escape from the cask or that they would be small enough to become a significant health hazard. Because this scenario requires even more aspects of the sabotage event to proceed perfectly, it becomes increasingly unlikely.

2.2.1.4. The thermal properties of shielding material have little effect on the predicted geometry of penetration from use of a high-energy-density device (HEDD). Penetration is unrelated to thermal effects; it is related to density, depth, and to some extent, strength of the materials with which the device would interact. Thus, the use of swept volume scaling to estimate aerosol production is a reasonable approach. As indicated in Luna, Neuhauser, and Vigil (DIRS 104918-1999), the SCAP computer code predicted penetration depth closely in two very different configurations involving different materials. There is good confidence that penetration estimates in lead, uranium, and fuel are sufficiently accurate for the analysis performed and for the estimate of swept mass.

Since the publication of the Draft EIS and Luna, Neuhauser, and Vigil (DIRS 104918-1999), additional data has become available in a paper by Luna (DIRS 157201-2000). This paper describes three experiments in which an unspecified HEDD penetrated a ductile cast-iron CASTOR cask containing nine mocked-up pressurized-water reactor fuel assemblies. Each assembly was made up of pressurized fuel rods filled with unirradiated fuel pellets. Two experiments were substantially the same. Each yielded a respirable release exterior to the cask of about 1 gram of aerosol. A third experiment was done with the cask interior at a pressure of 0.8 atmosphere, which yielded a release of about 0.3 gram of respirable aerosol. These releases include the cask purging effect of the release of rod plenum gases. The experiment described in Sandoval et al. (DIRS 156313-1983) yielded a respirable release of 3 grams but included no rod pressurization to create a purging flow that would force additional respirable material out of the cask. The two results are close, but the conditions for each were different.

Luna (DIRS 157201-2000) used the swept mass concept to relate these experiments. The respirable release fraction scaled to swept mass for the first two experiments was about a factor of 2 smaller (DIRS 156313-Sandoval et al. 1983). Based on the CASTOR experiments that suggested that little of the aerosol in assemblies behind the first one penetrated was likely to find its way to the entry hole and be released, the fractional respirable aerosol release fraction was found to be quite close to the value for the Sandoval et al. (1983) experiment. This value includes the effect of releasing rod pressurization gas. This suggests that scaling the release to swept mass is a workable concept for translating experimental results to other situations.

2.2.2. There are two assertions in this section. One deals with the experimental data used to extrapolate to a 5-percent respirable source term and seeks to discredit that estimate. The second assertion is that all material not specifically accounted for in Sandoval et al. (DIRS 156313-1983) should have been assumed to be respirable.

Experiments. The materials used in the experiments cited in Luna, Neuhauser, and Vigil (DIRS 104918-1999) were not "chosen to be refractory to ensure that melting and vaporization were not observed," as suggested. They were typical of spent nuclear fuel and other waste forms. This comment seems to separate temperature effects from energy density effects when, in fact, temperature and pressure are indicators of energy density and were included in the experiments used in the report. The work cited (hammer experiments) is not irrelevant to estimating the respirable particles produced, as suggested. In addition, this comment does not recognize that Sandoval et al. (DIRS 156313-1983) saw no evidence of melting or vaporization-generated uranium oxide aerosols in their experiments. Similarly, there were none in the hammer-related studies.

Respirable Particulate. Because the experiments in Sandoval et al. (DIRS 156313-1983) did not account for all materials in all volumes on all surfaces and there was potential for gas release from rods to move more respirable material from the cask to the environment, Luna, Neuhauser, and Vigil (DIRS 104918-1999) corrected the original source term estimate from Sandoval et al. (1983). This comment suggests that the 5-percent respirable estimate used for this purpose was too low and that a new experiment is needed. As stated above, a more recent experiment suggests that the original Sandoval et al. (1983) result was correct and that the 5-percent respirable aerosol estimate derived in Luna, Neuhauser, and Vigil (1999) might be an overestimate. DOE believes that the current analysis, based on past and recent experiments, provides a reasonable estimate of the potential consequences of a very unlikely event.

2.2.3. The spent nuclear fuel-to-surrogate fuel ratio is important in the estimation of the source term. The approach taken in Luna, Neuhauser, and Vigil (DIRS 104918-1999) was to use a value of 3 for the ratio, justified on the grounds that it was a central value. In fact, the mode of the values given is 2.8 and the median is about 2.6, which are other measures of central tendency for which a value of 3 is somewhat conservative. This comment suggests the use of a geometric mean value and estimates that value to be 4 (the actual geometric mean of the nine values given is actually about 2.1). The comment then suggests that the range is so wide that there is no reproducible relationship and DOE should perform a full-scale experiment with spent nuclear fuel. However, there is a body of data [of which the Jardine data used in Luna, Neuhauser, and Vigil (1999) are a part] that suggests that there is a definite relationship between particulate production and energy density in impacts in brittle solids. That being the case, there should be a reasonably well-defined relationship for aerosol production between various brittle materials like spent nuclear fuel and UO_2. The fact that it was too expensive to do many correlation experiments in the 1980s experiments does not mean that the relationship does not exist. The experiments performed suggest a central value of about 3, as used in Luna, Neuhauser, and Vigil (1999).

2.3 SCAP Computer Code Used Without Sufficient Benchmarking.

The application for which the SCAP code was used was well suited to its capability. The comment overlooked the three benchmarking calculations on a variety of cask and cask-like configurations. These calculations included the averaging of surrogate fuel and open space to represent fuel assemblies. The prediction of depth of penetration, which is a key issue in the analysis, was correct. The need to adjust the diameter predicted by the SCAP code by a factor of 2 seems preferable to using the predicted diameter and introducing a known underestimate. This normalization is not likely to introduce major unconservative errors in the analysis.

2.4 Omission of Two Important Sabotage Scenarios

The commenter identifies two additional scenarios, which involve an intermodal transfer station and barge transport. Spent nuclear fuel casks at an intermodal transfer facility would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules aimed specifically at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR Part 73), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under the control of unauthorized persons.

DOE considered barge transport sabotage scenarios in Appendix J of the EIS. While there could be the opportunity for a radiation dose from releases to surface water as a result of a barge accident or sabotage, the consequences are likely to be much less than releases to the atmosphere (DIRS 157052-Ostmeyer 1986).

1.5 Failure to Identify/Profile Threat Groups

The threats that spent nuclear fuel shipments must be protected against are known as "Design Basis Threats." Design basis threats are defined in 10 CFR Part 73. Profiling of threat groups is beyond the scope of this EIS.

Improper Dismissal of Considering the Probability of Terrorist Events

With regard to the probability of terrorist acts, because of the attacks on September 11, 2001, DOE and other agencies are reexamining the protections built into their physical security and safeguards systems. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

1.6 Failure to Present a True Worst-Case Scenario for Consequence Analysis

An EIS is not required to present a "true worst-case scenario" because the Council on Environmental Quality rescinded the requirement to perform a worst-case analysis in an EIS in 1986 (51 *FR* 15618, April 25).

2.7.1 Use of Averaged Wind Conditions Instead of Wind Blowing in One Direction. The atmospheric data used in the sabotage analysis was a joint frequency of wind speed and stability class. As suggested by this comment, the wind was assumed to blow toward the population, and consequences were estimated for an urban area.

2.7.2 Use of Average (Neutral) Wind Conditions, Instead of Worst-Case Conditions. As mentioned above, the Council on Environmental Quality rescinded the requirement to perform a worst-case analysis in an EIS in 1986 (51 *FR* 15618, April 25).

2.7.3 One-Bullet Assumption. As discussed above, while multiple holes could lead to an increased release fraction, as suggested by the commenter, the result is unlikely to be additive. This results because the driving pressure from rod pressurization that was postulated to enhance the release fraction over that measured in Sandoval et al. (DIRS 156313-1983) would be lower for each hole as the number of undamaged fuel pins got smaller. Without a mechanism for producing a strong flow out of the cask, respirable material within the cask would be likely to plate out on the huge surface area within the cask. Thus, DOE believes that it has adequately bounded the sabotage consequence scenario.

2.7.4 Failure to Consider Effects of a Breached Cask Coupled with a Long-Duration Fire. It is possible that a sabotage attack could involve fires. Whether the fires could enhance the consequences would depend on their locations in relation to the cask and duration. A fire collocated with the cask could cause a greater release of material, but that material would be transported aloft in the plume of smoke and become unavailable for causing radiological impacts near the cask. The additional dispersion from fire-generated turbulence would mean that radiological doses a kilometer (0.6 mile) or so downwind of the cask would be only slightly higher.

2.8 Failure to Assess Social, Psychological, Environmental or Economic Costs

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. Section J.1.4.2.5 discusses environmental restoration after a release of radioactive material. Social and psychological issues are discussed in Appendix N.

8.10.1 (12200)
Comment - EIS010485 / 0004
Given the September 11, 2001, hijacking of commercial jets, it is not difficult to imagine similar events taking place on our highways, irrespective of the claims made for the strength of the spent fuel/nuclear waste containers.

These possibilities are not [addressed] by the EIS.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. Nuclear Regulatory Commission safeguards rules require the capability to immobilize the cab or cargo-carrying portion of the vehicle, so that a hijacked truck could not be moved. Aircraft crashes into spent nuclear fuel casks are discussed in Section 6.3.3.1 of the EIS. This analysis showed that an aircraft crash into a spent nuclear fuel cask would not penetrate the cask.

8.10.1 (12359)
Comment - EIS010489 / 0003
As of September 11, 2001 I can't see how a plan to transport such toxic waste across our nation could even be considered. Not only would there be the nuclear power plants as terrorists' targets but in addition our highways and communities throughout our nation would become targets.

Response
Transportation shipments would be protected from sabotage. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection or safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the safeguards regulations are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons.

However, because of the attacks on September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

8.10.2 EMERGENCY RESPONSE

8.10.2 (114)
Comment - 89 comments summarized
Commenters stated that the Draft EIS did not examine what emergency response personnel, training, and equipment would be needed along transportation routes or what the specific impacts of a transportation accident would be. Commenters wanted to know who would respond in the event of an accident: would local responders be the first to arrive at the scene of an accident or would transport vehicles be escorted with a response team? Other commenters asked who would train people and what level of training would be received and when would the hospitals and personnel in their communities be trained and equipped to handle radiation victims. Others asked how long it would take to train all of the necessary personnel for a potential nuclear "catastrophe." Other commenters noted that heavy trucks would be used to haul the spent nuclear fuel and high-level radioactive waste and were concerned that most cities, towns, and villages would not have the equipment available to move these vehicles in the event of an accident.

A state public utility commission noted that it would be involved in providing the funds and technical assistance to the affected communities in its state, both in the routing process and in supplying funds to train emergency responders. Another commenter noted that the emergency response training should be separate from the current Occupational Health and Safety Administration training requirements of first responders to hazardous materials incidents. Other commenters stated that training needed to be conducted early to allow local responders to learn what would be involved in responding to an accident and that no spent nuclear fuel or high-level radioactive waste should be transported until the infrastructure for proper containment, transportation, and safety response/community education was in place. Commenters were concerned that without the proper equipment and training, fatalities would increase among first responders and others. Others stated that, because DOE would avoid identifying specific routes, that would contribute to a lack of training for the emergency response crews along those proposed routes.

Response
As discussed in Section 6.2.4.2 of the EIS, accidents involving the transportation of spent nuclear fuel or high-level radioactive waste shipments could occur. However, of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. As a consequence, the likelihood that a first responder or other emergency personnel would become contaminated, even in very severe accidents, would be remote. The only expected radiological exposure of first responders would be from any gamma radiation and neutrons penetrating the shielding of the casks. These radiation levels would be low, easily measured, and controlled to meet the limits of Nuclear Regulatory Commission regulations. Additional information on cask safety and testing is provided in Section M.4. Additional information on emergency response following an accident is provided in Section M.5.

As described in Section M.5 of the EIS, as with any transportation accident, state and tribal governments have primary responsibility to respond to and protect the public health and safety in their jurisdictions in accidents involving radioactive materials. This includes providing, managing, and maintaining responsibility for emergency response capabilities. Although DOE would originally provide the funding, each state and tribe would determine how it would administer that funding. Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for addressing emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress.

The schedule in the proposed policy and procedures for implementation of Section 180(c) of the NWPA (63 *FR* 23753, April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. Based on interactions with stakeholders, DOE believes that this would be sufficient time for emergency responders to receive the training to prepare them to respond to an accident involving DOE shipments. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) policy and procedures.

If there was an accident involving a shipment to the proposed repository, the first responders and response time would be the same as those for any transportation accident. The primary public health and safety issue would be emergency care for those involved in the accident and the safety of those who responded. As discussed in Appendixes J and M of the EIS, accidents involving a spent nuclear fuel or high-level radioactive waste shipment would be likely over the proposed shipping period. Most real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask into a river, and similar extreme accident conditions, would not be likely to result in release of radioactive materials from the shipping casks.

In the unlikely event someone was contaminated as the result of an accident involving shipments to a repository, there are several means to deal with such incidences. The Department has several programs available to provide assistance to state, tribal, and local governments in response to radioactive material accidents. The Radiological Assistance Program, for example, provides trained personnel with equipment to evaluate, assess, advise, and assist in the mitigation and monitoring of potential immediate hazards associated with a transportation accident. As part of the program, DOE maintains eight Regional Coordinating Offices across the country that are staffed 24 hours a day, 365 days a year. The staff consists of nuclear engineers, health physicists, industrial hygienists, public affairs specialists, and other personnel who provide field monitoring, sampling, decontamination, communications, and other services, as requested. In addition, DOE's Radiation Emergency Assistance Center/Training Site (REAC/TS) focuses on providing rapid medical attention to people involved in radiation accidents. REAC/TS maintains a 24-hour response center to provide direct support, including deployable equipment and personnel trained and experienced in the treatment of radiation exposure, to assist Federal, state, tribal, and local organizations.

Recovering 23-metric-ton (25-ton) truck casks or rail casks weighing up to 140 metric tons (150 tons) loaded with spent nuclear fuel would involve methods commonly used to recover heavy trucks following truck accidents or railcars and locomotives following rail accidents. Capability to lift such weights exists for rail and truck modes and would be deployed as required. Railroads use emergency response contractors with the capability to lift derailed locomotives that could weigh as much as 140 metric tons.

At this time many years before shipments to the proposed repository at Yucca Mountain could begin, DOE is not ready to make decisions on which specific transportation routes would be used for shipping spent nuclear fuel and high-level radioactive waste. The routes used in the EIS transportation analyses might not be the routes used for actual shipments. The route selection process would be conducted in accordance with applicable U.S. Department of Transportation regulations on route selection, state or tribal routing designations allowable under existing regulations, and the processes described in Section M.3.2.1.2 of the EIS. Section J.4 identifies the representative truck and rail routes DOE used in the impact analyses.

8.10.2 (194)
Comment - 8 comments summarized
Commenters expressed concern about the welfare of workers such as police and fire department personnel and first responders in the event of an emergency and stated that the Draft EIS inadequately assessed the potential increased exposure of and health risks to emergency first responders. Other commenters stated that the Draft EIS did not consider the impacts of accidents on hospital workers and health care professionals who might be in direct contact with high-level radioactive waste via the injured and at the scene. Another commenter was particularly concerned about rural areas where local emergency workers and health care professionals without specialized training might be the first and only workers on an accident scene for many hours. Commenters questioned what provisions would be provided for the families of workers and first responders since there would be a loss of income while injured victims recuperated. Other commenters asked how first responders to potential accidents would be notified of potential life threatening exposures. Others stated that millions of Americans could be put at risk in addition to emergency responders. Some commenters asked whether DOE would provide the necessary planning mechanism, Material Safety Data Sheets, and levels of personal protection equipment to the local emergency planning committees to distribute to first responders.

Response
In response to public comments, DOE has modified Section 6.2.4.2.1 of the EIS to include estimated radiological impacts to emergency personnel who would respond to transportation accidents. The analysis assumed a first responder would be trained and would follow guidance in the *2000 Emergency Response Guidebook* (DIRS 155776-DOT 2000) when responding to transportation accidents involving shipments of radioactive materials. The maximum estimated dose to a first responder would be 830 millirem. This dose, which is about 40 percent of the limit for annual dose to radiation workers at DOE facilities, would lead to an increase of about 0.03 percent in the individual's lifetime risk of a latent fatal cancer. Health care professionals would likely receive smaller doses from caring for radioactively contaminated accident victims or workers.

In addition, DOE has added information to the EIS on the proposed operational aspects of spent nuclear fuel and high-level radioactive waste transportation, emergency response planning, and financial assistance programs. (See Sections M.3 through M.6.) Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for addressing emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 for a discussion of the DOE Section 180(c) policy and procedures.

DOE has several programs available to provide assistance to state, tribal, and local governments in response to radioactive material accidents. The Radiological Assistance Program, for example, provides trained personnel with equipment to evaluate, assess, advise, and assist in the mitigation and monitoring of potential immediate hazards associated with a transportation accident. As part of the program, DOE maintains eight Regional Coordinating Offices across the country that are staffed 24 hours a day, 365 days a year. The staff consists of nuclear engineers, health physicists, industrial hygienists, public affairs specialists, and other personnel who provide field monitoring, sampling, decontamination, communications, and other services, as requested. In addition, DOE's Radiation Emergency Assistance Center/Training Site (REAC/TS) focuses on providing rapid medical attention to people involved in radiation accidents. REAC/TS maintains a 24-hour response center to provide direct support, including deployable equipment and personnel trained and experienced in the treatment of radiation exposure to assist Federal, state, tribal, and local organizations.

DOE would provide information concerning shipments to the state-designated point of contact for advance notification of the shipments. If approved by the Nuclear Regulatory Commission, states and tribes could monitor the shipments by a satellite tracking and communications system. Drivers of trucks and crews of trains transporting radioactive material would carry shipping papers, as required by U.S. Department of Transportation regulations. These papers would identify the cargo as required by regulations in 49 CFR Part 172, Subpart C. In addition, placards that identify the cargo as radioactive would be prominently displayed on transport vehicles, as required by Department of Transportation regulations.

With respect to compensation for losses associated with an accident involving spent nuclear fuel and high-level radioactive waste, the Price-Anderson Act (discussed in Section M.8 of the EIS) establishes a system of financial protection for persons liable for and for persons injured by a nuclear accident or incident. The Price-Anderson Act establishes a system of private insurance and Federal indemnification that generally ensures that up to $9.43 billion is available to compensate for damages suffered by the public, regardless of who causes the damages. Beyond that level, Congress will consider further action it determines is necessary to provide full and prompt compensation to the public. The Price-Anderson Act indemnifies all persons liable for the nuclear damage including state, local, and tribal governments, emergency response workers, health care personnel, victims, and any other citizens or members of the public.

8.10.2 (200)
Comment - 20 comments summarized
Commenters stated that no baseline emergency response capability was established along the potentially affected routes or in affected communities. Because no baseline was established in the affected communities, the impact on community emergency preparedness could not be determined; therefore, the Draft EIS failed to meet National Environmental Policy Act requirements. They stated that a credible evaluation would identify the adequacy or inadequacy of emergency response capacity along routes and allow the state and local authorities to deploy the necessary resources. Commenters stated that emergency response capabilities must be described as part of the affected environment and that emergency services are an essential part of local public services. Other commenters questioned whether the emergency medical facilities, fire departments, and police departments in an affected community would be adequately equipped and trained to handle an emergency situation. Commenters stated that the EIS should identify what emergency response, equipment, facilities (for example, isolation rooms for radioactively contaminated individuals), and trained personnel are available in these communities. One commenter stated that radioactive materials can be shipped safely with no significant risk to any population, including emergency responders, if basic measures are taken, such as identifying the emergency response agency having jurisdiction over a specific route, providing that agency with a copy of the training materials, and providing each agency the opportunity to have personnel attend an instructor-led class.

Response
In evaluating the potential impacts of transportation accidents in the EIS, DOE conservatively assumed that no emergency response would occur and evaluated the full impacts of the accident on the surrounding population. The analysis of impacts of transportation accidents in the EIS (Section J.1.4.2.1) does not take credit for emergency response efforts to reduce exposures to individuals. Therefore, the impacts consider the range of what could happen regardless of the emergency response capabilities of jurisdictions along transportation routes. If responders followed standard emergency response procedures, such as avoiding the downwind smoke of a major fire, exposures would be low. However, because DOE could not predict what type of emergency response would be available, it could not factor any mitigation of impacts as a result of such measures into the EIS analysis.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions the Department would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for addressing emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) policy and procedures.

If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Department has issued a draft Request for Proposals requiring each Regional Servicing Contractor to prepare a transportation plan that describes the contractor's operational strategy and delineates the steps it would implement to ensure compliance with all regulatory and other DOE requirements. This includes identification of proposed routes and associated routing considerations, coordination and communication with all participating organizations and agencies, including other Regional Servicing Contractors, DOE, state, tribal, and local governments, and interactions with appropriate Federal and state organizations. The route and mode determinations would be interactive. If, during the course of the mode or route determinations, one of the previously determined factors changed, the site-specific mode and route analysis would be reevaluated to ensure consistency. The Regional Servicing Contractor would consult with other Regional Servicing Contractors as appropriate to ensure continuity and consistency of routes and to ensure trained emergency response personnel capability.

After identifying a specific route, the Regional Servicing Contractor would submit the route plan to DOE for approval prior to its submittal to the Nuclear Regulatory Commission in accordance with 10 CFR 73.37 [a][7]. Additional mode and route selection factors are in a U.S. Department of Transportation report, *Identification of Factors for Selecting Modes and Routes for Shipping High-Level Radioactive Waste and Spent Nuclear Fuel* (DIRS 103718-DOT 1998).

For highway shipments, the Regional Servicing Contractor's transport carriers would use "preferred" routes as specified in 49 CFR 397.101[b][1]. Section M.3 of the EIS contains more information about the proposed role of the Regional Servicing Contractor.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

8.10.2 (203)
Comment - 21 comments summarized
Issues Commenters expressed concern about communities or counties in either rural or remote areas located along transportation routes because the necessary equipment, trained personnel, or funding would not be available to respond to an accident involving spent nuclear fuel and high-level radioactive waste. Other commenters noted that

the distance to the nearest hospital could be as much as 145 kilometers (90 miles) in some communities and that because of this the response time could exceed 90 minutes. Another commenter stated that transporting spent nuclear fuel and high-level radioactive waste through rural areas with limited emergency response capabilities would increase the risk associated with transportation incidents and asserted that the risk would be higher because of the lack of response capability and the time delay for personnel to respond. Commenters noted that the closest hospital might not be equipped to handle an emergency involving a nuclear accident. Commenters stated that the Draft EIS assumed that the risk of transporting spent nuclear fuel and high-level radioactive waste through rural areas in Nevada would be no greater than through urban communities. However, the commenter stated that assumption was incorrect because first responders and emergency medical service providers in rural areas would be largely unprepared to handle radiation emergencies. Commenters stated that rural communities would be helpless, at least immediately, in the event of a serious accident.

Response

In response to public comments, DOE has added information (see Appendix M of the EIS) on the proposed operational aspects of spent nuclear fuel and high-level radioactive waste transportation, the safety of transportation casks, emergency response planning, and financial assistance programs (see Section M.5). In addition, based on the revised analyses DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 presents consequences for accidents that could release radioactive materials.

In evaluating the potential impacts of transportation accidents in the EIS, DOE conservatively assumed that no emergency response would occur and evaluated the full impacts of the accident on the environment and the surrounding population. The analysis of impacts of transportation accidents in the EIS (Section J.1.4.2.1) does not take credit for emergency response efforts to reduce exposures to individuals. Therefore, the impact assessment considered the range of what could happen regardless of the emergency response capabilities of jurisdictions along transportation routes. If responders followed standard emergency response procedures, such as avoiding the downwind smoke of a major fire, estimated exposures would be reduced. Standard emergency response actions could reduce or prevent radiological exposures. The transportation analyses do take into account the differing transportation accident rates in rural and urban areas in calculating accident probabilities.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for addressing emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) of the NWPA (63 *FR* 23753, April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) policy and procedures.

If there was an accident involving a shipment of spent nuclear fuel or high-level radioactive waste, the first responders and response time would be the same as for any transportation accident. If a release occurred, and local officials were not prepared to deal with it, immediate assistance could be obtained from the DOE Radiation Emergency Assistance Center/Training Site. Appendix M of the EIS contains additional information that addresses these issues.

8.10.2 (212)

Comment - 49 comments summarized

Commenters stated that their communities would be totally unprepared for the consequences of an accident, sabotage, or terrorism and stated that all Native American tribal, state, and local jurisdictions must be fully prepared for spent nuclear fuel and high-level radioactive waste shipments and should be involved in the development of emergency preparedness plans. Others stated that acceptable emergency response plans should be developed and implemented before the initiation of shipments. Other commenters noted that transportation companies and railways would require emergency plans before any shipment could occur. Commenters wanted to know where radioactively contaminated victims would be taken and noted that many hospitals do not have isolation rooms for this type of situation. Others asked how many hospitals in this country would have the capability of handling such an emergency. Other commenters stated that the Draft EIS did not adequately evaluate the potential demands on affected local government related to public health and safety with respect to activities that could occur, such as identifying evacuation routes within city limits.

Commenters stated that the Draft EIS was inadequate because there was neither analysis of potential activities and cost during all phases of emergency management, nor were data given regarding the development of emergency action plans for any metropolitan area affected by potential transportation of spent nuclear fuel and high-level radioactive waste to the proposed repository. One commenter stated that the Draft EIS did not specifically address emergency preparedness along rail spurs, heavy-haul and legal-weight truck routes, or at prospective intermodal transfer stations. Another commenter stated that the Draft EIS must describe specific responsibilities for providing, managing, and maintaining emergency response capabilities, including identifying responsibility for emergency management and response training, responsibility for mitigating accidents, and responsibility for administering funds for emergency response assistance. One commenter stated that the state agencies that would be responsible for overseeing shipments of radioactive spent nuclear fuel and high-level radioactive waste through their communities would ensure that the appropriate shipping standards would be met. Another commenter stated that DOE should seek to enter into a memorandum of understanding with each corridor state to spell out responsibilities, liability, compensation, response times, cleanup, and other duties connected with emergency situations.

Response

As discussed in Section 6.2.4.2 of the EIS, accidents involving the transportation of spent nuclear fuel or high-level radioactive waste shipments could occur. However, of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. As a consequence, the likelihood that a first responder or other emergency personnel would become contaminated, even in very severe accidents, would be remote. The only expected radiological exposure of first responders would be from gamma radiation and neutrons penetrating the shielding of the casks. These radiation levels would be are low, easily measured, and controlled to meet the limits of Nuclear Regulatory Commission regulations. Additional information on cask safety and testing is provided in Section M.4 of the EIS. Additional information on emergency response following an accident is provided in Section M.5.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for addressing emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) of the NWPA (63 *FR* 23753, April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. Additional information on Section 180(c) is provided in Section M.6 of the EIS.

Although DOE and its contractors would develop their own emergency response plans, the preparation and implementation of emergency response and evacuation and contingency plans are a state or tribal responsibility for lands within their jurisdictions. Section 180(c) funding would be provided to eligible jurisdictions for the preparation of these plans, as well as emergency response and safe routine transportation planning and coordination activities.

In the unlikely event someone was contaminated as the result of an accident involving shipments to a repository, there are several means to deal with such incidents. Major hospitals are equipped to deal with radioactive contamination because they routinely handle medical radioisotopes. In cases where there is no training or procedures to handle a contaminated individual, assistance can be obtained from the DOE Radiation Emergency Assistance Center/Training Site (REAC/TS). REAC/TS is on call 24 hours a day to provide direct or consultative help when people have been involved in a radiation accident.

As with any transportation accident, state and tribal governments have primary responsibility to respond and to protect the public health and safety in their jurisdictions in accidents involving radioactive materials. This includes providing and managing emergency response capabilities. Although DOE would provide the funding for Section 180(c) activities, each state and tribe would determine how it would administer that funding.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors, who would perform waste acceptance and transportation operations. Each Regional Servicing Contractor would be required to provide detailed written procedures for how it would respond to an incident and arrange for repair/replacement of equipment or recovery, as appropriate. In accordance with ANSI Standard N14-27 (DIRS 156289-ANSI 1987), the carrier is expected to provide appropriate resources for addressing the consequences of an accident, isolating and cleaning up contamination, and maintaining working contact with the responsible governmental authority until the latter has declared the incident to be satisfactorily resolved and closed. Section M.3 of the EIS contains more detail on the proposed role of the Regional Servicing Contractors.

Existing Federal and state regulations and DOE documents delineate responsibility for duties connected with emergency situations. Section M.5 of the EIS contains additional information on emergency response.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

8.10.2 (218)
<u>Comment</u> - 7 comments summarized
Commenters expressed specific concerns regarding what equipment would be available to first responders for use in the event of an incident. One commenter asked if state highway patrolmen carried monitoring devices for performing radiation checks in the event of an accident, because a radiation survey would need to be performed immediately. Others stated that emergency responders should be provided with appropriate equipment such as suitable detection devices, heavy shielding for construction equipment, adequately shielded ambulances and instrumentation to permit monitoring in the event of an accident. Others stated that DOE should provide corridor jurisdictions with in-vehicle radio repeaters, binoculars, cellular telephones and other equipment. Another commenter stated that each jurisdiction along affected transportation routes should be provided with two new detection instruments and ongoing calibration services in conjunction with training. Other commenters recommended that the Federal Government encourage the development of and help fund sophisticated state emergency management communication centers in transportation corridors to enhance emergency preparedness and response along potential routes. Commenters stated that DOE should distribute to local public safety and emergency response agencies surplus equipment for use in the event of an emergency.

<u>Response</u>
In response to public comments, in Section 6.2.4.2.1 of the EIS, DOE provides estimates of radiological impacts to emergency personnel who would respond to transportation accidents in which the severity and consequences would be the maximum reasonably foreseeable. In developing the estimates, DOE assumed a first responder would be trained and would follow guidance contained in the U.S. Department of Transportation's *2000 Emergency Response Guidebook* (DIRS 155776-DOT 2000). For example, on arriving at the scene of an accident, a trained responder

determines the presence and identification of hazardous materials that might be involved, cordons off the area to protect members of the public, rescues injured persons, initiates protective actions such as moving upwind and at a distance from the accident scene, and calls for assistance. DOE estimated the maximum dose to a first responder to a rail accident would be 830 millirem from external radiation. The analyzed accident would be one in which forces or heat would be great enough to cause a loss of a portion of a cask's lead shield. The resulting dose to the first responder, which would be about 40 percent of the limit for annual dose to radiation workers at DOE facilities, would lead to an increase of about 0.03 percent in the individual's lifetime risk of a latent fatal cancer. First responders to very severe accidents involving truck shipments would receive much lower doses.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. In 1998, DOE published a Notice of Revised Proposed Policy and Procedures in the *Federal Register* (63 *FR* 23753; April 30, 1998) that sets forth the proposed mechanisms for implementing the requirements of Section 180(c). As part of this program, about 4 years prior to the first shipments eligible jurisdictions would receive a one-time planning grant to assess their training needs. In accordance with the Draft Section 180(c) Policy and Procedures, jurisdictions may use a certain percentage of their financial assistance to purchase appropriate (for example, training-related) equipment that can be used for training, inspections, and for emergency response. This could include the detection equipment mentioned in the comment. See Section M.6 of the EIS for a detailed discussion of the Section 180(c) provisions and emergency response programs. If requested, DOE and other Federal agencies could assist in responding to an incident.

DOE has several programs available to provide assistance to state, tribal, and local governments in response to radioactive material accidents. The Radiological Assistance Program, for example, provides trained personnel with equipment to evaluate, assess, advise, and assist in the mitigation and monitoring of potential immediate hazards associated with a transportation accident. As part of the program, DOE maintains eight Regional Coordinating Offices across the country that are staffed 24 hours a day, 365 days a year. The staff consists of nuclear engineers, health physicists, industrial hygienists, public affairs specialists, and other personnel who provide field monitoring, sampling, decontamination, communications, and other services, as requested. In addition, DOE's Radiation Emergency Assistance Center/Training Site (REAC/TS) focused on providing rapid medical attention to people involved in radiation accidents. REAC/TS maintains a 24-hour response center to provide direct support, including deployable equipment and personnel trained and experienced in the treatment of radiation exposure to assist Federal, state, tribal, and local organizations.

With regard to communications, DOE intends to use a satellite tracking system to monitor shipments to Yucca Mountain. If approved by the Nuclear Regulatory Commission under regulations contained in 10 CFR Part 73, DOE would provide training on, and equipment for, states and tribes to track and communicate about shipments under the NWPA. Additional information on satellite tracking of shipments is in Section M.3.2.1.5 of the EIS.

8.10.2 (579)
Comment - EIS000066 / 0003
In the event of an accident which results in the release of spent nuclear fuel and radioactive waste, an extensive water sampling program would be required to ensure that there are no adverse health effects. This sampling, coupled with spill control and contamination prevention measures, could result in the closing of water and wastewater treatment plants which would, thereby, create water shortages and sanitation problems. Consideration should be given to plans for providing emergency supplies of potable water and emergency wastewater treatment.

Using a list of all populated areas through which a Kentucky route passes, an emergency notification guide needs to be prepared. The guide needs to list for each populated segment a 24-hour telephone number for the local water and wastewater authorities. The drivers of the highway vehicles or the crews of the trains with the railroad cars containing the spent nuclear fuel and radioactive waste need to have instructions to notify those local authorities so that appropriate action could be taken to protect:

- the intakes and facilities of water treatment plants,
- wastewater treatment plants by having the spilled material held in interceptors or routed to bypass the plant, and
- the operators of water and wastewater plants.

Transporters need to comply with the federal Hazardous Materials Transportation Safety Act (49 U.S.C. Section 1801 *et seq.*) requirements including contingencies for response contractors, phone notifications, and special requirements for monitoring Cleaning.

Response
It is extremely unlikely an accident involving shipments of spent nuclear fuel or high-level radioactive waste would result in the release of spent nuclear fuel or radioactive waste. The Nuclear Regulatory Commission regulates the design, construction, use, and maintenance of shipping containers or casks for shipments of spent nuclear and high-level radioactive waste. The casks must be designed to withstand a series of impact, puncture, and fire environments, thereby providing reasonable assurance that packages would withstand serious transportation accidents. See Section M.4 of the EIS for additional information on cask safety and testing.

States and tribes through whose jurisdictions shipments would be made would receive prior notification of the shipments in accordance with Nuclear Regulatory Commission requirements. The notification process is discussed in Section M.3.2.2.1 of the EIS. The contractor providing transportation services to DOE would be required to have an Emergency Response Plan that provided for appropriate notifications to Federal agencies and state, tribal, and local units of government in the event of an emergency. Continuous real-time tracking of all shipments to the repository would provide the location of any incident. However, if an accident with release of radioactive waste was to occur, the state or tribe could request assistance from Federal agencies. DOE, the Environmental Protection Agency, and the Department of Agriculture would monitor water and wastewater to determine contamination and appropriate treatment in accordance with the Federal Radiological Emergency Response Plan. These agencies, as well as the Federal Emergency Management Agency and the Department of Health and Human Services, would help to ensure the distribution of potable water supplies if needed. Section M.6 describes the assistance available in greater detail.

Transporters would be in compliance with the U.S. Department of Transportation's Hazardous Materials Transportation Safety regulations. These regulations implement the provisions of the Hazardous Materials Transportation Safety Act.

8.10.2 (680)
Comment - EIS000205 / 0005
Roughly 50,000 truck shipments will ultimately travel through 43 states past millions of people over the lifetime of the project. Accidents will happen, and we cannot be sure that communities will be prepared to respond when they do. The DEIS does not sufficiently discuss the proposed shipping routes or the training and equipment necessary for emergency response personnel in communities along the route. This information is an essential part of determining the safety of the shipments.

Response
As discussed in Section J.1.2.2 of the EIS, DOE has not yet determined the specific modes or routes it would use to ship spent nuclear fuel and high-level radioactive waste to the proposed repository. During the long period before shipments could begin, many factors affecting route designation could change. However, DOE used current U.S. Department of Transportation regulations governing highway shipments (49 CFR 397.101) and historic rail industry practices to select existing highway and rail routes for the analyses presented in the EIS. Additional information on procedures and protocols on how routes would be eventually selected is provided in Section M.3.2.1.2. Section J.4 presents state maps showing the routes used in the analysis.

The training and equipment required for emergency response for shipments of spent nuclear fuel and high-level radioactive waste would be determined by the state, tribal, and local governments through whose jurisdictions shipments would pass. DOE has proposed a one-time only planning grant to every eligible state and tribe to aid in this determination. A discussion of funding and technical assistance for the training and associated equipment necessary for emergency response personnel in communities along shipping routes is provided in DOE's Draft Proposed Policy and Procedures for implementing the requirements of Section 180(c) of the NWPA [see Section M.6 of the EIS for additional information on emergency response responsibilities and capabilities and Section M.6 for additional information on implementation of Section 180(c)].

8.10.2 (999)
Comment - EIS000235 / 0006
The Draft EIS is silent on the need for local emergency medical capabilities. The extent to which Section 180(c) and other DOE-funded enhancements to local emergency response capabilities might reduce risk below even existing levels should be addressed within the Final EIS.

Response
As discussed in Section J.1.4.2 of the EIS, in an effort to consider the associated range of potential impacts from accidents, the analyses in the EIS did not take credit for or assume emergency response interdiction, dose mitigation, or evacuation to reduce accident consequences. Nonetheless, impacts of accidents are estimated to be small for transporting spent nuclear fuel and high-level radioactive waste either using legal-weight trucks or rail transportation. Thus, although it could be possible to reduce consequences of the most severe accidents, reductions in risk that could be achieved through enhancements in local emergency response capabilities would be small.

Under Section 180(c) of the NWPA, eligible states and tribes will be provided funds to determine their emergency response capabilities and training needs. Section M.5 of the EIS provides additional information on the implementation of Section 180(c).

8.10.2 (1325)
Comment - EIS000991 / 0003
The IAFC [International Association of Fire Chiefs] is primarily concerned with the safety of the actual transport of the nuclear waste materials. In the event of a transportation accident, a local fire department will most often be the first responder. Thus our interest in the rules and regulations governing the transportation of nuclear waste materials. Prior to any shipment we believe the following rules, regulations, and protocols must be in place:

- Require cask designs able to withstand severe accident scenarios with substantial built-in safety factors. A safe container will assure that no material will leak from a cask involved in a large catastrophic accident. This will protect the responders, citizens, and the environment from danger and contamination.

- Require proper marking, labeling, placarding, shipping papers and emergency response information as regulated by U.S. Department of Transportation for rail and highway shipments be in place.

- Require the filing of written route plans to include origin/destination of the shipment, routes, planned stops, estimated arrival, and emergency telephone numbers in each state through which the shipment will traverse.

- Require carriers to use preferred routes for highway shipments - interstate highways, bypasses and beltways. States may propose alternate routes to the interstate highway system. However, fire and emergency response agencies in the potentially affected states and localities must be consulted in designation of alternate routes.

- Require that shippers notify the governor seven days in advance of the material being transported through the state.

- Recommend that legislation and regulation require governors and their emergency managers to notify the response forces in each jurisdiction through which shipment will pass. It is critical for local planning purposes that this notification be made.

- Require a tail escort for each shipment. This escort needs to be knowledgeable of radiation, have appropriate equipment and instruments, be uniformed, be knowledgeable of the Incident Command System and be ready to provide intelligence information to the Incident Commander about the condition associated with the radioactive materials involved. After shipments become a routine matter, consideration may be given eliminating the escort.

Response
DOE agrees with the International Association of Fire Chiefs that a primary concern is the safety of the transport of spent nuclear fuel and high-level radioactive waste. Most of the recommendations in the comment are incorporated

in the regulations that DOE and its contractors would observe strictly, and are reflected in the transportation protocols included in the discussion of processes and protocols included in the draft Request for Proposals, *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153487-DOE 1998), summarized in Section M.3.1 of the EIS. A response to each recommendation follows.

Casks would be designed to meet Nuclear Regulatory Commission regulations in 10 CFR Part 71. Studies have shown that casks would survive severe real-world accidents.

All U.S. Department of Transportation regulations for marking, labeling, placarding, shipping papers, and emergency response information would be rigorously followed.

Route plans would be prepared as required by the Nuclear Regulatory Commission regulations in 10 CFR 73.37. In addition to the information recommended by the commenter, the route plans would include the location of safe havens.

Carriers would use preferred routes for highway shipments, as required by Federal regulations at 49 CFR Part 397, Subpart D.

The governor or the governor's designee would be notified as required by Nuclear Regulatory Commission regulations at 10 CFR 73.37(f). Notification of local response forces would be provided in accordance with individual state procedures. However, 10 CFR 73.37(g) requires any individual, whether or not a licensee of the Commission, to protect schedule information against unauthorized disclosure as specified in 10 CFR 73.21. In addition, the regulations require the shipper to provide that arrangements have been made with local law enforcement agencies along the routes of road and rail shipments, and at U.S. ports where vessels carrying spent nuclear fuel shipments are docked, for their response to an emergency or a call for assistance.

Training requirements for shipment escorts are specified in Appendix D of 10 CFR Part 73.

8.10.2 (1745)
Comment - EIS000366 / 0001
I want to talk about emergency response to mobile Chernobyl, if you would. When and where there is a transportation accident – it's a foregone conclusion by the general public -- some questions arise. (1) What agency will provide the first response -- federal, state, or local agency? (2) What training will have been provided to the responders and by whom? (3) Who will bear the overall financial responsibility for such training and equipment necessary for local containment? And, lastly, who will bear the costs beyond the emergency response, such as regional effects like the river contamination that happened at Dunsmuir on the Sacramento River and contaminated Shasta Lake a few years back?

Response
As discussed in Section M.5.1 of the EIS, states and Native American tribes are primarily responsible for the health and safety of their citizens. Although the transporting personnel would be at the scene, state, local, or tribal emergency response personnel would be the first public safety officials to respond to hazardous materials accidents and would assume incident management on arrival (Section M.5.2 contains more information). The state, local, or tribal government could request assistance from Federal agencies under the Federal Radiological Emergency Response Plan. Section M.6 contains more information on available assistance.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for determining the need for and training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would ship spent nuclear fuel and high-level radioactive waste. This training would cover procedures for dealing with incident-free transportation and emergency response situations. It would be up to state, local, and tribal authorities to determine who would receive training and what equipment would be required. DOE would provide funds for training and the associated purchase of equipment for safe routine transportation and emergency response. Costs beyond emergency response would be borne by the transportation contractor's insurance and by coverage under the Price-Anderson Act. The Price-Anderson Act provides for indemnification of liability up to $9.43 billion to cover claims that might arise from an accident in which radioactive materials were released or one in which an authorized precautionary evacuation was made (see Section M.8 of the EIS for a more complete discussion of the Price-Anderson Act).

8.10.2 (2273)
Comment - EIS000669 / 0002
The residents of Lincoln County and the City of Caliente are already facing risks of hazardous and radiological materials.

Daily, several hundred box cars and tankers pass through Caliente on rail with chlorine, propane, and other pressurized toxic chemicals which, if the tanker is ruptured, escape into the environment, especially chlorine would be virtually instantaneously fatal for virtually the whole valley here.

Approximately 1,000 box cars of explosives annually travel through this community. Thousands of tankers of toxic non-pressurized chemicals go through here in 10,000 gallon units in the tankers. Currently we have scheduled shipments of low-level radiological waste passing through this community, and the frequency which will accelerate as the bad weather closes off the northern routes and they have to further drive down the highways in the southern routes. This is one of the areas that they drive through to get to the NTS [Nevada Test Site].

Current levels of capabilities of handling chemicals or radiological contaminations -- let's pretend that one of us was chemically contaminated with a fuel or some other chemicals.

They take us out to the gutter outside the hospital, strip us down as far as necessary, and that may include everything. Wash us off with a garden hose until the chemical contamination was released and then they'd be able to put us on a gurney and take us into the facility since we'd be simply a patient.

As far as I'm concerned, that's unacceptable.

Response
The potential for accidents involving transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain is discussed in Chapter 6 and Appendix J of the EIS. The potential for a release of radioactive material and contamination of individuals is very small and is not expected to occur during the 24-year period of transportation. Of the thousands of shipments completed over the last 30 years, none has resulted in an identifiable injury through release of radioactive material. The Nuclear Regulatory Commission regulates the design, construction, use and maintenance of shipping containers or casks for shipments of spent nuclear fuel and high-level radioactive waste. The casks must be designed to withstand a series of impact, puncture, and fire environments, thereby providing reasonable assurance that packages would withstand serious transportation accidents. Additional information on cask safety and testing is provided in Section M.4.1.

In addition, emergency responders would be prepared in the event of an accident. Section 180(c) of the NWPA requires DOE to provide financial and technical assistance to states and tribes to train emergency responders. DOE is committed to providing funding to the State of Nevada – which would in turn provide funding to potentially affected cities and counties - for emergency planning and emergency response training in event of accidents involving Yucca Mountain-bound material. If additional resources were required to handle an accident, the state or tribe could call upon Federal agencies for assistance. For example, in providing treatment to a person who might have become contaminated, assistance could be requested from the DOE Radiation Emergency Assistance Center/ Training Site (REAC/TS). REAC/TS is on call 24 hours a day to provide direct or consultative help with cases where people have been involved in a radiation accident. Additional information of emergency responsibilities and capabilities is provided in Section M.5.1 of the EIS. Section M.6 provides additional information on the provisions of Section 180(c).

8.10.2 (2350)
Comment - EIS000707 / 0001
What provisions have been made to equip the medical community, not only in Nevada, but the other 43 states along the transportation route, to handle a radioactive hazard waste accident?

- Will the DOE train the appropriate medical staff to respond to such an emergency?
- Who will incur the cost of such training?
- Who will be responsible for the cost of medical treatment of any victims?
- How will these people who are exposed to nuclear waste be compensated for time lost from work?
- In the event of a terminal illness, as a result of the nuclear accident, who would be responsible for [retribution] to the families?

Response
Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training public safety officials of units of local government and Native American tribes through whose jurisdictions spent nuclear fuel or high-level radioactive waste would be transported on its way to a repository. This technical assistance and training covers procedures required for safe routine transportation of these materials, as well as for dealing with emergency response situations. The training could apply to state, local, or tribal emergency personnel including medical emergency responders.

States and tribes are primarily responsible for the health and safety of their citizens. However, in the event of an accident that released radioactive materials, a jurisdiction could request assistance from Federal agencies under the Federal Radiological Emergency Response Plan and Federal Radiological Monitoring and Assessment Plan. DOE has several assets that could assist, including the Radiation Emergency Assistance Center/Training Site (REAC/TS). REAC/TS is on call 24 hours a day to provide direct or consultative help with cases where people have been involved in a radiation accident.

With regard to who would pay for costs such as medical treatment, compensation for time lost from work, and compensation to families for terminal illnesses resulting from an accident, the U.S. Department of Transportation requires transporters of hazardous materials to carry insurance covering accidents. Costs associated with accidents would be borne by the transportation contractor's insurance and by coverage under the Price-Anderson Act. The Price-Anderson Act provides for indemnification of liability up to $9.43 billion to cover claims that might arise from an accident in which radioactive materials were released or one in which an authorized precautionary evacuation was made (see Section M.8 of the EIS for a more complete discussion of the Price-Anderson Act).

8.10.2 (2740)
Comment - EIS000641 / 0004
The next thing in health and safety, I guess it's been rehashed, but I would like to say it anyway, monitoring. Whose responsibility is it to monitor these things? The air quality, the ground quality, the water quality, this sort of thing. Who is to participate in this? Is it to be the federal government, the regulatory agencies, county, and where does the money come from?

You don't believe the county is tight, ask Pete. And he won't spend any money, I guarantee that.

Response
As discussed in Section M.5.1 of the EIS, states and tribes are primarily responsible for the health and safety of their citizens. However, Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for determining the need for and training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would ship spent nuclear fuel and high-level radioactive waste. This training would cover procedures for dealing with incident-free transportation and emergency response situations. It would be up to state, local, and tribal authorities to determine who would receive training and what equipment would be required. DOE would provide funds for training and the associated purchase of equipment for safe routine transportation and emergency response.

In addition, several Federal agencies have training and available capabilities should states or tribes request them. If an accident with release of radioactive waste occurred, affected states and tribes could request assistance from DOE, Environmental Protection Agency, Department of Agriculture, Department of Health and Human Services, and the

Federal Emergency Management Agency. These agencies, in cooperation with states, tribes, and each other, would monitor and assess radioactive materials in air, ground, agricultural products, and water in accordance with the Federal Radiological Emergency Response Plan and the Federal Radiological Monitoring and Assessment Plan. The costs for such services would be borne by the Federal agencies.

Costs associated with accidents would be borne by the transportation contractor's insurance and by coverage under the Price-Anderson Act. The Price-Anderson Act provides for indemnification of liability up to $9.43 billion to cover claims that might arise from an accident in which radioactive materials were released or one in which an authorized precautionary evacuation was made (see Section M.8 of the EIS for a more complete discussion of the Price-Anderson Act).

Section M.3.2 of the EIS describes the operating protocols, including monitoring of the conduct of transportation activities, that DOE's Regional Servicing Contractors would carry out. In addition, states could require and perform monitoring of transportation activities as a part of their permitting process.

8.10.2 (3213)
Comment - EIS001120 / 0003
Currently our local area, as well as other rural regions, is grossly understaffed, under budgeted, and unprepared to respond to current accidents involving the release of hazardous waste. DOE promises to provide local entities with assistance to prepare for the eventuality of a nuclear waste release occurring from an incident involving one of the 49,000 truck shipments and/or 13,000 rail shipments.

A minimum of 1/3 of our state is covered by mountains where distances between towns is not measured by miles, but by how many hours it takes to get from one place to another. With waste being transported from 72 commercial sites and five DOE facilities, how could DOE respond (or any other regional response team) in an adequate time given the restraints of geography, the enormous size of region the waste is being transported across and the sheer volume of waste being shipped over the next two decades?

Each community cannot afford its own emergency response team to prepare for the possibility of a nuclear clean up. The time that lapses between notification and response could mean the difference between total and partial ruination of a local habitat, area, region or watershed. What possible solution could DOE design to eliminate concerns of response time? Transportation of this waste is an endangerment to all living things.

Many of our major highways run parallel to our major drainages and waterways. Containment of this type of waste would be impossible once it has reached one of those watersheds. The Colorado River serves as basin providing water to a minimum of five states and Mexico. No amount or duration of response and resulting attempts to clean up a spill will return the environment to what it once was, not in our lifetime, not in our children's lifetime. Your proposal is endangering not only the livelihood of local communities and their inhabitants, but also a threat to the very ecosystem that sustains all life here on earth.

Response
If there was an accident involving shipments of spent nuclear fuel or high-level radioactive waste to a repository, the response time would be the same as it would for any transportation accident. Funds provided under Section 180(c) of the NWPA would help emergency responders prepare for any accidents involving these shipments. If additional resources, over and above what are available locally, were needed the state or tribe could request them from various Federal agencies.

It is extremely unlikely an accident involving shipments to the repository would result in the release of spent nuclear fuel or radioactive waste. The Nuclear Regulatory Commission regulates the design, construction, use, and maintenance of shipping containers or casks for shipments of spent nuclear and high-level radioactive waste. The casks must be designed to withstand a series of impact, puncture, and fire environments, thereby providing reasonable assurance that packages would withstand serious transportation accidents. As discussed in Appendixes J and M of the EIS (see Section M.4.1), most real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask into a river, and similar extreme accident conditions, would not be likely to result in release of radioactive materials from the shipping casks. A study conducted for the Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000) estimated that less than 0.01 percent of accidents would result in a release of radioactive material from a shipping cask that met the requirements of regulations in 10 CFR Part 71. These regulations ensure that the casks would be extremely robust. Chances of contaminating major drainages and waterways following a rail or truck accident would be extremely unlikely. Section M.4.1 contains additional information on cask safety and testing.

8.10.2 (4242)
Comment - EIS001160 / 0057
Transportation routes identified by the State of Nevada and evaluated in Appendix J go through White Pine County's most populated area and county seat, Ely. Here, ninety percent of the County's population exists within a 15 mile radius of the Ely city center and proposed transportation route. The main highway to the southwest goes five miles uphill along a winding, mountainous two lane route to Murry Summit (which is 7,300 feet high) passing within yards of the main water supply for the city. For six to eight months of many years, U.S. Hwy 6 is often icy and snow covered. It is not unusual for emergency first responders to take an hour to reach an accident site on any major highway because of the distances involved. If any highway is closed there are limited alternatives for routing traffic. The resulting economic impact could be devastating. Fog and snow can and has closed the only airport. The only hospital has limited capabilities. Volunteers are relied upon for fire and EMS [emergency medical support] resources. The DEIS does not adequately address these issues. The FEIS should include an assessment of unique circumstances impacting upon effective emergency first response in White Pine County.

Studies need to be undertaken to provide accurate assessments for those who are making transportation decisions concerning this area. Resources are limited and often inadequate without adding another demand on them. Money needs to be provided to increase the capabilities to specified levels and it must be provided to maintain those levels. Communications systems, support facilities, shelters, training and equipment, as well as qualified personnel are really inadequate to handle any serious accident. If a decision is made to route radioactive wastes through the county the costs associated with providing proper health and safety response agencies must be considered. There are some problems which money cannot solve. The DEIS then, must consider a combination of mitigation and compensation if risk management through effective emergency first response is to occur.

Before any decision is made concerning routing shipments through White Pine County a thorough assessment needs to be conducted and the results conveyed to those who will make the decision. This information, if not contained within the FEIS, should be a component in a subsequent supplement to the FEIS.

Carrier and shipper responsibilities and emergency response procedures require that response entities have a response team on call 24 hours a day. Will DOE and its carriers require/request 24 hour response capabilities of local first responders? The regulations at 10 CFR, Part 73, govern special safeguards. These regulations specify that transport vehicles carry personal communications devices. The DEIS should evaluate the extent to which such devices will function in rural Nevada and the extent to which rural emergency first responders have compatible communications capabilities. Of particular concern is the extent of communication "dead spots" located in areas of high accident hazard (i.e. canyons). Measures to mitigate communication deficiencies should be identified and evaluated within the DEIS (i.e. repeaters). The DEIS should recognize that communications would be helpful to situation assessment. Keeping in mind that there is a lot of highway area and distance to travel, emergency first responders would benefit from knowing what was occurring at the incident before these Emergency Response Teams from White Pine County arrive. The FEIS should consider what enhancements in local communications capabilities would be required to facilitate such communication. The FEIS needs to include more investigation, study and planning if transportation is to be safe for both the environment and the communities within White Pine County.

Response
As discussed in Section J.1.2.2 of the EIS, DOE has not yet determined the specific modes or routes it would use to ship spent nuclear fuel and high-level radioactive waste to the proposed repository. During the period before shipments could begin, many factors affecting route designation could change. As discussed in Section J.1.2.2, DOE evaluated potential alternate highway routes the State of Nevada could designate to assess the sensitivity of impacts that could occur in the State and nationally. Additional information on procedures and protocols on how routes would be eventually selected is provided in Section M.3.2.

Under current DOE planning, operation of a transportation system would be conducted by Regional Servicing Contractors under the procedures and protocols outlined in the request for proposals summarized in Section M.3.2 of the EIS. These protocols implement the multitude of requirements promulgated in U.S. Department of Transportation and Nuclear Regulatory Commission regulations, including security, safety, and communications.

As outlined in the DOE Draft Policy and Procedures for implementing Section 180(c) of the NWPA, eligible state and Native American jurisdictions would receive a one-time planning grant of $150,000 to conduct an assessment of their needs for safe routine transportation and emergency response. Additional technical assistance and funds for training would be provided by the Department for local emergency responders. Additional information on the provisions of Section 180(c) Policy and Procedures is provided in Section M.6 of the EIS.

States and tribes are primarily responsible for the health and safety of their citizens and would set the requirements for availability of first responders in their jurisdictions. For the purposes of communication, DOE intends to use satellite tracking communications and to make this equipment and training on the equipment available to all eligible jurisdictions after receiving Nuclear Regulatory Commission approval that the use of the satellite tracking technology does not violate Commission safeguards s and security regulations. Satellite tracking has been used successfully throughout the country regardless of the length of highway area and the far distances.

8.10.2 (4790)
Comment - EIS001475 / 0007
So this transportation, this is what is going to happen. There's no emergency response, either. On our reservation we only have one fire hydrant for our emergency response.

DOE won't admit to accidents. They're not going to let the public know who get affected. And these people, where they have these skills, you know, they're not going to drive a mile. That's what we say, how safe it is. How about the future generations, generations down the road? Will they be affected? I'm sure they will.

Response
Based on the analysis presented in the EIS, DOE believes the impacts from shipments of spent nuclear fuel and high-level radioactive waste to the proposed repository would be low. The impacts from incident-free transportation as well as from accidents are discussed in Appendix J of the EIS. It should be noted that of the thousands of shipments of these materials over the last 30 years, none has resulted in an identifiable injury through the release of radioactive material. As discussed in Appendixes J and M (see Section 4.2), most real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask into a river, and similar extreme accident conditions, would not likely result in release of radioactive materials from the shipping casks. A study conducted for the U.S. Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000) estimated that less than 0.01 percent of accidents would result in a release of radioactive material from a shipping cask that meets the requirements of regulations in 10 CFR Part 71. These regulations ensure that the casks would be extremely robust.

Under Section 180(c) of the NWPA, DOE is required to provide technical assistance and funds to states for training public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would make shipments of spent nuclear fuel and high-level radioactive waste to a repository. Additional information on Section 180(c) is provided in Section M.6 of the EIS.

DOE anticipates providing financial and technical assistance to eligible jurisdictions at least 5 years before the commencement of shipments to a repository.

Comment - EIS001441 / 0055
Transportation routes identified by the State of Nevada and evaluated in Appendix J go through White Pine County's most populated area and county seat, Ely. Here, ninety percent of the County's population exists within a 15 mile radius of the Ely city center and proposed transportation route. The main highway to the southwest goes five miles uphill along a winding, mountainous two lane route to Murry Summit (which is 7,300 feet high) passing within yards of the main water supply for the city. For six to eight months of many years, U.S. Hwy 6 is often icy and snow covered. It is not unusual for emergency first responders to take an hour to reach an accident site on any

major highway because of the distances involved. If any highway is closed there are limited alternatives for routing traffic. The resulting economic impact could be devastating. Fog and snow can and has closed the only airport. The only hospital has limited capabilities. Volunteers are relied upon for fire and EMS [emergency medical support] resources. The DEIS does not adequately address these issues. The FEIS should include an assessment of unique circumstances impacting upon effective emergency first response in White Pine County. The Ely Shoshone Tribe is not adequately prepared for any emergency response situations. The Ely Shoshone Tribe currently relies on the White Pine County emergency response team.

Studies need to be undertaken to provide accurate assessment for those who are making transportation decision concerning this area. Resources are limited and often inadequate without adding another demand on them. Money needs to be provided to increase the capabilities to specified levels and it must be provided to maintain those levels. Communications systems, support facilities, shelters, training and equipment, as well as qualified personnel are really inadequate to handle any serious accident. If a decision is made to route radioactive wastes through the county the costs associated with providing proper health and safety response agencies must be considered. There are problems which money cannot solve. The DEIS then, must consider a combination of mitigation and compensation if risk management through effective emergency first response is to occur.

Before any decision is made concerning routing shipments through the Ely Shoshone Reservation and White Pine County a thorough assessment needs to be conducted and the results conveyed to those who will make the decision. This information, if not contained within the FEIS, should be a component in a subsequent supplement to the FEIS.

Carrier and shipper responsibilities and emergency response procedures require that response entities have a response team on call 24 hours a day. Will DOE and its carriers require/request 24-hour response capabilities of local first responders? The regulations at 10 CFR, Part 73, govern special safeguards. These regulations specify that transport vehicles carry personal communications devices. The DEIS should evaluate the extent to which such devices will function in rural Nevada and the extent to which rural emergency first responders have compatible communications capabilities. Communications would be helpful to situation assessment. Keeping in mind that there is a lot of highway area and distance to travel emergency first responders would benefit from knowing what was occurring at the incident before what Emergency Response Teams from White Pine County arrive. The FEIS should consider what enhancements in local communications capabilities would be required to facilitate such communication. The FEIS needs to include more investigation, study and planning if transportation is to be safe for both the environment and the communities within White Pine County.

Response
As discussed in Section J.1.2.2 of the EIS, DOE has not yet determined the specific modes or routes it would use to ship spent nuclear fuel and high-level radioactive waste to the proposed repository. During the period before shipments could begin, many factors affecting route designation could change. . As discussed in Section J.1.2.2, DOE evaluated potential alternate highway routes the State of Nevada could designate to assess the sensitivity of impacts that could occur in the State and nationally. At the time of selection, the Department would initiate consultations with responsible State, tribal, and local authorities to assess potential impacts and appropriate mitigative measures. Additional information on procedures and protocols on how routes would be eventually selected is provided in Section M.3.2.

Under current DOE planning, operation of a transportation system would be conducted by Regional Servicing Contractors under the procedures and protocols outlined in the request for proposals summarized in Section M.3.2 of the EIS. These protocols implement the multitude of requirements promulgated in U.S. Department of Transportation and Nuclear Regulatory Commission regulations, including security, safety, and communications, and require consultations with responsible agencies.

As outlined in the Draft Proposed Policy and Procedures for implementing Section 180(c) of the NWPA, eligible state and tribal jurisdictions (those through which NWPA shipments would pass) would receive a planning grant of $150,000 to conduct an assessment of their needs for safe routine transportation and emergency response. Additional technical assistance and training would be provided by the Department for local emergency responders. Additional information on the provisions of Section 180(c) Policy and Procedures is provided in Section M.6 of the EIS.

States and tribes are primarily responsible for the health and safety of their citizens and would set the requirements for availability of first responders in their jurisdictions. For the purposes of communication, DOE intends to use satellite tracking communications and to make this equipment and training on the equipment available to all eligible jurisdictions after receiving Nuclear Regulatory Commission approval that the use of the satellite tracking technology does not violate the Commission's safeguards and security regulations. Satellite tracking has been used successfully throughout the country regardless of the length of highway area and the far distances.

8.10.2 (5276)
Comment - EIS000968 / 0001
The transportation of high-level nuclear waste through our County is of grave concern, and requires major planning to prepare for, respond to, and safely mitigate any accidents that may occur. Our review of the Draft Environmental Impact Statement (DEIS) leaves us with many more questions than answers, and makes planning virtually impossible. Therefore:

The Clark County Local Emergency Planning Committee (LEPC) believes the Yucca Mountain Draft Environmental Impact Statement is an insufficient analysis of the impacts of the Yucca Mountain Project on Clark County because it fails to provide specific detail about the Maximum Reasonably Foreseeable Accident and because it fails to describe how Section 180c of the Nuclear Waste Policy Act as Amended (NWPAA) will be implemented.

Response
Sections 6.2.4 and J.1.4.2.1 of the EIS describe the maximum reasonably foreseeable accidents analyzed in the EIS. The information in Appendix J has been updated and expanded to reflect the findings of a recent study, *Reexamination of Spent Fuel Risk Estimates* (DIRS 152476-Sprung et al. 2000).

In response to comments on the Draft EIS, additional information has been provided in Section M.5.1 of the EIS on the proposed operational aspects of spent nuclear fuel and high-level radioactive waste transportation, emergency response planning, and in Section M.6 for financial assistance programs. Section 180(c) of the NWPA requires DOE to provide technical and financial assistance to states and tribes to train public safety officials in emergency response and safe routine transportation. As a result of this program first responders would likely have sufficient training to be knowledgeable of the hazards to which they could be exposed from spent nuclear fuel and high-level radioactive waste shipments. Part of the Section 180(c) funds are for planning and coordination activities. States and tribes may use a percentage of the funding to purchase equipment for training purposes, which may then be used for emergency response, if necessary. States and tribes may request additional support from various Federal agencies in the event of an incident.

A draft Proposed Policy and Procedures for implementing the requirements of Section 180(c) was issued in 1998. A final Policy and Procedures would be issued if a repository site was approved.

8.10.2 (5520)
Comment - EIS001660 / 0034
Discussion of transportation emergencies, emergency assistance, emergency response, and carrier and shipper responsibilities is vague, misleading, and inadequate (p. 6-30). No consideration is given, to local jurisdictions choosing not to respond to radiological incidents, that them may not have the capabilities to respond even if assistance and training are available, or that limited emergency response may itself create impacts. Specifically:

The statement that "DOE would, as requested, assist state, tribal and local governments in several ways to reduce consequences of accidents related to the transportation of (SNF [spent nuclear fuel] and HLW [high-level radioactive waste])" (p. 6-30) does not provide sufficient information regarding the adequacy of emergency response capabilities;

Although DOE may provide assistance to state, local and tribal governments, this assistance may not be adequate for necessary emergency responses;

There is no guarantee or assurance that DOE assistance is forthcoming.

The statement that "(u)nder Section 180(c) of the NWPA, the Department would provide technical assistance and funding to train state, local, and tribal public safety officials" does not completely address the need for, or potential effectiveness of training of emergency responders; does not address whether such training is even desired by all jurisdictions; does not make it clear that the money is granted only to states; or does not even identify an amount. Potential assistance under Section 180(c) does not constitute assistance needed to help local jurisdictions deal with transportation emergencies, and the DEIS does not analyze whether it is the only assistance needed by state, local, and tribal governments.

The statement the DOE would require its transportation contractors to comply with the ANSI [American National Standards Institute] standard for carrier and shipper responsibilities and emergency response procedures does not adequately cover the need to discuss carrier and shipper responsibilities. The reference to carriers' and shippers' responsibilities for preparation of an emergency response plan, provision of information and assistance to emergency responders, and resources for dealing with the consequences of an accident fails to analyze whether these requirements would lessen the impacts of the proposed action and any of its alternatives.

The discussion of transportation emergencies does not fully address the local emergency response that would be expected or required, even if federal or private response resources were available and dispatched. Also, it does not identify constraints on local emergency response or the consequences of prolonged delays due to lack of local resources.

Response

States and tribes are primarily responsible for the health and safety of their citizens. However, in the event of an accident that released radioactive materials, a state or tribe could request assistance from Federal agencies under the Federal Radiological Emergency Response Plan and Federal Radiological Monitoring and Assessment Plan. DOE has several assets that could assist including the Radiation Emergency Assistance Center/Training Site (REAC/TS). REAC/TS is on call 24 hours a day to provide direct or consultative help with medical and health physics problems associated with an accident or incident involving radioactive materials.

Regarding the concern about jurisdictions refusing to respond to emergencies, it is the intent of Section 180(c) of the NWPA that first responders would be sufficiently trained to respond safely to an incident involving the shipment of spent nuclear fuel and high-level radioactive waste. In addition, the Emergency Planning and Community Right-to-Know Act mandates the formation of emergency planning and response capability by states. Under this provision, emergency responders cannot simply refuse to respond to an emergency.

Regarding the adequacy of assistance for emergency responses, DOE has published several *Federal Register* notices outlining its intentions regarding technical and financial assistance for states and tribes for training. Interested parties have had numerous opportunities to comment on these notices. The majority of commenters have indicated that training to the awareness-level for emergency response and inspector training for safe routine transportation is adequate preparation for shipments of spent nuclear fuel and high-level radioactive waste. In addition, as stated in the *Federal Register* notices, DOE would provide funding for equipment and additional technical assistance under Section 180(c), as requested. Additional information on the provisions of Section 180(c) is provided in Section M.6 of the EIS.

Regarding the assurance that the assistance from DOE would be forthcoming, the Department is required under Section 180(c) of the NWPA to provide technical and financial assistance for training in safe routine transportation and emergency response. The assistance mandated by that section would be provided at least 4 years before shipments began. This is the timeframe committed to by the Department on numerous occasions in numerous public forums and publicly issued documents.

The *Federal Register* notices make it clear that the funding would go to states and tribes. Local governments would not be eligible to receive Section 180(c) grants directly. However, states and tribes, if they have subjurisdictions, would have to coordinate their planning with local jurisdictions, indicating in the application that the needs of local public safety officials have been considered and how the training assistance would be provided to local jurisdictions and their appropriate public safety officials.

The Draft RFP for acquisition of Regional Servicing Contractors (DIRS 153487-DOE 1998) outlines the responsibilities, processes, and protocols for planning and operation of the transportation system. Though it focuses in detail on these responsibilities, it identifies other related responsibilities. Additional information on the responsibilities and processes is provided in Section M.3.2 of the EIS. For a more detailed discussion of roles and responsibilities of local, State, and Federal emergency responders, see Section M.5.1.

Regarding constraints on local emergency response, DOE places no constraints on emergency responders and feels that the Draft Policies and Procedures for implementing Section 180(c) of the NWPA are adequate to prepare states, tribes, and local governments for emergency situations.

8.10.2 (5718)
Comment - EIS001887 / 0331
Page 6-37; Section 6.3 - Nevada Transportation

The assessment of socioeconomic impacts associated with Nevada transportation fails to address impacts on State and local governments. Specifically, any response to an incident, accident, or even a simple vehicle breakdown will impact a large group of responders. The Draft EIS does not discuss facilities, equipment, and mitigation, etc. that will be required. It refers only to the transporter's responsibilities regarding these issues, not the impact on public safety (response) agencies. Some of the issues are:

- Availability of equipment to deal with the large (size and weight) transportation casks in the event of vehicle breakdowns, load shifting, accidents, etc.; and

- Response costs for breakdowns and incidents/accidents. Timely responses would require staged equipment, trained and equipped personnel, and the associated infrastructure to support them.

Response
In accordance with the draft RFP for the Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management (available at *www.rw.doe.gov/wasteaccept/wasteaccept.html*), transportation contractors would be responsible for providing a Transportation Plan addressing, among other things, the handling and correction of off-normal events. The contractor would provide the drivers and crews with specific written procedures clearly defining detailed actions to be taken in the event of an off-normal event. These procedures would address repair or replacement of equipment, or recovery, as appropriate. These requirements would be applicable to transport by truck and rail. If an accident occurred at an intermodal transfer station, the contractor operating that facility would be responsible for providing the necessary cleanup and recovery equipment.

Regarding the concern about response times, if there was an incident involving shipments of spent nuclear fuel and high-level radioactive waste, shipment drivers and escorts would be on the scene and trained to respond until local authorities arrived. Local first responders would respond in the same period that they would respond to any emergency. Section 180(c) funds would help them prepare for this type of emergency. Given the integrity of the casks transporting the waste, and the fact that more than 2,700 shipments of spent nuclear fuel have been safely transported in the last 30 years with no fatalities, injuries, or environmental damage caused by the radioactive nature of the cargo, the chances of contamination of local communities and the environment from an incident involving this type of waste are extremely unlikely and not expected to occur. DOE feels that this waste can, indeed, be transported safely.

The training of public officials who could be called upon to respond to an accident or incident involving shipments to a repository would be funded under Section 180(c) of the NWPA. Additional information on this issue is contained in Section M.6 of the EIS.

8.10.2 (5824)
Comment - EIS001728 / 0002
Require the shippers not only to notify the state government's office, but also that the emergency responders along the route have to have a general idea when this is coming through. At two o'clock in the morning when the responders respond, they need to know what they're dealing with and what they may encounter. They also -- that during the early stages of shipment when the campaign starts, we feel that a tail escort, knowledgeable person, escort

this material to give the incident commander adequate information, have instrumentation to be able to help the incident commander decide if there is a problem and how to handle it. We feel that later on that we'll be able -- you could be able to probably eliminate that escort.

Most importantly, emergency response forces along the route must be trained to deal with an emergency, should one occur. We believe that currently there is adequate training programs available on the subject, but we fear that these programs may go too far in-depth into the subject matter and will never reach the core group of responders who need them. Training should be self-sustaining, it should be simple, it should be fairly shipment-specific so the people understand, and it's got to get to the people on the street. It's got to get to those on the local level. All too often we develop great programs and they end up at the state level and they never get to the people on the street, so we're very much in favor of some legislation that will make sure that the responders along the route get that education.

Response
DOE is required by the Nuclear Regulatory Commission (10 CFR 71.97) to notify the state or tribal designated point of contact. It is the state or tribal representative's responsibility to coordinate with local officials and emergency responders. The emergency responders would receive information about the shipments of spent nuclear fuel and high-level radioactive waste before they reached their jurisdictions through various means. In addition to the advance notification, DOE would conduct dialogues with state and tribal authorities regarding projected shipments. DOE would also track the shipments through a satellite tracking system such as the TRANSCOM system, which would be available to states and tribes if the Nuclear Regulatory Commission determined that it did not violate safeguards and securities regulations. As required by the U.S. Department of Transportation (49 CFR Part 172), the vehicle would be properly placarded and the containers marked so that emergency responders would have knowledge of the cargo. The carrier would possess shipping papers describing the cargo contents.

Regarding the issue of training, DOE would provide financial assistance for training emergency responders at least 5 years before the commencement of shipments of spent nuclear fuel and high-level radioactive waste. As indicated in Section 180(c) of the NWPA, states and tribes, in coordination with local public safety officials, would determine who received training to the awareness level. The regulation clearly provides that the emergency responders on the local level should be trained. See Section M.6 of the EIS for additional information regarding Section 180(c).

Shipments of spent nuclear fuel and high-level radioactive waste would be physically protected by trained personnel as required by the Nuclear Regulatory Commission requirements (10 CFR 73.37). Additional information regarding physical protection of shipments in provided in Section M.7 of the EIS.

8.10.2 (6405)
Comment - EIS001114 / 0001
I would have to assume transport by road is the safest way to go so the only thing I would suggest is that all of the municipalities this convoy goes through takes part in safe passage with one or two fire trucks equipped with hazardous waste spill material and also a police escort front and rear with co-op from Ill, state Police and the Feds, under this controlled situation can you create the safe transportation that will be needed.

Response
The transportation of spent nuclear fuel and high-level radioactive waste by either truck or rail is considered safe. Of the thousands of shipments completed over the last 30 years, none has resulted in an identifiable injury through release of radioactive material. DOE plans to use rail where possible to reduce the number of shipments.

The Nuclear Regulatory Commission requires shipments to be escorted for security reasons, but there is no requirement for them to be escorted by emergency response personnel. It is believed that, in the event of an emergency, state, tribal, and local emergency response capabilities would be able to respond effectively. Technical assistance and funds for training these emergency response assets are available from DOE through the provisions of Section 180(c) of the NWPA. Additional information on these issues can be found in Section M.6 of the EIS.

8.10.2 (6428)
Comment - EIS001819 / 0002
The City [Kirkwood, Missouri] recommends, at a minimum, that local emergency management officials and fire chiefs be notified in advance of shipments passing through Kirkwood; local fire and emergency management personnel be provided training and procedures to follow in the event of an accident; and that, rail cars be adequately marked as to their radioactive contents.

Response
As stated in Section 2.1.3 of the EIS, DOE would comply with all applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission (NRC). As required by NRC regulations (10 CFR Part 73), the state's and tribe's designated points of contact would receive advance notification regarding shipments of spent nuclear fuel and high-level radioactive waste. It is the responsibility of the states and tribes to notify local emergency management officials and fire chiefs. This notification process is discussed in Section M.3.2.2.1 of the EIS. The contractor providing transportation services to DOE would be required to have an Emergency Response Plan that provided for appropriate notifications to Federal agencies and state, tribal, and local units of government in the event of an emergency. Continuous real-time tracking of all shipments to the repository would provide the location of any incident.

As required by Section 180(c) of the NWPA, local fire and emergency management personnel would receive funding for training through their states and tribes. Additional information on emergency response and provisions of Section 180(c) is provided in Sections M.5.1 and M.6 of the EIS, respectively.

Railcars would be placarded when transporting radioactive materials consistent with U.S. Department of Transportation regulations (49 CFR Part 172).

8.10.2 (6505)
Comment - EIS001774 / 0011
During an accident who's in charge? Where are the evaluations of costs, risks and route-specific data on possible accidents, population density, weather?

Response
As discussed in Section M.5.1 of the EIS, according to the Federal Radiological Emergency Response Plan, state and local governments have the primary responsibility for determining and implementing measures to protect life, property, and the environment, with support provided, upon request, by Federal agencies, including DOE. State and local governments deal with transportation accidents involving hazardous materials on a daily basis across the United States. According to the Notice of Revised Proposed Policy and Procedures, DOE would provide funding and technical assistance to states and tribes along transportation routes to address incremental training requirements resulting from shipments of spent nuclear fuel and high-level radioactive waste to the repository. DOE would allow a variety of activities an applicant state or tribal jurisdiction might consider appropriate for training under the Section 180(c) program. Along a specific transportation route, it would be the applicant's decision as to who received training.

Section J.1.4.2 of the EIS discusses the methods and data used to evaluate the risks and consequences to populations and individuals of transportation accidents. This section includes discussions of the population density data, accident rate data, and the weather conditions used in the analyses. The risks and consequences associated with transportation accidents are summarized Sections 6.2.4.2.1 and 6.2.4.2.2. As discussed in these sections, radiological risks to populations within 80 kilometers (50 miles) of an accident ranged from about 0.5 person-rem for the mostly legal-weight truck scenario to 1 person-rem for the mostly rail scenario. The consequences to the population of maximum reasonably foreseeable, but highly unlikely, transportation accidents ranged from about 1,100 person-rem for the mostly legal-weight truck scenario to about 9,900 person-rem for the mostly rail scenario.

A review of previous estimates of the costs associated with severe transportation accidents have been added to Appendix J of the EIS. These costs ranged from $200,000 to an estimate by the State of Nevada of $270 billion. The extreme costs estimated in some analyses are based on consequences estimated using extremes of estimates for all parameters in the analysis and are considered not reasonably foreseeable and therefore not useful for decisionmaking. Furthermore, DOE believes that estimating the costs associated with severe, but highly unlikely, transportation accidents requires a high degree of speculation and that speculation of this kind is not required by the National Environmental Policy Act.

8.10.2 (6566)
Comment - EIS001632 / 0053
The EIS recognizes the need to prepare for and respond to accidents. Page 6-30 highlights Section 180(c) of the NWPA under which DOE will provide technical assistance and funding to state, local and tribal public safety programs on transportation emergencies. This page also describes how transportation contractors must prepare an emergency response plan and take other steps to deal with the consequences of accidents.

Response
Thank you for your comment. Information presented in Section M.5.1 of the EIS provides additional information related to emergency response planning and Section M.6 provides additional information on financial assistance programs.

8.10.2 (6697)
Comment - EIS001878 / 0063
The DEIS fails to adequately assess the potential public health and safety impacts of the proposed Carlin rail corridor and other corridors (pp. 6-11, -37, -39 to -41, -49, -63) in a number of important areas. (For additional discussion of this point, see the January 19, 2000, letter to the DOE from Eureka County's Local Emergency Planning Committee [LEPC].

Transportation of SNF [spent nuclear fuel] and HLW [high-level radioactive waste] through areas with limited emergency response capabilities, including Eureka County and much of rural Nevada, increases the risks associated with transportation incidents. Risks are higher because of the lack of initial response capability and the time delay for responding personnel. Some jurisdictions may choose not to respond to incidents involving SNF and HLW due to financial and personnel considerations. Jurisdictions with volunteer fire departments and other volunteer emergency responders may decide not to respond to incidents in which they cannot participate safely. The DEIS must address these scenarios.

The discussion of transportation emergencies, emergency assistance, emergency response, and carrier and shipper responsibilities is vague, misleading, and inadequate. (p. 6-30) It does not consider that local jurisdictions may choose not to respond to radiological incidents, that they may not have the capabilities to respond even if assistance and training are available, or that limited emergency response may itself create impacts. Specifically:

The statement that "DOE would, as requested, assist state, tribal and local governments in several ways to reduce consequences of accidents related to the transportation of [SNF and HLW]" (p. 6-30) does not provide sufficient information regarding the adequacy of emergency response capabilities;

Although DOE may provide assistance to state, local, and tribal governments, that assistance may not be adequate for necessary emergency responses;

There is no guarantee or assurance that assistance from the DOE will be forthcoming, or that it will be adequate;

The statement that "[u]nder Section 180(c) of the Nuclear Waste Policy Act, the Department would provide technical assistance and funding to train state, local, and tribal public safety officials" does not completely address the need for or potential effectiveness of training for emergency responders; address whether such training is even desired by all jurisdictions; make it clear that the money is granted only to states; or identify an amount;

Potential assistance under Section 180(c) does not constitute the universe of assistance needed to help local jurisdictions deal with transportation emergencies, and the DEIS does not analyze whether it is the only assistance needed by state, local, and tribal governments;

The statement that DOE would require its transportation contractors to comply with the ANSI standard for carrier and shipper responsibilities and emergency response procedures does not adequately cover the need to discuss carrier and shipper responsibilities;

The reference to carriers' and shippers' responsibilities for preparation of an emergency response plan, provision of information and assistance to emergency responders, and resources for dealing with the consequences of an accident fails to analyze whether these requirements would lessen the impacts of the proposed action or any of its alternatives;

The discussion of transportation emergencies does not fully address the local emergency response that would be expected or required, even if federal or private response resources were available and dispatched; and
The discussion of transportation emergencies does not identify constraints on local emergency response or the consequences of prolonged delays due to the lack of local resources.

Response
Public health and safety impacts as well as other impacts of each of the rail corridor implementing alternatives in Nevada are discussed in Section 6.3.2.2 of the EIS. States and tribes have the primary responsibility for the health and safety of their residents. The Federal Government supports the states and tribes when requested. At this time, with five rail corridors being evaluated in the EIS, specific public health and safety issues, including emergency preparedness and response, would not be addressed until a single corridor and alignment within the corridor was selected. The Department would then initiate National Environmental Policy Act activities for the chosen rail corridor/alignment, initiate consultations with Federal, state, and tribal authorities, and evaluate these specific considerations in detail in an attempt to mitigate as many potential impacts as possible.

It is the intent of Section 180(c) of the NWPA that first responders would be sufficiently trained to respond safely to an incident involving the shipment of spent nuclear fuel and high-level radioactive waste. DOE has committed to providing technical and financial assistance for training as mandated by Section 180(c) beginning approximately 4 years before shipments began. In addition, the Emergency Planning and Community Right-to-know Act mandates the formation of emergency planning and response capability by the states. The *Federal Register* notices make it clear that the funding would go to states and tribes. Local governments would not be eligible to receive Section 180(c) grants directly. However, states and tribes would be required to coordinate their planning with local jurisdictions, indicating in their applications that the needs of local public safety officials have been considered and describing how the training assistance would be provided to local jurisdictions and their appropriate public safety officials.

DOE recognizes that emergency preparedness capabilities and needs vary from jurisdiction to jurisdiction. To assist states and tribes to determine what their needs are and where the 180(c) funds and assistance can best be applied, DOE would provide a one-time planning grant to aid in making this determination. Additional discussion of Section 180(c) can be found in Section M.6 of the EIS.

In the event of an incident or accident involving radioactive materials, states, tribes, and local governments can request assistance from the Federal Government under the Federal Radiological Emergency Response Plan. Assistance is available from 17 different agencies. In addition, DOE maintains eight Regional Coordinating Offices across the country that are ready to provide assistance. Information concerning these resources can be found in Section M.5.1 of the EIS.

The Regional Servicing Contractor would be required to provide drivers and crews with specific written procedures that clearly define detailed actions to be taken in the event of an emergency or incident. The Draft Request for Proposals, *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153487-DOE 1998) focuses in detail on these responsibilities, as well as on other related responsibilities. Carrier and shipper responsibilities regarding emergency situations are discussed in Section M.5.1 of the EIS.

8.10.2 (8601)
Comment - EIS001837 / 0006
Upon a cursory review of your Draft DEIS it became apparent that if the DOE intends to go forward with this, DOE needs to rewrite and circulate the DEIS because it is inadequate, deficient and fatally flawed in the following ways:

1. No Evacuation Plan or Contingency Plan has been proposed and no alternative routes across the California Desert Conservation Area (the East Mojave) and through Needles, California have been assessed. This is akin to putting in a huge housing development in, with only one road to go in and out on and no fire escape route. Obviously, if alternate routes are assessed for this major proposal of massive shipments of the most lethal materials known to humanity, the DOE would be forced to include California Environmental Quality Act (CEQA) regulations and write a Environmental Impact Report meeting the requirements of CEQA regulations. In other words, your DEIS should be an DEIS/R. It is no wonder that you held only one meeting in Lone Pine, California. The DOE was obviously playing hide and seek from the People of the State of California.

Response
The preparation and implementation of evacuation and contingency plans is a state or tribal responsibility. Section 180(c) of the NWPA provides funds to eligible jurisdictions for the preparation of these plans as well as emergency response and safe routine transportation planning and coordination activities.

The routes used in the transportation analyses in the EIS are routes that are representative of ones DOE could use to make shipments to a Yucca Mountain Repository. DOE has not selected routes that it would propose to use. At least 4 years prior to the first shipments, DOE plans to notify affected states of preliminary routes it could use. See Section M.6 of the EIS for more information on Section 180(c) and Sections M.3.2.2 and M.5 for more information on emergency response.

8.10.2 (8831)
Comment - EIS001834 / 0014
The DEIS fails to identify what emergency response personnel training and equipment would be needed in all of the communities along the transportation routes. Many communities' emergency responders lack the special equipment and training necessary to respond to a radiological accident. Further, many hospitals do not have isolation rooms for radioactively contaminated victims. This analysis should at the very least be done for the major population centers along the transportation routes (populations of 100,000 or more). The DEIS should indicate what emergency response equipment, facilities, and trained personnel are available in these communities, and what the effects of a transportation accident could be based on what is currently available. For instance, if an accident occurs, and the driver of a nuclear waste truck is radiated, and there is no isolation room in the hospital, what are the impacts?

Response
State, tribal, or local governments must make the determination as to whether a jurisdiction has adequate emergency response capabilities. To aid in this process, a one-time planning grant will be available to eligible jurisdictions under Section 180(c) of the NWPA. In addition, technical assistance and funds will be made available under the provisions of this section for training of public safety officials. Section M.6 of the EIS provides additional information concerning Section 180(c).

In addition to the assistance available under Section 180(c), specific advice and support in the handling of individuals who might have been contaminated in an incident involving radioactive materials can be obtained 24 hours a day from the DOE Radiation Emergency Assistance Center/Training Site (REAC/TS).

The analysis of impacts of transportation accidents in the EIS (see Section J.1.4.2.1 for a discussion of methods and assumptions used) does not take credit for emergency response efforts to reduce exposure to individuals. Therefore the impacts represent what could happen regardless of the emergency response capabilities of jurisdictions along transportation routes. Federal- and state-supported training for responding to accidents involving hazardous materials, including radioactive materials, as well as training that would be supported by DOE for repository shipments, makes it unlikely that a first responder would receive a dose as high as that estimated in the EIS for a maximally exposed individual. The estimated doses from accidents to maximally exposed individuals in Section 6.2.4.2 are high estimates for maximum reasonably foreseeable accidents that could occur, which would have a likelihood of occurring between once in 1 million years and once in 10 million years. These doses were estimated with the assumption that a maximally exposed individual would be present for the full duration of an accident at the location where exposure to radioactive materials in the air and on the ground would lead to the maximum dose that could occur. The doses for a legal-weight truck accident and for a rail accident would be 0.75 rem and 29 rem, respectively, for the maximally exposed individuals. In addition, DOE has included estimates of the dose to an emergency responder to a severe accident. The largest estimated dose for a first responder would be 0.83 rem. This dose is estimated for a first responder to a severe rail accident where a portion of the cask's lead shield had been displaced. This dose, which is less than the administratively imposed annual limit of 2 rem for DOE's radiation workers, would lead to an estimated increase in the risk of a latent fatal cancer of about 3.3 in 10,000 over the individual's lifetime.

8.10.2 (8987)
<u>Comment</u> - EIS001040 / 0022
Where will Missouri's accident response center be located?

<u>Response</u>
Each state is responsible for the health and safety of its people. Therefore, any decisions concerning an accident response center are left to each individual state. As stated in Chapter 2 of the EIS, consistent with the provisions of Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states and tribes for training local public safety officials in the areas of safe routine transportation and emergency response, but it will not dictate to states and tribes where they are to locate any accident response centers. Additional information on emergency response responsibilities and capabilities and the provisions of Section 180(c) is provided in Sections M.5.1 and M.6 of the EIS, respectively.

8.10.2 (9434)
<u>Comment</u> - EIS001888 / 0124
The DEIS failed to consider local and regional conditions with regard to communication among agencies in emergency situations. Any discussion of mitigation, support or compensation must address the development and maintenance of an adequate communication system for a transportation incident involving radioactive waste. The system must include such aspects as area of coverage, interagency arrangements, and backup systems.

<u>Response</u>
The communications needed in response to an incident involving radioactive waste would be no different than that needed to deal with any transportation incident or accident. However, in addition to the equipment that states, tribes, and local governments have in place to deal with other public safety emergencies, DOE plans to use a satellite tracking system such as TRANSCOM to track and provide communications for shipments to a repository (Section M.3.2.1.5). As outlined in Section 180(c) of the NWPA (see Section M.6 of the EIS), DOE would provide funding for equipment and training on the satellite tracking system to states and tribes to allow them access to these communications (if the Nuclear Regulatory Commission approves). DOE would provide funding for states and tribes to coordinate with local public safety officials in the areas of emergency response and communications.

8.10.2 (9457)
<u>Comment</u> - EIS001888 / 0134
DEIS Statement (pg. 240) 2.1.3.2 - In the event of an accident involving a shipment of spent nuclear fuel or high-level radioactive waste, the transportation vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities as appropriate to mitigate such an incident.

Clark County Comment - The DEIS stated that "DOE would make resources available to local authorities as appropriate to mitigate" an incident. It did not explain how or when such assistance will be made available. Will local governments and the State of Nevada be burdened with the front-end costs of an incident and have to wait for reimbursement from DOE. If a significant incident occurred, it could be beyond the financial resources of a local entity. The DEIS should clearly state that the DOE will pay for any incident and pay for it up front. NEPA [National Environmental Policy Act] Regulation: Sec. 1502.1 Purpose; Sec. 1502.22 Incomplete or unavailable information.

Response
As discussed in Section M.5.1 of the EIS, states and tribes are primarily responsible for the health and safety of their citizens. However, Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for determining the need for and training of public safety officials of appropriate units of local government and tribes through whose jurisdictions the Department would ship spent nuclear fuel and high-level radioactive waste. This training would cover procedures for dealing with incident-free transportation and emergency response situations. It would be up to state, local, and tribal authorities to determine who would receive training and what equipment would be required. DOE would provide funds for training and the associated purchase of equipment for safe routine transportation and emergency response.

In addition, several Federal agencies have training and available capabilities should the states or tribes request them. If an accident with release of radioactive waste occurred, affected states and tribes could request assistance from DOE, Environmental Protection Agency, Department of Agriculture, Department of Health and Human Services, and the Federal Emergency Management Agency. These agencies, in cooperation with states, tribes, and each other, would monitor and assess radioactive materials in air, ground, agricultural products, and water in accordance with the Federal Radiological Emergency Response Plan and the Federal Radiological Monitoring and Assessment Plan. The costs for such services would be borne by the Federal agencies.

Costs associated with accidents would be borne by the transportation contractor's insurance and by coverage under the Price-Anderson Act. The Price-Anderson Act provides for indemnification of liability up to $9.43 billion to cover claims that might arise from an accident in which radioactive materials were released or one in which an authorized precautionary evacuation was made (see Section M.8 of the EIS for a more complete discussion of the Price-Anderson Act).

8.10.2 (9595)
Comment - EIS001888 / 0269
Incident Response

An essential concern for local governments is the speed and ability to respond to incidents. The DOE's requirement to reduce and mitigate the impact of a radioactive waste spill is an important part of the DOE's program. The DEIS should have discussed how the transportation system will be organized to enhance public safety respond to accidents. The DEIS should at least provide some information about the minimum incident response performance standards required of the RSCs [Regional Servicing Contractors].

Response
The first response to an incident during the transportation of radioactive materials is the responsibility of local officials in the jurisdiction where the incident occurs. Section M.6 of the EIS discusses DOE's responsibilities, as defined in Section 180(c) of the NWPA. That section states that DOE is required to provide technical and financial assistance to states and tribes for training public safety officials in jurisdictions through which it plans to transport spent nuclear fuel or high-level radioactive waste. Regional Servicing Contractors would be required to develop an Emergency Response Plan that addressed activities to be conducted by shippers and carriers in an accident or off-normal incident. The Plan would provide for a knowledgeable representative of the Regional Servicing Contractor to be at the scene as soon as possible after being notified by DOE to provide technical assistance. In addition, the Regional Servicing Contractor would be responsible for providing or having carriers provide drivers and crews with specific written procedures that clearly define detailed actions to be taken in the event of an emergency. Discussions of additional requirements imposed by Section 180(c) on DOE and the requirements imposed on the Regional Servicing Contractors by DOE are provided in Sections M.6 and M.3.2, respectively.

8.10.2 (9614)
Comment - EIS002075 / 0001
I especially brought to the attention of the tribes the matter of the emergency response and preparedness and how we, as tribes, are unprepared at this time and how the federal government and other agencies can look upon the tribes to assume that responsibility. And as was stated, we lack training. We lack staff. We lack equipment. We lack funds to be prepared for any kind of spills near us. And coming from an area where the President has just proclaimed close to our area, two national monuments; one is the Grand Staircase National Monument, and the other one is Grand Canyon, a national monument. As these are developed, there will be more visitors. There will be more

tourists. We will have more visitors from other countries. And tribes are expected to assume full responsibility for their safety when it comes to the use of our highways, our rail systems, and transportation of the waste products that are being sent to Yucca Mountain. Should there be a spill along the way, then our people are not going to be prepared to take care of that, although the general public will look upon us as assuming that responsibility. Then we're going to have environmental justice cases that probably will stem from those problems. So therefore, I think that the EIS needs to address our concerns on emergency response and preparedness and our environmental justice issues.

Response
Section 180(c) of the NWPA requires DOE to provide technical assistance and funds for emergency response training to states and tribes that would have shipments move through their jurisdictions on the way to a repository. A percentage of these funds may be used to obtain equipment. If additional resources are required to deal with an accident, assistance can be requested from Federal agencies. See Section M.6 of the EIS for additional information on Section 180(c) and emergency response.

It is the intent of Section 180(c) of the NWPA that first responders would be sufficiently trained to respond safely to an incident involving the shipment of spent nuclear fuel and high-level radioactive waste. The Department has committed to providing technical and financial assistance for training as mandated by Section 180(c) approximately 4 years before shipments commence. In addition, the Emergency Planning and Community Right-to-Know Act mandates the formation of emergency planning and response capability by the states. The *Federal Register* notices make it clear that the funding will go to states and tribes. Local governments will not be eligible to receive Section 180(c) grants directly. However, states and tribes would be required to coordinate their planning with local jurisdictions, indicating in the application that the needs of local public safety officials have been considered and how the training assistance will be provided to local jurisdictions and their appropriate public safety officials.

DOE recognizes that emergency preparedness capabilities and needs vary from jurisdiction to jurisdiction. To assist states and tribes to determine what their needs are and where the 180(c) funds and assistance can best be applied, DOE will provide a one-time planning grant to aid in making this determination. Additional discussion of Section 180(c) can be found in Section M.6 of the EIS.

In the event of an incident or accident involving radioactive materials, states, tribes, and local governments can request assistance from the Federal Government under the Federal Radiological Emergency Response Plan. Assistance is available from seventeen different agencies. In addition, DOE maintains eight Regional Coordinating Offices across the country that are ready to provide assistance. Information concerning these resources can be found in Section M.5.1 of the EIS.

The Regional Servicing Contractor would be required to provide drivers and crews with specific written procedures that clearly define detailed actions to be taken in the event of an emergency or incident. The Draft Request for Proposals, *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153487-DOE 1998), focuses in detail on these responsibilities, as well as on other related responsibilities. Carrier and shipper responsibilities regarding emergency situations are discussed in Section M.3.2.2.5 of the EIS.

Sections 4.1.13.4 and 6.1.2.12 of the EIS discuss the issue of environmental justice. The analysis in the EIS determined that the impacts from transportation to humans and other impacts that could affect populations of Native Americans would not be disproportionately high and adverse.

8.10.2 (9831)
Comment - EIS001888 / 0409
[Clark County summary of comments it has received from the public.]

Draft Comments on NOI [Notice of Intent] for Yucca [Mountain] EIS. Savings from delay of EIS could be used also to complete studies of fund distribution to state, local gov't, and tribes for ER [emergency response] preparedness and to clarify risk. Impact assessment approaches to be used by DOE.

Response
Section 180(c) of the NWPA authorizes DOE to provide funding and technical assistance for training of safety and emergency response personnel. Planning grants would be provided at least 4 years prior to commencement of shipments. This should allow sufficient time to prepare for shipments. In addition, states and tribes are allowed to use their initial planning grants to conduct risk assessment and other assessment activities. Section M.6 of the EIS provides additional information on the provisions and timing of Section 180(c) grants and funding. It is not necessary to delay work on the EIS, because sufficient time is built into the Section 180(c) implementation process to conduct these studies.

8.10.2 (10135)
Comment - EIS001865 / 0011
Section 2.1.3.2 of the EIS first acknowledges that the NWPA Section 180(c) requires DOE to provide technical and financial assistance to states and tribes for training public safety officials in jurisdictions through which [DOE] plans to transport spent nuclear fuel and high-level radioactive waste (page 2-40). In Section 6.2.4.2, Transportation Accident Scenarios, (page 6-30) the document clarifies that Section 180(c) also provides for "technical assistance and funding" to "local ... public officials." This inconsistency is confusing. Please clarify whether local assistance is mandated by law. If, in fact, local assistance is available, please consider this response letter as the County's request to be provided with this assistance, including funding.

Response
DOE agrees that the wording used in the text box could be confusing, and has revised Section 6.2.4.2 of the EIS accordingly. Local governments are not eligible to apply for Section 180(c) grants directly. However, states and tribes, if they have subjurisdictions, would be required to coordinate their planning with local jurisdictions, and indicate in their applications for Section 180(c) assistance that they have considered the needs of local public safety officials and describe how the training assistance would be provided to local jurisdictions and their appropriate public safety officials.

8.10.2 (10227)
Comment - EIS002115 / 0002
The DEIS does not adequately address specific community, local government, statewide and regional impacts. Rural counties do not have money to handle radioactive accidents. The cost to ensure that the rural counties would be able to accommodate the transportation of the radioactive waste would probably exceed the no action alternative, uncertainty used in models and data used for site characterization and repository performance.

Response
Section 180(c) of the NWPA requires DOE to provide technical assistance and funds for emergency response training to states and tribes that would have shipments move through their jurisdictions on the way to a repository. A percentage of these funds may be used to obtain equipment. If additional resources are required to deal with an accident, assistance can be requested from Federal agencies. See Section M.6 of the EIS for additional information on Section 180(c) and emergency response.

It is the intent of Section 180(c) of the NWPA that first responders would be sufficiently trained to respond safely to an incident involving the shipment of spent nuclear fuel and high-level radioactive waste. The Department has committed to providing technical and financial assistance for training as mandated by Section 180(c) approximately 4 years before shipments commence. In addition, the Emergency Planning and Community Right-to-Know Act mandates the formation of emergency planning and response capability by the states. The *Federal Register* notices make it clear that the funding will go to states and tribes. Local governments will not be eligible to receive Section 180(c) grants directly. However, states and tribes would be required to coordinate their planning with local jurisdictions, indicating in the application that the needs of local public safety officials have been considered and how the training assistance will be provided to local jurisdictions and their appropriate public safety officials.

DOE recognizes that emergency preparedness capabilities and needs vary from jurisdiction to jurisdiction. To assist states and tribes to determine what their needs are and where the 180(c) funds and assistance can best be applied, DOE will provide a one-time planning grant to aid in making this determination. Additional discussion of Section 180(c) can be found in Section M.6 of the EIS.

In the event of an incident or accident involving radioactive materials, states, tribes, and local governments can request assistance from the Federal Government under the Federal Radiological Emergency Response Plan. Assistance is available from 17 different agencies. In addition, DOE maintains eight Regional Coordinating Offices across the country that are ready to provide assistance. Information concerning these resources can be found in Section M.5.1 of the EIS.

The Regional Servicing Contractor would be required to provide drivers and crews with specific written procedures that clearly define detailed actions to be taken in the event of an emergency or incident. The Draft Request for Proposals, *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153487-DOE 1998), focuses in detail on these responsibilities, as well as on other related responsibilities. Carrier and shipper responsibilities regarding emergency situations are discussed in Section M.3.2 of the EIS.

8.10.2 (10305)
Comment - EIS001873 / 0082
Lincoln County Independent Research:

The County, under its federally funded Nuclear Waste Oversight Program, has produced numerous studies containing information concerning local impacts of the Yucca Mountain Project. As the County has stated in comments on the DEIS, the DOE has evidently not made any use of the County effort, which has cost approximately five million dollars to date. Following are some of the findings of the County studies. (My own observations are in parentheses.)

Lincoln County Emergency Preparedness Inventory 1992

Documents the County's lack of preparedness to handle accidents involving nuclear waste.

Response times in much of the county would be in excess of one hour.

In a preamble on local perception of risk the study notes that less than half of Caliente residents believe that radioactive waste can be transported safely.

Response
As stated in Section 2.1.3 of the EIS, DOE intends to comply with all applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission in the transport of spent nuclear fuel and high-level radioactive waste. In addition, the Department would comply with all aspects of the NWPA. Section 180(c) of the Act would provide funding and technical assistance for training of safety and emergency response personnel at least 4 years prior to the commencement of shipments. This should allow sufficient time to prepare for the shipments. In addition, as stated in the Draft Policy and Procedures for Section 180(c) (see Section M.6 of the EIS), if the route for a shipment was selected too close to the start of the shipment to allow for Section 180(c) implementation or if for any reason the responsible jurisdictions along a selected route lacked adequate training, DOE could use escorts with more training and equipment than those normally used for the purpose of security until a reasonable period for training has expired.

Regarding the commenter's concerns about response times, if there were an incident involving shipments of spent nuclear fuel and high-level radioactive waste, shipment drivers and escorts would be on the scene and trained to respond until local authorities arrived. Local first responders would respond in the same time period that they would respond to any emergency. Section 180(c) funds would help them prepare for this type of emergency. Given the integrity of the casks transporting the waste, and the fact that more than 2,700 shipments of spent nuclear fuel have been safely transported in the last 30 years with no fatalities, injuries, or environmental damage caused by the radioactive nature of the cargo, the chances of contamination of local communities and the environment from an incident involving this type of waste are extremely unlikely and not expected to occur. DOE feels that this waste can, indeed, be transported safely.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in

predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.10.2 (10747)
Comment - EIS002101 / 0009
I just read the summary, but first responders? This place should be filled with ambulance and policemen. When I talk to them about it, because I drive that nuclear waste cask around in my time when I can, I talk to first responders a lot, and they say they're trained. If they hear there's a nuclear accident, they turn their lights on, head home, get their family and go. Because that's the only response.

Response
It is the intent of Section 180(c) of the NWPA that first responders would be sufficiently trained to respond safely to an incident involving the shipment of spent nuclear fuel and high-level radioactive waste. In the event that local capabilities are not considered adequate for the task, the state, tribe, or local government may request assistance from Federal agencies under the Federal Radiological Emergency Response Plan. Additional information on emergency response and Section 180(c) is available in Section M.6 of the EIS.

8.10.2 (10997)
Comment - EIS001952 / 0012
DOE is relying upon local community assistance for fire, EMT [emeergency medical technician], and police assistance, should [the] need arise. DOE must consider local interpretation of democracy. Charges against the Village of Sardinia's police chief were subject of special village council meeting. Council member who expressed concern that background checks may be less than adequate was told that she didn't ask to see the personnel file before employment. She didn't verify what she was told and she didn't ask the right questions, apparently. In response to members of council who felt village residents and council were entitled to answers:

The mayor told members who were questioning actions that he could air dirty laundry of people at this table. When asked by a councilman whether investigation would be appropriate response to residents concerns, the mayor responded by saying:

...if residents weren't happy they would have attended the meeting. (Attachment VII... THE BROWN COUNTY PRESS, "Sardinia Council Alleges Mayor Withholding Data, 2/27/00, pg. 1.)

Note that council met in special session!! Previous council meeting adjoined out of the public view to discuss matters of personnel.

Response
The commenter is correct in stating that DOE assumes that local, state, or tribal public safety officials would most likely be the first to respond to an accident involving radioactive materials. Section 180(c) of the NWPA requires

DOE to provide funds and technical assistance for emergency response training to states and tribes that would have shipments move through their jurisdictions.

DOE recognizes that emergency preparedness capabilities and needs vary from jurisdiction to jurisdiction. To assist states and tribes to determine what their needs are and where the 180(c) funds and assistance can best be applied, DOE will provide a one-time planning grant to aid in making this determination. Additional discussion of Section 180(c) can be found in Section M.6 of the EIS.

The remainder of the comment is outside the scope of this EIS.

8.10.2 (11365)
Comment - EIS002278 / 0002
I would also like to talk a little about my concerns about the fact that the Department of Energy and their predecessors have a track record that is abysmal.

We know that every place that they have dealt with nuclear energy, they have leaks and contaminations. We know Hanford now is leaking into the Columbia River, and it's becoming the most nuclear polluted river in the world. And yet here we have an aquifer that they are willing to perch massive amounts of plutonium above and seem to have no problem with: Well, oops, we made another mistake.

They say, you know, it will be dry waste they will be transporting; but they said that about the wastes that they transported from Fernald that was found leaking in a truck stop that came in outside of Kingman, Arizona.

Response
Spent nuclear fuel and high-level radioactive waste would be dangerous sources of radiation if they were not safely contained and shielded and, as with other hazardous materials, directly exposing people would lead to health, and possibly life-threatening, consequences. For these reasons, the regulations of the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as DOE's own internal orders, specify containment, shielding, thermal, and nuclear safety requirements for shipping containers (casks). These regulations are designed to preclude even a remote chance of direct exposure. Nonetheless, spent nuclear fuel and high-level radioactive waste are not easily dispersed; they do not dissolve in water; they are not liquids or gasses that can be easily spilled or leaked, and, with the exception of a very small, nearly undetectable effect, radiation from them does not make other materials radioactive. Spent nuclear fuel and high-level radioactive waste are solids. They are hard, tough, and dense ceramics, metals, or glasses contained within tough metal barriers.

The incident to which the commenter refers occurred in December 1997 and involved the shipment of low-level radioactive waste from the Fernald Site in Ohio to the Nevada Test Site. The driver of the truck noticed en route that the liquid was leaking from the container and followed the proper steps to notify local authorities and DOE of the leak. Subsequent investigation revealed that the liquid was not contaminated and that, while there are some steps that should be taken to prevent such an incident from occurring again, there was no harm to workers or the environment.

8.10.2 (11409)
Comment - EIS002251 / 0007
They have said that today, it would be 2010 before they begin shipments. In St. Louis, they said, quote, 2004 possibly. They said today that they would have four years of training before shipment. And so to me, that doesn't jibe if they are saying that it could start in 2004, and I know for a fact that there's been evidence in this room and Las Vegas that there's no training going on.

Response
Section 2.1.2 of the EIS discusses the schedule for the repository and other facilities and operations. The current schedule calls for shipments to begin in 2010. For a 2010 start of shipments, training of emergency response personnel would begin no later than 2006.

8.10.2 (11572)
Comment - EIS002281 / 0002
I do know toxic waste goes through Shoshone, and I was told just a few months ago a truck was stopped in Shoshone that was leaking, and I don't know how many hours before they finally got it cleaned up because Shoshone is so far – it's 60 miles from Baker and Baker isn't much to talk about. 60 miles from Death Valley, which has no services that could help for that.

Response
The spent nuclear fuel and high-level radioactive waste would be transported to the proposed repository in shipping casks which would be designed, manufactured, and operated under the regulations of the Nuclear Regulatory Commission. Of the thousands of shipments completed over the last 30 years, none has resulted in an identifiable injury through release of radioactive material. Additional information concerning cask safety can be found in Section M.4.1 of the EIS. The materials destined for the proposed repository would be in solid form, so there is no possibility of a leak.

DOE is required by Section 180(c) of the NWPA to provide technical assistance and funding to states for the training of public safety officials of appropriate units of local governments and tribes through whose jurisdictions these shipments would be made. Under this program, a one-time planning grant would be provided to determine the needs of these jurisdictions for safe routine transportation and emergency response. It would be appropriate in this assessment to determine how to handle incidents in remote areas.

8.10.2 (11582)
Comment - EIS002235 / 0005
What is the contingency plan? How will the responsive team be mobilized? Where are the workers to come from? To where will the victims be transported and how will they be housed during these days? How will 42 square miles and everything in it be decontaminated? In my brief 20 years cleaning up hazardous waste sites, I would expect decades, not 460 days.

Response
Local, state, and tribal governments are responsible for responding to accidents, including those involving radioactive materials, in their jurisdictions. The Federal Government and, in particular, DOE have radiological response resources available to assist when requested.

As required by Section 180(c) of the NWPA, DOE will provide financial and technical assistance to states and tribes for training local public safety officials in the areas of emergency response and safe routine transportation. DOE expects to provide this assistance beginning at least 4 years before shipments commence to a repository through a particular jurisdiction. Additional information on Section 180(c) is provided in Section M.6 of the EIS.

Although DOE and its contractors would develop their own emergency response plans, the preparation and implementation of emergency response, evacuation and contingency plans is a state or tribal responsibility for their jurisdictions. Section 180(c) funding will be provided to eligible jurisdictions for the preparation of these plans as well as emergency response and safe routine transportation planning and coordination activities.

In the unlikely event someone was contaminated as the result of an accident involving shipments to a repository, there are several means to deal with this. Major hospitals are equipped to deal with radioactive contamination because they routinely handle medical radioisotopes. In cases where there is no training or procedures to handle a contaminated individual, assistance can be obtained from the DOE Radiation Emergency Assistance Center/Training Site (REAC/TS). REAC/TS is on call 24 hours a day to provide direct or consultative help with cases where people have been involved in a radiation accident. Federal Government assistance is regionally based and can be mobilized and on the scene in a few hours, although it might take as long as 48 hours to be fully functional. A discussion of accident cleanup is in Section J.1.4.2.5 of the EIS. Additional information on emergency response can be found in Section M.5.2.

8.10.2 (11605)
Comment - EIS002237 / 0003
What happens if there is an accident? That's what everybody has talked about today. Nye County fears that the high level will follow the same avenue as low level is today.

You have got to realize that in my district where I live, I can leave home before daylight, drive all day, never pass through a town, get home after dark and never get out of the county. That's how big it is. And there's absolutely no radio communication out there, no medical facilities. We have to rely on our volunteers.

Just recently the Federal government funded the State of Nevada for safety and training, but what about Nye County? Is this how you thank Nye County for wanting to work with you?

Response
As required by Section 180(c) of the NWPA, DOE will provide financial and technical assistance to states for training public safety officials of appropriate units of local government and tribes in the areas of emergency response and safe routine transportation. DOE expects to provide this assistance beginning at least 4 years before shipments to the proposed repository commence in a jurisdiction. The proposed policy and procedures that address the implementation of Section 180(c) state it is DOE policy that each responsible jurisdiction would have the training necessary for safe routine transportation of spent nuclear fuel and high-level radioactive waste and to respond to incidents or accidents involving these shipments. DOE will provide the funds and technical assistance to obtain this training. Additional discussion of Section 180(c) can be found in Section M.6 of the EIS.

8.10.2 (12083)
Comment - EIS002310 / 0002
[The Oak Ridge Reservation Local Oversight Committee] strongly urges that the federal government provide sufficient funds to Nye County and other Nevada counties impacted by waste transport to Yucca Mountain for the purpose of ensuring adequate local capabilities for emergency preparedness, communications, and response.

Response
In response to comments, additional information has been provided in Section M.3.2.2 of the EIS on the proposed operational aspects of spent nuclear fuel and high-level radioactive waste transportation, emergency response planning, and financial assistance programs. Section 180(c) of the NWPA requires DOE to provide technical and financial assistance to states and tribes to train public safety officials in emergency response and safe routine transportation. As a result of this program first responders would likely have sufficient training to be knowledgeable of the hazards to which they could be exposed from spent nuclear fuel and high-level radioactive waste shipments. Part of the Section 180(c) funds are for planning and coordination activities. States and tribes may use a percentage of the funding to purchase equipment for training purposes, which may then be used for emergency response, if necessary. States and tribes may request additional support from various Federal agencies in the event of an incident.

8.10.2 (12250)
Comment - EIS000995 / 0016
What is the ratio of emergency personnel who are trained to respond to high-level radioactive waste transport accidents to the general population in any give area, or say, in Oakland, Missouri, where my family lives?

Response
Section M.6 of the EIS identifies the need for providing technical assistance and training for emergency response related to transportation of spent nuclear fuel and high-level radioactive waste. DOE did not determine the ratio of emergency responders to the general population in the EIS. Once a repository site was approved, DOE would implement Section 180(c) of the NWPA. Under this provision, DOE would provide technical assistance and funds to states to determine the need for and training of public safety officials of appropriate units of local government and tribes through whose jurisdictions shipment would be made to the repository. It is up to the eligible state and tribe, in consultation with local governments and first responders along the routes, to select who gets this funding and technical assistance. A one-time planning grant would be provided to every eligible state and tribe to determine the needs for this funding. In their applications for Section 180(c) funds, DOE expects states and tribes to consider the needs of, and show how training would be provided to, local jurisdictions and their appropriate public safety

officials. Additional information concerning implementation of Section 180(c) can be found in Section M.6 of the EIS.

8.10.2 (12251)
Comment - EIS000775 / 0002
First responders in such states should be notified and be on alert for potential exposure to radioactive material in case of an accident. 'First responders' should be added to the list of maximally exposed individuals on page J-43, Section J.1.3.2.2, with appropriate calculation of potential exposures (person-rem, dose-risk) added to appropriate tables throughout Chapter 6, Environmental Impacts of Transportation.

Section J.1.2.2, page J-23 states that the Office of Civilian Radioactive Waste Management plans to identify the preliminary routes for shipments of waste and notify governors and tribal leaders. It may be appropriate for the OCRWM to take responsibility to notify appropriate authorities regarding 'first responder' safety.

Response
One purpose of the DOE proposed policy and procedures (see Sections 6.2.4.2 and M.6 of the EIS) for implementing Section 180(c) of the NWPA is to describe the steps DOE plans to take to provide technical assistance and funding to states and tribes in the area of training, including training for emergency preparedness, for safe routine transportation and emergency response for shipments of spent nuclear fuel and high-level radioactive waste. DOE expects first responder safety would be fully addressed during training supported by DOE funds and technical assistance required under the provisions of Section 180(c).

At least 4 years prior to the first shipment of spent nuclear fuel and high-level radioactive waste from generator sites to Yucca Mountain through a state or tribal jurisdiction, DOE plans to notify the associated governors and tribal leaders. This notification would be the basis for states to submit applications to DOE for grants for determining training needs, and funding and technical assistance under Section 180(c).

Federal- and state-supported training for responding to accidents involving hazardous materials, including radioactive materials, as well as training that would be supported by DOE for shipments of spent nuclear fuel and high-level radioactive waste, makes it unlikely that a first responder would receive a dose as high as that estimated in the EIS for a maximally exposed individual. The estimated doses from accidents to maximally exposed individuals presented in Section 6.2.4.2 of the EIS are high estimates for maximum reasonably foreseeable accidents that could occur, which would have a likelihood of occurring between once in 1 million years and once in 10 million years. These doses are estimated with the assumption that a maximally exposed individual was present for the full duration of an accident at the location where exposure to radioactive materials in the air and on the ground would lead to the maximum dose that could occur. The doses for a legal-weight truck accident and for a rail accident show 0.75 rem and 29 rem, respectively, for the maximally exposed individuals. In addition, DOE has included estimates of the dose to an emergency responder to a severe accident. The largest estimated dose for a first responder is 0.83 rem. This dose is estimated for a first responder to a severe rail accident where a portion of the cask's lead shield had been displaced. This dose would lead to an estimated increase in the risk of a latent fatal cancer of about 3.3 in 10,000 over the individual's lifetime.

8.10.2 (12263)
Comment - EIS002175 / 0008
Many hospitals do not have isolation rooms for radioactively contaminated victims. This analysis should at least be done for the major population centers along the transportation routes (populations of 100,000 or more). The DEIS should indicate what emergency response equipment, facilities, and trained personnel are available in these communities, and what the effects of a transportation accident could be based on what is currently available.

Response
The analysis of the impacts of transportation accidents in the EIS did not take credit for the mitigating effects of emergency response activities. Therefore, no attempt was made to determine emergency response capabilities along the routes analyzed. In the unlikely event someone was contaminated as the result of an accident involving shipments to a repository, there are several means to deal with this. Major hospitals are equipped to deal with radioactive contamination because they routinely handle medical radioisotopes. In cases where there is no training or procedures to handle a contaminated individual, assistance can be obtained from the DOE Radiation Emergency

Assistance Center/Training Site (REAC/TS). REAC/TS is on call 24 hours a day to provide direct or consultative help with cases where people have been involved in a radiation accident.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds for emergency response training to states and tribes that would have shipments move through their jurisdictions on the way to a repository. Under the current plan, a one-time planning grant will be provided to eligible states and tribes to assess the need for this technical assistance and funds. Additional discussion of Section 180(c) can be found in Section M.6 of the EIS.

8.10.2 (12604)
Comment - EIS001775 / 0004
Another person asked where was the EPA [Environmental Protection Agency]; not necessary for an environmental impact statement. Have you calculated the cost of training HAZMAT [hazardous material] teams all along the travel route? Is it even possible for local HAZMAT teams to cope with a nuclear incident should a train derail or a truck overturn? How many HAZMAT teams would there have to be, spaced how far apart? Are the utility companies going to pay for that, are local governments, are the U.S. Taxpayers? Can local hospitals even cope with such a nuclear accident?

The federal government does not have a flawless record on projects involving technology and you know about the Mars probe, the Y2 glitch and the spy satellite, MTVE and the EPA and then we see the failure of a new advanced anti-missile system. A miscalculation or a glitch or an accident would not only be another failure in technology, it could mean disaster for an entire community, an entire region of the country such as the midwest, indeed the whole nation itself.

Response
Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel or high-level radioactive waste. The costs of providing this technical assistance and training have not yet been determined but the funds would come from the Nuclear Waste Fund and would be authorized by the Congress. According to the Notice of Revised Proposed Policy and Procedures published in the *Federal Register* (63 *FR* 23753-23766, April 30, 1998), a one-time planning grant of $150,000 would be provided to eligible states and tribal jurisdictions for the determination of training and funding needs and for preparation of the application for funds about 5 years before shipments.

State and local governments deal with transportation accidents involving hazardous materials on a daily basis across the U.S. According to the Notice of Revised Proposed Policy and Procedures, DOE would provide funding and technical assistance to eligible jurisdictions along transportation routes to address incremental training requirements resulting from shipments of spent nuclear fuel and high-level radioactive waste to the repository. DOE would allow a variety of activities an applicant state or tribal jurisdiction might consider appropriate for training under the Section 180(c) program. Along a specific transportation route, it would be the applicant's decision as to who received training.

The DOE Radiation Emergency Assistance Center/Training Site (REAC/TS) has been working with state and local groups, including hospitals, to provide medical emergency response training, as well as providing treatment and medical consultation for injuries resulting from radiation exposure and contamination. Among the training courses offered are courses in the handling of radiation accidents by emergency staff, and medical planning and care in radiation accidents.

8.10.3 LIABILITY

8.10.3 (182)
Comment - 12 comments summarized
Commenters expressed concern regarding liability for transportation accidents involving spent nuclear fuel or high-level radioactive waste. Issues raised included who would be liable, who would pay the cost of cleaning up, and how would people be compensated for damages suffered as a result of a transportation accident. Commenters noted that insurance policies routinely exclude nuclear and radioactive accidents from policy coverage and wondered if taxpayers would be levied an additional tax burden for increased indigent medical funds. Commenters brought up

the financial burden that could be imposed on state or local governments as a result of a transportation accident. One commenter sought a total buyout of property damaged in a nuclear accident. Some commenters sought additional information regarding who would be responsible for cleanup.

Response
With respect to damages associated with an accident involving spent nuclear fuel and high-level radioactive waste, the Price-Anderson Act (see Section M.8 of the EIS) establishes a system of financial protection for persons who might be liable for, and for persons who might be injured by, a nuclear accident or incident. The Act provides liability coverage to DOE activities (including transportation) involving spent nuclear fuel and high-level radioactive waste. Specifically, the Price-Anderson Act establishes a system of private insurance and Federal indemnification that generally ensures that up to $9.43 billion is available to compensate for damages suffered by the public, regardless of who causes the damages. Persons indemnified include contractors, subcontractors, suppliers, state, local, and tribal governments, and any workers or persons who might be sued for damages. This indemnification would include operators of a spent nuclear fuel and high-level radioactive waste repository at Yucca Mountain and to transporters from commercial nuclear utilities and DOE sites to the repository. Congress will consider action on compensation plans to pay victims for damages that might exceed the $9.43 billion amount.

An accident that does not involve the release of radioactive materials or an authorized precautionary evacuation would not be covered by the Price-Anderson Act. Instead, it would be subject to normal state tort law applicable to any type of accident. Carriers may have private insurance to cover liability from a non-nuclear incident and for environmental restoration for such non-nuclear accidents. All motor vehicles carrying spent nuclear fuel or high-level radioactive waste are required by the Motor Carrier Act and implementing regulations (49 CFR Part 387), to maintain financial responsibility of at least $5 million. Federal law does not require rail, barge, or air carriers of radioactive materials to maintain liability coverage, although these carriers often voluntarily carry such insurance. Private insurance policies often have a nuclear exclusion to exclude coverage of nuclear accidents to reflect that those accidents involving the release of radioactive materials are covered under Price-Anderson Act indemnification. Thus, private insurance policies apply only to the extent that the Price-Anderson Act is not applicable.

Under the Price-Anderson Act, DOE does not require its contractors to carry private liability insurance as financial protection for nuclear incidents. Rather, DOE provides full indemnification to its contractors and all other persons indemnified to pay damages and provide compensation for nuclear incidents arising in connection with DOE contractual activity. To the extent Price-Anderson indemnification applies, there is no need or requirement to invoke existing private insurance policies.

DOE and the carrier would work with the appropriate government agencies to address who shall perform and who shall pay for cleanup activity where there was no release of radioactive material. In the case of a release of radioactive materials, payment for liability for the costs of the cleanup would be made under the Price-Anderson Act.

8.10.3 (7724)
Comment - EIS002018 / 0001
I am concerned about the side effects of a nuclear spill. Our health insurance will not cover us if we are exposed to the easterners waste. This isn't fair, because Nevada doesn't even produce nuclear waste.

Response
In Section 6.2.4 of the EIS, DOE recognizes the potential for transportation accidents and analyzed impacts resulting from transportation accidents. Although, given the number of shipments, traffic accidents are expected to occur, DOE does not believe that any accident would result in the release of radioactive material, primarily because of the structural integrity of the casks in which the material would be transported. In the more than 2,700 shipments involving spent nuclear fuel over the past 3 decades, there have been seven accidents, with no release of radioactive materials to the environment.

In the event of a nuclear accident or incident, the Price-Anderson Act establishes a system of private insurance and Federal indemnification that generally ensures that up to $9.43 billion is available to compensate for damages suffered by the public, regardless of who causes the damages. Damages that occur as a result of a nuclear accident or incident at the Yucca Mountain site or during the transportation campaign would be subject to the Price-Anderson Act indemnification. Additional information on liability for nuclear incidents is provided in Section M.8 of the EIS.

8.10.3 (9468)
Comment - EIS001888 / 0139
DEIS Statement (pg. 2.51) 2.1.3.3.3.1 - To enable intermodal transfers and heavy-haul shipments to the repository, an intermodal transfer station would be built and operated in Nevada.

Clark County Comment - The DEIS is silent as to who is responsible for protecting shipments during the intermodal transfer. Further, the DEIS states that "it could build and operate an intermodal station." Is DOE committed to constructing and operating the intermodal transfer station, or is DOE going to contract this to the private sector? If so, who will have the liability from an incident at the intermodal station? Since most accidents with spent fuel occur with the transfer of waste, it is very important to know who will be responsible for this task; how it will be managed; and what role if any will be expected of local governments. Further, will local governments have the right to access such a facility to ensure compliance with regulatory standards?

NEPA [National Environmental Policy Act] Regulation: Sec. 1502. 1 Purpose; Sec. 1502.14 A Alternatives including the proposed action; Sec. 1502.16 Environmental consequences.

Response
As discussed in Chapter 2 of the EIS, DOE would be responsible for shipments of spent nuclear fuel and high-level radioactive waste during the entire shipping campaign, regardless of whether private contractors were actually conducting the shipments or operating the associated facilities. In addition, the Department and its contractors would comply with all applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission. Under these regulations, states and tribes could have authority to inspect shipments of spent nuclear fuel and high-level radioactive waste originating in or passing through their jurisdictions. Access to, or inspection of, facilities for enforcing compliance with Federal regulations would likely remain the responsibility of Federal agencies.

As discussed in Section 6.3 of the EIS, the shipping casks would remain sealed at all times during intermodal transfer facility operation. The forces to which the casks could be subjected during handling accidents at the facility would be significantly less than those required to cause a breach. Therefore, the radiological risks to the public from accidents at the intermodal facility would be very low.

The Price-Anderson Act establishes a system of private insurance and Federal indemnification that generally ensures that as much as $9.43 billion is available to compensate for damages suffered by the public in a nuclear accident or incident, regardless of who causes the damages. Damages that occurred as a result of a nuclear accident or incident at the Yucca Mountain site or during the transportation campaign, including at an intermodal transfer facility, would be subject to Price-Anderson Act indemnification. The liability of all responsible parties is limited to the amount of coverage provided by the Price-Anderson system. State and local governments cannot be required to provide additional compensation. Additional information on nuclear incident liability is provided in Section M.8 of the EIS.

As described in DOE's current planning for transportation operations, physical protection of shipments would be the responsibility of the Regional Servicing Contractors and transporters as described in Sections M.2 and M.7 of the EIS. Physical protection of shipments would comply with requirements of the U.S. Nuclear Regulatory Commission presented in 10 CFR Part 73.

8.10.3 (12543)
Comment - EIS001282 / 0002
The Draft Environmental Impact Statement acknowledges that it is not a question of whether an accident will happen while these high-level radioactive waste materials are being transported across our country. Section 6.2.4, "Accident Scenarios," explains that a certain number of accidents are "reasonably foreseeable." The questions are where and when the accidents will occur.

Will the emergency responders; the police, fire, and hospitals, be prepared? All responders, hospital personnel and anyone else coming in contact with this nuclear waste have the right to know how to respond when accidents take place! Who will provide support when accidents occur, a representative in Washington or somewhere else in the country? This is unacceptable! Who will be liable for the damages and expense resulting from these accidents?

Our highways and rail corridors are designed to connect population centers and to bring goods to market, not to transport high-level radioactive waste. Transporting this dangerous material via highway and rail pulls the City of Cleveland and the citizens of the City of Cleveland directly into harm's way. It will take a full-scale effort, well in advance of any transportation of radioactive material, to provide protection against the inevitable accidents. The cost of fully training and equipping the emergency responders, in all the cities along the transportation routes, to handle an accident involving high-level radioactive waste must be factored into the cost equation for the Yucca Mountain Project. The cost of the necessary preparation for accidents and liability for damages must be assigned to someone other than the local governments of cities standing, unfortunately, between the nuclear waste producers and the final disposal site.

Response
As required by Section 180(c) of NWPA, DOE would provide technical assistance and funds to states and for training public safety officials of appropriate units of local governments and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as for dealing with emergency response situations. DOE would institute its program to implement the requirements of Section 180(c) before beginning shipments to the repository. In the event of an incident involving spent nuclear fuel or high-level radioactive waste, the vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities as appropriate to mitigate such an incident. Sections M.3.2.2, M.5, and M.6 of the EIS contain more information on emergency response capabilities and the provisions and implementation of Section 180(c), respectively.

In the event of a nuclear accident or incident, the Price-Anderson Act establishes a system of private insurance and Federal indemnification that generally ensures that as much as $9.43 billion is available to compensate for damages suffered by the public, regardless of who causes the damages. Damages that occurred as a result of a nuclear accident or incident at the Yucca Mountain site or during the transportation campaign would be subject to the Price-Anderson indemnification. Section M.8 of the EIS contains more information on liability for nuclear incidents.

8.11 Transportation - Affected Environment and Impacts

8.11.1 LAND USE

8.11.1 (134)
Comment - 11 comments summarized
Commenters expressed concern that the Draft EIS did not adequately examine the impacts to land use from the construction of a rail line in Nevada. Specific concerns include impacts to recreation (camping, hiking, fishing, hunting, nature study, back Country travel, sightseeing, and Wilderness Areas); continued access to recreation areas due to blocked roads; mining and mineral resource potential (especially through parts of north Central Nevada where active mining is occurring and where the mineral potential is high); timber lands; and private property (including ranches and patented mining land). Some wanted to know if private property would be condemned along and near the rail line, and if so, would the property owners be given fair market value for their land.

Some commenters said that any rail line in Nevada would conflict with existing land-use plans developed by the Bureau of Land Management. The EIS will remain insufficient until a complete inventory of land use and land management impacts are addressed, particularly in consultation with affected Federal and State of Nevada land management agencies.

Others said that construction of a branch rail line would be much more destructive than the use of trucks on existing roads, especially considering that the rail line would be used only for several decades.

Response

In Chapter 8 of the EIS, DOE considered past, present, and reasonably foreseeable actions of DOE, other agencies, and other organizations in its presentation of cumulative impacts. Future actions, which were included, were based on publicly announced and approved future actions and have documented evidence (for example, a Proposed Action would have a scheduled start and obligated funding, or there are other demonstrations of commitment that an action would occur and should be considered).

Section 6.3 discusses the scope of land-use information deemed appropriate for assessing potential impacts on land use of transportation implementing alternatives in Nevada. The sources of information need to identify the current ownership of the land that would be disturbed, and the present and anticipated future uses of the land. The region of influence for land-use and ownership impacts consists of land areas that would be disturbed or whose ownership or use would be changed as a result of the construction and use of a branch rail line, intermodal transfer station, midroute stopover for heavy-haul trucks, and an alternative truck route near Beatty, Nevada. These disturbances in land use would include camping, hiking, fishing, hunting, nature study, back-country travel, sightseeing, mining, ranching, timber, and wilderness areas.

In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example, as discussed in Chapter 6 of the EIS, impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. With these mitigating measures, the impacts would be lessened and considered small. If an action could result in departures from existing uses, and mitigation could not remedy the conflict, the effects could be more substantial. For example, as discussed in the Carlin and Caliente Corridor sections of Chapter 6 (Sections 6.3.2.2.1 and 6.3.2.2.2), the Bonnie Claire Alternate passes directly through the portion of the newly established Timbisha Shoshone Trust Lands near Scottys Junction. If this alternate was chosen, the construction of a branch rail line could limit or enhance economic development in the Timbisha Shoshone Trust Lands parcel and could limit the use for housing by restricting access. Factors considered included the uniqueness of a geographic area; presence of historic, scientific, and cultural resources; potential effects on endangered species; and compliance with Federal, State, or local law. Based on information available, potential land-use impacts associated with Yucca Mountain transportation activities could be minimized through judicious alignment of the branch rail line or through mitigation. Overall, the land-use impacts would not be substantial because of the use of various optional and alternate routes within the corridor, mitigation measures, and the judicious routing of the branch rail line within the corridor.

Additional information about impact-reduction features, procedures and safeguards, and mitigation measures under consideration are included in Chapter 9 of the EIS. Chapter 9 identifies ongoing studies that could eventually influence mitigation measures related to the project plan and design. For example, Section 9.3 discusses mitigation measures intended to address impacts from the possible construction of a branch rail line or an intermodal transfer station in Nevada; construction of other transportation routes; upgrading of existing Nevada highways to accommodate heavy-haul vehicles; transportation of spent nuclear fuel and high-level radioactive waste from existing storage sites to the proposed repository; and fabrication of casks and canisters. As suggested in the Foreword to the EIS, if DOE pursued consideration of a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes, more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews would be conducted that would help ensure potential land-use conflicts associated with Yucca Mountain transportation activities were minimized.

The documents cited in Section 3.2.2.1.1 of the EIS are source documents used by DOE for land-use considerations, and they include possible future actions within the transportation corridor. The more notable land-use features and potential influences that exist on lands within the corridors are presented in Section 6.3.2. For example, the land features within the Carlin Corridor are presented in Section 6.3.2.2.2. The listing of communities in Section 6.3.2.2.2 serves two purposes: (1) to identify communities potentially affected by the Carlin Corridor and (2) as map reference points. Gold Acres and Tenabo are historic reference points in the vicinity of the Carlin Corridor.

Commenters are referred to the corridor-specific parts of Section 6.3.2.2, where DOE identifies potential conflicts with existing or future land uses and land-use plans that could be affected by a given corridor.

Regarding private property along the rail corridor, DOE is required to use fair market value in the acquisition of real property. DOE must comply with the policies contained in the Uniform Relocation Assistance and Real Property Acquisition Policies Act, Title III, which includes the provision that the Agency (DOE) offer just compensation.

8.11.1 (1015)
Comment - EIS000254 / 0005
The project should offer up-front a reverter clause or a right of first refusal to recover the property ownership once the 30-year period of usage has expired. The clause should also state that all lands will be restored to existing conditions with the reversion. The reversion price would be the price at which the land was purchased. This would have the effect of making family ownerships whole at the end of the usage term.

Response
This comment concerns land for the candidate Carlin branch rail line for transporting spent nuclear fuel and high-level radioactive waste. The Carlin Corridor evaluated in the EIS passes through the Crescent Valley region of Nevada.

Regarding private property along the rail corridor, DOE is required to use fair market value in the acquisition of real property. DOE must comply with the policies contained in the Uniform Relocation Assistance and Real Property Acquisition Policies Act, Title III, which includes the provision that the Agency (DOE) offer just compensation.

Prior to a decision to dispose of lands it no longer needed for transporting spent nuclear fuel and high-level radioactive waste to the repository, DOE would consider alternatives for disposition. These alternatives would include restoration of the lands to their prior existing conditions.

8.11.1 (1186)
Comment - EIS000114 / 0007
Isn't - isn't it amazing that the proposed railroad route happens to follow the Valley Electric easement lines coming from Jean?

And - and - and I happen to notice that - that we rendered into an agreement with Yucca Mountain to provide them with power.

I would like to see Valley Electric provide me with a written copy of that agreement to see in fact if they made agreements with the Department of Energy to allow transportation along the east side of 160 along their easement corridor for power.

Response
The Jean Rail Corridor is one of five candidate corridors that DOE is considering as a possible route to the proposed Yucca Mountain Repository. Each rail corridor at some point along its route crosses or passes adjacent to existing rights-of-way for utility or road corridors, as described in Section 3.2.2.1.1 of the EIS.

In Section 2.6 of the EIS, DOE identified rail as its preferred mode of transportation both nationally and in Nevada. At this time, DOE has not identified a preference among the five candidate rail corridors within Nevada. If the Yucca Mountain site was recommended and approved, DOE would issue at some future date a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would then identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada.

8.11.1 (1239)
Comment - EIS000226 / 0002
Pages 25 and 26 of the County/City EIS Scoping Report note that construction and operation of a rail line may impair access to forage and water by domestic livestock. The DEIS indicates that rail corridors would cross grazing allotments but does not describe the impacts construction and use of a rail line would have on domestic livestock operations in Lincoln County.

Response
Land use and ownership impacts common to the construction and operation of all five of the branch rail lines are discussed Section 6.3.2.1 of the EIS and impacts specific to the Caliente Corridor are discussed in Section 6.3.2.2.1. The EIS determines that a branch rail line could create a barrier to livestock movement, and quantitatively addresses the acres of grazing lands potentially affected by candidate rail corridors.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

If a corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify specific land uses to be avoided. DOE would avoid land-use impacts and private land to the maximum possible extent. For example, access to grazing areas, forage, and water could be addressed in the early design phase of the rail corridor/alignment. This process would address Bureau of Land Management standard operating procedures for rights-of-way, construction and operation. Water wells would be required along the rail corridor in some areas for soil compaction and dust control during rail construction. It could be possible to improve grazing allotments if the Bureau permitted the use of this water for grazing. Grazing allotment access could be accomplished by designing at-grade structures to permit cattle to cross underneath the railbed.

8.11.1 (1553)
Comment - EIS000357 / 0012
Page 1-14. 1.4.1. Is DOE considering withdrawal of rail and highway transport routes that would be constructed exclusively for transport of canisters to Yucca Mountain?

Response
For purposes of analysis, DOE assumed rail lines in Nevada for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain would be devoted exclusively to the transport of materials to the repository (see Section 2.1.3.2.2 of the EIS). However, shared use could be considered later. For national highways and railways (non-Nevada) and Nevada highways, DOE is not considering exclusive use.

However, if the Yucca Mountain site was approved, and mostly rail selected as the transportation mode, then DOE would construct a branch rail line from an existing main track in Nevada to the site. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, DOE would consider the potential for shared use of the branch rail line, as discussed in Section 8.4.2 of the EIS. If the site was approved, then decisions regarding shared use would be made.

8.11.1 (1689)
Comment - EIS000804 / 0001
I live in Austin, Nevada. I understand that you folks want to put a nuclear railroad line running down behind my town. [It's] to run from [Beowawe] to Yucca Mountain. [It's] called the "Carlin" route.

Have you talked with the Forest Service? They want to shut down a bunch of roads so as to make some of the R.R. right-o-ways into [scenic] or "Wilderness" areas.

How come you can run a nuke train thru [potential] wilderness areas? What does the Forest Service say?

Response
Appendix C of the EIS addresses interagency and intergovernmental interactions. Although the Department has initiated many interactions (see Table C-1) and has received many requests for cooperating agency status (see Table C-2), the Department has not discussed this subject on a formal basis with the U.S. Forest Service. However, discussions regarding wilderness study areas and existing wilderness areas have occurred with the Bureau of Land Management.

Table J-38 of the EIS indicates that the Steiner Creek Alternate of the Carlin Corridor passes close to, but not through, the Steiner Creek Wilderness Study Area. Results of discussions with the Bureau of Land Management indicated that the corridor would not have an impact on wilderness areas or Wilderness Study Areas if a branch rail line was built.

8.11.1 (2204)
Comment - EIS000615 / 0002
Lander County has a public federally administrated land plan manual that is just coming into effect. I know you haven't taken that into consideration, but it will be available.

Response
DOE did obtain and review the *Lander County Revised Policy Plan for Federally Administered Lands* (DIRS 157310-Lander County 1999), as well as closely associated resource management plans issued by the Elko and Battle Mountain Districts of the Bureau of Land Management. The Lander County Policy Plan was developed to provide state and locally developed land management policies for use by the various Federal land management agencies. While DOE cannot at this time definitively identify specific tracts of land that could be affected along the Carlin Corridor (which traverses Lander County), DOE is sensitive to and aware of plan elements such as the County's desire to see certain Federal lands prospectively transferred to the private sector (see Appendix A of the Lander County Policy Plan). A number of other plan elements are to one extent or another considered in this EIS. For example, DOE has incorporated the best available population data from the Nevada State Demographer into its estimates of the socioeconomic impacts to the State, including Lander County; has identified mitigation measures that could be useful in the minimization of impacts to animal grazing units; and has identified the rail corridor's proximity to recreation and wildlife management areas, known cultural resource sites, and other potentially sensitive features. In the initial siting of potential transportation corridors, the Department attempted to minimize traversing private lands while remaining within engineering specifications. Should the Carlin rail corridor be selected as a likely transportation route for spent nuclear fuel and high-level radioactive waste, DOE would conduct more detailed route investigations.

8.11.1 (2324)
Comment - EIS000614 / 0011
The following issue needs to be addressed and thoroughly analyzed concerning direct impacts to Lander County in a detailed manner: the wilderness areas.

Response
Section 6.3.2.2.2 of the EIS provides a discussion of the Carlin Corridor implementing alternative, including potential impacts on land use and ownership and biological resources. Table J-42 indicates that the Steiner Creek Alternate of the Carlin Corridor pass close to, but not through, the Steiner Creek Wilderness Study Area. Results of discussions with the Bureau of Land Management indicated that the corridor would not have an impact on wilderness areas or Wilderness Study Areas if a branch rail line was built.

Comment - EIS000692 / 0004
On page 3-121 in the chapter on affected environment, the DEIS states that: "Rainbow Canyon is used for variety of recreational purposes and is a route for the Union Pacific Railroad." I'm sure that many ranchers down the canyon would be delighted with the description of their livelihood.

<u>Response</u>
The quote from Section 3.2.2.2 of the Draft EIS is correct. The EIS has been modified to include ranching as an existing land use of Rainbow Canyon in Section 3.2.2.2.1.

8.11.1 (2747)
<u>Comment</u> - EIS000641 / 0006
The third area is near and dear to my heart and probably a few others in here, it is called property, taking of. The corridor as marked on the map, every other mile will probably pass through a portion of private property. Now, will this just be condemned? Will the people be compensated? Will it be assessed as market value? Will it be assessed at the BLM [Bureau of Land Management] value of the neighboring properties? Those questions weren't answered to my satisfaction.

Recreation and ranching, land use. We have a tremendous amount of trails, access roads, Jeep trails, some you can even barely walk on, some horses break their legs on, but they are all trails and usable all the time. We put this quarter mile corridor through here, are these trails going to be blocked off and have limited access? I didn't find that addressed either. And if they are blocked off and limited access, then you have just taken a lot larger portion of the property away from the citizens of the area than the quarter mile corridor.

And that also holds true for the ranchers for their historical or their - not historical, I guess. They haven't been here long enough to be history. But their normal ways of moving their livestock and animals and moving from place to place on their rangeland, grazing land, grazing permits, et cetera.

The other one was the corridors. It doesn't address that either, whether the corridors will be fenced and whether these corridors, if they are fenced, who is going to police them. The fence is just a novelty if you don't have somebody back there to kick you out of it.

<u>Response</u>
As discussed in Section 2.3.3.1 of the EIS, DOE chose candidate rail corridors in Nevada to maximize the use of Federal lands (with the exception of U.S. Air Force-controlled lands), provide access to regional rail carriers, and minimize, to the extent possible, obvious land-use conflicts. As discussed in Section 6.3.2.2, all of the candidate branch rail lines would require the use of mostly Federal land and very little private land. For example, the Caliente and Valley Modified Corridors would require the use of almost no private land (less than 1 percent). The Carlin and Jean Corridors would require only 7 and 5 percent private land, respectively.

Regarding private property along the rail corridor, the DOE is required to use fair market value in the acquisition of real property. The DOE must comply with the policies contained in the Uniform Relocation Assistance and Real Property Acquisition Policies Act, Title III, which includes the provision that the Agency (DOE) offer just compensation.

DOE acknowledges the recreational resources afforded by open space within parts of Nevada. In Section 6.3.2 of the EIS, DOE identifies potentially affected natural resource areas within each corridor. DOE would seek to minimize any restriction to or control over public lands used for recreational purposes and would develop specific mitigation measures to alleviate potential impediments to continued use of public lands. A branch rail line could be constructed across a trail or road access. However, access would not be restricted with the exception of that portion where the actual roadbed was constructed. Access to either side of a valley traversed by a branch rail line would be possible. Sufficient crossing structures would be constructed to allow access from either side.

Land use and ownership impacts common to the construction and operation of all five of the branch rail lines are discussed Section 6.3.2.1 of the EIS and impacts specific to each route are discussed in the appropriate subsection. The EIS determines that a branch rail line could create a barrier to livestock movement, and quantitatively addresses the acres of grazing lands potentially affected by proposed rail corridors.

If a corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify specific land uses to be avoided. For example, access to grazing areas, forage, and water could be addressed in the early design phase of the rail corridor/alignment. This process would address Bureau of Land Management standard operating procedures for rights-of-way, construction, and operation. Water wells would be required along the rail corridor in some areas for soil compaction and dust control during rail construction. It could be possible to improve grazing allotments if the Bureau permitted the use of this water for grazing. Grazing allotment access could be accomplished by designing at-grade structures to permit cattle to cross underneath the railbed.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (2826)

Comment - EIS001056 / 0001

We have reviewed the proposed rail corridor to link the UP [Union Pacific Railroad] line located in Carlin, Nevada to the Yucca Mountain facility. We note that all possible routes must pass through our Forest Service and BLM [Bureau of Land Management] winter grazing allotments.

If this project is to be [implemented], there are several factors that must be addressed to minimize the effects it would have on our permit and also to [ensure] the safe passage of rail traffic on this line.

Due to the topography of the area, there are few watering locations for our livestock to water. This is especially evident in the Rye Patch Canyon and the Smokey Valley portions of our grazing allotment. It is [mandatory] and obvious for the safety of this rail line that it be fenced on both sides to prevent not only grazing cattle but the wild horse and antelope populations from derailing a shipment. Since it is not hauling a load of potatoes, I think that this would only be obvious to insure [ensure] safe passage.

For this reason it would impair the ability of our livestock to utilize our permit without adequate [trestles] or DOE installed watering locations on both sides of the line.

Response

Land-use and ownership impacts common to the construction and operation of all five of the branch rail lines are discussed Section 6.3.2.1 of the EIS and impacts specific to the proposed Carlin route are discussed in Section 6.3.2.2.2. The EIS determines that a branch rail line could create a barrier to livestock movement, and quantitatively addresses the acres of grazing lands potentially affected by candidate rail corridors.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

If a corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify specific land uses to be avoided. DOE would avoid land-use impacts and private land to the maximum possible extent. For example, access to grazing areas, forage, and water could be addressed in the early design phase of the rail corridor/alignment. This process would address Bureau of Land Management standard operating procedures for rights-of-way, construction and operation. Water wells would be required along the rail corridor in some areas for soil compaction and dust control during rail construction. It could be possible to improve grazing allotments if the Bureau permitted the use of this water for grazing. Grazing allotment access could be accomplished by designing at-grade structures to permit cattle to cross underneath the railbed.

<u>Comment</u> - EIS001195 / 0002
Because of the nature of our business and the required permitting processes, Cortez Gold Mines has extensively studied the physical environment in the area. As such, we have detailed geologic, hydrologic, and other information which may be of interest to DOE should the Carlin route be seriously considered. We would be willing to discuss and perhaps share this data with DOE to help avoid or mitigate potential impacts.

<u>Response</u>
DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and the Carlin Corridor selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use. Cortez Gold Mines would be a part of these consultations and studies for selection of the final rail alignment.

8.11.1 (3066)
<u>Comment</u> - EIS000619 / 0006
Because over 87 percent of our county is managed by the Bureau of Land Management, it seems that more input is required from that agency regarding the variety of impacts that the rail route could have on land and resources that they manage.

We were surprised to read in Appendix C that the Department only met once with BLM and that there are no ongoing communication or interactions mentioned regarding the Department's multi-faceted proposal.

We would hope that BLM would not hold the Department's proposed action to any lesser standard than they require of the mining and the ranching industries.

<u>Response</u>
In the course of preparing the EIS, DOE coordinated with a number of government agencies and other organizations, including the Bureau of Land Management, by conducting formal consultations as required by the National Environmental Policy Act. Appendix C of the EIS documents these interagency and intergovernmental consultations. Nonetheless, Appendix C does not include the many staff-level interactions that occurred between the Bureau and DOE and were necessary for the development of the EIS. Information exchanges have occurred frequently in the past and are ongoing. These range from DOE providing informal status reports to the Bureau providing Geographic Information System data for utility corridors.

Should the Yucca Mountain site be approved, the branch rail line implementing alternative be selected, and a preferred rail corridor identified, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (3164)
<u>Comment</u> - EIS001195 / 0001
Cortez Gold Mines is a large surface mining operation located in the southern end of Crescent Valley. Facilities and operations are located in both the eastern and western portions of the valley, with haulage and access roads linking both sides of the valley. Ancillary facilities include several infiltration basin galleries, some of which are located near the center of the valley. Attendant to the operations is a substantial private land position, along with numerous mining claims on public lands managed by the Bureau of Land Management. Part of our private land holding includes the 48,000 acre Dean Ranch, located in the center of the valley. The maps describing the Carlin rail corridor provided in the DEIS and those obtained at the December 9, 1999, public meeting in Crescent Valley depicts the corridor crossing portions of both the Dean Ranch and Cortez Gold Mines areas. Naturally, we are concerned about the impact that the rail corridor may have on our operations, land ownership, mining claims and future exploration.

Response
DOE is aware of the Cortez Gold Mines operation in Crescent Valley and has included a discussion of the mine area in Section 6.3.2.2.2 of the Final EIS. Table 8-1, Figure 8-5, and Sections 8.1 and 8.4 provide a discussion of the Cortez Gold Mines Pipeline Project and possible cumulative impacts.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

For any land that would be required, the Department would fairly compensate landowners under Federal acquisition procedures. DOE is required to use fair market value in the acquisition of real property. DOE must comply with the policies contained in the Uniform Relocation Assistance and Real Property Acquisition Policies Act, Title III, which includes the provision that the Agency (DOE) offer just compensation.

In other cases, as indicated in Section 9.3 of the EIS, mitigation measures would be developed where construction and operation of transportation facilities would result in (1) impacts to publicly used lands such as grazing allotments, (2) direct and indirect land loss, and (3) displacement of capital improvements.

8.11.1 (3166)
Comment - EIS001195 / 0004
As mentioned above, the [Carlin] corridor crosses a significant portion of our private lands and mining claims on public lands. Obviously, this raises several concerns related to right-of-way, access, land use, water rights, mining, exploration and agricultural activities such as grazing. We would expect DOE to work closely with us on resolving any conflicts that may arise in these areas.

Response
Section 6.3.2.2.2 of the EIS recognizes private and public land uses and lists the several Bureau of Land Management grazing allotments that could be affected, which includes 12 grazing areas, mining areas, and other land uses.

For any land that would be acquired, including mineral claims, landowners would be fairly compensated under Federal eminent domain procedures. When affected property was not acquired by eminent domain, mitigation measures would be evaluated and implemented as appropriate, as indicated in Section 9.3.1 of the EIS, when construction and operation of transportation facilities would result in (1) impacts to publicly used lands such as grazing allotments, (2) direct and indirect land loss, and (3) displacement of capital improvements.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and the Carlin Corridor selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (3526)
Comment - EIS000721 / 0003
The 1,400 page Department of Energy's Impact Statement contains many sections that can be considered either inadequate or incomplete.

Land use and strategic plans that guide area development have not been considered in the DOE program. Some routes actually dissect large planned developments.

Response
Section 3.2.2.1.1 discusses the estimated current ownership or control of the land in each candidate rail corridor. Plans and documents that contain detailed land-use information are listed.

Land-use and ownership impacts are included in Section 6.3.2.2 of the EIS for each of the corridors.

Maps of potential land-use conflicts are presented in Section J.3.1.2.

8.11.1 (4306)
Comment - EIS001160 / 0116
Page 9-16: Not considered among the land use mitigation measures considered here is the need for additional 'safe havens' for operators of legal weight and heavy haul trucks along Nevada highways. Additional land areas, and resources, especially security resources will need to be allocated for provisions of safe havens along any and all designated routes.

Response
Legal-weight trucks would follow existing rights-of-way and hence no mitigation measures would be required for safe parking areas. As described in Section M.3.2.1.3 of the EIS, safe parking areas would be identified by the Regional Servicing Contractor and would include DOE facilities and specific designated areas such as U.S. Department of Defense facilities and rail sidings (with railroad concurrence)

Section 9.3.1 of the EIS states that mitigation would not necessarily be required if a heavy-haul truck route was selected, because these trucks would follow existing rights-of-way and would require little additional land disturbance for safe parking.

The security for the vehicles in the safe parking areas would be the same as the security used en route (see Section M.7 of the EIS).

8.11.1 (4465)
Comment - EIS001232 / 0009
Will mining claims be divided and access be restricted?

Will the free access of the residents be restricted across the valley (across the tracks)?

Response
A branch rail line could be constructed across a mining claim. However, access to claims would not be restricted with the exception of that portion where the actual roadbed was constructed. Access to either side of a valley traversed by a branch rail line would be possible. Sufficient crossing structures would be constructed to allow access from either side.

8.11.1 (5150)
Comment - EIS001444 / 0002
Impacts to Range
Two rail routes to Yucca Mountain go through our planning area. If either of these routes are selected we would have larger impacts during construction than after the railroad is finished.

Impacts from construction:
It may become difficult for livestock to gain access to areas and waters on the opposite side of the new construction. Cattle may avoid using areas with construction activity or temporary camps making it difficult to manage livestock or rotate use. This disruption might continue in an allotment for months. Construction would make more work for permittees. More cattle may be killed on the highway and along roads used during construction.

Impacts from the finished project:
There would be a small loss of AUMs [animal unit months] in large allotments that are unlikely to impact the operation. The loss of AUMs in small allotments may impact the permittee's operation.

The BLM [Bureau of Land Management] would request fencing along the railroad line. Drainage underpasses might allow cattle access to the opposite side of the railroad. These underpasses would need gates to allow access. When fenced, the railroad would block access to the opposite side of the track. This would cause problems in areas with few waters requiring water hauling. The track would divide allotment into pastures that could be used to rotate use allowing for new grazing management options. This would benefit livestock and vegetation management.

The Caliente route comes in from Lincoln County into Reveille, Stone Cabin, Ralston, Montezuma and Razorback allotments. The new route from Caliente, the Caliente Chalk Mountain Rail Corridor, will not cross our planning area.

Reveille allotment. Goes through south end of Railroad Valley up Reveille Valley across the Kawich near the Highway. This would split Reveille Valley into two pastures. This provides some good opportunities for some complete rest of the range in this valley and southern Railroad Valley. Dividing Reveille provides opportunities for improved grazing management. Livestock waters are well distributed in Reveille. Water hauling may not be necessary in Reveille. There would be a small loss of AUMs that would not likely affect the permittee's operation.

Stone Cabin allotment Colvin and Son. Goes southwest along the west side of the Kawich to the Test Site boundary into Ralston Allot. The potential rail corridor would split Tom Colvin's portion of the Stone Cabin Allotment into two separate pastures. This could be useful to us for management purposes. We could develop a three pasture rest-rotation with the two pastures in Stone Cabin and a third in the Ralston Allotment. The railroad corridor would have to be fenced off to keep Tom Colvin's cattle off the railroad tracks. New waters will also need to be developed and underpasses will need to be available for access into the other portions of the allotment. There would be a small loss of AUMs that would not likely affect the permittee's operation.

Ralston allotment Colvin and Son. Goes along the test site boundary into Montezuma allot. There are currently no permanent permits issued in the Ralston Allotment. The potential rail corridor runs through South Ralston along the test site boundary fence.

The BLM has issued a Temporary Nonrenewable Permit in South Ralston adjacent to the proposed track. The track will not cut off access to water and will not effect the AUMs permitted. The railroad corridor will need to be fenced through this area to keep cattle off the tracks.

Montezuma allotment. Follows the east side of the allotment until Scotty's Junction, crosses the highway and back to go around Scotty's Junction. Continues down the corridor to Razorback.

Razorback allotment. (Plate 12, C, D & E, 1 & 2) At this time the permittee in Razorback is taking nonuse and will not be affected by the railroad. If in the future the rancher activates his permit the railroad will cut through the private land in Oasis Valley cutting off Coffer's ranch from the rest of the allotment. Water is available at the ranch. The area east of the ranch does not have water. There is some water available north of Oasis Valley on the Test Site. If the railroad is fenced, drainage underpasses should allow cattle access to water. The rancher may need to provide water on the northeast side of the allotment. The railroad will also cut off approximately 16 sections in the southwest end of the allotment. This includes Bare mountain and Specie Spring. No water is available on the remaining 30 sections of valley south of Yucca Mountain, east of the railroad. Drainage underpasses will provide some access to specie spring. Cattle may tend to overuse the west side of the railroad. Water should be provided on the east side of the railroad to alleviate any overuse on the west side.

The Carlin route has 3 different routes in our area. It starts in Beowawe goes into Lander County and splits at Hickison Summit. One route goes through Monitor Valley the other through Smoky Valley.

The Smoky Valley route cuts through Smoky, San Antone, Monte Cristo and Montezuma allotments. It meets the Caliente route south of Tonopah.

The Monitor Valley route cuts through Monitor, Ralston, San Antone and Hunts Canyon. It meets the Smoky route either north of the San Antone Mountains or south of Tonopah.

Smoky allotment. The route cuts through the center of the valley not along the road. Near Round Mountain it crosses the highway into Francisco.

Francisco allotment. (Plate 4, A & B4) There are two possible routes in Francisco. The southern route will follow the highway fence in the south pasture opposite Round Mountain approximately 3 1/2 miles then turning southwest for 2 miles cutting approximately 640 acres off of the southeast corner of Francisco near the alfalfa field. The route has no benefit to the livestock operation. The rancher will loose a small amount of AUMs if the track does not cut through the winterfat flats. However it appears that the track will go through one of the winterfat flats. The rancher will need a reduction of permitted AUMS. This route does not appear to cut the rancher off from developed waters. It may cut access off to the winterfat in the 640 acres in the southeast corner if no underpasses are put in.

The northern route will cut the north pasture in half making a east and west half. It will also divide the south pasture into east and west sides (40% east and 60% west). When the corridor is fenced, Francisco will be a 4 pasture allotment. This will allow for new grazing management options. Drainage underpasses could be used to move cattle in and out of pastures. There are few developed waters on the west side. This might cause some difficulties for the permittee. They will need to haul water to new pastures. Some forage may be lost to the new railroad right of way but it may not significantly effect the livestock operation if the railroad does not run through the winterfat flats. If the railroad does there may need to be a reduction of AUMs for the permit.

San Antone allotment. The Smoky valley route enters San Antone just south of Francisco allotment and travels south to the Cypress Mine and south near the paved road to the highway. The Monitor Valley route enters San Antone from the east just above the Cypress Mine and then follow the Smoky route south.
Monte Cristo allotment. The railroad would only cut off the far eastern corner of this allotment near Tonopah. This does not impact the livestock operation in Monte Cristo.

Montezuma allotment. The Carlin route would cut through the far northeastern corner of the allotment. The route then meets the Caliente route north of Goldfield and follows that route to Yucca Mountain.

Monitor allotment. The Monitor Valley route travels down the middle of Monitor Valley to just east of Belmont. At this point there is no permit on this allotment. In the future if use is permitted on Monitor the railroad will cut the allotment in half making a east and west pasture. When fenced this will make Monitor into a two pasture allotment allowing for new grazing management options. Drainage underpasses could be used to move cattle in and out of pastures. There may be a need to haul water to the new pastures. Some forage may be lost to the new railroad right of way but it will not significantly effect any future permit.

Ralston allotment-Stone Cabin Partnership and Colvin and Son. The Monitor Valley route runs through Ralston allotment from Belmont to north of the San Antone Mountains. The southern route runs east of highway 376 to the Test Site near Mud Lake where it meets the Caliente route. This route would split the two smaller pastures into four pastures. The railroad corridor would possibly cut off part of the Thunder Mountain use area. If this occurs there would be access to the west side of the tracks through underpasses. There may need to be a small reduction in AUMs permitted in Thunder Mountain depending on the actual location of the tracks. Thunder Mountain is used on a temporary basis only. There is no permit in Ralston at this time.

Hunts Canyon allotment-Stone Cabin Partnership. The Monitor route runs south through the middle of Hunts Canyon allotment. This route will divide the Hunt's Canyon Allotment into east and west pastures. When fenced this will allow new grazing management options. Drainage underpasses could be used to move cattle in and out of pastures. There may be a need to haul water to the new pastures. Some forage may be lost to the new railroad right of way but it will not significantly effect any future permit if the tracks do not run through the winterfat flats in the center of the allotment. A reduction in AUMs may be necessary if winterfat is lost. This may affect the livestock operation. New grazing management in Hunts Canyon may alleviate the need for the temporary non-renewable permit outside the allotment by allowing periodic rests on Hunts Canyon. Water haul sites and access routes under the corridor would need to be established to make the pastures useable.

Razorback allotment. See the Caliente route.

The Caliente route appears to be less disruptive to livestock operations than the Carlin route. The Caliente route follows the Test Site boundary farther than the Carlin route can. Since the test Site boundary is already fenced and only one side of the railroad may need to be fenced. The portion of both routes which run through Montezuma, south of Stonewall, along the east of Highway 95, is in an area that is little used by livestock and may not require any fencing. The Caliente route would have less of an impact on range operations in our Field Station. There would be less impact if the train follows the test site boundary closely. Then only one fence would need to be built.

Response
Land-use and ownership impacts common to the construction and operation of all five of the branch rail lines are discussed in Section 6.3.2.1 of the EIS and impacts specific to the proposed Caliente route are discussed in Section 6.3.2.2.1. Land-use impacts specific to the Carlin route are discussed in Section 6.3.2.2.2. The EIS determines that a branch rail line could create a barrier to livestock movement, and quantitatively addresses the acres of grazing lands potentially affected by candidate rail corridors.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

If a corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify specific land uses to be avoided. DOE would avoid land-use impacts and private land to the maximum possible extent. For example, access to grazing areas, forage, and water can be addressed in the early design phase of the rail corridor/alignment. This process would address Bureau of Land Management standard operating procedures for rights-of-way, construction and operation. Water wells would be required along the rail corridor in some areas for soil compaction and dust control during rail construction. It could be possible to improve grazing allotments if the Bureau permitted the use of this water for grazing. Grazing allotment access could be accomplished by designing at-grade structures to permit cattle to cross underneath the railbed.

8.11.1 (5154)
Comment - EIS001444 / 0007
The document does not identify what land use restrictions will be associated with the new 1/4 mile wide railroad. Will this restrict locatable/leasable minerals, surface occupancy, grazing, recreation, etc.?

The number of acres disturbed will be much greater than discussed in the document. A railroad grade and associated road will exceed the projections. This does not consider the number of acres that will be disturbed by construction and access.

Response
Land-use and ownership impacts common to the construction and operation of all five of the branch rail lines are discussed Section 6.3.2.1 of the EIS and impacts specific to each route are discussed in the appropriate subsections. Table 2-10 summarizes the amount of land that would be disturbed for each corridor. The EIS determines that a branch rail line could create a barrier to livestock movement, and quantitatively addresses the acres of grazing lands potentially affected by candidate rail corridors.

DOE acknowledges the recreational resources afforded by open space within parts of Nevada. In Section 6.3.2 of the EIS, DOE identifies potentially affected natural resource areas within each corridor. DOE would seek to minimize any restriction to or control over public lands used for recreational purposes and would develop specific mitigation measures to alleviate potential impediments to continued use of public lands.

For any land that would be acquired, including mineral claims, landowners would be fairly compensated under Federal eminent domain procedures. When affected property was not acquired by eminent domain, mitigation measures would be evaluated and implemented as appropriate, as indicated in Section 9.3.1 of the EIS, when construction and operation of transportation facilities would result in (1) impacts to publicly used lands such as grazing allotments, (2) direct and indirect land loss, and (3) displacement of capital improvements.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

If a corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify specific land uses to be avoided. DOE would avoid land-use impacts and private land to the maximum possible extent. Grazing allotment access could be accomplished by designing at-grade structures to permit cattle to cross underneath the railbed. It is possible that a branch rail line could be constructed across a mining claim. However, access to claims would not be restricted with the exception of that portion where the actual roadbed was constructed. Access to either side of a valley traversed by a rail branch line would be possible. Sufficient crossing structures would be constructed to allow access from either side.

8.11.1 (5160)
Comment - EIS001444 / 0013
The "Carlin" rail transportation corridor passes through Cortez Canyon and adjacent areas which have a high potential for containing valuable mineral deposits. The document indicates that no preferred transportation corridor has been selected and that if/when such specific routes are to be selected additional field surveys, resource analysis, consultation, and NEPA [National Environmental Policy Act] review will be initiated. Also, Appendix J indicates that one of the alternative routes associated with the "Carlin" corridor would circumvent the Cortez area. The document provides no detailed maps depicting the corridors and the potential for additional significant mineral development in the Cortez area is a real possibility and could pose a definite conflict with the proposed rail corridor.

There is no discussion of the Cortez Gold Mine in the discussion of the Carlin corridor.

Response
DOE is aware of the Cortez Gold Mines operation in Crescent Valley and has included a discussion of the mine area in Section 6.3.2.2.2 of the EIS. Table 8-1, Figure 8-5 (map), and Sections 8.1 and 8.4 provide a discussion of the Cortez Gold Mines Pipeline Project and possible cumulative impacts.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

For any land that would be required, the Department would fairly compensate landowners under Federal acquisition procedures. DOE is required to use fair market value in the acquisition of real property. DOE must comply with the policies contained in the Uniform Relocation Assistance and Real Property Acquisition Policies Act, Title III, which includes the provision that the Agency (DOE) offer just compensation.

In other cases, as indicated in Section 9.3 of the EIS, mitigation measures would be developed where construction and operation of transportation facilities would result in (1) impacts to publicly used lands such as grazing allotments, (2) direct and indirect land loss, and (3) displacement of capital improvements.

8.11.1 (5394)
Comment - EIS001887 / 0102
Page 2-47; Section 2.1.3.3.2 - Nevada Rail Scenario

DOE's rail corridor selection study is flawed. The first selection criteria used by DOE to select potential routes was land use compatibility. For this criteria, DOE selected corridors based upon using "land under public ownership, to the greatest extent possible, to minimize land-use conflicts." Favorable topography was used as a selection criteria only within "areas not excluded because of land-use conflicts" (Nevada Potential Repository Preliminary Transportation Strategy, Study 1, April 1995, page 25).

There are serious problems with this approach. Land ownership does not accurately reflect land-use. Most western ranching operations are based upon a combination of privately owned fee land and grazing leases on publicly owned lands. In many, if not all cases, the ranching unit depends on these grazing leases to be economically viable. Most grazing leases are held by the ranches that can access the lease as a logical part of their operation. Splitting an existing operation with a rail line that will limit access to the leased land can have significant adverse effects on the operation of the ranch. Using the avoidance of privately owned land as the corridor selection process without regard to the existing ranching operations' use of private and public lands may very well result in greater impact on an operation than using private land.

Most of the private land in western States with high percentages of federally owned land is land with gentle topography. Early settlers selected the flatter land for their own. The land with rugged topography was not settled and remained in public ownership. This shift to rugged terrain to avoid private land is a dominant factor in most of the routes selected for further study in the 1990 Preliminary Rail Access Study, as reflected by the following: "An option was selected from the Caliente area in order to avoid land use impacts encountered in most of the southern areas of Nevada.... The base route has the most favorable land-use compatibility, but would incur significant costs due to the complex engineering and construction required to traverse rough terrain" (page 17). "However, the checkerboard pattern of private and public land ownership surrounding the railroads across northern Nevada makes the complete avoidance of private land difficult. The minimum impact departure point is a location about 5 miles west of Carlin. The terrain in this area is so rugged that private developers were uninterested in the land, and as a result, the greater portions of the terrain were left in BLM [Bureau of Land Management] ownership" (page 21).

By using land ownership for the first selection criteria, DOE's selection process actually favored more rugged terrain where construction of the proposed rail line is more difficult. This creates many additional land-use impacts due to the extensive cuts and fills required by unfavorable topography. These cuts and fills will further exacerbate the problem faced by ranchers in moving livestock and equipment across the rail line.

Response
Sections 2.1.3.3 and 2.3.3 of the EIS describe the methods used to select and describe the proposed alternative routes and modes for transportation in Nevada. Section 6.3 describes the potential impacts for these routes and modes.

DOE's objective, with respect to rail corridors, was to identify reasonable and representative 400-meter (0.25-mile)-wide corridors that would produce the least environmental and stakeholder impact based on published environmental and land-use data. Another consideration was to evaluate corridors that are cost-effective (for example, balancing cut and fill to the extent possible).

In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example, as discussed in Chapter 6, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. By providing these mitigating measures, the impacts would be lessened and considered small. If an action could result in departures from existing uses, and mitigation could not remedy the conflict, the effects could be more substantial.

Factors considered included the uniqueness of a geographic area; presence of historic, scientific, and cultural resources; potential effects on endangered species; and compliance with Federal, State, or local law. Based on information available, potential land-use impacts associated with Yucca Mountain transportation activities could be minimized through judicious alignment of the branch rail line or through mitigation. Overall, the land-use impacts would not be substantial due to the use of various optional and alternate routes within the corridor, mitigation measures, and the judicious routing of the branch rail line within the corridor.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (5396)
Comment - EIS001887 / 0104
Page 2-47, Section 2.1.3.3.2

Roadless areas are also more likely to be found in rugged terrain. Virtually all potential wilderness areas are located on public lands. The selection criteria that avoids private lands results in more potential impact to roadless areas and potential wilderness areas.

Response
Sections 6.3.2.1 and 6.3.2.2 of the EIS discuss the common impacts that could be caused by the construction and operation of branch rail lines in Nevada and the specific impacts that would occur for specific branch rail line alternatives, respectively. Although the candidate rail corridors pass through some roadless areas, Tables J-41 through J-45 list the variations for each of the corridors and describe potential conflicts, including those for wilderness study areas. For example, Table J-45 lists the two wilderness study areas involved in the Valley Modified Corridor as recommended by the Bureau of Land Management as “not recommended for Wilderness” designation.

In some instances, mountainous terrain could not be avoided with candidate corridors due to the fact that the majority of the mountains in Nevada are oriented in a north-south direction. Whenever possible, mountainous terrain was avoided for construction or operational purposes (speed and maintenance) and cost-effectiveness.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (5489)
Comment - EIS001660 / 0024
The DEIS fails to analyze impacts of the proposed action on agriculture in Nevada. Some residents of Mineral County depend on agriculture for their livelihoods. The BLM [Bureau of Land Management] administers numerous grazing allotments that are leased to Mineral County ranchers. The DEIS must disclose the impacts upon Mineral County agriculture of: (1) construction and operation of access roads and railroads, (2) introduction and spread of noxious weeds, (3) increased risk of wildfire, and (4) increased risk to animals. The DEIS must address both the short-term construction impacts and the longer-term impacts upon the range.

Response
DOE does not expect any direct impacts to Mineral County because none of the candidate rail corridors, legal-weight truck routes, or heavy-haul truck routes pass through the County (see Figures 6-13, 6-14, and 6-20). The closest branch rail line would be the Carlin Corridor, which lies to the east in Nye County.

Similarly, because DOE does not anticipate that transportation or Yucca Mountain Repository workers would reside in Mineral County, it does not believe there would be discernible influences on the county's land-use and community development.

8.11.1 (5511)
Comment - EIS001660 / 0030
The DEIS fails to adequately address the impacts of the proposed action on land use and community development in Mineral County. Mineral County (MC) will be promoting tourism. One area for tourism is hiking and outdoor activities.

Another consideration for MC's land would be to have a private prison in an area close to one of the possible routes. Issues of concern to Mineral County residents include: (1) the protection of private property rights and value of land assets; (2) the fiscal, agricultural, and groundwater impacts from parcelization of land; and (3) the need to acquire land from the BLM [Bureau of Land Management] for community expansion, to increase the amount of private land, and to erase restrictions on the use of federal lands. The DEIS fails to describe impacts on Mineral County's land use and community development, and does not evaluate whether the proposed action conflicts with its policies. The DEIS does not adequately address the potential effects that this project could have on property values within Mineral County. Since agriculture is one of Mineral County's economic producers, the nuclear stigma could affect not only property values, but also crop prices. Such stigma could stymie Mineral County's efforts to diversify the local economy, retain existing businesses, and attract new businesses to the county. The DOE seems to assume that land uses of rural communities are not significant, while land uses by federal agencies are. The DEIS must disclose and evaluate: (1) the DOE's planned use of eminent domain to take private land for transportation routes and rail corridors; (2) the effect of the proposed action on private property values, including the perceived risk and stigmatization and the effects of improved or restricted access to private property; and (3) the potential growth-effects of the proposed action, and whether it would result in additional parcelization of private land.

Response
DOE does not expect any direct impacts to Mineral County because none of the candidate rail corridors, legal-weight truck routes, or heavy-haul truck routes pass through the County (see Figures 6-13, 6-14, and 6-20). The closest branch rail line would be the Carlin Corridor, which lies to the east in Nye County.

Similarly, because DOE does not anticipate that transportation or Yucca Mountain Repository workers would reside in Mineral County, it does not believe there would be discernible influences on the county's land-use and community development.

8.11.1 (5569)
Comment - EIS001887 / 0196
Page 3-100; Section 3.2.2.1.1 - Land Use and Ownership

The definition of region of influence for land use is too narrow. Impacts to land use may occur that do not result in a change of ownership or use. For example, bisecting a ranch with a rail line will have substantial impacts on that operation. It will be difficult for the rancher to move equipment and livestock from one side of the rail line to the other. Because of the difficulty in operating the ranch that is now split into two pieces, the value of the ranch will be reduced. This will have significant impact on the rancher without changing the ownership or the use of the land. The region of influence for land use should include all of the land under the ownership or lease of agricultural operations that will be crossed. (Note: this same discussion applies to the intermodal transfer station and heavy-haul routes.)

Response
Section 3.2.2.1.1 of the EIS does state that area disturbed and change in land ownership were criteria used in evaluating land use. However, Section 3.2.2 describes in more detail the information and data collected about the

alternative transportation routes in Nevada. The Department's objective, with respect to rail corridors, was to identify reasonable and representative 400-meter (0.25-mile)-wide corridors that would produce the least environmental and stakeholder impact based on published environmental and land-use data. Another consideration was to evaluate corridors that are cost-effective (for example, balancing cut and fill to the extent possible).

In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example, as discussed in Chapter 6, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. By providing these mitigating measures, the impacts would be lessened and considered small. If an action could result in departures from existing uses, and mitigation could not remedy the conflict, the effects could be more substantial.

DOE is aware that a rail corridor would have impacts to ranching, recreational uses, and other activities and has described those potential impacts for the alternative rail corridors for legal-weight trucks in Section 6.3.2 of the EIS and 6.3.3 for heavy-haul trucks.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (5693)
Comment - EIS001887 / 0308
Page 6-8 to 6-9; Section 6.1.2.1 - Land Use

DOE has not accurately identified or assessed the land use impacts of the Nevada transportation alternatives. Even where DOE has identified land use impacts, DOE has understated the nature and severity of the impacts. The failure by DOE to accurately describe the Proposed Action also prevents an adequate assessment of land use impacts. For example, the land use impacts associated with the development of ballast and sub-ballast quarries, solid waste disposal facilities, construction lay-down areas, and construction staging areas cannot be assessed until these areas are identified.

The conclusions regarding land use impacts in the Draft EIS rely primarily on disturbed acreage. Although this is one measure of land use impacts, it is not the only one. For linear facilities such as a branch rail line, an assessment of land use impacts should also include an evaluation of the impacts of bisecting current and future land uses. As discussed above in the comment on Section 2.1.3.3.2, Nevada Rail Scenario, splitting an area with a branch rail line can have significant impacts on the entire area, not just the area within the right-of- way. This is particularly true for ranching operations. DOE has not assessed this type of land use impact in the Draft EIS.

DOE has identified a number of land use conflicts with the proposed rail line, but has not accurately characterized the impact of these conflicts. For example, potential rail corridors cross the Simpson Park Habitat Management Area (Carlin), the Old Spanish Trail/Mormon Road special recreation management area (Jean), Wilderness Study Areas (Valley Modified), and the Desert National Wildlife Range (Valley Modified). A rail line through these special land use areas would have significant impact on the purpose of these special areas. The EIS does not even discuss these impacts. It is particularly difficult to understand why DOE has not eliminated the Caliente Chalk Mountain alternative. The U.S. Air Force has unequivocally stated that this alternative is unacceptable due to its impacts on the Nellis Air Force Range.

Proposed rail line corridors also cross areas of potential future community growth. Although DOE identifies these areas, the Draft EIS does not contain an assessment of the impacts of this conflict on future community growth patterns. The area of particular concern is the impact of the proposed Valley Modified route on growth in the north Las Vegas urban area.

Many of the areas crossed by potential rail corridors are currently remote, undeveloped areas. Much of the area is currently roadless, including Wilderness Study Areas. Regardless of the decision by the land management agency regarding classification as wilderness, construction of a rail line through a remote, roadless area will have land use impacts. These changes in land use should be identified and assessed.

From a land use perspective, the only rail alternative that does not have serious land use conflicts is the Caliente corridor. Even this corridor could impact the Nellis Air Force Range. All other rail alternatives cross or impact areas designated as special purpose land use. These conflicts are summarized below:

[Please see document image file to view table.]

DOE lists the Caliente/Chalk Mountain corridor as a non-preferred alternative, based upon the Air Force's statement that no route that traverses Nellis Air Force Range is acceptable. Based upon this comment, the route (and the associated heavy-haul route) should have been eliminated from the alternatives included in the Draft EIS and listed in Section 2.3 as an alternative considered but eliminated from detailed study.

Response

Sections 6.3.2.1 and 6.3.2.2 of the EIS address the potential common and specific impacts of Nevada rail implementing alternatives, respectively, including land-use impacts. In an effort to provide decisionmakers and stakeholders with the information needed to make a rail or heavy-haul truck transportation decision for Nevada, regions of influence were developed and the level of information needed within those regions defined.
In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example, as discussed in Section 6.3.2.1, the EIS determines that a branch rail line could create a barrier to livestock movement, and quantitatively addresses the acres of grazing lands potentially affected by rail corridors. However, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. By providing these mitigating measures, the impacts would be lessened and considered small. If an action could result in departures from existing uses, and mitigation could not remedy the conflict, the effects could be more substantial. Factors considered when assessing impacts included the uniqueness of a geographic area; presence of historic, scientific, and cultural resources; potential effects on endangered species; and compliance with Federal, State, or local law.

As described in the introduction to Chapter 6, in response to interest and suggestions by the public and to better describe potential impacts of transportation alternatives in Nevada, DOE modified analyses and presentations of impacts in the EIS. For example, additional details, when available, and evaluations are included for wilderness study areas, grazing allotments, sensitive biological resources, management areas, cultural resources, and hydrologic resources.

Section 6.3.2.2.5 of the EIS describes the impacts from construction and operation of the Valley Modified Corridor Implementing Alternative. The land-use discussion has been expanded and discusses the relationship of the Sheep Mountain Alternate and the Wilderness Study Areas raised by the commenter. In addition, a new subsection has been added to Section J.3.1.2 that presents potential land-use conflicts. Figure J-20 shows the Quail Springs Wilderness Study Area and the Nellis A, B, and C Wilderness Study Areas in relation to the Valley Modified Corridor.

In comments on the Draft EIS, the Air Force restated its position that routes across the Nevada Test and Training Range would not be consistent with its national security uses. The Air Force concluded that use of such a corridor or route could adversely affect critical and sensitive national security activities. In response, DOE reevaluated whether the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route should be eliminated from further evaluation. DOE met with the Air Force (see Appendix C of the EIS), considered the information they provided, and concluded that the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route implementing alternatives should remain identified as "nonpreferred alternatives" in this Final EIS.

DOE believes, however, that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. In addition, the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (5729)
<u>Comment</u> - EIS001887 / 0335
Page 6-43; Section 6.3.2.1 - Impacts Common to Nevada Branch Rail Line Implementing Alternatives
Land Use and Ownership: The Draft EIS fails to adequately evaluate potential land use impacts for the various rail spur alternatives. Table 1 below shows the land use conflicts that should have been fully studied:

[Please see document image file to view table.]

<u>Response</u>
Section 6.3.2.1 of the EIS describes the impacts common to the five branch rail line implementing alternatives. As discussed in Section 2.3.3.1, DOE chose candidate rail corridors in Nevada to maximize the use of Federal lands (with the exception of lands controlled by the Air Force), provide access to regional rail carriers, and minimize, to the extent possible, obvious land-use conflicts. As discussed in Section 6.3.2.2, all of the candidate branch rail lines would require the use of mostly Federal land and very little private land. For example, the Caliente and Valley Modified Corridors would require the use of almost no private land (less than 1 percent). The Carlin and Jean Corridors would require only 7 and 5 percent private land, respectively.

In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example, as discussed in Chapter 6, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. By providing these mitigating measures, the impacts would be lessened and are considered small.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (5760)
Comment - EIS001887 / 0363
Page 10-6; Section 10.1.2.1 - Land Use

The Draft EIS assumes that 0.04 square kilometers could be needed to construct a bypass near Beatty. The Draft EIS ignores the fact that at least two other locations will also require bypasses - Tonopah and Goldfield.

Response
As indicated in Section 6.3 of the EIS, DOE believes a new section of road would be required near Beatty, Nevada, to accommodate potential heavy-haul truck traffic. The road would be required because of the severity of road turns in the existing roadway. Based on the engineering studies that DOE has conducted, however, DOE does not believe new sections of road or bypasses would be required in Tonopah and Goldfield. The existing roadways could be sufficiently upgraded to accommodate the heavy-haul truck traffic.

8.11.1 (5989)
Comment - EIS001879 / 0014
Not only does the Draft EIS underestimate the radiological risk of routine transportation through rural communities along US-95, it also provides an incomplete assessment of the potential effects of routine transportation of highly radioactive wastes through these communities over a 30-40 year period. Specifically, the Draft EIS does not address the potential effects of such transport on the value of commercial and residential properties along the transportation routes, or the potential effects on visitors and travelers to patronize lodging along the transportation routes. The EIS must address the potential impacts of this lost socioeconomic opportunity.

Response
Based on the results of the impact analyses presented in Chapter 6 and Appendix J of the EIS, as well as the results published in numerous other studies and environmental impact analyses cited in the EIS, DOE is confident that spent nuclear fuel and high-level radioactive waste can be and would be safely transported to Yucca Mountain. DOE believes, as the EIS reports, that the potential impacts of this transportation would be so low for individuals who live and work along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured. The analysis presented in the EIS factored in the characteristics of spent nuclear fuel and high-level radioactive waste, the integrity of shipping casks that would be used in transport, and the regulatory and programmatic controls that would be imposed on shipping operations (see Appendix M). The EIS analytical results are supported by numerous technical and scientific studies which have been compiled through decades of research and development by DOE and other Federal agencies of the United States, including the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as by the international community, including the International Atomic Energy Agency.

Regarding the potential for economic impacts along routes that shipments would use, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents,

which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.11.1 (6645)
Comment - EIS001878 / 0034
The land use descriptions for the rail corridors in Nevada are inadequate. (p. 3-101 to -103) The land use regions of influence are narrowly drawn (limited only to disturbed lands and changes in ownership), and the only information provided for the Carlin corridor (for example) is the amount of public and private land. Although the DEIS says that "detailed information on land use is available" in other documents, it fails to describe their contents even briefly, as required by 40 CFR 1502.21. According to testimony before the DOE at the Crescent Valley public hearing on December 9, 1999, the description in the DEIS of existing land uses is inadequate and inaccurate. On page 6-61, the DEIS names two towns, Gold Acres and Tenabo, that are not presently inhabited, witnesses said.

Response
Section 3.2.2.1 of the EIS provides the baseline environmental information for assessing the potential impacts of implementing Nevada rail implementing alternatives. The more notable land-use features and potential influences that exist or could exist on lands within the corridors are presented in Chapter 6. For example, the land features within the Carlin Corridor are presented in Section 6.3.2.2.2.

The listing of communities in Section 6.3.2.2.2 of the EIS served two purposes: (1) to identify potentially affected communities, and (2) as map references points. Gold Acres and Tenabo are historic reference points in the vicinity of the Carlin Corridor.

In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example, as discussed in Chapter 6, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. By providing these mitigating measures, the impacts would be lessened and considered small. If an action could result in departures from existing uses, and mitigation could not remedy the conflict, the effects could be more substantial. Factors considered included the uniqueness of a geographic area; presence of historic, scientific, and cultural resources; potential effects on endangered species; and compliance with Federal, State, or local law.

As described in the introduction to Chapter 6, in response to interest and suggestions by the public and to better describe potential impacts of transportation alternatives in Nevada, DOE modified analyses and presentations of impacts in the EIS. For example, additional details, when available, and evaluations are included for wilderness study areas, grazing allotments, sensitive biological resources, management areas, cultural resources, and hydrologic resources.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (6679)
Comment - EIS001878 / 0051
The DEIS fails to analyze impacts of the proposed action on agriculture in Nevada and specifically Eureka County. Many residents of Eureka County depend on agriculture for their livelihoods. The BLM [Bureau of Land Management] and the U.S. Forest Service administer numerous grazing allotments that are leased to ranchers in Eureka County and neighboring counties. The DEIS says that the Carlin corridor would cross 12 allotments, that

construction of the rail line would require "conversion of land" within those allotments, but that "functionality" would not be affected. (p. 6-61) These statements are vague and unsupported by any evidence.

The DEIS must disclose the impacts upon Eureka County agriculture of: (1) conversion of water rights or agricultural land to other uses, (2) fragmentation of range or grazing allotments, (3) damage to forage from land disturbance, introduction of weeds, increased wildfire, or other factors, (4) restrictions on livestock movement, (5) loss of water supplies, or restricted access to water supplies, (6) loss of livestock hit by trains or other motor vehicles, and the associated public safety implications, (7) changes in value of agricultural lands or permits, (8) changes in the costs of agricultural production, and (9) increases in harassment of livestock. The impact analysis must address both construction and operation of fences, water wells, the railroad bed and tracks, and access roads along and perpendicular to the tracks. The DEIS must also disclose whether fragmentation of grazing allotments or changes in values of agricultural lands and associated appurtenances would be a taking of private property rights requiring compensation under the Constitution of the United States.

Regarding fences, testimony at the public hearing before the DOE at Crescent Valley on December 9, 1999, indicated that numerous railroad right-of-way fences were destroyed during recent range fires in Eureka County and neighboring counties, and that requests by the Board of Eureka County Commissioners to the railroads to repair the fences have not been filled. Thus, the DEIS must disclose how fences will be maintained, as well as the possible impacts on agriculture from poorly maintained right-of-way fences.

Response
Section 6.3.2.2.2 of the EIS discusses the potential impacts specific to the Carlin Corridor. For example, the land-use section lists the 12 grazing allotments that the corridor crosses. The EIS determines that a rail line could create a barrier to livestock movement, and quantitatively addresses the acres of grazing lands potentially affected by candidate rail corridors.

If the Carlin Corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify specific land uses to be avoided. DOE would avoid land-use impacts and private land to the maximum possible extent. For example, access to grazing areas, forage, and water could be addressed in the early design phase of the rail corridor/alignment. This process would address Bureau of Land Management's standard operating procedures for rights-of-way, construction and operation. Water wells would be required along the rail corridor in some areas for soil compaction and dust control during rail construction. It could be possible to improve grazing allotments if the Bureau permitted the use of this water for grazing. Grazing allotment access can be accomplished by designing at-grade structures to permit cattle to cross underneath the railbed. DOE would be responsible for track maintenance, including fencing.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (6691)
Comment - EIS001878 / 0060
The DEIS fails to adequately address the impacts of the proposed action on land use and community development in Eureka County. (pp. 6-36, -43, -44, -60) Impacts on land use would extend far beyond a 60-meter construction zone or a 400-meter corridor with construction camps. (p. 6-44) Almost 60 percent of the assessed private parcels of land in Eureka County are within 10 miles of the Carlin rail corridor, which would affect 1,730 acres of private land along its length. (p. 6-7) (See Exhibit G.) County residents also use public lands for mining, agriculture, and other

uses. Eureka County's Master Plan (January 1997) and its Land Use Element (July 1998) identify land use issues of concern to county residents, including (among others):

- The protection of private property rights and the value of land assets;
- The fiscal, agricultural, and groundwater impacts from parcelization of land; and
- The need to acquire land from the BLM [Bureau of Land Management] for community expansion, to increase the amount of private land, and to ease restrictions on the use of federal lands.

The goals and policies of the Land Use Element:

- Discourage federal actions that threaten to impair the use or value of private property rights;
- Encourage the transfer of public land to private ownership; and discourage transfer of private land to public ownership.

The DEIS fails to describe the Eureka County Master Plan and its land use element, and fails to evaluate whether the proposed action conflicts with its policies. The DOE appears to assume that land uses of rural residents are not significant, while land uses by federal agencies are. The DEIS must disclose and evaluate: (1) the DOE's planned use, if any, of eminent domain to take private land for the rail corridor, (2) the effect of the proposed action on private property values, including the effects of perceived risk and stigmatization and the effects of improved or restricted access to private property, and (3) the potential growth-inducing effects of the proposed action, and whether it would result in additional parcelization of private land. The DEIS must also disclose whether changes in values of private lands affected by a rail corridor would be a taking of private property rights requiring compensation under the Constitution of the United States.

Response
DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. In addition, the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative and the Carlin Corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

Specifically, Section 6.3.2.2 of the EIS notes that the branch rail lines would require conversion of land within existing grazing allotments. DOE expects the potential impacts of construction to have a greater effect upon grazing lands than would operations. During the construction phase, it could be difficult for cattle to access water if the construction zone divided the grazing allotment. Construction activity and temporary camps with the presence of construction crews could result in disrupting ranch operations and livestock rotations. There is a possibility that some livestock could be killed along roads used during construction.

DOE, however, expects that after construction, operational impacts would be less even though the branch rail lines could divide some grazing lands. Input received by DOE from the Bureau of Land Management indicates that dividing grazing lands would result in a small loss of animal unit months in large allotments but would be unlikely to affect ranch operations. The loss of animal unit months in small allotments could affect the grazing permittee's operation. The Bureau also indicated that if a branch rail line divided an allotment into separate pastures, such pastures could provide an opportunity to rotate grazing area use, allowing for new grazing management options. This opportunity could benefit livestock and vegetation management.

If the Carlin Corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify specific land uses to be avoided. DOE would avoid land-use impacts and private land to the maximum possible extent. For example, access to grazing areas, forage, and water could be addressed in the early design phase of the rail corridor/alignment. This process would address Bureau of Land Management standard operating procedures for rights-of-way, construction and operation. Water wells would be required along the rail corridor in some areas for soil compaction and dust control during rail construction. As indicated in Section 9.3.1 of the EIS, DOE would evaluate appropriate mitigation actions that specifically address access to publicly owned lands, including grazing permits and leases. These actions could include providing access to lands on both sides of a branch rail line with underpasses and assisting in providing water should there be a need. It could be possible to improve grazing allotments if the Bureau permitted the use of this water for grazing.

Regarding private property along the rail corridor, DOE is required to use fair market value in the acquisition of real property. DOE must comply with the policies contained in the Uniform Relocation Assistance and Real Property Acquisition Policies Act, Title III, which includes the provision that the Agency (DOE) offer just compensation.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.11.1 (6702)
Comment - EIS001878 / 0068
The DEIS fails to address the impacts of the proposed action on recreation in Eureka County and neighboring counties. Residents of Eureka County, as well as residents of other parts of Nevada and other states, rely on open spaces within the county for its unique recreation opportunities, including camping, hunting, fishing, nature study, history study, back country travel, horse pack trips, and sightseeing. Eureka County and its neighboring counties include large unspoiled areas that could be affected, directly or indirectly, by the proposed action.

The DEIS must analyze the anticipated impacts of the proposed action on recreation. Specifically, the DEIS must consider the impacts of: (1) constructing and operating a raised railroad bed and access road through back country areas and hunting ranges, (2) constructing and operating roads connecting the rail corridor to resources such as borrow pits, (3) constructing fences, (4) restricting or improving access to the back country, (5) direct and indirect damage to recreational, historical, and natural resources, and (6) direct and indirect impacts on fish and game.

The DEIS says, “Each corridor has areas the public uses and areas available for sale and transfer. As a consequence, the rail line could result in limited access to areas currently in use by the public.” (p. 6-44) Does this mean that areas traditionally available for outdoor recreation, including hunting and fishing, will be off limits? Does it mean that a person would need permission from the DOE or the rail operator to have access to such areas?

Response
DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative and the Carlin Corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

DOE acknowledges the recreational resources afforded by open space within parts of Nevada. In Section 6.3.2 of the EIS, DOE identifies potentially affected natural resource areas within each rail corridor. DOE would seek to minimize any restriction to or control over public lands used for recreational purposes and would develop specific mitigation measures to alleviate potential impediments to continued use of public lands.

A branch rail line could be constructed across a trail or road access. However, access would not be restricted with the exception of that portion where the actual roadbed was constructed. Access to either side of a valley traversed by a rail branch line would be possible. Sufficient crossing structures would be constructed to allow access from either side.

8.11.1 (6986)
Comment - EIS002068 / 0003
One question I have is what happens to the mineral and Steam rights etc? Personally I think the Mineral etc rights should still belong to the owners of the land at the time of the Sale to the Gov.

Response
Sections 6.3.1, 6.3.2, and 6.3.3 of the EIS address the potential impacts of Nevada legal-weight truck, heavy-haul truck, and branch rail line implementing alternatives, respectively, including land-use impacts. These sections recognize and describe the impacts related to rights-of-way acquisition for branch rail lines and developing or upgrading highways. The Department is interested in acquisition of rights-of-way or land withdrawal from public and private land only for constructing and operating a branch rail line or expanding existing roads for heavy-haul trucks. The acquisition of mineral or steam rights would not be sought.

8.11.1 (7150)
Comment - EIS001337 / 0047
The County [Lincoln] and City [Caliente] urged DOE to assess rail construction related losses in forage for livestock grazing. While the DEIS recognizes that some forage might be lost and that livestock movements might be impeded, no estimate of lost animal unit months (AUM’s) of forage is provided within the DEIS.

Response
Because definitive information is not available on specific tracts of land that could be required in a given transportation alternative, DOE did not quantify potential impacts to animal unit months. Input received from the Bureau of Land Management, however, indicated that dividing grazing lands would result in a small loss of animal unit months in large allotments but would be unlikely to affect ranch operations. The loss of animal unit months in small allotments could affect a permittee’s operation. The Bureau also indicated that if a branch rail line divided an allotment into separate pastures, this could provide grazing management options, potentially benefiting livestock and vegetation management.

8.11.1 (7212)
Comment - EIS001337 / 0092
Page 3-101 Table 3-33. This table does not appear to reflect Bureau of Indian Affairs lands that would be crossed in the vicinity of U.S. 95 north of Las Vegas.

<u>Response</u>
Table 3-33 of the EIS does not include the Bureau of Indian Affairs lands referred to in this comment because the DOE analysis was limited to lands within the candidate rail corridors. However, Figure 3-1 does recognize lands controlled by Native American tribes in Nevada.

Section 6.3.2.2.5 of the EIS indicates that the Valley Modified Corridor would pass within about 1.6 kilometers (1 mile) of the Las Vegas Paiute Indian Reservation north of Las Vegas.

8.11.1 (7237)
<u>Comment</u> - EIS001337 / 0119
Page 8-87 Section 8.4.2.1. This section should recognize that before the Caliente Intermodal site could be used by DOE the existing City of Caliente wastewater treatment facilities would have to be relocated. A site for such relocation would need to be obtained by DOE.

<u>Response</u>
Section 6.3.3.2.1 of the EIS acknowledges that the northern site includes an existing wastewater treatment plant. The EIS has been revised by stating that a transfer of property from the Bureau, the City of Caliente, or other entities to DOE would be required.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Nonetheless, should the heavy-haul truck implementing alternative be selected for transporting large rail casks to the Yucca Mountain site, and the Caliente Route implementing alternative be identified as preferred, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including location of facilities.

8.11.1 (7416)
<u>Comment</u> - EIS001912 / 0011
Lander County is opposed to the Crescent Valley rail alternative. The lack of proposed mitigation, limited impact analysis, and failure to consult appropriate land management agencies brings into question DOE's commitment to building a transportation facility which adequately protects public health and implement mitigation which eliminates the radiological risks again imposed on Nevada communities.

<u>Response</u>
DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

With regard to risk reduction and mitigation, DOE is committed to protecting human and environmental health as its first priority. Transportation of spent nuclear fuel and high-level radioactive waste would be conducted and risks would be managed in accordance with Federal regulations. DOE would consider the costs and benefits of additional protective and mitigative measures as more detailed transportation planning and studies are conducted to support the proposed repository. Section 9.3 of the EIS discusses potential measures under consideration by DOE to mitigate the impacts of transporting spent nuclear fuel and high-level radioactive waste to the proposed repository.

Appendix C of the EIS presents a list of Federal, state, local, and tribal government agencies and other organizations with which DOE has initiated interactions during the preparation of the EIS. As stated in Section C.2.4, Lander County is one of the units of local government that has been offered the opportunity to submit documents providing perspectives of issues associated with the EIS. DOE has held formal meetings twice a year with the affected units of local government.

8.11.1 (7453)
Comment - EIS001969 / 0009
The need for rights of way across public lands to access the Yucca Mountain Facility could create conflicts with existing land uses in the area through traffic, construction, accidents and incidental spillage of nuclear materials containers. How will these be addressed?

Response
Sections 6.3.1, 6.3.2, and 6.3.3 of the EIS address the potential impacts of Nevada legal-weight truck, heavy-haul truck, and branch rail line implementing alternatives, respectively, including land-use impacts. These sections recognize and describe the impacts related to construction and operation of branch rail lines and developing or upgrading highways, including traffic impacts. Section 6.2.4.2 addresses impacts from accidents, including spills.

DOE acknowledges that some land-use conflicts could be inevitable during the construction and operation of a transportation corridor for the Yucca Mountain Repository. The implementing alternatives for transportation described in the EIS were based in part on attempts to avoid or minimize potential land-use conflicts.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (7518)
Comment - EIS001912 / 0049
Section 3.2.2.1. The Baseline Description in the DEIS does not provide for the following:

- Outdoor recreation use
- Appropriate visual analysis including visual characteristics of surrounding lands.
- Specific land uses residential, commercial, agricultural
- Mining claims and activity-patented mining claims
- Grazing-allotment, name of permit holder, season of use, total aums

Land use maps showing types of ownership and uses along the routes should be included in the DEIS. Simply referencing other BLM [Bureau of Land Management] documents is not sufficient. Lander County is not in the Tonopah Resource Area. All of the aforementioned resources and uses need to be shown on maps with discussion of various resources. Did any DOE staff or contractors actually visit the areas along proposed routes? Please identify the resource expert and the type of site visits made.

Response
Sections 6.3.2.1 and 6.3.2.2 of the EIS address the potential common and specific impacts of Nevada rail implementing alternatives, respectively, including land-use impacts. As described in the introduction to Chapter 6,

in response to interest and suggestions by the public and to better describe potential impacts of transportation alternatives in Nevada, DOE modified analyses and presentations of impacts in the EIS. For example, additional details, when available, and evaluations are included for wilderness study areas, grazing allotments, sensitive biological resources, management areas, cultural resources, and hydrologic resources.

Section 3.2.2.1 of the EIS is based on a combination of published information and field observations. Based on published environmental data, 54 springs, perennial streams, and Bureau of Land Management-designated riparian areas were visited by DOE biologists to determine if those sites contain wetlands (DIRS 155378-Reilly and Smith 1997). Fifteen locations with sensitive species were visited to ensure that the sites still had suitable habitat for the species (DIRS 154825-CRWMS M&O 1997). In addition, DOE engineers made an initial visual survey of all rail corridor alternatives as a part of the routing analysis. Topography, land use, and known areas of environmental concern were observed as a part of the corridor centerline selection to minimize impacts to stakeholders (DIRS 131242-CRWMS M&O 1997). Cultural resources, noise, aesthetics, and existing visual conditions were observed by contractor personnel on a field trip along proposed heavy-haul truck routes and rail corridors. Additional interviews with responsible State and Federal agencies were conducted and additional literature searches were performed during the trip. A report has been prepared detailing the information obtained during the trip (DIRS 155826-Nickens and Hartwell 2001) and the relevant information is included in Chapter 6 of the EIS.

DOE acknowledges the recreational resources afforded by open space within parts of Nevada. In Section 6.3.2 of the EIS, DOE identifies potentially affected natural resource areas within each corridor. DOE would seek to minimize any restriction to or control over public lands used for recreational purposes and would develop specific mitigation measures to alleviate potential impediments to continued use of public lands.

For any land that would be acquired, including mineral claims, landowners would be fairly compensated under Federal eminent domain procedures. When affected property was not acquired by eminent domain, mitigation measures would be evaluated and implemented as appropriate, as indicated in Section 9.3.1 of the EIS, when construction and operation of transportation facilities would result in (1) impacts to publicly used lands such as grazing allotments, (2) direct and indirect land loss, and (3) displacement of capital improvements.

DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (7625)
Comment - EIS001912 / 0081
P. 6-36 looks only at disturbed lands and not lands which are surrounding the corridors which could be impacted.

Response
DOE has not limited its assessment of land use to disturbed lands or changes in ownership. In fact, impacts to land use could occur even if ownership did not change or there was no direct land disturbance. For example, dividing grazing land in a rail corridor could result in the creation of a barrier to cattle movement and could affect a rancher's ability to get cattle to water.

DOE is aware of the possible restrictions inherent in the construction and operation of a transportation corridor and would consider appropriate mitigation actions. For example, the discussions of the corridors in Section 6.3.2.2.1 of the EIS identify potential conflicts with existing or future land uses that a corridor could affect.

8.11.1 (8044)
Comment - EIS000391 / 0010
Other transportation issues of the waste to the Yucca Mtn. site are:

Land use consideration of present and planned land uses along possible routes identified.

Response
In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example as discussed in Chapter 6, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. By providing these mitigating measures, the impacts would be lessened and considered small. If an action could result in departures from existing uses, and mitigation could not remedy the conflict, the effects could be more substantial.

Factors considered when assessing impacts included the uniqueness of a geographic area; presence of historic, scientific, and cultural resources; potential effects on endangered species; and compliance with Federal, State, or local law. Based on information available, potential land-use impacts associated with Yucca Mountain transportation activities could be minimized through judicious alignment of the branch rail line or through mitigation. Overall, the land-use impacts are not deemed substantial because of the use of various optional and alternate routes within the corridor, mitigation measures, and the judicious routing of the branch rail line within the corridor.

Section 8.4.2 of the EIS discusses the impacts that reasonably foreseeable future actions could have on the construction and operation of a branch rail line.

8.11.1 (8100)
Comment - EIS000406 / 0019
The following issues need to be addressed and thoroughly analyzed concerning direct impacts to Lander County in a detailed manner:

Ranching and grazing allotment impacts

Response
Land-use and ownership impacts common to the construction and operation the five branch rail lines are discussed Section 6.3.2.1 of the EIS and impacts specific to the Carlin Corridor are discussed in Section 6.3.2.2.2. The EIS determines that a branch rail line could create a barrier to livestock movement, and quantitatively addresses the acres of grazing lands potentially affected by candidate rail corridors.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

If a corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify specific land uses to be avoided. DOE would avoid land-use impacts and private land to the maximum possible extent. For example, access to grazing areas, forage, and water can be addressed in the early design phase of the rail corridor/alignment. This process would address Bureau of Land Management standard operating procedures for rights-of-way, construction and operation. Water wells would be required along the rail corridor in some areas for soil compaction and dust control during rail construction. It could be possible to improve grazing allotments if the Bureau permitted the use of this water for grazing. Grazing allotment access could be accomplished by designing at-grade structures to permit cattle to cross under the railbed.

8.11.1 (8128)
Comment - EIS001653 / 0080
Pg. 6-38 Section 6.3.1 states, "As a consequence, impacts to land use ... would not be large. With respect to land use, what process or methodology did DOE use to determine that impacts would not be large? Did DOE consider impacts to real estate development and values along the proposed route?

Response
In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example, as discussed in Chapter 6, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. By providing these mitigating measures, the impacts would be lessened and considered small.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty
- Much of the uncertainty is irreducible, and
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.11.1 (8145)
Comment - EIS001653 / 0088
DOE has not considered impacts to grazing allotments, mining, recreation use, and hunting. Are there any patented mining claims within the proposed rail corridor? How will DOE compensate mining claim holders? How many animal units months will be lost? What will DOE do to maintain access to water and movement of livestock in and around the rail corridor? What are BLM's [Bureau of Land Management's] standard operating procedures for rights of way, construction and operation?

Response
Land-use and ownership impacts common to the construction and operation of all five of the branch rail lines are discussed in Section 6.3.2.1 of the EIS and impacts specific to each proposed route are discussed in the appropriate subsection. The EIS indicates that a branch rail line would affect grazing allotments, mobility of grazing animals, watering capabilities, and recreational access. Based on current information provided by the Bureau of Land Management, the patented mining claims were skirted as much as possible by the five candidate rail corridors.

DOE acknowledges the recreational resources afforded by open space within parts of Nevada. In Section 6.3.2 of the EIS, DOE identifies potentially affected natural resource areas within each corridor. DOE would seek to minimize any restriction to or control over public lands used for recreational purposes and would develop specific mitigation measures to alleviate potential impediments to continued use of public lands.

For any land that would be acquired, including mineral claims, landowners would be fairly compensated under Federal eminent domain procedures. When affected property was not acquired by eminent domain, mitigation measures would be evaluated and implemented as appropriate, as indicated in Section 9.3.1 of the EIS, when construction and operation of transportation facilities would result in (1) impacts to publicly used lands such as grazing allotments, (2) direct and indirect land loss, and (3) displacement of capital improvements.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

If a corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify specific land uses to be avoided. DOE would avoid land-use impacts and private land to the maximum possible extent. For example, access to grazing areas, forage, and water could be addressed in the early design phase of the rail corridor/alignment. This process would address Bureau of Land Management's standard operating procedures for rights-of-way, construction and operation. Water wells would be required along the rail corridor in some areas for soil compaction and dust control during rail construction. It could be possible to improve grazing allotments if the Bureau permitted the use of this water for grazing. Grazing allotment access can be accomplished by designing at-grade structures to permit cattle to cross underneath the railbed.

A branch rail line could be constructed across a mining claim. However, access to claims would not be restricted with the exception of that portion where the actual roadbed was constructed. Access to either side of a valley traversed by a rail branch line would be possible. Sufficient crossing structures would be constructed to allow access from either side.

8.11.1 (9505)
Comment - EIS001888 / 0164
[Summary of comments noted by Clark County Nuclear Waste Division staff at various citizens' meetings.]

It seems obvious that DOE did not look at the site plan for Summerlin or the Las Vegas Valley and all the residential and commercial uses planned along the western beltway.

Response
The representative highway routes identified for the EIS analysis conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, developed for transport of Highway Route Controlled Quantities of Radioactive Materials, require such shipments to be on preferred routes selected to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or an alternate rout designated by a state or tribal routing agency. Alternate routes could be designated by states or tribes under Department of Transportation regulations (49 CFR 397.103) that require consideration of the overall risk to the public and prior consultation with local jurisdictions and other states and tribes. The State of Nevada has not designated an alternate route, so DOE used the western Las Vegas Beltway for the EIS analysis.

8.11.1 (9646)
Comment - EIS001888 / 0310
Another issue is ongoing interaction between the Bureau of Land Management and the local governments in southern Nevada and California. Although the BLM [Bureau of Land Management] manages most of the land in the region, the BLM has made agreements with various local governments in the region. It is likely that major

construction of rail lines, heavy haul roads, and intermodal facilities will conflict with these agreements. The DEIS does not address the issue.

Response
Section 6.3 of the EIS describes the methods that were used to analyze the potential impacts to the many resource areas in Nevada from implementation of alternative transportation modes and routes. These analyses, discussed in subsequent sections, include land use and ownership and describe land-use and ownership issues for all three modes and the five candidate rail corridors. Existing land use and ownership is described, as are potential impacts on private, Bureau of Land Management, and other landowners.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (9851)
Comment - EIS001888 / 0415
[Clark County summary of comments it has received from the public.]

Commenters suggested that the EIS evaluate the impacts to current land uses along the potential regional rail and heavy-haul routes. Land uses and related issues identified for evaluation include: (1) the availability of public lands, (2) the ease of obtaining rights-of-way, (3) consideration of eminent domain, (4) impacts to hunting and fishing opportunities and other recreational water uses, (5) effects on grazing allotments and livestock permittees, (6) public travel across Big Smokey Valley, and (7) potential interference with U.S. Air Force operations on the Nellis Bombing and Gunnery Range.

Response
Section 6.3.2.2 of the EIS notes that the branch rail lines could require conversion of land within existing grazing allotments. DOE expects the potential impacts of construction to have a greater effect upon grazing lands than would operations. During the construction phase, it could be difficult for cattle to access water if the construction zone divided the grazing allotment. Construction activity and temporary camps with the presence of construction crews could result in disrupting ranch operations and livestock rotations. There is a possibility that some livestock could be killed along roads used during construction.

DOE, however, expects that after construction, operational impacts would be less even though the branch rail lines could divide some grazing lands. Input received by DOE from the Bureau of Land Management indicates that dividing grazing lands would result in a small loss of animal unit months in large allotments but would be unlikely to affect ranch operations. The loss of animal unit months in small allotments could affect the grazing permittee's operation. The Bureau indicated that if a branch rail line divided an allotment into separate pastures, such pastures could provide an opportunity to rotate grazing area use, allowing for new grazing management options. This opportunity could benefit livestock and vegetation management.

As indicated in Section 9.3.1 of the EIS, DOE would evaluate appropriate mitigation actions that specifically address access to publicly owned lands, including grazing permits and leases. These actions could include providing access to lands on both sides of a branch rail line through underpasses and assisting in providing water should there be a need.

DOE acknowledges the recreational resources afforded by open space within parts of Nevada. In Section 6.3.2 of the EIS, DOE identifies potentially affected natural resource areas within each corridor. DOE would seek to minimize any restriction to or control over public lands used for recreational purposes and would develop specific mitigation measures to alleviate potential impediments to continued use of public lands.

For any land that would be acquired, including mineral claims, landowners would be fairly compensated under Federal eminent domain procedures. When affected property was not acquired by eminent domain, mitigation measures would be evaluated and implemented as appropriate, as indicated in Section 9.3.1 of the EIS, when construction and operation of transportation facilities would result in (1) impacts to publicly used lands such as grazing allotments, (2) direct and indirect land loss, and (3) displacement of capital improvements.

DOE is aware of the operational issues associated with the Nellis Air Force Range. Section 8.1.2.2 of the EIS discusses Nellis in the context of potential cumulative impacts. DOE has initiated interagency and intergovernmental interactions with a number of governmental agencies and other organizations, including the U.S. Air Force. Appendix C provides a summary of DOE's interactions with other organizations.

8.11.1 (10851)
Comment - EIS000359 / 0007
DOE also doesn't assume any mitigation for the transportation accident scenario, which is misleading given that in the unlikely event of a severe accident, emergency response will occur swiftly and a comprehensive plan will be developed to mitigate the consequences of an accident. We have emergency response capability on a federal level to respond to the radiation accidents in the United States, and radiation workers would be available to assist in the unlikely event of an accident, as well as to train emergency response workers across the states.

Response
The analysis of the impacts of transportation accidents in the EIS did not take credit for the mitigating effects of emergency response activities. However, in response to comments, additional information on emergency response activities following transportation accidents has been added to Section M.5 of the EIS.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) (63 *FR* 23753, April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

DOE has several programs available to provide assistance to state, tribal, and local governments in response to radioactive material accidents. The Radiological Assistance Program, for example, provides trained personnel with equipment to evaluate, assess, advise, and assist in the mitigation and monitoring of potential immediate hazards associated with a transportation accident. As part of the program, DOE maintains eight Regional Coordinating Offices across the country that are staffed 24 hours a day, 365 days a year The staff consists of nuclear engineers, health physicists, industrial hygienists, public affairs specialists, and other personnel who provide field monitoring, sampling, decontamination, communications, and other services, as requested. In addition DOE's Radiation Emergency Assistance Center/Training Site (REAC/TS) focus on providing rapid medical attention to people involved in radiation accidents. REAC/TS maintains a 24-hour response center to provide direct support, including deployable equipment and personnel trained and experienced in the treatment of radiation exposure to assist Federal, state, tribal, and local organizations.

8.11.1 (11282)
Comment - EIS001814 / 0016
DEIS Page 2-47
Under this scenario, DOE would construct and operate a branch line in Nevada. Based on previous studies (described in Section 2.3), DOE has narrowed its consideration for a new branch rail line to five potential rail corridors Caliente, Carlin, Caliente Chalk Mountain, Jean, and Valley Modified.

DOE's corridor selection study is flawed. The first selection criteria used by DOE to select potential routes was land use compatibility. For this criteria, DOE selected corridors based upon using "land under public ownership, to the greatest extent possible, to minimize land-use conflicts." Favorable topography was used as a selection criteria only within "areas not excluded because of land-use conflicts" (Nevada Potential Repository Preliminary Transportation Strategy, Study 1, April 1995, page 25).

There are serious problems with this approach. Land ownership does not accurately reflect land-use. Most western ranching operations are based upon a combination of privately owned fee land and grazing leases on publicly owned lands. In many, if not all cases, the ranching unit depends on these grazing leases to be economically viable. Most grazing leases are held by the ranches that can access the lease as a logical part of their operation. Splitting an existing operation with a rail line, that will limit access to the leased land, can have significant adverse effects on the operation of the ranch. Using the avoidance of privately owned land as the corridor selection process without regard to the existing ranching operations' use of private and public lands may very well result in greater impact on an operation than using private land.

Most of the private land in western States with high percentages of federally owned land is land with gentle topography. Early settlers selected the flatter land for their own. The land with rugged topography was not settled, and remained in public ownership. This shift to rugged terrain to avoid private land is a dominant factor in most of the routes selected for further study in the 1990 Preliminary Rail Access Study as reflected by the following: "An option was selected from the Caliente area in order to avoid land use impacts encountered in most of the southern areas of Nevada, ... The base route has the most favorable land-use compatibility, but would incur significant costs due to the complex engineering and construction required to traverse rough terrain" (page 17). "However, the checkerboard pattern of private and public land ownership surrounding the railroads across northern Nevada makes the complete avoidance of private land difficult. The minimum impact departure point is a location about 5 miles west of Carlin. The terrain in this area is so rugged that private developers were uninterested in the land, and as a result, the greater portions of the terrain were left in BLM [Bureau of Land Management] ownership" (page 21).

By using land ownership for the first selection criteria, DOE's selection process actually favored more rugged terrain where construction of the proposed rail line is more difficult. This creates many additional land use impacts due to the extensive cuts and fills required by unfavorable topography. These cuts and fills will further exacerbate the problem faced by ranchers of moving livestock and equipment across the rail line.

Crucial habitat for big game is frequently located in or near rugged terrain. This is especially true for crucial winter habitat. Daylight cuts required to traverse rugged terrain also pose a significant threat to big game, which tend to use these areas for movement, especially in times of heavy snow cover. When trapped in a daylight cut, big game cannot escape from an oncoming train, resulting in significant mortality rates for big game in these areas. Thus, the selection criteria that favors more rugged terrain by virtue of avoiding private land ownership greatly increases the potential impact on biological resources.

Roadless areas are also more likely to be found in rugged terrain. Virtually all potential wilderness areas are located on public lands. The selection criteria that avoids private lands results in more potential impact to roadless areas and potential wilderness areas.

Response
Sections 2.1.3.3 and 2.3.3 of the EIS describe the methods used to select and describe the alternative routes and modes for transportation in Nevada. Section 6.3 describes the potential impacts for these routes and modes.

DOE's objective, with respect to rail corridors, was to identify reasonable and representative 400-meter (0.25-mile)-wide corridors that would produce the least environmental and stakeholder impact based on published environmental and land-use data. Another consideration was to evaluate corridors that are cost-effective (for example, balancing cut and fill to the extent possible).

In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example, as discussed in Chapter 6, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. By providing these mitigating measures, the impacts would be lessened and considered small. If an action could result in departures from existing uses, and mitigation could not remedy the conflict, the effects could be more substantial.

Factors considered included the uniqueness of a geographic area; presence of historic, scientific, and cultural resources; potential effects on endangered species; and compliance with Federal, State, or local law. Based on information available, potential land-use impacts associated with Yucca Mountain transportation activities could be minimized through judicious alignment of the branch rail line or through mitigation. Overall, the land-use impacts are not deemed substantial because of the use of various optional and alternate routes within the corridor, mitigation measures, and the judicious routing of the branch rail line within the corridor.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (11298)
Comment - EIS001814 / 0027
DEIS Page 2-70
One new route, Valley Modified, was added in the 1995 Study based on updated information from the Bureau of Land Management on the status of two Wilderness Study Areas that represent possible land-use conflicts for the Valley route in the original evaluation.

The potential land use constraints for the Valley Modified route have not been eliminated. 1995 Study states "The original Valley route identified in the Preliminary Rail Access Study was considered not feasible due to possible land use conflicts with two BLM [Bureau of Land Management]-administered areas (Quail Springs WSA NV-050-411 and Nellis WSA NV-050-4R A, B, and C) that were studied for potential designation as Wilderness Areas. Due to uncertainties on the final land use of these areas (based on recent discussion with BLM Las Vegas District personnel), the Valley Modified route was added to the list of alternatives" (Nevada Potential Repository Preliminary Transportation Strategy, Study 1, TRW, April 1995, p. 34). Uncertainty in the final land use for an area does not mean that the land-use constraint has been eliminated. These same land-use conflicts with the wilderness study areas are reiterated in the 1996 analysis (Nevada Potential Repository Preliminary Transportation Strategy, Study 2, TRW, February 1996, p. 2-18).

Response
Section 2.3.3.1 of the EIS discusses the process used to evaluate the 13 candidate rail routes in Nevada and which routes were eliminated from further study.

Section 6.3.2.2.5 of the EIS describes the impacts from construction and operation of the Valley Modified Corridor Implementing Alternative. The land-use discussion has been expanded and discusses the relationship of the Sheep Mountain Alternate and the Wilderness Study Areas raised by the commenter. Although the Bureau of Land Management considers the Wilderness Study Areas unsuitable for inclusion in the National Wilderness System, DOE would have to consult with the Bureau before it could build a branch rail line.

In addition, based on public comments, a new subsection has been added to Section J.3.1.2 of the EIS that discusses potential land-use conflicts. Figure J-20 shows the Quail Springs Wilderness Study Area and the Nellis A, B, and C Wilderness Study Areas in relation to the Valley Modified Corridor.

8.11.1 (11309)
Comment - EIS001814 / 0038
DEIS Page 6-8
Land-use impacts would be greatest for the mostly rail scenario, with disturbed land areas ranging from about 5 square kilometers (1,200 acres) for the Valley Modified route to 19 square kilometers (5,000 acres) for the Carlin route.

DOE has not accurately identified or assessed the land-use impacts of the Nevada Transportation alternatives. Even where DOE has identified land-use impacts, DOE has understated the nature and severity of the impacts. The failure by DOE to accurately describe the proposed action also prevents an adequate assessment of land-use impacts. For example, the land-use impacts associated with the development of ballast and sub-ballast quarries, solid waste disposal facilities, construction lay-down areas, and construction staging areas cannot be assessed until these areas are identified.

The conclusions regarding land-use impacts in the DEIS rely primarily on disturbed acreage. Although this is one measure of land-use impacts, it is not the only one. For linear facilities such as a branch rail line, an assessment of land-use impacts should also include an evaluation of the impacts of bisecting current and future land-uses. As discussed above in the comment on Section 2.1.3.3.2 Nevada Rail Scenario, splitting an area with a branch rail line can have significant impacts on the entire area, not just the area within the right-of-way. This is particularly true for ranching operations. DOE has not assessed this type of land-use impact in the EIS.

DOE has identified a number of land-use conflicts with the proposed rail line, but has not accurately characterized the impact of these conflicts. For example, rail potential corridors cross the Simpson Park Habitat Management Area (Carlin), the Old Spanish Trail/Mormon Road special recreation management area (Jean), Wilderness Study Areas (Valley Modified) and the Desert National Wildlife Range (Valley Modified). A rail line through these special land-use areas would have significant impact on the purpose of these special areas. The EIS does not even discuss these impacts. It is particularly difficult to understand why DOE has not eliminated the Caliente Chalk Mountain alternative. The U.S. Air Force has unequivocally stated that this alternative is unacceptable due to its impacts on the Nellis Air Force Range.

Proposed rail line corridors also cross areas of potential future community growth. Although DOE identifies these areas, the EIS does not contain an assessment of the impacts of this conflict on future community growth patterns. The area of particular concern is the impact of the proposed Valley Modified route on growth in the North Las Vegas urban area.

Many of the areas crossed by potential rail corridors are currently remote, undeveloped areas. Much of the area is currently roadless, including Wilderness Study Areas. Regardless of the decision by the land management agency regarding classification as wilderness, construction of a rail line through a remote, roadless area will have land-use impacts. These changes in land-use should be identified and assessed.

From a land-use perspective, the only rail alternative that does not have serious land-use conflicts is the Caliente corridor. Even this corridor could impact the Nellis Air Force Range. All other rail alternatives cross or impact areas designated as special purpose land-use. These conflicts are summarized below:

Caliente: Requires use of land on Nellis AF [Air Force] Range. Alternatives cross difficult terrain.

Carlin: Requires use of land on Nellis AF Range. Alternatives cross difficult terrain.
Bates Mountain Antelope Release Area
Simpson Park Habitat Management Area

Caliente/Chalk Mountain: Traverses Nellis AF Range, which is unacceptable to AF.

Jean: Impacts Pahrump potential community growth
Old Spanish Trail/Mormon Road special recreation management area
Adjacent to Stateline Wilderness Area

Valley Modified: Encroaches on the Desert National Wildlife Range
Impacts community growth in the North Las Vegas urban area
Crosses Nellis A, B, & C and Quail Spring WSA [Wilderness Study Area]
Impacts Nellis AFB small arms range
Impacts Indian Springs Auxiliary Field facilities

Response
Sections 6.3.2.1 and 6.3.2.2 of the EIS address the potential common and specific impacts of Nevada rail implementing alternatives, respectively, including land-use impacts. In an effort to provide decisionmakers and stakeholders with the information needed to make a rail or heavy-haul truck transportation decision for Nevada, regions of influence were developed and the level of information needed within those regions defined.

In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example, as discussed in Section 6.3.2.1, the EIS determines that a branch rail line could create a barrier to livestock movement, and quantitatively addresses the acres of grazing lands potentially affected by candidate rail corridors. However, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. By providing these mitigating measures, the impacts would be lessened and considered small. If an action could result in departures from existing uses, and mitigation could not remedy the conflict, the effects could be more substantial. Factors considered when assessing impacts included the uniqueness of a geographic area; presence of historic, scientific, and cultural resources; potential effects on endangered species; and compliance with Federal, State, or local law.

As described in the introduction to Chapter 6, in response to interest and suggestions by the public and to better describe potential impacts of transportation alternatives in Nevada, DOE modified analyses and presentations of impacts in the EIS. For example, additional details, when available, and evaluations are included for wilderness study areas, grazing allotments, sensitive biological resources, management areas, cultural resources, and hydrologic resources.

Section 6.3.2.2.5 of the EIS describes the impacts from construction and operation of the Valley Modified Corridor. The land-use discussion has been expanded and discusses the relationship of the Sheep Mountain Alternate and the Wilderness Study Areas raised by the commenter. In addition, a new subsection has been added to Section J.3.1.2 that discusses potential land-use conflicts. Figure J-20 shows the Quail Springs Wilderness Study Area and the Nellis A, B, and C Wilderness Study Areas in relation to the Valley Modified Corridor.

DOE acknowledges the recreational resources afforded by open space within parts of Nevada. In Section 6.3.2 of the EIS, DOE identifies potentially affected natural resource areas within each corridor. DOE would seek to minimize any restriction to or control over public lands used for recreational purposes and would develop specific mitigation measures to alleviate potential impediments to continued use of public lands.

In comments on the Draft EIS, the Air Force restated its position that routes across the Nevada Test and Training Range would not be consistent with its national security uses. The Air Force concluded that use of such a corridor or route could adversely affect critical and sensitive national security activities. In response, DOE reevaluated whether the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route should be eliminated from further evaluation. DOE met with the Air Force (see Appendix C of the EIS), considered the information they provided, and concluded that the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route implementing alternatives should remain identified as “nonpreferred alternatives” in this Final EIS.

DOE believes, however, that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. In addition, the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (11760)
Comment - EIS001660 / 0054
The land use descriptions for the rail corridors in Nevada are inadequate. (p. 3-101 to -103). The land use regions of influence are narrowly drawn (limited only to disturbed lands and changes in ownership), and the only information provided for the Carlin corridor (for example) is the amount of public and private land. Although the DEIS says that “detailed information on land use is available” in other documents, it fails to describe their contents even briefly, as required by 40 CFR 1502.21.

Response
Section 3.2.2.1 of the EIS provides the baseline environmental information for assessing the potential impacts of implementing Nevada rail implementing alternatives. The more notable land-use features and potential influences that exist or could exist on lands within the corridors are presented in Chapter 6. For example, the land features within the Carlin Corridor are presented in Section 6.3.2.2.2.

In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed use of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example, as discussed in Chapter 6, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. By providing these mitigating measures, the impacts would be lessened and considered small. If an action could result in departures from existing uses, and mitigation could not remedy the conflict, the effects could be more substantial.

Factors considered included the uniqueness of a geographic area; presence of historic, scientific, and cultural resources; potential effects on endangered species; and compliance with Federal, State, or local law. Based on information available, potential land-use impacts associated with Yucca Mountain transportation activities could be minimized through judicious alignment of the branch rail line or through mitigation.

As described in the introduction to Chapter 6, in response to interest and suggestions by the public and to better describe potential impacts of transportation alternatives in Nevada, DOE modified analyses and presentations of impacts in the EIS. For example, additional details, when available, and evaluations were included for wilderness study areas, grazing allotments, sensitive biological resources, management areas, cultural resources, and hydrologic resources.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.11.1 (11873)
Comment - EIS001887 / 0388
The statement in the last sentence of the second paragraph that "no new land acquisition and construction would be required to accommodate these shipments" is misleading. There may well be additional land acquisitions and construction required once DOE identifies the specific shipping routes nationwide (something the Draft EIS fails to do). In the case of transuranic waste shipments to the Waste Isolation Pilot Plant in New Mexico, DOE agreed to pay for bypasses around/near Santa Fe and Roswell. There were also safe parking facilities that needed to be improved in other states. It is very likely that, once states and cities become aware of the nature, volume, and duration of the shipping campaign needed to support the Proposed Action, DOE will be forced to assist with the construction of bypasses or other infrastructure improvements.

Response
Section 6.2 of the EIS discusses other potential impacts of national transportation of spent nuclear fuel and high-level radioactive waste. Because existing rail and highway systems would be adequate for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain, except under conditions where heavy-haul trucks would be used, infrastructure upgrades would not be necessary and therefore are not included in the analysis. The EIS assumes that sites identified as being served by a railroad would use rail and that sites that do not have rail service (for example, needing rail spur upgrades) would ship using heavy-haul trucks or barges to the nearest railheads.

8.11.1 (12530)
Comment - EIS000630 / 0004
The EIS does not have adequate information about the impacts on grazing. The EIS states that fencing decision rests with the Bureau of Land Management and US Fish and Wildlife. The information on fencing is not definitive and excludes local government, the local community, and most of all, those livestock permittees that will be impacted. They need input.

Response
Land-use and ownership impacts common to the construction and operation of all five of the branch rail lines are discussed Section 6.3.2.1 of the EIS and impacts of specific routes are discussed in appropriate subsections. The EIS determines that a branch rail line could create a barrier to livestock movement, and quantitatively addresses the acres of grazing lands potentially affected by rail corridors.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should the branch rail line implementing alternative be selected and a preferred rail corridor identified, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

If a corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify specific land uses to be avoided. DOE would avoid land-use impacts and private land to the maximum possible extent. For example, access to grazing areas, forage, and water could be addressed in the early design phase of the rail corridor/alignment. This process would address Bureau of Land Management standard operating procedures for rights-of-way, construction and operation. Water wells would be required along the rail corridor in some areas for soil compaction and dust control during rail line construction. It could be possible to improve grazing allotments if the Bureau permitted the use of this water for grazing. Grazing allotment access can be accomplished by designing at-grade structures to permit cattle to cross underneath the railbed.

8.11.2 AIR QUALITY

8.11.2 (1410)
Comment - EIS000355 / 0005
I'm as much concerned about the excess heat in the summertime, and the potential below zero temperatures in the wintertime. And I don't see anything like that being addressed with my scientific accuracy. And if you're going to

do an environmental impact statement, you have to consider every aspect of the environment all along the way. Because each is particular, each is specific.

Response
The EIS describes the means of extreme temperature data given current climatic conditions in Section 3.1.2.2. DOE evaluated the effect of extreme temperatures on facility safety systems and transportation casks in the preliminary repository design and preliminary transportation operational plans. Section 4.1.8 describes accident scenario impacts where extreme weather (including extreme episodes of fog, frost, hail, ice cover, etc.) were considered as accident-initiating events. Appendix I provides detailed supporting information on the calculation of the environmental consequences of long-term repository performance, which included evaluating three different climate scenarios and its effect on repository performance.

8.11.2 (4362)
Comment - EIS001157 / 0007
Air quality in the Las Vegas Valley is in the "serious" non-attainment category for carbon monoxide and PM10 particulates. Any induced traffic congestion, such as that created by slow-moving vehicles on a heavy-haul route through the valley, and its associated air quality impacts must be quantified and addressed. Using 10,815 as the number of shipments (Appendix J), there would be about 2 heavy-haul trucks using the roadways every day for 24 years. The DEIS did not propose any mitigation measures to alleviate the deterioration in air quality caused by oversized, heavy-haul vehicles creating congestion.

Response
Section 6.3.3.1 of the EIS notes the potential impacts of temporary but large traffic obstructions on the planned Las Vegas Beltway from heavy-haul trucks. Each of the three implementing alternatives with Las Vegas Valley routes (Caliente/Las Vegas, Sloan/Jean, and Apex/Dry Lake) note the air quality impacts to the Las Vegas Valley airshed from the operation of a few heavy-haul trucks and associated traffic congestion would be very small in comparison to the amount of pollutants emitted by automobile travel and other commercial vehicles in the basin. DOE believes that quantification of such comparatively small impacts is unnecessary. However, DOE anticipates transportation authorities of the State of Nevada and Clark County would require heavy-haul trucks that used the Las Vegas Beltway to travel at times that would not coincide with the heaviest traffic densities (rush-hour periods). Travel-time restrictions and other requirements for heavy-haul vehicles using the Beltway would mitigate impacts to traffic congestion and associated potential air quality impacts.

8.11.2 (5497)
Comment - EIS001660 / 0025
The DEIS fails to analyze impacts of the proposed action on air quality in Nevada and Mineral County (pp. 6-9,-36). Residents and visitors of Mineral County benefit from excellent air quality conditions that could be affected by the proposed action. The DEIS says that air emissions would affect a very large area (p. 6-44) but provides little or no additional information.

The DEIS must disclose the impacts upon Mineral County's air quality from: (1) fugitive dust releases during construction and operations, (2) diesel engine emissions during construction and operations, including emissions from water trucks, and (3) increased risk of wildfire. The analysis must address visual range (i.e., haze) in addition to bulk emissions and concentrations of criteria pollutants.

Response
The Proposed Action would cause no air quality impacts to Mineral County. None of the proposed transportation routes that would require road or rail construction or upgrade activities enter Mineral County. The "large area" in Section 6.3.2.1 of the Draft EIS noted by the commenter refers to the area that could be affected by construction activities that could generate fugitive dust emissions along the length of a corridor. As noted in the EIS, these effects would be temporary and limited to those areas affected by the construction activities. Because of the distance from Mineral County to the proposed repository, there would be no air quality impacts in Mineral County due to repository construction, operation, and closure.

With the exception of the Las Vegas Valley, the areas potentially affected by transportation activities in Nevada are unclassified and therefore “in attainment” with National Ambient Air Quality Standards. Section 3.1.2.1 of the EIS has been clarified to note that these areas are unclassified and in attainment.

8.11.2 (6669)
Comment - EIS001878 / 0052
The DEIS fails to adequately analyze impacts of the proposed action on air quality in Nevada and Eureka County. (pp. 6-9, -36) Appendix G, Air Quality, does not address transportation-related impacts at all. Residents of Eureka County benefit from excellent air quality conditions that could be affected by the proposed action. The DEIS says that air emissions would affect a very large area (p. 6-44) but provides little or no additional information.

The DEIS must disclose the impacts upon Eureka County’s air quality from: (1) fugitive dust releases during construction and operations, (2) diesel engine emissions during construction and operations, including emissions from water trucks, and (3) increased risk of wildfire. The analysis must address visual range (i.e., haze) in addition to bulk emissions and concentrations of criteria pollutants.

Response
Chapter 6 and Appendix J of the EIS address potential impacts of repository-related transportation on air quality. Impacts to air quality from the construction and operation of a branch rail line, including one in the Carlin Corridor that could cross the northwest corner of Eureka County, are discussed in Section 6.3.2.1. Emissions during construction would be temporary and would move as construction progressed along the length of the corridor. Based on Federal standards for locomotives, train emissions would not have a significant impact on air quality. Because potential highway upgrades, construction of an intermodal transfer station, or heavy-haul truck operations would not occur in Eureka County, the air quality in the county would not be affected by these activities.

With the exception of the Las Vegas Valley, all areas of Nevada potentially affected by transportation activities addressed in the EIS are “unclassified” and, therefore, considered to be “in attainment” with National Ambient Air Quality Standards. Section 3.1.2.1 of the EIS has been revised to clarify this issue.

There would be no meaningful impacts related to increased risk of wildfire and visual haze in Eureka County from Yucca Mountain Repository-related transportation impacts.

8.11.2 (6901)
Comment - EIS001539 / 0005
Meteorology: The potential for atmospheric inversions increases risks to Denver residents from accidental releases. DEH assumes these risks are unacceptable, until demonstrated otherwise by DOE.

In the DOE/EIS, accidental release scenarios are calculated using two meteorological conditions, the most conservative of which is stated to be “...stable (slowly dispersing) conditions that would not be exceeded (more still) about 95 percent of the time...” (p. 6-30), as based on national weather data (p. J-8). Weather conditions in the Denver area can differ significantly from those in other parts of the country. During the winter months, the Denver air basin commonly experiences atmospheric inversion layers that trap air constituents near ground level and prevent dispersion. DOE must provide documentation that the air modeling procedures conducted in the DOE/EIS are conservative for the inversion/stable weather conditions that may occur in the Denver area.

Response
The national meteorological data set included 5 years of meteorological data from Denver. The data DOE used in its analysis represented stable inversion-type atmospheric conditions that are not unique to Denver. The 95th-percentile characteristics noted are Pasquill-Gifford stability class F (moderately stable) and a wind speed of 0.89 meter per second (2 miles per hour). DOE believes that the 95th-percentile meteorological data used with other selected accident analysis parameters represent conditions that tend to maximize potential credible accident consequences. Selection of worst-case values for all parameters, including meteorology, would lead to accident consequence estimates that are very unrealistic and even incredible when the analysis considers probabilities of occurrence.

8.11.2 (7082)
Comment - EIS001337 / 0031
The County [Lincoln] and City [Caliente] noted that the DEIS should include a description of ambient air quality conditions within potentially impacted basins of Lincoln County. Information regarding current air quality conditions in the County were provided to DOE during EIS scoping. The DEIS Affected Environment section on Air Quality does not even refer to Lincoln County specifically and offers only very general observations not useful to determine impacts.

The County and City noted in scoping comments that although construction and operation of repository system components within Lincoln County will not likely affect regional climate, local climatic conditions may impact upon safe operation of the repository system, particularly transportation. The County and City recommended that DEIS consider impacts of climate upon safe transport of radioactive wastes. Aspects of the climate recommended by the County and City for consideration included precipitation (particularly snow and ice), temperature (as may impact upon highway infrastructure and road surface conditions), and fog. The DEIS section on Affected Environment offers only a modest description of the climate within Lincoln County which provides insufficient information upon which to determine potential effects of climate upon safe transportation.

Response
With the exception of the Las Vegas Valley, all areas of Nevada potentially affected by transportation activities are unclassified for air quality and, therefore, "in attainment" with National Ambient Air Quality Standards. A change in air quality resulting from transportation activities associated with the proposed repository project would be unlikely. DOE has revised Section 3.1.2.1 of the EIS to note that these areas of Nevada are unclassified and, therefore, in attainment.

DOE used U.S. Department of Transportation accident and vehicle fatality rate data (DIRS 103455-Saricks and Tompkins 1999) to analyze the impacts presented in Chapter 6 of the EIS. These data include accident statistics for each state under the full range of climatic, road, and traffic conditions that occurred in the United States from 1994 to 1996. Thus, the EIS analysis considered the effects of weather and road conditions in Nevada such as those identified in the comment. In response to public comments, DOE has included Section M.3 to the EIS to discuss transportation protocols that would be implemented for the travel of vehicles carrying spent nuclear fuel or high-level radioactive waste in the event of inclement weather.

U.S. Department of Transportation regulations for routing shipments of Highway-Route Controlled Quantities of Radioactive Materials (49 CFR Part 397) include rules to minimize radiological risk and consider overall public safety. Highway shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain would comply with these regulations. Preferred routes (see 49 CFR 397.103) that the State of Nevada might designate would comply with these regulations.

8.11.2 (9568)
Comment - EIS001888 / 0241
The DEIS fails to examine the likely interaction of the Yucca Mountain Program Federal activities in Nevada. For example, Clark County is non-attainment for National Ambient Air Quality Standards (NAAQS). The DEIS does not analyze the effect construction of the Heavy Haul infrastructure improvements or a rail line will have on the Regional Transportation Plan.

Response
DOE has updated the information on potential impacts of Yucca Mountain transportation activities in Nevada throughout the EIS. For the example cited in the comment, repository activities would cause no air quality impacts to Clark County; potential impacts at the land withdrawal boundary would be small fractions of the National Ambient Air Quality Standards (see Section 4.1.2 of the EIS). Section 6.3 describes potential air quality impacts from transportation-related construction and infrastructure improvements. While portions of Clark County do not comply with National Ambient Air Quality Standards because of vehicular traffic, any Yucca Mountain-related activities would not cause further deterioration of the existing air quality in this area. The three heavy-haul truck route scenarios through the Las Vegas basin evaluated in the EIS assumed that the affected segments of the Las Vegas Beltway would be completed by 2010, the same year shipments would begin under current DOE plans. Because the required construction and infrastructure upgrades on the planned Las Vegas Beltway would be

completed an estimated 10 years before the current estimated completion date of 2020, traffic congestion in the Las Vegas Valley would be improved and the action would complement the Regional Transportation Plan. If DOE selected one of the three heavy-haul truck routes through the Las Vegas basin, it would consult with Clark County on specific impacts to the transportation system caused by the heavy-haul truck route improvements.

8.11.2 (9644)
Comment - EIS001888 / 0309
The DEIS is insufficient because it fails to consider how the Yucca Mountain Program may impact other federally mandated programs that are ongoing in Clark County, Nevada. The best example of this is the issue of air quality. Clark County is nonconforming for Federal air quality standards for both ozone and particulate matter emissions. Construction of rail lines or heavy haul infrastructure proposed in the DEIS will have an effect on air quality in Clark County. It is likely that the Regional Transportation Plan, the Statewide Implementation Plan and Transportation Improvement Program will all be affected by the construction of the infrastructure necessary to support the Yucca Mountain Project. The DOE must establish a provision to perform a conformity analysis for the proposed projects necessary to demonstrate that these construction activities will have no impact on Clark County's air quality. Other federal activities related to the environment, endangered species, flood control and land management must also be addressed by the DEIS.

Response
All of the areas cited in this comment are addressed in Section 4.1.2 of the EIS for the proposed repository and Sections 6.1.1 and 6.1.2 for transportation-related activities. The specific examples noted for air quality are addressed below.

The Las Vegas Air Basin, part of Clark County, is in nonattainment for carbon monoxide and particulate matter (PM_{10}), but is in attainment for ozone. An analysis of the transportation options that specifically focused on carbon monoxide and PM_{10} has been conducted for the EIS (see Chapter 6) and in a separate Clean Air Act conformity review.

Potential air quality impacts from construction of a branch rail line that would cross the Las Vegas Air Basin are addressed in Section 6.3.2.2.5 of the EIS. DOE used comparisons to Clark County's EIS for the northern and western Las Vegas Beltway project to determine there would be no significant impacts to air quality in this area from branch rail line construction.

The potential impacts of the intermodal transfer station that is part of the Sloan/Jean heavy-haul truck implementing alternative are discussed in Section 6.3.3.1 of the EIS. The site of this intermodal transfer station could be in the Las Vegas Air Basin, and thus subject to analysis of air quality attainment status. However, the results of the analyses in Section 6.3.2.1 show that impacts from the construction and operation of the intermodal transfer station would be below the emission threshold rates and, therefore, would meet the requirements for Clean Air Act conformity. Highway upgrades in the Las Vegas Air Basin would not be necessary, so there would be no associated emissions.

In addition, DOE conducted a conformity review to evaluate the potential for air quality impacts of vehicle emissions in the Las Vegas Air Basin arising from transport of materials and personnel for constructing and operating a repository at Yucca Mountain. Because the estimated direct and indirect emissions would be below threshold emission rates for each pollutant of concern established by Environmental Protection Agency regulations (see Section 6.3.3.2.4 of the EIS), DOE determined conformity requirements for the Las Vegas Air Basin would not apply to repository-related transportation activities.

DOE believes that the EIS adequately analyzes the potential for air quality impacts of transportation in the Las Vegas Air Basin. Section 6.3.2.1 of the EIS addresses resource areas common to Nevada branch rail line implementing alternatives and Section 6.3.3.1 addresses those for Nevada heavy-haul truck implementing alternatives. Sections 6.3.2.2 and 6.3.3.2 discuss impacts specific to each Nevada branch rail line or heavy-haul truck implementing alternative, respectively. Once a specific rail corridor or heavy-haul truck route was selected, additional engineering and environmental studies and appropriate National Environmental Policy Act reviews would be conducted, together with consultations with responsible Federal, State, tribal, and local authorities. Mitigative actions would be developed to preclude or compensate for potential impacts.

8.11.2 (9808)
Comment - EIS001888 / 0395
[Clark County summary of comments it has received from the public.]

Several commenters noted that construction and operation of the repository and transportation facilities could degrade current air-quality attainment status (Lincoln and Clark Counties), and that emissions of fugitive dust could impair visibility and reduce the safety of waste transport. Thus, the EIS should describe existing air- quality and meteorological conditions (severity of storms, temperature extremes, fog) in each affected area, and assess the potential environmental consequences to air quality and the extent to which meteorological conditions could affect waste transport.

Response
With the exception of the Las Vegas Valley, all areas of Nevada potentially affected by transportation activities are unclassified and therefore "in attainment" with National Ambient Air Quality Standards. The text in Section 3.1.2.1 has been clarified to specifically note that those areas of Nevada potentially affected by the Proposed Action (including Lincoln County) are unclassified and, therefore, in attainment.

Potential air quality impacts from construction and operations at the repository are described in Section 4.1.2 of the EIS. There would be no impacts to air quality on Lincoln or Clark counties from activities at the repository site. Potential air quality impacts from transportation-related construction and operation are described in Sections 6.3.2 and 6.3.3. If DOE selected the Valley Modified Corridor, which passes through the Las Vegas Valley, for the construction and operation of a branch rail line, the final plans, specifications, and estimates would include the Clark County Health District PM_{10} emissions control measures.

No additional climate description is necessary for those areas where the only potential inputs are related to candidate transportation routes. Any roads that would be considered or designated for transportation of spent nuclear fuel and high-level radioactive waste would have to meet the criteria for safe transportation, meaning that they must be constructed in such a manner to allow for safe transportation considering normal meteorological conditions such as rain, snow, ice, and fog. Normal roadway maintenance such as snow removal can be considered, and in the event of severe meteorological conditions such as a blizzard, trucks could be ordered off the road to wait out such conditions.

8.11.2 (10248)
Comment - EIS002115 / 0010
Weather and natural disasters. Although weather does not seem to be an issue, Mineral County believes it's a big issue. Most of the radioactive waste would be transported through the northern part of Nevada. This part of the state may have bad weather from November to May as well as many other states from east, central and northwest America. Will the radioactive waste be transported during their timeframe? The DEIS does not have adequate information in case of road closures due to inclement weather, nor provide complete information about safe havens or alternate trucks and siting for rail.

Response
The climate along the transportation routes being considered in the EIS was not described because DOE would consider or designate for the transportation of spent nuclear fuel and high-level radioactive waste only those roads that meet the criteria for safe transportation of these materials. Such roads must be constructed in a manner that enables safe transportation considering normal meteorological conditions such as rain, snow, ice, and fog. DOE would purchase services and equipment from Regional Servicing Contractors, who would perform waste acceptance and transportation operations. As described in Section M.3.2.1.4 of the EIS, the Regional Servicing Contractor would obtain route weather forecast information as part of the preshipment planning and notification and shipment process. At the time of departure, current weather conditions would have to be acceptable for safe vehicle operation. Shipments would not travel when severe weather conditions developed along routes or adverse road conditions made travel hazardous. In the event of severe meteorological conditions such as blizzards, trucks could be ordered off the road to wait out such conditions. Similar types of requirements would apply for rail shipments. The appropriate documentation would be prepared on safe havens when a specific route and mode of transportation were selected.

8.11.2 (10886)
Comment - EIS000817 / 0147
P. 6-89. What is the total of pollutants from the total transport of the waste? Here we are trying to cut back on all this, and instead, this project adds to the problem. Are we creating more air hazards to bury a waste?

Response
DOE did not calculate the total quantity of pollutants generated over time from transportation activities and determined that national transportation of spent nuclear fuel and high-level radioactive waste by truck and rail would not constitute a meaningful source of air pollution along the nation's highways and railroads. As noted in Section J.1.3.2.3 of the EIS, human health impacts to vehicle exhaust depend principally on the distance traveled in an urban population zone and on the impact factors for particulates and sulfur dioxide from truck or rail emissions, fugitive dust generation, and tire abrasion. National transportation of spent nuclear fuel and high-level radioactive waste would use existing highways and railroads and would average 14.2 million truck kilometers (8.8 million miles) per year for the mostly truck case and 3.5 million railcar shipments per year from the mostly rail case. The national yearly average for total highway and railroad traffic is 186 billion truck kilometers (116 billion miles) and 49 billion railcar kilometers (30 billion miles) (DIRS 148081-BTS 1999). Therefore, the transport of spent nuclear fuel and high-level radioactive waste would represent 0.008 percent and 0.007 percent of truck and railcar-kilometers traveled, respectively.

8.11.2 (11008)
Comment - EIS001896 / 0006
Section 3.2.2.1.2

The Valley-Modified Rail Corridor crosses Clark County, which could impact PM_{10} attainment.

Response
Section 6.3.2.1 of the EIS provides a summary discussion of the Conformity Review of the Nevada Rail Implementing alternatives for PM_{10}. Part of this Conformity Review evaluates PM_{10} emissions in the Las Vegas nonattainment area. A significant portion of PM_{10} emissions in the nonattainment area are the result of construction activities (DIRS 155557-Clark County 2001). The Valley Modified Corridor would require construction within the nonattainment area. DOE has made quantitative estimates of PM_{10} releases from rail-line construction, based on the limited amount of information available. These PM_{10} releases would include the emissions from disturbing the ground and from fuel combustion of the construction equipment. Dust abatement measures (for example, water applications) are assumed to reduce fugitive dust PM_{10} emissions by 70 percent. Given these assumptions, PM_{10} emissions during the construction phase of the Valley Modified Corridor are estimated to be up to 190 percent [120 metric tons (130 tons) per year] of the General Conformity threshold level for a PM_{10} serious nonattainment area, 64 metric tons (70 tons) per year (40 CFR 93.153). This value could be reduced by lengthening the construction time, extremely diligent attention to dust suppression measures, or more detailed task planning to reduce the sources of particulate emissions. Valley Modified Corridor emissions into the nonattainment area would occur during the much longer operations phase, as locomotives passed through the nonattainment area on their way to the Yucca Mountain site. The operations emissions of PM_{10} for the Valley Modified Corridor were estimated to be less than 3 percent of the General Conformity threshold levels. In addition, the Conformity Review compared the PM_{10} release estimates to the Nevada PM_{10} State Implementation Plan's (DIR 155557-Clark County 2001) estimated annual [154,788 metric tons (170,625 tons) per year (2001 estimate)] and daily [653 metric tons (719.78 tons) per year (2001 estimate)] inventories of PM_{10} for the nonattainment area. The Valley Modified Corridor PM_{10} emissions estimates are less than 0.08 percent of these inventories during construction.

8.11.2 (11009)
Comment - EIS001896 / 0007
Section 3.2.2.2.2

The Sloan/Jean Intermodal Transfer Station could impact PM_{10} attainment.

Response
Section 6.3.3.1 of the EIS discusses potential impacts from constructing and operating an intermodal transfer station that could be part of the Sloan/Jean heavy-haul truck implementing alternative. Implementation of this

implementing alternative could result in an intermodal transfer station in the Las Vegas Air Basin. Tables 6-83 and 6-84 of the EIS lists annual criteria pollutant releases from constructing and operating an intermodal transfer station over 24 years. The results of the analyses discussed in Section 6.3.3.1 demonstrate that the PM_{10} emissions from construction and operation of the intermodal transfer station would not exceed General Conformity threshold levels for areas such as the Las Vegas Valley, which is classified as a serious nonattainment level.

8.11.2 (13187)

Comment - EIS010243 / 0034

The EPA [Environmental Protection Agency] issued transportation conformity regulations on Nov 24, 1993 to implement section 176(c)(4) of the Clean Air Act as amended. The transportation conformity regulations apply to actions of the FHWA [Federal Highway Administration] and FTA [Federal Transit Administration]. Actions of other federal agencies, including other transportation agencies are covered by the general conformity regulations issued by the EPA on November 30, 1993. The DOE is covered by these general conformity regulations.

The Las Vegas Valley is classified by the U.S. Environmental Protection Agency as a serious non-attainment area for carbon monoxide (CO) and particulate matter (PM_{10}). The Clark County Regional Transportation Commission is responsible for establishing CO and PM_{10} emissions and for demonstrating conformity. Because Clark County is a non-attainment area for air quality emissions, the pollutants generated by the NPA are of concern. Air quality impacts are important to Clark County for regulatory purposes that are not considered in the SDEIS. The construction and operation of NPA transportation facilities effects the ability of Clark County to meet national air quality standards. Failure to meet these standards will harm Clark County's ability to obtain Federal funding for transportation facilities and will generally harm the quality of life in Clark County.

Vehicular emissions are the primary source of CO pollutants, whereas construction activities are the primary source of dust (PM_{10}) in the Valley. In addition to vehicle miles of travel, congestion is a significant contributor to increased CO emissions.

Projected carbon monoxide emissions calculated by the Regional Transportation Commission for the projected roadway types, travel speed characteristics, and emission factors using the Mobile 5b model are:

Facility Type Major Arterial (four lane)
Posted Speed 45 mph
Free Flow Speed 45 mph
Average Travel Speed 35 mph
Congested Speed 20 mph

Figure 3 Uncongested Travel Speed Characteristics and Carbon Monoxide Emissions

45 mph 4.87 grams/mile
35 mph 6.82 grams/mile
20 mph 13.51 grams/mile

Figure 2 Emission Factors and carbon dioxide emission factors

These emission factors are used to calculate the amount of air quality impact on Clark County attributable to the YMP [Yucca Mountain Project].

The emissions for the construction phase air quality impact cannot be calculated because not enough information is provided by the SDEIS on the vehicle trips required to construct and operate the facility. During the operational phase of the NPA there will be significant air quality problems. The impacts on air quality due to legal-weight truck shipments will be very substantial. The results of the analysis are presented below.

Pollutants Truck Air Quality Impacts
CO2 48,213,000
PM10 47,223,000

Figure 3 Total Grams of Air Pollutants During the Operational Phase

The cumulative impacts due to the shipment of LLW [low-level radioactive waste] to the NTS [Nevada Test Site] are assumed to be the emissions from the legal-weight trucks that will traverse the valley en route to the NTS. Because these shipments take place on the region's freeways, the emission factors for higher speeds are used. The cumulative impacts of LLW transportation are below.

Air Quality Impact Cumulative Impacts
CO2 182,274,840
PM10 869,450,987

Figure 4 Cumulative Air Quality Impacts

The air quality impacts due to the YMP [Yucca Mountain Project] will substantially degrade Clark County's air quality. They will make it increasingly difficult for local government to meet air quality goals and could cause other Federal agencies to take punitive action on Clark County due to the YMP. The NPA should have been prepared to accommodate the regional transportation plans and conform to the FHWA's [Federal Highway Administration] regulations for statewide planning.

Response

DOE agrees with the Clark County Regional Transportation Commission comment that the Las Vegas Valley is classified by the Environmental Protection Agency as a serious nonattainment area for carbon monoxide and particulate matter less than 10 micrometers in diameter (PM_{10}). Section 6.3 of the EIS describes the impacts of these emissions and other listed pollutants from cars, trucks, rail, and other conveyance vehicles that would travel through the Las Vegas Valley and construction activities within the Valley. In Appendix J of the EIS, DOE states that it has developed the transportation conformity documentation to demonstrate that carbon monoxide and particulate matter emissions would not hinder the Las Vegas Valley in their efforts to meet national ambient air quality standards. DOE has recognized the carbon monoxide and PM_{10} State Implementation Plans in the EIS and would abide by the requirements of the plan in any actions taken following a decision to proceed with the repository and related transportation program.

DOE has converted the results of the analyses performed by the Clark County Regional Transportation Commission, as presented in the comment, to the units used in the Carbon Monoxide State Implementation Plan (Table 8-3) (DIRS 156706-Clark County 2000) and determined the percent of 2000 "daily budget" that they would represent. For legal-weight trucks transporting spent nuclear fuel and high-level radioactive waste, the 48,213,000 grams of carbon monoxide emissions during the repository operation period (24 years) would be 0.0029 percent of the "daily budget" for on-road mobile sources. For legal-weight trucks transporting low-level radioactive waste to the Nevada Test Site, the 182,274,840 grams of carbon monoxide emissions during the same period would be 0.011 percent of the "daily budget".

DOE converted the results of the analyses performed by the Clark County Regional Transportation Commission, as presented in the comment, to the units used in the Particulate Matter (PM_{10}) State Implementation Plan (Table 3-8) (DIRS 155557-Clark County 2001) and determined the percent of 2001 "annual inventory" that they would represent. For legal-weight trucks transporting spent nuclear fuel and high-level radioactive waste, the 47,223,000 grams of PM_{10} emissions during the repository operation period (24 years) would be 0.0027 percent of the "annual inventory" for on-road mobile sources. For legal-weight trucks transporting low-level radioactive waste to the Nevada Test Site, the 869,450,987 grams of PM_{10} emissions during the same period would be 0.051 percent of the "annual inventory." Note that the transportation of low-level radioactive waste to the Nevada Test Site is not part of the proposed Yucca Mountain Repository action but would be a cumulative impact under the National Environmental Policy Act going on at the same time in the same area as the proposed action. Cumulative impacts, including the transportation of low-level radioactive waste to the Nevada Test Site, are given in Chapter 8 of the EIS.

It is DOE's opinion that these potential air quality impacts would be very small and that adequate information on potential air quality impacts of transportation of spent nuclear fuel and high-level radioactive waste, including cumulative impacts, is provided in the EIS to support current decisionmaking.

8.11.3 HYDROLOGY/GEOLOGY

8.11.3 (3019)
Comment - EIS000593 / 0004
Mineral County's flood plain map is incorrect. If this is so, how reliable is the information gathered for Yucca Mountain and other areas?

Response
DOE has added more information to the floodplain/wetland assessment in Appendix L of the EIS to address flooding along candidate Nevada transportation routes. Appendix L now identifies 100-year flood zones that the rail corridors and their alternative alignment segments would cross, based on information from the Federal Emergency Management Agency.

The EIS does not, however, show or discuss floodplain areas in Mineral County, because none of the rail corridors or heavy-haul truck routes under consideration in the EIS pass through Mineral County.

8.11.3 (3020)
Comment - EIS000593 / 0005
The flood plain report in the DEIS is too generalized. Mineral County would like to have a detailed flood plain analysis done of Yucca Mountain and each affected county.

Response
The floodplain/wetland assessment in Appendix L of the EIS examines the effects to floodplains and wetlands of the construction of a branch rail line or intermodal transfer station, along with its associated route for heavy-haul trucks to Yucca Mountain. Appendix L compares the impacts from construction on the floodplains/wetlands along the candidate rail corridors, and at candidate intermodal transfer stations and associated heavy-hail truck routes. The assessment does not evaluate potential effects along existing routes because such roads should be designed to meet 100-year floodplain design specifications. For the Final EIS, DOE selected rail as the preferred mode of waste transport to the repository. A more detailed floodplain/wetland assessment of the rail alignment in Nevada would be conducted.

8.11.3 (4197)
Comment - EIS001160 / 0015
White Pine County has recently adopted a plan for managing the abundant and high-quality surface and ground water resources which characterize the area. Said plan envisions significant portions of these waters being put to beneficial use by way of beverage bottling to meet an ever-growing demand for beverages in the Western United States. The DEIS does not reference the White Pine County Water Resources Management Plan nor the potential for transportation of radioactive wastes through the County to stigmatize area water resources.

Response
If the repository was to be approved, and if a mode and route to transport waste through Nevada were selected, DOE would conduct additional detailed field surveys, government consultations, analyses, and appropriate National Environmental Policy Act reviews. If any waste-transport route could affect White Pine County, the Water Resources Management Plan for the County would be examined, along with other county-specific information on the physical, biological, cultural, and socioeconomic conditions in the County.

During scoping for the EIS, DOE received comments on the need to address perception-based and stigma-related impacts. DOE considered these issues and was guided by the results of its own research and those of the State of Nevada, and by relevant conclusions reached by reviews of this subject matter by the Nuclear Waste Technical Review Board (an independent board established by the Nuclear Waste Policy Act of 1982) in 1995 and other researchers up through about 1997. During preparation of the Draft EIS, DOE concluded that analysis of perception-based or stigma-related impacts would be uncertain or speculative at best and thus would not have been meaningful in the context of the EIS. Therefore, DOE addressed, but did not quantify, whether or how individual members of the public, or the public collectively, could or would respond to the perception of risk, whether or not this risk was real.

For this Final EIS, however, DOE elected to reexamine the relevant literature and the state of research into perception-based impacts and stigma effects. DOE reevaluated the independent reviews conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others, and identified and assessed relevant studies that have been published in the interim. DOE has concluded that while there might be a modest relationship between negative perceptions and human behaviors that could adversely affect the local economy, there are no known analytical methods by which the occurrence, timing, and extent of such impacts can be accurately predicted as they relate to the transportation or disposal of radioactive materials.

8.11.3 (5539)
Comment - EIS001660 / 0041
The DEIS fails to adequately disclose the impacts of the proposed action on water and water rights (pp. 6-10,-36,-61,62). The State Engineer oversees use of waters of the State of Nevada for the long-term benefit of residents. Given the and climate and the scarcity of surface water resources, the quality and quantity of groundwater are particularly important to Mineral County and the state as a whole. The DOE must consult the State Engineer to determine whether the utilization of groundwater from wells in the Nevada affected counties (p. 6-10) would be consistent with the water laws of the State of Nevada, affect the water rights of the existing holders of such rights, or affect the cost of water for domestic and agricultural use. The DEIS must also disclose the risk to groundwater resources that could be affected by a radiological accident and hazardous waste discharge associated with the proposed action on any surface transportation route. The DEIS must describe the permitting, construction, and closure of the wells, and any environmental impacts (i.e., impacts caused by drilling muds).

Response
Section 3.1.4.2.1 of the EIS summarizes the status of water usage and appropriations in the region of the proposed repository. The EIS recognizes that there are large water appropriations in surrounding areas such as Oasis Valley, Crater Flat, and Amargosa Desert, compared to estimates of the amount available (the perennial yield), but that the actual amounts withdrawn are much lower. With regard to areas of the State that candidate transportation routes would cross, the EIS does not present the level of detail it does for the repository area. However, Sections 3.2.2.1.3.2 and 3.2.2.2.3.2 identify each groundwater basin or hydrographic area that each rail corridor and heavy-haul truck route would cross and that the State classifies as "designated groundwater basins." These are the areas where permitted water rights approach or exceed the estimated perennial yield and where the water resources are depleted or require additional administration by the State. The analyses performed for Chapter 6 indicate that impacts to water resources along the transportation routes would be minor and, with respect to groundwater, would be limited to the possibility of withdrawing water. In addition, Chapter 6 discusses the options available to DOE to obtain water for construction activities. If water was unavailable in one area of the corridor or route, DOE could consider alternative areas and means for getting water. Chapter 6 discusses the fact that the quantities of water and the duration of the need would be relatively small for construction.

The level of detail required to obtain a water appropriation permit is not required for this EIS, but DOE has identified the requirement as being applicable to the project. Section 11.2.2 of the EIS identifies Nevada Statutes related to water and water quality that would be applicable to the Proposed Action. These statutes address the water appropriation process and licensing requirements for drilling, construction, and plugging of wells.

With respect to the evaluation of transportation accidents, the EIS does not consider possible impacts to groundwater resources because DOE believes the scenario of contaminants reaching groundwater does not represent a realistic contributor to exposures from a transportation accident. Accident scenarios evaluated in the EIS assume releases of radionuclides from the transportation cask.

The predominant threats to human health from a transportation accident, and those considered in the EIS analysis, would be exposures that occurred relatively quickly before the start of controls and countermeasures. Exposure pathways considered in the accident evaluations were associated with people close to the release (direct exposure) or exposed to materials in the air (gases and particulates). Exposure to airborne materials includes inhalation of and direct exposure to a passing cloud of contaminants, direct exposure to materials deposited on the ground, and inhalation of materials resuspended from the ground by wind. Ingestion from contaminated crops is an exposure pathway for accidents in rural areas. DOE believes that these acute exposures present a conservative estimate of the risks associated with a serious transportation accident. Contamination of groundwater and subsequent exposure of people to that groundwater would be a long-term chronic condition, and it would include assumptions of the availability of a contaminant migration pathway and a long period of inaction with respect to responding to the accident release. DOE believes such assumptions are not realistic and, even if they were included in the evaluations, the exposures would be minor in comparison to the acute exposures that are included. Section J.1.4.2 of the EIS contains more information on transportation accident scenarios.

8.11.3 (5601)
Comment - EIS001887 / 0227
Page 4-24; Section 4.1.3.2 - Impacts to Surface Water from Construction, Operation and Monitoring, and Closure

The statement "If DOE selected a rail corridor or heavy-haul route..." should be changed to "When a rail corridor or heavy-haul route is selected...." Also, wouldn't NEPA [National Environmental Policy Act] documents other than a floodplain/wetlands assessment be required?

Response
DOE believes that the EIS text is appropriate because: (1) the mostly legal-weight truck scenario described in the EIS is still a viable option; and (2) more importantly, if the proposed repository action did not go forward, there would be no need to select a transportation corridor or route.

Section 4.1.3.2 of the EIS deals with potential impacts to surface waters from repository construction, operation and monitoring, and closure, so discussion of the floodplain/wetlands assessment (Appendix L) is appropriate. This is not an appropriate section to discuss other National Environmental Policy Act-type documents or assessments. As stated in the EIS (Chapter 6), DOE would conduct more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews before deciding on a specific route.

8.11.3 (7225)
Comment - EIS001337 / 0098
Page 3-130 The text here implies that heavy-haul routes are in proximate parallel location to flowing surface waters. This is not the case at all. In most cases, these routes are 800 or meters from any flowing surface water, except for the occasional spring. Additional field work and revision to this section is needed.

Response
The text on the cited page that appears to fit this comment is in the discussion of the candidate Caliente-Las Vegas heavy-haul truck route. The opening paragraph of this discussion states, "From Crystal Springs to Las Vegas, the route parallels the White River through Pahranagat Valley, and then through Coyote Springs…." This statement does not imply anything about the nature of the White River or its proximity to the route (U.S. Highway 93), only that the highway and the river both head southward through the Pahranagat Valley. The White River flows only intermittently over much of its length. The important issue with respect to the White River in this area is that flow from Ash Springs is toward the White River channel and that U.S. 93 crosses the flow from the spring in the area between the spring and the river. Section 3.2.2.2.3.1 of the EIS identifies Ash Springs as a water resource associated with the Caliente-Las Vegas route, and Section 3.2.2.2.4 discusses biological resources, including the endangered White River springfish that occurs in the Ash Springs flow.

Before selecting a specific rail alignment in a corridor, the Department would conduct additional consultations, field surveys, analyses of water and biological resources, and appropriate National Environmental Policy Act reviews.

8.11.3 (7901)
Comment - EIS001653 / 0051
Section 3.2.2.1.3.1 contains two small paragraphs and a table of surface waters for alternative rail corridors. This section needs to have maps which show the location of surfaces waters in relationship to corridors, flow and discharge information, uses of the water permitted or otherwise, and flood plain information, and information on recharge.

Response
Sections 3.2.2.1.3.1 and 3.2.2.2.3.1 of the EIS include tables that identify surface-water features near the candidate Nevada transportation routes. The tables identify water resources along route segments to provide a general idea of the location of water resources. In addition, the discussion of heavy-haul truck routes identifies flood zones in areas

DOE is considering for the associated intermodal transfer stations. The floodplain/wetlands assessment in Appendix L of the EIS contains additional information on areas of potential flooding along the Nevada transportation routes. Specifically, Appendix L identifies 100-year flood zones that rail corridors cross, based on information from the Federal Emergency Management Agency.

The comparable groundwater discussions in Sections 3.2.2.1.3.2 and 3.2.2.2.3.2 of the EIS include information on recharge estimates. These sections identify each groundwater basin, or hydrographic area, that each rail corridor or heavy-haul truck route crosses, and contain estimates of perennial yield for each area. Perennial yield is the amount of water that can be withdrawn from the basin on an annual basis without adversely affecting the reservoir; it can be considered the average amount of recharge and underflow that reaches the area's groundwater each year.

DOE believes that the amount of detail in the EIS on water resources along alternative rail corridors and heavy-haul truck routes is appropriate. Before selecting a specific rail alignment in a corridor, the Department would conduct additional consultations, field surveys, analyses of water and biological resources, and appropriate National Environmental Policy Act reviews.

8.11.3 (8473)
Comment - EIS000817 / 0145
Can DOE "lease temporary water rights from individuals along the rail corridor?" Do those individuals own the water to give the right to DOE? This needs a great deal of thought. The future is full of water concerns. Just how much water will Nevada lose to DOE in this whole operation of transport and disposal? Water is scarce in Nevada, isn't it? Who uses and needs that water? Are water predictions correct? Who really has the right to give that water to DOE? It almost appears as a threat here to the State of Nevada, saying, "If you don't give us water rights to drill wells, we'll pay off private individuals for rights."

Response
DOE did not intend to sound as if it was making threats when it stated that it could obtain water necessary to support construction of transportation routes from individuals already holding water rights. The Department views this simply as a potentially available option; not to discuss it in the EIS would be contrary to the objective of full disclosure. State statutes, as stated in the *Nevada State Water Plan* (DIRS 155775-NDWP 1999), allow this option: "Water right owners are entitled to buy, sell or trade their water rights to others under free market conditions. However, changes in the point of diversion, or place or manner of use must be approved prior to the change in accordance with the state water law, and state and Federal Court decrees and regulations."

Section 4.1.3.3 of the EIS estimates the amount of water DOE would need to support the repository. Sections 6.3.2.2 and 6.3.3.2 estimates water needs for each rail corridor and heavy-haul truck route, respectively. With respect to the amount of groundwater available in the areas discussed in the EIS, DOE identifies estimates of perennial yield used by the State of Nevada. Because most of the water demand associated with the Proposed Action would occur at the repository, the EIS presents a range of water availability (or perennial yield) estimates for the groundwater basin in that area.

8.11.3 (9794)
Comment - EIS001888 / 0379
[Clark County summary of a comment it received from a member of the public.]

Another commenter requested that the EIS identify sites in Lincoln County for borrow material (chiefly for the railbed) and include geologic and soil maps for all potentially impacted areas in Lincoln County.

Response
DOE has examined information from the Natural Resource Conservation Service to determine if the candidate rail corridors would cross prime farmlands and to identify potential serious engineering constraints caused by soil conditions. DOE did not include the level of geologic and soil data requested by the commenter for several reasons. The Department believes that most variations in soil and geologic conditions in a rail corridor or along a heavy-haul truck route would primarily present construction and cost issues rather than environmental issues. If unique resources (water, cultural, biological, etc.) are associated with a type of geology or soil, the EIS discussion is in terms of those resources rather than the type of geology or soil.

DOE agrees that site-specific information on geology and soils would be necessary before the construction of a branch rail line or road upgrades to support heavy-haul truck shipping. As stated in Chapter 6 and Section 11.2.2 of the EIS (subsection on Compliance with Floodplain/Wetlands Environmental Review Requirements), more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews would be prepared if a decision was made to select a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes. These would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. They also would include field surveys (as applicable) and more detailed assessments and analyses of wetlands and other waters; floodplains; sensitive species; soils; and other related issues.

With regard to the commenter's request that the EIS identify potential sites for borrow material, DOE believes that this information would be of little value at this stage of the project. For a rail corridor, the normal design process would include an effort to lay out track elevations such that excavation and borrow quantities are roughly equal. This would minimize the amount of new material DOE would have to bring to the construction site. In addition, it assumes that excavated material would be suitable for fill. However, the design has the flexibility to control where borrow material is needed along the corridor, if at all. During construction of a branch rail line, it would be fairly easy to get borrow materials to the construction area. That is, the fact that the project consists of building a railroad greatly enhances the ability to bring in construction materials. A review of geologic and soil maps could help identify potential borrow sites, but until the repository project enters a more detailed rail-design process, such an effort would not provide meaningful information to support current decisionmaking. As stated in the Overview to the Summary:

"DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada…Other transportation decisions, such as selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews."

8.11.3 (9803)
Comment - EIS001888 / 0390
[Clark County summary of comments it has received from the public.]

Commenters stated that the EIS must fully describe the existing environment (wells, springs, drinking and agricultural water sources including the Humboldt River, depth to groundwater, water quantity and quality, spring-discharge rates), and examine possible impacts to these resources from construction and operation of regional transportation facilities and the repository, including acts from repository failure.

Response
DOE believes that the EIS adequately addresses the baseline environmental conditions mentioned in the comment in Chapters 3 and 6 of the EIS. There are no permanent bodies of surface water in the immediate vicinity of the proposed repository, as described in Section 3.1.4.1. On a regional basis, Section 3.1.4.1 describes significant areas of spring discharge, particularly those in the Ash Meadows area. Discussions of groundwater in the region of the repository (see Section 3.1.4.2) include depths to the water table, direction of flow, water quality, water-use rates, and water appropriations.

The EIS does contain less detail for the alternative rail corridors and heavy-haul truck routes compared to the repository site. DOE believes that areas over which transportation routes would cross are much less susceptible to environmental impacts because of the safety of the shipping casks. As stated in Chapter 6 of the EIS, DOE would conduct more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews before deciding on a specific route. However, the information in the EIS does present a broad overview of existing surface-water (springs, creeks, reservoirs, riparian areas, etc.) and groundwater conditions along the rail corridors and heavy-haul truck routes. Groundwater conditions are described in terms of the basins that the route would cross, their perennial yields, and whether the State considers them "designated groundwater basins." Designated basins are areas where permitted water rights approach or exceed the estimated perennial yield and the water resources are being depleted or require additional administration by the State.

With regard to the evaluation of potential impacts to water resources from construction and operation of regional transportation facilities and the repository, DOE believes that the scope of analysis in the EIS is consistent with the concern expressed in the comment. Sections 6.3.2 and 6.3.3 of the EIS discuss potential impacts to water resources in areas along rail corridors and heavy-haul truck routes, respectively. Section 4.1.3 addresses environmental impacts to water resources from the construction, operation and maintenance, and closure of the proposed repository. Chapter 5 addresses the long-term performance of the repository. A major element of Chapter 5 is the projection of potential impacts associated with the eventual failure of waste packages (over tens of thousands to hundreds of thousands of years) where migration of contaminants to and through groundwater would be the primary mechanism of exposure to the environment. Section 5.7 discusses disruptive events such as earthquakes and volcanic activity that could disturb the repository. The conclusion of the analysis, even with disruptive events, is that repository impacts would not exceed standards established for protection of health and safety and the environment.

8.11.3 (11150)
Comment - EIS000692 / 0006
Also, so far I find no mention in the DEIS that Lincoln County water drains into the Colorado River system, water which is used, haggled and fought over, with five western states.

Response
DOE recognizes that water is a valuable and scarce resource in southern Nevada. Because of the limited amount of surface water along the candidate Nevada transportation routes, the EIS analyses assumed that water to support the construction of a transport route would come from groundwater resources. Accordingly, the EIS discusses the potential to affect local surface water through activities such as disturbing flow, increasing sedimentation, or releasing contaminants; the discussion of groundwater includes more regional concerns such as availability over entire groundwater basins. The EIS identifies the groundwater basins, or hydrographic areas, over which rail corridors or heavy-haul truck routes would pass and which the State classifies as "designated groundwater basins." These are areas where permitted water rights approach or exceed the estimated perennial yield and where water resources are being depleted or require additional administration by the State. In discussing the more regional issues associated with groundwater, the EIS (Section 3.2.2.2.3.2) recognizes that the site of the intermodal transfer station under consideration near Caliente is in the Colorado River Basin.

8.11.3 (12453)
Comment - EIS001337 / 0032
The County [Lincoln] and City [Caliente] recommended that they include a description of wells and springs within Lincoln County hydrographic basins potentially hosting repository system construction activities, including rail or highway improvements. DOE was encouraged to include in said description depth to groundwater, flow attributes of existing springs, and existing water quality. While the DEIS Affected Environment section does address surface and groundwater conditions along candidate transportation corridors in Lincoln County, the baseline data is not sufficient to enable conclusions about impact to hydrologic resources to be derived. For example, despite a request by the County and City for said information be included in the document, the DEIS does not describe depth to groundwater, flow attributes of potentially impacted springs or existing water quality of potentially impacted water resources.

During scoping, the County and City suggested that surface hydrology might impair safe transport and/or handling of radioactive wastes and might be significantly altered by construction activities. The County and City recommended that for all areas within Lincoln County potentially impacted by repository system construction and operations (including transportation), mapping of surface hydrology and estimates of baseline flows should be included within the DEIS. The DEIS section on Affected Environment does not include any description of existing surface hydrologic conditions (particularly estimates of the duration and intensity of peak flows) within Lincoln County. This is despite the fact that the DEIS does attempt to describe potential hydrologic impacts of transportation in Lincoln County (Section 6 of EIS).

Response
The EIS identifies surface-water resources along the candidate rail corridors and heavy-haul truck routes (see Sections 3.2.2.1.3 and 3.2.2.2.3 of the EIS, respectively). The description in Section 3.2.2.2.3 of the Caliente sites DOE would consider for an intermodal transfer station includes a discussion of the candidate locations in relation to 100- and 500-year flood zones of Meadow Valley Wash. The floodplain/wetlands assessment in Appendix L of the EIS contains additional information on potential flooding areas along the Nevada transportation routes. Specifically, Appendix L identifies 100-year flood zones that rail corridors and their alternative alignment segments would cross, based on information from the Federal Emergency Management Agency. However, as noted in the EIS, these maps provide only limited coverage for Lincoln County.

DOE believes that the amount of detail in the EIS on water resources along candidate rail corridors and heavy-haul truck routes is appropriate. However, as stated in the EIS in Chapter 6 and Section 11.2.2 (subsection on Compliance with Floodplain/Wetlands Environmental Review Requirements), more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews would be prepared if a decision was made to select a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes. These would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. They also would include field surveys (as applicable) and more detailed assessments and analyses of wetlands and other waters; floodplains; sensitive species; and other related issues.

8.11.4 BIOLOGY AND SOILS

8.11.4 (42)
Comment - 7 comments summarized
The Draft EIS does not adequately address the impacts of development of a rail line or heavy haul route on springs, streams, and other waters; floodplains; wetlands; groundwater resources; soils; native vegetation; spread of noxious weeds; risk of wildfire; game and nongame wildlife habitat and migration; loss of hunting revenue; and wild horses and burros. The EIS should include a detailed inventory of the biological and surface-water resources along the potential routes and conduct a species- and site-specific analysis of impacts, particularly if DOE wishes to decide among rail corridors or heavy-haul truck routes.

Response
The *Environmental Baseline File for Biological Resources* (DIRS 104593-CRWMS M&O 1999, all) includes descriptions and maps of springs, riparian areas, and other potential wetlands; game habitat and migration corridors; sensitive species; and wild horse and burro herd management areas within 5 kilometers (3 miles) of the transportation alignments and routes considered within Nevada. Sections 3.2.2.1.3, 3.2.2.1.4, and 3.2.2.2.4 and associated tables of the EIS highlight the biological resources close to the corridors and routes that are most likely to be affected by Nevada transportation activities. Impacts on those resources are discussed in Chapter 6. DOE agrees with the commenters that site-specific information would be necessary prior to construction of a branch rail line or road upgrades to support heavy-haul truck shipments. However, DOE believes that the EIS provides sufficient information on impacts to biological resources to make informed decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments), as well as the choice among alternative transportation corridors and routes in Nevada. If the site was approved, DOE anticipates that the project plan and design will continue to evolve, creating additional opportunities for mitigation and potentially eliminating the need for some mitigation measures currently under consideration. Section 9.1.1 (and subsequent sections in Chapter 9) describes DOE's initial list of commitments available at this time and identifies DOE-determined impact reduction features, procedures and safeguards and mitigation measures under consideration for inclusion in the project plan and design. Chapter 9 identifies ongoing studies that could influence mitigation measures related to the project plan and design.

As noted in Chapter 6 and Section 11.2.2 of the EIS, if a repository was to be constructed at Yucca Mountain, more detailed field surveys, government consultations, analyses, and appropriate National Environmental Policy Act reviews would be conducted with regard to the transport of waste to Yucca Mountain. These activities would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. They also would include field surveys (as applicable) and more detailed assessments and analyses of wetlands and other waters; floodplains; sensitive species; effects of habitat fragmentation, interruption of movements, mortality, and harassment on wildlife, horses, and burrows; loss of hunter-generated revenue, spread of noxious weeds, and soils.

8.11.4 (1412)
Comment - EIS000355 / 0007
We have renewable resources, as well, which will be probably destroyed for years and years and years to come.

Response
As discussed in Section 10.1.3.4 of the EIS, DOE expects limited short- or long-term impacts to renewable biological resources. Vegetation and wildlife would be lost from small areas that DOE would develop for the repository or for transportation routes. Long-term impacts would be related to maintenance of the routes and to the repository. Over the long term, destruction of any resource would be unlikely to be more significant than impacts from original construction. If a specific road or rail route was proposed, DOE would consider specific mitigation measures to avoid or minimize adverse impacts to biological resources in additional National Environmental Policy Act documentation.

8.11.4 (5568)
Comment - EIS001887 / 0197
Page 3-100; Section 3.2.2.1.1 - Land Use and Ownership

The region of influence for biological resources is also too narrowly defined. Habitat outside the corridor is considered in the regional of influence only if that habitat is disturbed by rail line construction and operations. Several of the corridors cross or pass near to crucial big game habitat. Human activity is known to reduce the value of crucial habitat, particularly crucial winter habitat. Frequent trains passing through or near to crucial habitat could significantly reduce the value of that habitat even though the habitat was not physically “disturbed” by construction or operation. The region of influence for biological resources should include all habitat potentially affected, not just disturbed, by construction and operation of the rail line (Note: This same discussion applies to the intermodal transfer station and heavy-haul routes.)

Response
Lists of the threatened and endangered species, sensitive species, game habitat, springs, and riparian areas known to occur within 5 kilometers (3 miles) of rail corridors have been added to Section 3.2.2.1.4 of the EIS. Sections 6.3.2.1 and 6.3.2.2 have been modified to better describe the impacts to biological resources within 5 kilometers of the corridors.

The region of influence for heavy-haul truck implementing alternatives remains as habitat that would be disturbed, and the EIS only lists and discusses biological resources within 400 meters (0.25 mile) of the heavy-haul truck routes and intermodal transfer station. This region of influence was not changed because highway construction would occur on and adjacent to existing roads and therefore should have no additional effect on biological resources distant from those roads. An intermodal transfer station would not be large enough to disrupt movements or otherwise affect distant biological resources. Section 6.3.3.1 of the EIS has been modified to clarify DOE’s conclusion about the lack of impacts to biological resources distant from heavy-haul truck routes or intermodal facilities.

8.11.4 (5905)
Comment - EIS001622 / 0024
Need for Complete Description and Analysis of Impacts on Wildlife, Natural Habitat and Public Use Parks

The California State Park system includes 265 park units encompassing 1.4 million acres within which the State is responsible for preserving representative samples of the extraordinary natural and cultural resources and biological diversity of our State. Along these routes is approximately half of California’s park units including State parks, State historic parks, State beaches as well as National parks. The EIS should evaluate the potential impacts along shipment corridors to fish and wildlife populations, natural habitat, and public parks in California, as well as proposed mitigation measures to offset these impacts.

There is no discussion in the DEIS of potential long-term adverse impacts to animals and plants. All of the DEIS' long-term evaluations are based on human health considerations. The DEIS makes the faulty assumption that the few predicted latent cancer fatalities from the proposed project will result in no impacts on the aquatic, wildlife, and plant populations that are dependent upon the water resources potentially affected by the project. These natural populations have taken tens of thousands to millions of years to adapt to their current habitats. These time scales should be considered in determining potential impacts to these populations.

Further, transportation routes could potentially impact habitat for threatened or endangered species. The DEIS should include a description of transportation routes, including road or rail construction or improvements in California, and impacts to species identified as of concern. (See the attached letter from the California Department of Fish and Game.) For example, desert bighorn sheep in California could be adversely impacted by potential transportation corridors in the Death Valley region. Bighorn sheep movement, and consequently their ability to forage for food and reach water sources, could be severely impacted by the construction of new highways, railroads, or road improvements that include barriers or fences.

Recommendation: The DEIS should provide a complete description and analysis of potential transportation impacts on wildlife, natural habitat and public use parks.

Response
DOE does not plan to modify existing public highways or rail lines in California or elsewhere outside Nevada that would be used to transport materials, personnel, or shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. The only potential impacts to parks in California would be those described and analyzed in Sections 6.2.3 of the EIS for incident-free transportation and 6.2.4 for potential accidents. These activities would not further fragment habitat for bighorn sheep or other wildlife in California and additional information on those routes, therefore, is not necessary.

The potential long-term adverse impacts of the Proposed Action are analyzed in Section 5.9 of the EIS. DOE did not assume that relatively few predicted latent cancer fatalities would result in no impacts to aquatic, wildlife, and plant populations. Instead, DOE based its conclusion on the results of calculations that estimated dose rates would be less than 100 millirad per day. The International Atomic Energy Agency concluded that chronic dose rates of less than 100 millirad per day are unlikely to cause measurable detrimental effects in populations of even the more radiosensitive species in terrestrial ecosystems (DIRS 103277-IAEA 1992).

8.11.4 (5946)
Comment - EIS001622 / 0049
The Department commented on the Site Characterization Plan (SCP) on March 23, 1989, and those comments are hereby incorporated by reference. In addition, the Amargosa nitrophila, Nitrophila mohavensis, a plant species listed as Endangered by both the State of California and U.S. Fish and Wildlife Service, should be included on the list of species contained in the March 23, 1989 letter. [Text of March 23, 1989, memorandum follows.]

The Department of Fish and Game has reviewed the U.S. Department of Energy's Site Characterization Plan (SCP) for the proposed Yucca Mountain, Nevada, high-level nuclear waste repository. The SCP describes the detailed studies that will be performed to determine the suitability of the site for nuclear waste disposal, and the potential environmental impacts of construction and operation of the repository. The Department is interested in the SCP because of potential impacts the waste repository could have on water supplies for California fish and wildlife populations in and near Death Valley National Monument.

The Death Valley area is one of the most arid regions in North America. Perennial water supplies in the region are available only where groundwater surfaces in springs or short reaches of streams. Many fish and wildlife species are totally dependent on the unique habitats that these isolated water supplies provide. Some of these species occur nowhere else on earth. The Department is particularly interested in the following species:

Amargosa pupfish:	*Cyprinodon nevadensis amargosae*
Saratoga Springs pupfish:	*Cyprinodon nevadensis nevadensis*
Salt Creek pupfish:	*Cyprinodon nevadensis salinus*
Cottonball Marsh pupfish:	*Cyprinodon salinus milleri*
Shoshone pupfish:	*Cyprinodon nevadensis shoshone*
Amargosa vole:	*Microtus californicus scirpensis*
Saratoga Springs Belostoman bug:	*Belostoma saratogae*

In addition, two as yet unclassified forms of Amargosa speckled dace (Rhinichthys osculus ssp.) occur in the area, and some endemic snail species have recently been discovered in the area as well. Of these species, the Amargosa vole is both State- and Federally-listed as endangered, and the Cottonball Marsh pupfish is listed by the State as threatened. Other species may well qualify for listing in the future, when more is known about them.

Because these species are totally dependent on surfacing groundwater, the Department is concerned about any effects the waste repository may have on groundwater flows and groundwater supplies. The SCP indicates that the groundwater that supplies the springs and streams in California originates from recharge areas in Nevada. These groundwaters flow underground, past the Yucca Mountain disposal site, and then to California in a slow, complicated underground path that the SCP indicates is not well understood. If the construction or operation of the waste repository interrupts or depletes these groundwater flows, water supplies for the many fish and wildlife species listed above, and other plant and animal species as well, could be reduced or cut off. Because some of these species occur nowhere else on earth, this could cause the extinction of several fish and wildlife species.

The Department believes that the U.S. Department of Energy should perform the necessary studies to determine if the project will reduce or cut off groundwater flows to California. The Department notes that the SCP describes several planned studies that relate to groundwater. However, the SCP does not include a study element specifically aimed at addressing potential project effects on fish and wildlife populations dependent on groundwater supplies. The Department recommends that such a study element be added to the SCP as a separate and significant part of the overall study plan. Furthermore, the Department recommends that if this study determines that impacts on California's fish and wildlife populations could occur, the U.S. Department of Energy should implement alternative project features or modifications, or develop adequate mitigation measures, so that these impacts do not occur.

Response

Nitrophila mohavensis is listed in the description of sensitive species at Ash Meadows (Section 3.1.5.1.3 of the EIS). As stated in Section 4.1.3.3, DOE does not anticipate that groundwater withdrawals would affect the regional groundwater system to an extent that could affect downgradient groundwater use or users.

8.11.4 (6294)

Comment - EIS001727 / 0009

There's a failure to adequately assess impacts beyond radiation impacts in Nevada, and I don't have time to tell you about the potential impacts of building a rail spur to Yucca Mountain on big horn sheep migration routes, but it's important to remember we have a sensitive and fragile desert ecology, and radiation is not the only issue with this facility.

Response

The EIS (Sections 4.1.4, 5.9, 6.1.2.4, 6.3.1.2, 6.3.2, and 6.3.3) provide analyses of both the radiological and nonradiological impacts on the biological resources. Regarding impacts on bighorn sheep, EIS Sections 3.2.2.1.4 and 3.2.2.2.4 highlight the sheep populations most likely to be affected. The *Environmental Baseline File for Biological Resources* (DIRS 104593-CRWMS M&O 1999), which is referenced in the EIS, further describes and maps bighorn sheep populations and migration corridors near candidate rail corridors that were considered. It is acknowledged in Section 9.3.4.2 that construction of some transportation routes could disrupt movements of game animals. Section 9.3.4.2 states that DOE would mitigate to reduce habitat fragmentation and barriers to animal movements in the design and construction of branch rail lines, routes, and fencing after seeking advice from wildlife agencies and organizations. As stated in Chapter 6 and elsewhere, DOE would conduct more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews if a proposal was made to select a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes. These would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. They also would include field surveys (as applicable) and more detailed assessments and analyses of wetlands and other waters; floodplains; sensitive species; effects of habitat fragmentation, interruption of movements, mortality, and harassment on wildlife, horses, and burrows; loss of hunter-generated revenue, spread of noxious weeds, and soils.

8.11.4 (7223)
Comment - EIS001337 / 0097
Page 3-129 2nd paragraph. The Caliente intermodal site is the location of the City of Caliente's wastewater treatment facility. Lands on the site are irrigated with effluent. The site is fully developed. Moist areas are likely the result of irrigation and are not springs or wetlands. This site has been previously cleared through NEPA [National Environmental Policy Act] for construction of wastewater treatment facilities using federal funding.

Response
Sections 3.2.2.2.1 and 6.3.3.2.1 of the EIS state that there is a wastewater treatment facility near the site of a candidate intermodal transfer station at Caliente. DOE has changed the text of Section 3.2.2.2.4 to clarify that moist areas within the site might be wetlands or other waters of the United States resulting from adjacent springs or they might be caused by irrigation from the treatment facility.

8.11.4 (7441)
Comment - EIS001969 / 0003
Transportation of high level radioactive waste to Yucca Mountain by truck or rail from nuclear facilities nationwide also has the potential to impact wildlife resources should a breach in containment occur. There is an inherent risk associated with transportation of any hazardous material. Although DOE has conducted detailed analysis of worst case scenarios, even the best waste management strategies cannot predict every possibility. We understand that the radioactive waste would be transported in a virtually leak-proof stainless steel cask in the form of dry pellets which would make release of any waste material extremely remote. Nevertheless, there remains a potential environmental risk, albeit minuscule, at any given point along the proposed rail or highway transportation corridor.

Response
DOE agrees that a release of hazardous materials during accidents involving spent nuclear fuel or high-level radioactive waste would be very unlikely. With regard to the potential impacts to wildlife resources, a transportation accident could result in the dispersal or death of individual members of a species within a localized area but would be unlikely to have long-term detrimental effects upon a population as a whole.

8.11.4 (10189)
Comment - EIS001888 / 0560
[Clark County summary of comments it has received from the public.]

The EIS should evaluate the impacts to game habitat and protect species from potential transportation accidents.

Response
Sections 6.3.2 and 6.3.3 of the EIS assess the impacts of transportation activities on game habitat and protected species, including the extent of habitat disturbances and the possibility that trucks or trains could accidentally kill animals. DOE did not evaluate impacts from potential transportation accidents directly because their estimated rates (see Section J.1.4.2.3.2) would be so low (3.21×10^{-7} accidents per truck-kilometer; 5.39×10^{-8} per railcar-kilometer) that losses of habitats or individuals would be unlikely to have detectable impacts on the regional populations of any species. In addition, impacts would be small in comparison to losses due to other traffic on the highways or rail lines.

8.11.4 (11311)
Comment - EIS001814 / 0040
DEIS Page 6-10
Loss of habitat from construction of a branch rail line would be the greatest potential impact to biological resources, potentially affecting the desert tortoise, a threatened species.

DEIS Page 6-46
Game and Game Habitat. Each candidate rail corridor would cross or be near [within 5 kilometers (3 miles)] several areas the Bureau of Land Management and the Nevada Division of Wildlife have designated as game habitat. Construction activities in these areas would result in a loss of some habitat. Each rail corridor has the potential to disrupt movement patterns of game animals. The design of fences, if built, along the rail corridor, would accommodate the movement of these animals. Large animals including game species (elk, bighorn sheep, mule deer, etc), wild horses, and burros probably would avoid contact with humans at construction locations and would temporarily move to other areas during construction. Numerous special status species occur along each of the branch rail lines. Construction of a branch rail line could lead to habitat loss and fragmentation for the special status species, as well as to mortality of individuals.

DOE has significantly understated the impact to biological resources. Loss of habitat would not be limited only to the physical loss of habitat due to the construction of the rail line. The operation of the rail line would reduce the value of habitat crossed or near to the line, resulting in significantly greater loss in habitat than just the area physically within the rail line right-of-way.

All of the rail corridors except the Valley Modified cross and are near to critical habitat for many species of wildlife. Critical habitat is absolutely necessary for wildlife. Human activity, such as the operation of a rail line, in or even near critical habitat can seriously degrade the value of that habitat for wildlife. This is especially true of linear facilities, such as a rail line, that pass through habitat areas. Without undisturbed access to critical habitat, the wildlife using that habitat may abandon large areas of year-round habitat. Critical habitat crossed by or near to rail corridors includes bighorn sheep crucial winter range, mule deer crucial winter range, pronghorn winter range, sage grouse strutting areas, sage grouse nesting areas, chukar crucial habitat and quail crucial habitat.

The Carlin and Jean corridors also cross migration corridors for big game. Linear facilities such as rail lines can significantly impact the movement of big game. This is particularly true in areas where steep cuts or fills are required. The Jean corridor also crosses a potential migration corridor for bighorn sheep from winter range in the Devils Hole Hills to historic but currently unoccupied habitat at the northwest end of the Spring Mountains. Although currently not used, the disruption of this migration corridor would be a significant impact. Bighorn sheep are particularly susceptible to disease. An unoccupied habitat area represents the potential to establish another herd unit that could provide greater protection for the continued recovery of the bighorn sheep.

The Environmental Baseline File for Biological Resources (TRW 1999k) lists the following crucial habitats within each of the 400 meter wide rail corridors:

Caliente: Bighorn Sheep Crucial Winter Habitat (Cedar Range), Mule Deer Crucial Winter Range (Cedar Range), Quail Crucial Habitat in Meadow Valley

Carlin: 3 Sage Grouse Strutting Areas (Grass Valley, Rye Patch Canyon, and Monitor Valley), Sage Grouse Nesting Area (Monitor Valley), Pronghorn Winter Range, Ungulate Migration Corridor between Simpson and Toquima Ranges, Bates Mountain Antelope Release Area, Simpson Park Habitat Management Area

Caliente Chalk Mountain: Bighorn Sheep Crucial Winter Habitat (Cedar Range), Mule Deer Crucial Winter Range (Cedar Range), Crucial Areas for Quail (Meadow Valley)

Jean: Crucial Bighorn Sheep Winter Habitat (Wilson Pass) and Winter Habitat (west of Wilson Pass), Bighorn Sheep Migration Corridor and Potential Migration Corridor, Crucial Chukar Habitat (Goodsprings), Crucial Areas for Quail (Goodsprings, Pahrump, Johnnie), and Mule Deer Winter Habitat

Although the Valley Modified corridor does not contain crucial habitat, it does cross the Desert National Wildlife Refuge (DNWR) in several places, including the Corn Creek Springs area. The DNWR was set aside primarily for desert bighorn sheep. It also provides habitat for mule deer, other desert mammals, and migratory birds. The Corn Creek area contains an environment filled with trees, pasture and spring-fed ponds which attract a large number of migrating birds not common to the desert environment. The ponds are home to the endangered Pahrump poolfish.

Each of the corridors contain many additional biological resources within the corridor or within 5 kilometers of the corridor. Although these resources are identified in the Environmental Baseline File, the DOE makes no attempt to quantify the impacts of the rail line on most of these resources.

The EIS does not contain an assessment of the impact of fencing on wildlife. This is inexcusable, since the impact of fencing was identified by the Bureau of Land Management as a major issue (TRW 1999k, p 5-1).

Response
DOE has added lists of the threatened and endangered species, sensitive species, game habitat, springs, and riparian areas that are known to occur within 5 kilometers (3 miles) of rail corridors and described those resources more fully in Section 3.2.2.1.4 of the EIS. Sections 6.3.2.1 and 6.3.2.2 have been modified to describe the impacts on game animals. This information describes the impacts to biological resources from the construction of a branch rail line in a corridor. It is, therefore, sufficient for making decisions on the basic approaches for transportation and the choice among transportation corridors. As suggested in the Foreword to the EIS, Chapter 6, and elsewhere, DOE would conduct detailed field surveys, analyses, consultations with the Bureau of Land Management and Nevada Division of Wildlife, and appropriate National Environmental Policy Act reviews if there was a proposal to select a specific rail alignment in a corridor.

All candidate rail corridors but the Valley Modified would cross several areas the Bureau of Land Management and Nevada Division of Wildlife have designated as game habitat (see Section 3.2.2.1.4 of the EIS). In addition, the candidate rail corridors are within 5 kilometers (3 miles) of other game habitat and some cross areas identified as migration routes. An approximately 60-meter (200-foot)-wide section of game habitat would be cleared of vegetation or otherwise disturbed during construction, and other game habitat would be lost in borrow areas, access roads, and other disturbances required to construct a branch rail line. Some of this land would be reclaimed after construction, but the value of that land to game and other wildlife would be diminished for many years. The value of habitat adjacent to a branch rail line would be diminished if game animals avoided those areas due to noise or presence of humans. Construction of a branch rail line could disrupt movements between those habitats and along migration routes, especially if DOE had to fence the rail line. Fence design would accommodate the movements of game animals to the extent possible. The construction of a branch rail line could decrease hunting opportunities in and adjacent to habitat along a corridor.

8.11.4 (11749)
Comment - EIS002299 / 0007
California's State Park System contains 265 park units encompassing 1.4 million acres within which the State is responsible for preserving representative samples of the State's extraordinary biological resources and diversity. Nearly half of these park units, including State Parks, State Historic Parks, State Beaches and State Recreational Areas, are located along potential spent fuel shipment routes in California. In addition, the Death Valley National Park is located adjacent to potential routes in California.

California agencies, as well as the Superintendent of Death Valley National Park, expressed concern about potential transportation impacts in the Death Valley region as well as impacts from these shipments on parks adjacent to shipment corridors. These regions have remote and very limited emergency response capability. In addition, there is concern about the potential impacts on plant and animal populations in the Death Valley region in the event of radionuclide contamination and migration in groundwater, as well as potential adverse impacts on desert bighorn sheep from any roadway or rail construction or improvements.

Response
The calculations in Chapter 5 of the EIS indicate that predicted long-term levels of radionuclide concentration in groundwater and the resulting dose levels at the predicted discharge area in Amargosa Valley, Nevada, would be low. DOE does not expect that the dose rates to plants and animals at that location would cause measurable

detrimental effects in populations of any species because the rates would be less than 100 millirad per day. The International Atomic Energy Agency concluded that chronic dose rates of less than 100 millirad per day are unlikely to cause measurable detrimental effects in populations of even the more radiosensitive species in terrestrial ecosystems (DIRS 103277-IAEA 1992). DOE acknowledged in Section 3.1.4.2.1 of the EIS that a small amount of groundwater might move beyond the primary groundwater discharge point at Alkali Flat (Franklin Lake Playa) to discharge in the Furnace Creek area of Death Valley. However, even if this were to occur, any concentrations in the Furnace Creek area of California would be even less than the concentrations presented in Chapter 5 for the discharge location, because concentrations would decline with distance from the proposed repository.

DOE does not plan to modify highways in California or elsewhere outside Nevada that it would use to transport materials, personnel, or legal-weight truck shipments of spent nuclear fuel to Yucca Mountain. Therefore, these activities would not adversely affect bighorn sheep. Transportation-related habitat fragmentation could occur if highway upgrades were necessary in Nevada for heavy-haul trucks or during construction of a branch rail line. The *Environmental Baseline File for Biological Resources* (DIRS 104593-CRWMS M&O 1999, all) describes bighorn sheep populations and migration corridors near the routes DOE is considering, and Sections 3.2.2.1.4 and 3.2.2.2.4 of the EIS highlight the sheep populations most likely to receive impacts. DOE acknowledges in Section 9.3.4.2 that construction of some transportation routes could disrupt movements of game animals. Section 9.3.4.2 states that DOE would use mitigation measures to reduce habitat fragmentation and barriers to animal movements in the design and construction of branch rail lines, routes, and fencing after seeking advice from wildlife agencies and organizations. As stated in Chapter 6 and elsewhere in the EIS, DOE would conduct a more detailed assessment of potential impacts on wildlife habitat and movements if it selected a heavy-haul truck or rail route to evaluate and mitigate impacts to bighorn sheep and other resources.

8.11.4.1 Vegetation

8.11.4.1 (5151)
Comment - EIS001444 / 0003
Threatened & Endangered Plants and State Sensitive Plants

State law requires you to survey for cacti along both routes [Caliente and Carlin].

Both routes must be surveyed for T & E and State Sensitive plant species. The following is a list of state sensitive plants which must be surveyed for.

Asclepia eastwoodiana, Eastwood Milkweed - Check all of both the Carlin and Caliente routes north of Stonewall Mountain. The plant usually grows in washes or low hills.

Astragalus funereus, Black Woolypod - Check both routes south of Scotty's Junction into the Test Site. It generally grows on hillsides.

Cymopterus ripleyi var saniculoides, Sanicle Biscuitroot - Check the Carlin route through Smoky Valley to Tonopah. The plant usually grows in sandy soils.
Penstemon arenarius, Nevada Dune Beard-tongue - Check all of both the Caliente route. The plant usually grows in sandy soils.

Sclerocactus nyensis - Check both routes from Tonopah south into the Test Site. It grows on soils derived from volcanic ash.

The Carlin route through Smoky Valley appears to go by or through Cresent Dunes T.4 N., R.41 E., plate 6. This area has recreation value along with a number of State Sensitive species. The train should be run through the far western edge of the corridor to avoid Crescent Dunes if this route is chosen. If any of the above plants are found, mitigating measures need to be implemented at that time.

Response
The *Environmental Baseline File for Biological Resources* (DIRS 104593-CRWMS M&O 1999) contains detailed maps of the known locations of sensitive plant and animal species (including Bureau of Land Management-sensitive

species) within 5 kilometers (3 miles) of rail corridors. DOE obtained this information in part from meetings held with Bureau biologists in Battle Mountain (January 27, 1997) and Tonopah (February 14, 1997) and from Resource Management Plans. The Draft EIS included lists of those species. This information will allow DOE to determine if there would be any significant impacts to biological resources from upgrades of a highway to support heavy-haul vehicles or construction of a branch rail line with in any of the rail corridors. It is, therefore, sufficient for making decisions regarding the basic approaches for transportation, as well as the choice among alternative transportation corridors. As indicated in Chapter 6 and elsewhere in the EIS, if the site was approved DOE would conduct more detailed field surveys, analyses, consultations with the Bureau, and appropriate National Environmental Policy Act reviews to evaluate further the impacts associated with a specific rail corridors or heavy-haul truck route. These would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. They also would include field surveys (as applicable) and more detailed assessments and analyses of wetlands and other waters; floodplains; sensitive species; effects of habitat fragmentation, interruption of movements, mortality, and harassment on wildlife, horses, and burrows; loss of hunter-generated revenue, spread of noxious weeds, and soils.

8.11.4.2 Wildlife

8.11.4.2 (43)
Comment - 3 comments summarized
The EIS should evaluate the impacts that fencing of a rail line could have on the habitat and movement of wildlife.

Response
Section 3.2.2.1.4 of the EIS lists the big game habitat that is crossed by the candidate rail corridors. These habitats and other biological resources near the corridors are further described and mapped in the *Environmental Baseline File for Biological Resources* (DIRS 104593-CRWMS M&O 1999). It is acknowledged in Section 6.3.2.1 that construction of a branch rail line could disrupt movements of game animals and that fencing would be designed to accommodate movements of wildlife. Section 9.3.4.2 lists modification of branch rail lines, routes, and fencing as a mitigation measure to minimize impacts of rail line construction on animal movements. DOE agrees with the comments that additional, site-specific information on fencing would be necessary prior to construction of a branch rail line. However, DOE believes that the EIS provides sufficient information on impacts to biological resources to make informed decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments), as well as the choice among alternative transportation corridors. If the site was approved, DOE anticipates that the project plan and design would continue to evolve, creating additional opportunities for mitigation and potentially eliminating the need for some mitigation measures currently under consideration. Chapter 9 of the EIS, which provides DOE's initial list of commitments available at this time, identifies DOE-determined impact reduction features, procedures and safeguards; and mitigation measures under consideration for inclusion in the project plan and design. Chapter 9 also identifies ongoing studies that could eventually influence mitigation measures related to the project plan and design.

As noted in Chapter 6 and elsewhere in the EIS, if a repository was to be constructed at Yucca Mountain, a more detailed assessment of the potential impacts on wildlife habitat and wildlife movements would be prepared for a specific rail alignment.

8.11.4.2 (392)
Comment - EIS000039 / 0002
The Virgin River may be the home of certain endangered species of fish, other wildlife and fauna.

Response
On December 17, 1998, DOE requested a species list from the U.S. Fish and Wildlife Service and began a formal consultation to evaluate if the Proposed Action could affect endangered and threatened species, including those in the Virgin and Muddy rivers. DOE submitted its Biological Assessment of possible effects to the U.S. Fish and Wildlife Service on April 24, 2000. DOE and the U.S. Fish and Wildlife Service have completed consultation on the potential effects of repository construction, operation, and closure on threatened and endangered species. In its Biological Opinion, the Fish and Wildlife Service concluded that these actions would not jeopardize the continued existence of the Mojave population of the desert tortoise (see Appendix O of the EIS for the Final Opinion). Species in and near the Virgin River would not be affected.

8.11.4.2 (2211)
Comment - EIS000621 / 0001
My family and I own the Crescent Valley Mineral Hot Springs Trailer Park and Farms which is located one and-a-half miles from the proposed rail line outside of Crescent Valley at Hot Springs Point.

The rail line crosses between our place and town. We have a lot of concerns about the impact on our area there because it's a major riparian area and a wildlife area.

Response
DOE is aware of these springs (see DIRS 104593-CRWMS M&O 1999). The corridor is more than 2 kilometers (1.2 miles) from the springs and, therefore, should not affect the riparian areas or wildlife using them. As suggested in Chapter 6 of the EIS, if DOE chose the Carlin Corridor, it would conduct additional detailed field surveys, analyses, and appropriate National Environmental Policy Act reviews to further evaluate impacts to these springs. As stated in Section 9.3.4.2, DOE is committed to minimizing and mitigating impacts of construction and operation of a transportation route on springs and other riparian areas.

8.11.4.2 (2719)
Comment - EIS000637 / 0002
We own a hot springs, pool and house, one-half mile from the proposed rail line and a trailer one and-a-half miles on the other side. At our hot springs, there [are] a lot of different kind of birds that come there. We have a wetlands, and there's been about 50 different species of birds that land there and rest up before they go on to other places, and we have a lot of animals there, and if they build a railroad, all that noise is going to scare them away, and plus the train will scare them away when it comes through here.

Response
DOE is aware of these springs (see DIRS 104593-CRWMS M&O 1999). The corridor is more than 2 kilometers (1.2 miles) from the springs and, therefore, should not affect the riparian areas or wildlife using them. As indicated in Chapter 6 of the EIS, if DOE chose the Carlin Corridor, it would conduct additional detailed field surveys, analyses, and appropriate National Environmental Policy Act reviews to further evaluate impacts to these springs. As stated in Section 9.3.4.2, DOE is committed to minimizing and mitigating impacts of construction and operation of a transportation route on springs and other riparian areas.

8.11.4.2 (4147)
Comment - EIS001206 / 0002
The discussion of Environmental Impacts of Transportation to Biological Resources and Soils (Section 6.1.2.4) relating to the construction of a branch rail line is inadequate because it fails to properly consider and address the regional and rangewide implications of the loss of unique desert tortoise (Gopherus agassizii) populations and the genetic potential of these populations at northern extremes of this species range. It is inadequate because it fails to properly consider and address the regional and rangewide implications of increases in traffic on unique desert tortoise (Gopherus agassizii) populations at the northern extremes of this species range due to this activity. It is inadequate because it fails to properly consider and address the regional and rangewide implications of increases in raven populations and their increased levels of predation on unique desert tortoise (Gopherus agassizii) populations at the northern extremes of this species range due to this activity.

The discussion of impacts of construction of a branch rail line is inadequate because it fails to properly consider and address the regional and rangewide implications of loss of individuals and the loss of impacts on unique desert tortoise (Gopherus agassizii) populations at the northern extremes of this species range due to this activity.

The discussion of the Jean rail corridor is inadequate because it fails to consider that this corridor would pass through or near the Clark County Desert Tortoise Large-Scale Translocation Study Site (LSTS) west of Jean. Clark County has invested significant resources in establishing this site and funding studies to investigate the efficacy of translocating displaced desert tortoises. Currently more than 2,000 displaced desert tortoises have been successfully translocated to this site and many more will be translocated over the coming several years. This site is crucial to desert tortoise conservation and management in Clark County. The people of Clark County have overwhelmingly supported desert tortoise conservation actions because, in part, displaced tortoises have been humanely provided a wild home at the LSTS. Threats to the integrity of the LSTS would jeopardize public support for tortoise conservation efforts.

The discussion of impacts of construction of a branch rail line in the Valley Modified corridor is inadequate because it fails to properly consider and address the regional and rangewide implications of loss of individuals and that loss of impacts on unique desert tortoise (Gopherus agassizii) population at the northern extremes of this species range due to this activity.

Response
DOE did consider the regional and rangewide implications of the Proposed Action, the loss of genetic potential, and impacts of transportation options on desert tortoises and concluded that the Proposed Action could affect a few individual tortoises, but would not negatively affect the genetic potential or the long-term survival of regional populations of desert tortoises or jeopardize the continued existence of the species. The abundance of desert tortoises within most of the candidate rail corridors is low. In addition, DOE would implement all terms and conditions of the incidental take authorization included in the U.S. Fish and Wildlife Service's Biological Opinion, including those for minimizing impacts from ravens. Section 6.1.2.4 of the EIS has been modified to better clarify this conclusion.

DOE believes that the EIS provides the information necessary to make decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments), as well as the choice among alternative transportation corridors. As stated in the Chapter 6, more detailed field surveys, analyses, and appropriate National Environmental Policy Act reviews would be conducted if a specific branch rail line alignment was chosen. If necessary, this would include more detailed analyses of the impacts on desert tortoises, including the potential effects on translocation studies being conducted near Jean.

8.11.4.2 (4148)
Comment - EIS001206 / 0003
The discussion of Impacts of Nevada Mostly Legal-Weight Truck Transportation Scenario (Section 6.3.1.1) is inadequate because it fails to properly consider and address the regional and rangewide implications of the loss of unique desert tortoise (Gopherus agassizii) populations and the genetic potential of these populations at the northern extremes of this species range in the vicinity of the Repository and throughout Southern Nevada adjacent to I-15 and U.S. 95. It is inadequate because it fails to properly consider and address the regional and rangewide implications of increases in traffic on unique desert tortoise (Gopherus agassizii) populations at the northern extremes of this species range in the vicinity of the Repository and throughout Southern Nevada adjacent to I-15 and U.S. 95 due to this activity. It is inadequate because it fails to properly consider and address the regional and rangewide implications of increases in raven populations and their increased levels of predation on unique desert tortoise (Gopherus agassizii) populations at the northern extremes of this species range in the vicinity of the Repository and throughout Southern Nevada adjacent to I-15 and U.S. 95 due to this activity. The discussion of the contribution of truck traffic related to this activity and its impact on desert tortoise populations is lacking a consideration of noise and low frequency vibrations. This issue is of concern to Clark County because it is engaged in supporting significant conservation actions in areas adjacent to and in the regional vicinity of the Repository that may be indirectly impacted.

The discussion of the impacts of the Caliente-Las Vegas heavy-haul truck route (Section 6.3.3.1) is inadequate because it fails to properly consider and address the local, regional, and rangewide implications of the loss of unique desert tortoise (Gopherus agassizzi) populations and the genetic potential of these populations at the northern extremes of this species range in the vicinity U.S. 93 in Coyote Springs Valley due to construction activities in upgrading the roads. It is inadequate because it fails to properly consider and address the local, regional and rangewide implications of increases in raven populations and their increased levels of predation on unique desert tortoise (Gopherus agassizii) populations at the northern extremes of this species range in the vicinity of U.S. 93 in Coyote Springs Valley due to construction activities and increased traffic during operation. The discussion of the contribution of truck traffic related to this activity and its impact on desert tortoise populations is lacking a consideration of noise and low frequency vibrations and their impacts on desert tortoises. This issue is of concern to Clark County because it is engaged in supporting significant conservation actions in areas adjacent to and in the regional vicinity of the Repository and along the Caliente-Las Vegas heavy-haul truck route and in the regional vicinity of the route that may be indirectly impacted.

The discussion of the impacts of the Sloan/Jean heavy-haul truck route (Section 6.3.3.2.1) is inadequate because it fails to properly consider and address the local, regional, and rangewide implications of the loss of unique desert tortoise (Gopherus agassizii) populations and the genetic potential of these populations at the northern extremes of this species range in the vicinity I-15 in upper Ivanpah Valley due to construction activities in upgrading the roads and construction of the intermodal transfer station. It is inadequate because it fails to properly consider and address the local, regional, and rangewide implications of increases in raven populations and their increased levels of predation on unique desert tortoise (Gopherus agassizii) populations at the northern extremes of this species range in the vicinity of I-15 due to construction activities and increased traffic during operation. The discussion of the contribution of truck traffic related to this activity an its impact on desert tortoise populations is lacking a consideration of noise and low frequency vibrations and their impacts on desert tortoises. The discussion of the Sloan/Jean heavy-haul truck route is inadequate because it fails to consider that this route would pass through or near the Clark County Desert Tortoise Large-Scale Translocation Study Site (LSTS) west of Jean and west of I-15. Clark County has invested significant resources in establishing this site and funding studies to investigate the efficacy of translocating displaced desert tortoises. Currently more than 2,000 displaced desert tortoises have been successfully translocated to this site and many more will be translocated over the coming several years. This site is crucial to desert tortoise conservation and management in Clark County. The people of Clark County have overwhelmingly supported desert tortoise conservation actions because, in part, displaced tortoises have been humanely provided a wild home at the LSTS, Threats to the integrity of the LSTS would jeopardize public support for tortoise conservation’s efforts. This issue is of concern to Clark County because it is engaged in supporting significant conservation actions in areas adjacent to and in the regional vicinity of the Repository and along the Caliente-Las Vegas heavy-haul truck route and in the regional vicinity of the route that may be indirectly impacted.

This discussion of the impacts of the Apex/Dry Lake heavy-haul truck route (Section 6.3.3.1) is inadequate because it fails to properly consider and address the local, regional, and rangewide implications of the loss of unique desert tortoise (Gopherus agassizii) populations and the genetic potential of these populations at the northern extremes of this species range in the vicinity I-15 and U.S. 95 due to construction activities and increased traffic during operation. The discussion of the contribution of truck traffic related to this activity and its impact on desert tortoise populations is lacking a consideration of noise and low frequency vibrations and their impacts on desert tortoises. This issue is of concern to Clark County because it is engaged in supporting significant conservation actions in areas adjacent to and in the regional vicinity of the Repository and along the Caliente-Las Vegas heavy-haul truck route and in the regional vicinity of the route that may be indirectly impacted.

Response

As stated in Section 6.3.1.2 of the EIS, legal-weight truck shipments would have little or no additional effect on desert tortoises or the abundance of ravens because they would increase truck traffic on Nevada highways by less than 0.15 percent. Upgrading of highways to support heavy-haul trucks would have minimal impact on desert tortoises because associated land disturbances would occur adjacent to those highways, where tortoises are rare or absent. Section 6.1.2.4 has been modified to clarify this conclusion. DOE is unaware of any scientific information about adverse effects of noise or low-frequency vibrations on tortoises.

DOE believes that the EIS provides the information necessary to make decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments) as well as the choice among alternative transportation corridors. As indicated in Chapter 6 of the EIS, more detailed field surveys, analyses, and appropriate National Environmental Policy Act reviews would be prepared if a specific heavy-haul route was chosen. If necessary, this would include more detailed analyses of the impacts on desert tortoises, including the potential effects on translocation studies being conducted near Jean, Nevada.

8.11.4.2 (5148)

Comment - EIS001444 / 0001

Caliente Route

This route will impact the Reveille, Stone Cabin, Saulsbury, Goldfield, Stonewall, and Bullfrog Wild Horse and Burro Herd Management Areas.

Smoky Valley Route

This route will impact the Dunlap, Goldfield, Stonewall, and Bullfrog Wild Horse and Burro Herd Management Areas.

Monitor Valley Route
This route will impact the Saulsbury, Goldfield, Stonewall, and Bullfrog Wild Horse and Burro Herd Management Areas.

Impacts: The construction of a new haul road or of a rail line will result in several years (2.5 years according to the EIS) worth of disturbance to the Herd Management Areas (HMAs) which these routes will cross. Disturbance will include loss of habitat including forage and water, and may impact foaling areas and traditional winter use areas.

These animals have never seen trains before and the occurrence of such a large, noisy object may cause them to move to different areas to avoid the disturbance. Some of these areas may be outside of their current HMAs. Animals moving outside of their HMAs would have collateral damage on other programs and would likely result in the gathering and removal of these animals.

The loss of habitat is not limited to the direct ground disturbing exercises, but also includes the distance significant noise travels. This noise and activity may cause wild horses and burros to leave the area.

Direct impacts could also include being hit by the train or by the haul trucks. The EIS says “losses would be few and unlikely to affect regional populations of any species.” In areas with large numbers of animals this may be true. However, in HMAs with 30 or fewer individuals, the taking of one or two individuals a year may change the entire demographics of a herd. These additional losses coupled with existing losses raises the significance of the cumulative impacts in many areas.

The alternative of using trucks along existing routes will have the least impact on the wild horse and burro resources of this area.

Response
Section 3.2.2.1.4.1 of the EIS lists the wild horse and burro herd management areas mentioned in this comment. Sections 6.3.2.1 and 6.3.2.2 acknowledge the loss of horse and burro habitat and disruption of their movements. DOE modified Section 6.3.2.1 to describe the impacts of construction and operation to wild horses and burros and to include the comment’s concern that the potential loss of a few individuals could affect the demographics of small herds. DOE disagrees with the comment that heavy-haul trucks could hit horses and burros; these vehicles would travel at such slow speeds that collisions with horses and burros would be unlikely.

8.11.4.2 (5159)
Comment - EIS001444 / 0012
To make an accurate assessment to impacts to biological resources, a more detailed map will be needed.

The EIS and Appendix J had little information on affected environment and impacted environment to biological resources. A list of BLM [Bureau of Land Management] Sensitive Species that may be affected for the rail routes were not included and [were] referenced only as a number of SSS [state-sensitive species]. What about sensitive/non sensitive bats? These proposed routes will cross foraging habitat areas.

Carlin Rail Corridor
The proposed rail lines will cross through crucial habitat for the Western sage grouse. The routes will most likely have an affect on lekking, nesting, wintering birds, and predation of sage grouse. Studies conducted on the Modoc have shown adverse impacts to sage grouse leks and populations from overhead transmission lines. Sage grouse will be disturbed on leks (in close proximity of rail line), predation and nest loss will likely increase along the rail routes due to associated facilities (i.e. transmission lines that provide predator perches), and habitat fragmentation. Numerous other sensitive species need to be addressed.

Wetland habitats in Oasis Valley near Beatty, are currently being considered for an ACEC nomination under a Land Use Plan Amendment. A conservation agreement and strategy for the Amargosa toad is currently in draft form and will provide for management direction in/near toad habitat.

Has consultation with USFWS begun on desert tortoise?

Caliente Rail Corridor
Where is the location of Railroad Valley springfish on this route? Numerous other sensitive species need to be addressed.

Also issues addressed in the Carlin Route: tortoise, Amargosa-Oasis ACEC, and sage grouse to a lesser extent.

The discussion of special status species (raptors, sage grouse, plants, etc.) is inadequate and almost non-existent.

Response
Detailed maps of sensitive plant and animal species (including Bureau of Land Management sensitive species) within 5 kilometers (3 miles) of rail corridors are contained in the *Environmental Baseline File for Biological Resources* (DIRS 104593-CRWMS M&O 1999). Lists of those biological resources have been added to Section 3.2.2.1.4 of the EIS. This information, including a list of Bureau-sensitive species, was obtained in part from meetings held with Bureau biologists in Battle Mountain (January 27, 1997) and Tonopah (February 14, 1997) and from Bureau Resource Management Plans. The *Environmental Baseline File for Biological Resources* describes locations of sensitive species (including desert tortoise, bats, ferruginous hawk, San Antonio pocket gopher, chuckwalla, and Nevada sanddune beardtongue) and 12 areas of sage grouse habitat within 5 kilometers of the Carlin Corridor. It also describes and maps the Area of Critical Environmental Concern along the Amargosa River, which is more than 3 kilometers (2 miles) from the proposed alignment. Section 6.3.2.2.2 has been modified to better describe possible impacts to sage grouse and other biological resources along the Carlin Corridor. The information on biological resources in the EIS will allow DOE to determine whether there would be any significant impacts to those resources from construction of a branch rail line within any of the rail corridors. It is, therefore, sufficient for making decisions regarding the basic approaches for transportation as well as the choice among alternative transportation corridors. As indicated in Chapter 6 of the EIS, DOE would conduct more detailed field surveys, analyses, consultations with the Bureau, and appropriate National Environmental Policy Act reviews if a decision is made to select a specific rail alignment in a corridor.

DOE and the U.S. Fish and Wildlife Service recently completed consultation (as required by Section 7 of the Endangered Species Act) for construction, operation and monitoring and closure of a repository at Yucca Mountain (see Appendix O of the EIS). If a rail or heavy-haul truck route was selected, DOE would initiate consultation for construction activities.

The only population of the Railroad Valley springfish near a transportation corridor is the introduced population in Warm Springs. This spring is more than 3 kilometers (1.9 miles) north of the Caliente Corridor (see Section 3.2.2.1.4 of the EIS) and adjacent to U.S. 6, which is part of the proposed Caliente heavy-haul truck route (see Section 3.2.2.2.4).

8.11.4.2 (5395)
Comment - EIS001887 / 0103
Page 2-47, Section 2.1.3.3.2 - Nevada Rail Scenario

Crucial habitat for big game is frequently located in or near rugged terrain. This is especially true for crucial winter habitat. Daylight cuts required to traverse rugged terrain also pose a significant threat to big game, which tend to use these areas for movement, especially in times of heavy snow cover. When trapped in a daylight cut, big game cannot escape from an oncoming train, resulting in significant mortality rates for big game in these areas. Thus, the selection criteria that favors more rugged terrain by virtue of avoiding private land ownership greatly increases the potential impact on biological resources.

Response
DOE acknowledges that avoidance of private land in areas with gentle topography might have resulted in some alignments that would require cut slopes that could affect movements of big game. However, as stated in Section 2.3.3.1 of the EIS, "favorable topography (gently sloping, rather than rugged terrain)" was an important factor in the selection of candidate rail routes. Section 6.3.2.1 has been modified to more clearly state that some big game animals could be killed by trains during the operations phase. However, DOE disagrees with the comment that these losses would be significant because the proposed routes go through very few high-elevation mountain passes where snow would accumulate for long periods and because the frequency at which trains would be using a branch rail line

to Yucca Mountain would be low (average of five trains per week). As stated in Section 9.3.4.2, DOE is committed to reducing habitat fragmentation and barriers to animal movements in the design and construction of branch rail lines, routes, and fencing after seeking advice from wildlife agencies and organizations.

8.11.4.2 (5540)
Comment - EIS001660 / 0042
The DEIS fails to adequately address the impacts of the proposed action on wild and free-roaming horses and burros in Mineral County. Many horses and burros inhabit the public and private range lands of the county as well as many rural counties in Nevada. They are protected under the Wild and Free-roaming Horse and Burro Act and are important to the residents of Mineral County and other Nevada counties. The DEIS says (under the land use heading) that the Carlin corridor would cross five management areas (p. 6-60) or six management areas (p. 6-62), and that land would be "converted"; but, the DEIS does not discuss the impacts. The DEIS must analyze how the construction of the proposed Carlin rail corridor (and associated fences and access roads), and related alternative transportation route improvements would affect these horses and burros.

The DEIS stated the "There are no known endangered species on the Yucca Mountain site" (p. 11-15). Then stated that "the desert tortoise in the only threatened species found on the site" 11-15). The DOE maintains it will "fulfill the requirements of the Endangered Species Act, as appropriate, with regard to transportation impacts before making the recommendation determination" (p. 1- 15); yet, it does not identify any endangered species along the transportation routes. The American Buffalo (Bison) which is part of our American heritage inhabit many of the lands not only in the Nevada rural counties, but also in other counties across the country. These majestic animals are an endangered species. Would they be affected and how would they be protected? The DEIS only analyzed endangered species for the YM [Yucca Mountain] site. The DEIS must analyze endangered species along transportation routes, to include related alternative transportation route improvements and the construction of any rail corridors, and address how these animals would be affected.

The DEIS must address direct and indirect impacts on the horses, burros, bison and any endangered species along the transportation routes: (1) their movement and safety; (2) water supplies; (3) forage; and (4) harassment. Would the proposed action cause more damage to the range by restricting the forage for these animals?

Response
The herd management units, threatened and endangered species, and other biological resources most likely to be affected are highlighted in EIS Sections 3.2.2.1.4 and 3.2.2.2.4. As summarized in Chapter 6, the desert tortoise is the only threatened or endangered species that occurs within areas to be disturbed for construction or development of a branch rail line or upgrade of highways for heavy-haul trucks; therefore, DOE has concluded that the desert tortoise is the only such species that would be affected by the Proposed Action. The wood bison, which is found only in Canada, is the only bison classified by the U.S. Fish and Wildlife Service as threatened or endangered. The Proposed Action would have no impact on free-ranging populations of American buffalo.

DOE agrees with the comment that additional, site-specific information would be necessary prior to construction of a branch rail line or road upgrades to support heavy-haul truck shipping. However, DOE believes that the EIS provides sufficient information on impacts to biological resources necessary to make decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments), as well as the choice among alternative transportation corridors. As indicated in Chapter 6 and elsewhere in the EIS, more detailed field surveys, analyses, and appropriate National Environmental Policy Act reviews would be performed and consultations conducted with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies if a specific branch rail line alignment was chosen. These additional surveys, reviews and consultations would include, as appropriate, more detailed analyses on impacts to endangered species and wild horse herd management units.

8.11.4.2 (5697)
Comment - EIS001887 / 0311
Page 6-10; Section 6.1.2.4 - Biological Resources and Soils

DOE has significantly understated the impact to biological resources. Loss of habitat would not be limited only to the physical loss of habitat due to the construction of the rail line. The operation of the rail line would reduce the value of habitat crossed or near to the line, resulting in significantly greater loss in habitat than just the area physically within the rail line right-of-way.

All of the rail corridors except the Valley Modified cross and are near to critical habitat for many species of wildlife. Critical habitat is absolutely necessary for wildlife. Human activity, such as the operation of a rail line, in or even near critical habitat, can seriously degrade the value of that habitat for wildlife. This is especially true of linear facilities, such as a rail line, that pass through habitat areas. Without undisturbed access to critical habitat, the wildlife using that habitat may abandon large areas of year round habitat. Critical habitat crossed by or near to rail corridors includes bighorn sheep crucial winter range, mule deer crucial winter range, pronghorn winter range, sage grouse strutting areas, sage grouse nesting areas, chukar crucial habitat, and quail crucial habitat.

The Carlin and Jean corridors also cross migration corridors for big game. Linear facilities such as rail lines can significantly impact the movement of big game. This is particularly true in areas where steep cuts or fills are required. The Jean corridor also crosses a potential migration corridor for bighorn sheep from winter range in the Devil's Hole Hills to historic but currently unoccupied habitat at the northwest end of the Spring Mountains. Although currently not used, the disruption of this migration corridor would be a significant impact. Bighorn sheep are particularly susceptible to disease. An unoccupied habitat area represents the potential to establish another herd unit that could provide greater protection for the continued recovery of the bighorn sheep.

The Environmental Baseline File for Biological Resources (TRW 1999k) lists the following crucial habitats within each of the 400 meter wide rail corridors:

Caliente: Bighorn Sheep Crucial Winter Habitat (Cedar Range), Mule Deer Crucial Winter Range (Cedar Range), Quail Crucial Habitat in Meadow Valley

Carlin: 3 Sage Grouse Strutting Areas (Grass Valley, Rye Patch Canyon, and Monitor Valley), Sage Grouse Nesting Area (Monitor Valley), Pronghorn Winter Range, Ungulate Migration Corridor Between Simpson and Tacoma Ranges, Bates Mountain Antelope Release Area, Simpson Park Habitat Management Area

Caliente B Chalk Mountain: Bighorn Sheep Crucial Winter Habitat (Cedar Range), Mule Deer Crucial Winter Range (Cedar Range), Crucial Areas for Quail (Meadow Valley)

Jean: Crucial Bighorn Sheep Winter Habitat (Wilson Pass) and Winter Habitat (west of Wilson Pass), Bighorn Sheep Migration Corridor and Potential Migration Corridor, Crucial Chukar Habitat (Goodsprings), Crucial Areas for Quail (Goodsprings, Pahrump, Johnnie), and Mule Deer Winter Habitat

Although the Valley Modified corridor does not contain crucial habitat, it does cross the Desert National Wildlife Refuge (DNWR) in several places, including the Corn Creek Springs area. The DNWR was set aside primarily for desert bighorn sheep. It also provides habitat for mule deer, other desert mammals, and migratory birds. The Corn Creek area contains an environment filled with trees, pasture, and spring-fed ponds which attract a large number of migrating birds not common to the desert environment. The ponds are home to the endangered Pahrump poolfish.

Each of the corridors contain many additional biological resources within the corridor or within 5 kilometers of the corridor. Although these resources are identified in the Environmental Baseline File, the DOE makes no attempt to quantify the impacts of the rail line on most of these resources.

The Draft EIS does not contain an assessment of the impact of fencing on wildlife. This is inexcusable, since the impact of fencing was identified by the Bureau of Land Management as a major issue (TRW 1999k, p. 5B1).

Potential transportation impacts to biological resources and soils are only curtly addressed in this section. There is insufficient information and substance for the section to be meaningful.

This section should also include a rigorous analysis of potential impacts from the spread of noxious or invasive plant species as a result of rail spur construction, heavy-haul truck highway improvement, and other activities that facilitate or promote the proliferation of noxious weeds.

<u>Response</u>
Lists of biological resources within and near rail corridors (including those listed by the commenter) have been added to Section 3.2.2.1.4 of the EIS. Sections 6.3.2.1 and 6.3.2.2 have been modified to address the commenter's concerns and more clearly describe impacts of branch rail line construction and fencing on biological resources. This information on known locations of sensitive species, game habitat, springs, riparian areas, and other biological resources within and near the rail corridors will allow DOE to determine if there would be any significant impacts to biological resources from construction of a branch rail line within any of the corridors. It is therefore sufficient for making decisions regarding the basic approaches for transportation, as well as the choice among alternative transportation corridors. As indicated in Chapter 6 of the EIS, more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews would be conducted if a decision was made to select a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes. These would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. They also would include field surveys (as applicable) and more detailed assessments and analyses of the effects of habitat fragmentation, interruption of movements, mortality, and harassment on wildlife, horses, and burros; impacts of fencing, and spread of noxious weeds.

The Valley Modified Corridor is more than 4 kilometers (2.5 miles) from the Corn Creek Springs (see Section 3.2.2.1.4 of the EIS) and would not affect species there.

8.11.4.2 (6572)
<u>Comment</u> - EIS001632 / 0058
Page 6-38, Section 6.3.1.1: DOE recognizes that desert tortoises will be killed as a result of transportation operations. The Department reaches the conclusion that "any desert tortoises killed by trucks transporting spent nuclear fuel or high-level radioactive waste probably would be only a small fraction of all desert tortoises killed on highways." This may be true, but what is the anticipated impact of this operation relative to the desert tortoise population on the Nevada Test Site (NTS)? The higher concentration of shipments on the NTS could result in a proportionately higher impact than in the general environment. However, it may be possible that the impact on the tortoise population might be less than in the general environment since the NTS has a protection program in place.

<u>Response</u>
DOE and the U.S. Fish and Wildlife Service (see Appendix O of the EIS) have concluded that the loss of a small number of tortoises along roads and at the repository site would not affect the long-term survival of the local or regional population of desert tortoises. Tortoises are widespread throughout the region and large tracts of undisturbed tortoise habitat surround Yucca Mountain. Research at Yucca Mountain during site characterization confirms that activities similar to those proposed would have little effect on adjacent populations. The rate of tortoise mortality would remain comparable to that observed during site characterization because the amount of traffic would be similar. Under the legal-weight truck scenario, the repository would receive about 40 shipments a day of supplies, materials, and equipment (Section J.3.6.1 of the EIS), and six shipments of spent nuclear fuel or high-level radioactive waste (Section J.1.2.1). During site characterization, the daily average number of vehicles passing traffic counters in 1993 and 1994 was between 40 and 55 (DIRS 104294-CRWMS M&O 1999). The U.S. Fish and Wildlife Service has authorized an unlimited take of tortoises along roads at Yucca Mountain during repository construction and monitoring and closure in part because deaths due to vehicles are anticipated to be very infrequent (see Appendix O). Section 4.1 has been modified to better explain the conclusion that the Proposed Action would not affect the tortoise population.

8.11.4.2 (6717)
<u>Comment</u> - EIS001878 / 0075
The DEIS fails to adequately address the impacts of the proposed action on wild and free-roaming horses and burros. Many horses and burros inhabit the public and private range lands of Eureka County and neighboring counties. They are protected under the federal Wild and Free-roaming Horse and Burro Act and are of concern to the residents of Eureka County. The DEIS says (under the land use heading) that the corridor would cross five management areas (p. 6-60) or six management areas (p. 6-62), and that land would be "converted." But the DEIS does not discuss the impacts.

The DEIS must disclose the impacts upon Eureka County's wild horses and burros of: (1) conversion of range land to other uses, (2) fragmentation of herd management areas, (3) loss of forage from land disturbance, introduction of weeds, increased wildfire, or other factors, (4) restrictions on wild horse movement, (5) loss of water supplies, or restricted access to water supplies, (6) loss of horses hit by trains or other motor vehicles, and the associated public safety implications, (7) changes in the cost of wild horse management, , and (8) increases in harassment of horses. The impact analysis must address both construction and operation of fences, water wells, the railroad bed and tracks, and access roads along and perpendicular to the tracks.

The DEIS does not adequately address the impacts of the proposed action on wildlife. (pp. 6-10, -11, -37, -47, -60) Deer, antelope, sage grouse and other game and nongame species of wildlife inhabit the rangelands and uplands of Eureka County. The DEIS says that construction of the rail corridor would result in loss and fragmentation of habitat, disrupt wildlife, and kill individual animals (p. 6-47) but provides no specific information. The DEIS says under the land use heading that the corridor would cross the Bates Mountain antelope release area, three designated riparian habitats, and the Simpson Park habitat management area (p. 6-60) but does not discuss impacts on these areas. (According to the FEIS, Proposed Fallon Range Training Complex Requirements, Naval Air Station Fallon, NV [Department of the Navy and Bureau of Land Management, January 2000], the Simpson Park range is also the site of a wilderness study area. The DEIS does not disclose this fact, or discuss any impacts upon the study area.) Finally, the DEIS says on page 6-62 that the corridor would cross seven areas designated as game habitat, but does not discuss impacts on them either.

The DEIS must disclose the impacts upon Eureka County's wildlife of: (1) conversion of wildlife habitat to other uses, (2) fragmentation of habitat, (3) damage to forage from land disturbance, introduction of weeds, increased wildfire, or other factors, (4) restrictions on wildlife movement and migration, (5) loss of water supplies, or restricted access to water supplies, (6) loss of wildlife hit by trains or other motor vehicles, and the associated public safety implications, (7) changes in value of wildlife areas for hunting and fishing, (8) changes in the costs of wildlife management, and (9) increases in harassment of wildlife. The impact analysis must address both construction and operation of fences, water wells, the railroad bed and tracks, and access roads along and perpendicular to the tracks, and it must be species-specific.

The DEIS must specifically disclose the impacts of the proposed action on winter deer range in the vicinity of Beowawe, including the Horseshoe Ranch, and the impacts on deer migration between winter range in the Dry Hills northeast of Hot Springs Point and summer range to the north. Nevada's Division of Wildlife, the BLM [Bureau of Land Management], and others have spent large amounts of money restoring the winter range in this area, and the proposed action may negate those expenditures.

Response

Detailed maps of game habitat within 5 kilometers (3 miles) of rail corridors are contained in the *Environmental Baseline File for Biological Resources* (DIRS 104593-CRWMS M&O 1999). Lists of those biological resources have been added to Section 3.2.2.1.4 of the EIS. Sections 6.3.2.1 and 6.3.2.2 have been modified to address the commenter's concerns and more clearly describe impacts of branch rail line construction on biological resources, including impacts to horses, burros, and game animals and the likelihood and effects of the spread of weeds.

The information on biological resources in the EIS will allow DOE to determine if there would be any significant impacts to those resources from construction of a branch rail line within any of the rail corridors. It is therefore sufficient for making decisions regarding the basic approaches for transportation as well as the choice among alternative transportation corridors. As indicated in Chapter 6 of the EIS, more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews would be conducted if a decision was made to select a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes. These would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. They also would include field surveys (as applicable) and more detailed assessments and analyses of the effects of habitat fragmentation, interruption of movements, mortality, and harassment on wildlife, horses, and burrows; loss of hunter-generated revenue; and spread of noxious weeds.

The text in Section 6.3.2.2.2 of the EIS was corrected to state that the route passes through six wild horse and burro management areas.

Land-use impacts of the rail corridors and alternatives were analyzed in the EIS. The primary alternative for the Carlin Corridor does not pass through the Simpson Park Wilderness Study Area. However, the Steiner Creek variation of the Carlin Corridor does pass near or within the edge of that wilderness study area east of Grass Valley Ranch. The Bureau of Land Management has recommended that this area is not suitable for wilderness designation (DIRS 103366-BLM 1984). The EIS has been modified to include information on the corridor variations and a discussion of this wilderness study area, therefore, has been added.

The rail corridor is south of mule deer winter habitat in the vicinity of Beowawe and west of habitat in the Dry Hills and therefore would not affect deer in those areas.

8.11.4.2 (7213)
Comment - EIS001337 / 0093
Page 3-107 Section 3.2.1.4. [and Page 3-127 Section 3.2.2.4] This section should include reference to the Southwest Willow Flycatcher (Empidonax trallii extimus) which was listed by the U.S. Fish and Wildlife Service as endangered in February 1995. Habitat for this species may be found proximate to the Caliente, Caliente Chalk Mountain, Carlin, Jean and Valley Modified rail routes.

Response
DOE modified Sections 3.2.2.1.4 and 6.3.2.2.1 of the EIS to state that southwestern willow flycatchers have been observed in dense stands of riparian vegetation in Lincoln County; however, there is no suitable habitat for this species in the Caliente or Caliente-Chalk Mountain Corridor. DOE also modified Sections 3.2.2.2.4 and 6.3.3.2.1 to state that this species has been detected in Meadow Valley Wash, but there is no suitable habitat at the potential site of a Caliente intermodal transfer station. Finally, DOE modified Sections 3.2.2.2.4 and 6.3.3.2.3 to state that southwestern willow flycatchers occur in dense riparian vegetation in Pahranagat Valley, and that improvements of U.S. 93 along the candidate Caliente/Las Vegas heavy-haul truck route would not affect that habitat. These conclusions are based on the Biological Assessment of potential impacts of the Proposed Action on threatened and endangered species (DIRS 152511-Brocoum 2000).

8.11.4.2 (7231)
Comment - EIS001337 / 0121
Page 9-19 Section 9.3.4.1. The 3rd and 4th bulleted actions are inconsistent with the recently adopted Clark County multispecies habitat conservation plan. Clearance surveys have come to be of marginal value since the disposition of collected tortoises is often euthanasia.

Response
The Proposed Action would be consistent with Section 7 of the Endangered Species Act, which covers Federal actions, not Section 10, which covers private actions and requires a plan such as the Clark County Multiple Species Habitat Conservation Plan. The two actions referred to in the comment are terms and conditions required by the U.S. Fish and Wildlife service to mitigate the take of tortoises during repository construction and operation (see Appendix O of the EIS), and probably would be required for transportation-related construction. Clearance surveys are an effective method for protecting desert tortoises from linear (for example, a branch rail line) or relatively small disturbances in areas where tortoises are abundant. Moving tortoises or their eggs that are found to be in harm's way into suitable habitat adjacent to the proposed project area is an effective mitigation measure compared with placing them in captivity or killing them as is done in the Clark County Multiple Species Habitat Conservation Plan.

8.11.4.2 (7532)
Comment - EIS001912 / 0056
Pg. 3-107 Biological Resources-it appears from the description that the Nevada Division of Wildlife nor the U.S.F.W.S were consulted. Big Game habitats and other important habitats within the corridor need to be described and identified in relationship to proposed corridors.

Response
DOE compiled the description of biological resources in Sections 3.2.2.1.4 and 3.2.2.2.4 of the EIS from the best available information, including data from the Nevada Division of Wildlife, Nevada Natural Heritage Program, Bureau of Land Management, U.S. Fish and Wildlife Service, Forest Service, and National Park Service. Sections 3.2.2.1.4 and 3.2.2.2.4 summarize big game habitats and other important habitats for each transportation corridor.

The *Environmental Baseline File for Biological Resources* (DIRS 104593-CRWMS M&O 1999) describes these resources in detail.

8.11.4.2 (9478)
Comment - EIS001888 / 0221
[Summary of comments noted by Clark County Nuclear Waste Division staff at various citizens' meetings.]

Indicated that if a spill went into the Virgin River it could impact the "endangered" fish in the river.

Response
For a truck accident involving spent nuclear fuel or high-level radioactive waste to have an impact on threatened and endangered species, the accident would have to involve forces greater than those for which the casks were designed. Legal-weight trucks carrying spent nuclear fuel and high-level radioactive waste would travel at speeds well within predicted cask survivability requirements. Because of the high level of performance required by regulations, it is estimated that 99.99 percent of all accidents during the transport of spent nuclear fuel and high-level radioactive waste would result in no radiological releases (Section J.1.4.2.1 of the EIS). Severe accidents that could cause extensive damage to a shipping cask have been estimated to occur less than one time in 10 million truck accidents. Given the extremely small proportion of traffic carrying spent nuclear fuel and high-level radioactive waste and the normal low rate of accident occurrence, the likelihood of one of these vehicles being involved in an accident is extremely low. The additional likelihood that an accident would result in a damaged shipping cask and the release of radioactive materials is even lower. In addition, the likelihood that such an accident would occur in one of the few areas along routes where threatened or endangered species occur is very low. Based on this information, DOE has concluded in a Biological Assessment of the effects of the Proposed Action on threatened and endangered species (DIRS 152511-Brocoum 2000) that the probability of a transportation accident involving a legal-weight truck negatively affecting listed species in the Virgin River and elsewhere along existing highways is discountable.

8.11.4.3 Soils

8.11.4.3 (5528)
Comment - EIS001660 / 0038
The DEIS fails to adequately address the impacts of the proposed actions on soils in Mineral County other affected counties (pp. 6-11, -37, -47). Given Nevada's arid climate, the desert soils are fragile and easily disturbed, and may not recover on their own. Compaction of access roads would increase, not decrease, erosion (p. 6-47). Nevada's mines are subject to some of the most stringent reclamation requirements in the country. Reclamation is technically and financially demanding, careful planning, contouring, planting, maintenance; and, in many cases, irrigation during establishment of vegetation. The DEIS must analyze the impacts on soils from constructing a raised railroad bed and access roads, including extensive cut and fill operations, to constructing additional heavy-haul roads.
Response
None of the activities proposed would occur in Mineral County. Descriptions of the potential impacts of the construction of a branch rail line or heavy-haul truck route on soils in other counties are included in Sections 6.3.2.1 and 6.3.3.1 of the EIS. DOE recognizes that soils in arid climates are often easily disturbed and slow to recover and has developed successful methods for reclaiming disturbed sites at Yucca Mountain (see Section 4.1.4.4). DOE agrees with the commenter that additional, site-specific information on soils would be necessary prior to construction of a branch rail line or road upgrades to support heavy-haul truck shipping. As indicated in Chapter 6 of the EIS, more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews would be conducted if a decision was made to select a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes. These would include field surveys (as applicable) and more detailed assessments and analyses of soils and reclamation methods.

The sentence in Section 6.3.2.1 of the EIS has been modified to clarify that roads would be compacted, covered with gravel, or otherwise treated to reduce erosion and maintain their stability.

8.11.4.3 (6706)
Comment - EIS001878 / 0070
The DEIS fails to adequately address the impacts of the proposed action on soils in Eureka County and other counties. (pp. 6-11, -37, -47) Given Nevada's arid climate, the desert soils are fragile and easily disturbed, and may not recover on their own. Compaction of access roads would increase, not decrease, erosion. (p. 6-47) Nevada's mines are subject to some of the most stringent reclamation requirements in the country. Reclamation is technically and financially demanding, requiring careful planning, contouring, planting, maintenance, and--in many cases--irrigation during establishment of vegetation.

The DEIS must analyze the impacts on soils from constructing a raised railroad bed and access roads, including extensive cut and fill operations.

Response
DOE recognizes that soils in arid climates are often easily disturbed and slow to recover (see Section 4.1.4.4 of the EIS). Section 9.3.4.2 describes the mitigation measures that are being considered to minimize erosion and aid recovery of soils.

DOE agrees with the commenter that additional, site-specific information on soils would be necessary prior to construction of a branch rail line or road upgrades to support heavy-haul truck shipping. However, DOE believes that the EIS provides sufficient information on impacts to soils necessary to make decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments), as well as the choice among alternative transportation corridors. As indicated in Chapter 6 of the EIS, more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews would be conducted if a proposal was made to select a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes. These would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. They also would include field surveys (as applicable) and more detailed assessments and analyses of soils and biological resources.

DOE believes that compacting disturbances such as access roads (Section 6.3.2.1 of the EIS) would decrease erosion in comparison with uncompacted disturbed soils, but not in comparison with undisturbed soils that are probably in equilibrium with regard to wind and water erosion.

8.11.4.3 (7089)
Comment - EIS001337 / 0033
In scoping comments to the EIS, Lincoln County and the City of Caliente noted that baseline geology and soil conditions could impact upon construction and operation of repository system components, including transportation infrastructure. The County and City noted for example that fault and soil features might impair facility integrity and alteration of area soils might induce or exacerbate flooding, water quality, and air quality impacts. The County and City observed that construction of a rail spur through Lincoln County would require extensive quantities of ballast and other roadbed materials. The County and City recommended that the DEIS ,include an inventory of potentially suitable sites to borrow materials within Lincoln County and the DEIS include geologic and soils mapping for all candidate sites and corridors potentially hosting repository system components, including transportation, within Lincoln County. It was noted in the County and City scoping comments that such inventory of soils should be completed to also facilitate preparation of plans for revegetating areas disturbed by construction activities. To facilitate DOE consideration of soil conditions, the County offered to provide DOE county-wide digital soils map coverage at 1:100,000 scale, which had been developed by the County. The Affected Environment section of the DEIS provides no information on specific soil conditions within Lincoln County. This is despite analyses contained within Section 6 of the DEIS which attempt to describe impacts of transportation activities on soils.

Response
In response to this comment, DOE examined information from the Natural Resource Conservation Service to determine if any of the candidate rail corridors would cross prime farmlands and to identify serious engineering constraints that soil conditions could cause. The results of that analysis have been added to Sections 6.3.2.1 and 6.3.3.1 of the EIS to describe potential impacts of the construction of a branch rail line or heavy-haul truck route on soils. The Department agrees with this comment that more site-specific information on soils would be necessary

before the construction of a branch rail line or road upgrades to support heavy-haul trucks. As indicated in Chapter 6 of the EIS, DOE would conduct more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews if there was a decision to select a specific rail alignment in a corridor, or a specific location of an intermodal transfer station and the need to upgrade the associated heavy-haul truck routes. These would include more detailed analyses of soils and reclamation methods.

8.11.5 CULTURAL RESOURCES

8.11.5 (5499)
Comment - EIS001660 / 0026
The DEIS fails to analyze impacts of the proposed action on archeological and ethnographic resources in Nevada and Mineral County (pp. 6-11,-37,-47). Although the DEIS says that "Table 3-36 lists the cultural resource information currently available in each corridor", it lists only the number of recorded sites, of which there are approximately 110. Rather than saying that impacts could occur during construction and not during operations (p. 6-40, 48), the DEIS must specifically disclose anticipated impacts upon archeological and ethnographic resources in Nevada and Mineral County. The analysis must consider the impacts of improved access to archeological and ethnographic sites. Additional surveys and studies are needed to identify impacts (p. 6-11) and must be completed prior to a decision on a transportation mode, route, or corridor.

Response
DOE is adopting a phased approach to the identification, evaluation, and assessment of impacts to cultural resources, including archaeological, historic, and Native American, for Nevada transportation. Under this approach, existing data sets are examined for relevant information on the known occurrence of cultural resource properties in the candidate corridors for the EIS. Once DOE identified the preferred mode of transportation and routing, it would complete specific cultural resource and ethnographic field studies for the preferred route(s).

In this context, DOE reevaluated the adequacy of the existing baseline cultural resource data in the Draft EIS. To strengthen the analysis for Nevada transportation, this Final EIS incorporates data from the evaluation of additional sources in the cultural resource site files and literature.

8.11.5 (5572)
Comment - EIS001887 / 0198
Page 3-112; Section 3.2.2.1.5 - Cultural Resources

Although archaeological inventories and testing have occurred at Yucca Mountain itself as part of site characterization activities, historic property surveys meeting the Secretary of Interior's Standards have not been conducted for the railroad corridors. As the Draft EIS acknowledges, ethnographic studies for these corridors are lacking and must be conducted to identify sites to which a tribe might attach religious or cultural significance. Were any of the rail routes used historically as transportation routes? Direct impacts would occur as a result of the construction of lines, but the Draft EIS fails to note that historic or cultural landscapes might also be impacted as a result of this construction. Again, DOE needs to consult with the State Historic Preservation Office (SHPO) regarding the definition of this Area of Potential Effect (APE).

Additionally, the Programmatic Agreement (DOE 1988b, all), referenced in this section, regards site characterization activities solely and should not be used for the entire project. The programmatic agreement states that:

Whereas, development of the repository and other facilities specified in the NWPA are not within the scope of this Programmatic Agreement, but will be dealt with through additional consultation with the Advisory Council on Historic Preservation (Council) per the Council's regulations "Protection of Historic Properties" (36 CFR Part 800 as revised on September 2, 1986) (Appendix 1);

Amendments to the National Historic Preservation Act and subsequently to 36 CFR Part 800 necessitate a new agreement that includes Native Americans as signatories where the APE (as identified within the transportation systems) crosses the Moapa Indian Reservation and Las Vegas Paiute Indian Reservation. As per the new regulations, the SHPO is identified as a consulting party and should be involved in negotiations for a new programmatic agreement.

This section on cultural resources for the rail corridors provides insufficient data to determine location and numbers of historic properties. DOE needs to consult with SHPO to identify consulting parties and define an APE. DOE needs to prepare a new programmatic agreement that details how it will identify, evaluate, and treat historic properties and how the consultation process shall occur.

Response
The existing Programmatic Agreement between DOE and Advisory Council on Historic Preservation covers cultural resource requirements for site characterization activities at Yucca Mountain. DOE recognizes that construction of the repository and a Nevada transportation corridor or route would require a new and updated Programmatic Agreement. In coordination with the Advisory Council, the Nevada State Historic Preservation Office, involved Native American tribes and organizations, and other interested parties, DOE would complete a Programmatic Agreement, following the recently amended 36 CFR Part 800, Section 106, guidelines.

Known cultural resource data presented in the Draft EIS for the candidate rail corridors were collected during a site file search for previous fieldwork and recording of archaeological and historic sites within the designated region of influence. In addition, DOE reevaluated available information on archaeological, historic, and Native American cultural resources. These reevaluations are included in the analyses of candidate rail corridors, routes for heavy-haul trucks, and sites for intermodal transfer stations presented in Chapter 6 of the EIS. The information used in the analysis is sufficient to allow DOE to assess the potential for impacts to cultural resources along each of the candidate rail corridors, routes for use by heavy-haul trucks, and sites for construction of an intermodal transfer station.

DOE recognizes that project area-specific cultural resource surveys have not been conducted for the proposed transportation implementing alternatives and related project areas. Completion of archaeological surveys for all areas subject to ground-disturbing activities during transportation-related construction would be completed prior to initiation of any ground-disturbing actions.

Federal regulations provide for phased identification and evaluation of cultural resources in projects where alternatives under construction consist of corridors or large land areas (36 CFR 800.4). Due to the overall length of the proposed rail and heavy-haul truck implementing alternatives considered in the EIS, it is not practical nor cost-effective to conduct extensive field surveys prior to selection of the mode of transportation and corridor or route. Prior to initiation of the cultural resource surveys, identification of the corridor centerline and right-of-way boundaries would be required. Moreover, until selection of the final route is completed, related engineering studies to identify potential access needs and material sites cannot be completed. If and when these decisions have been finalized, cultural resource surveys would be completed in compliance with the requirements of applicable sections of the National Historic Preservation Act and 36 CFR Part 800.

8.11.5 (7216)
Comment - EIS001337 / 0094
Page 3-113 Table 3-36. This table is misleading in that it only reflects the number of sites identified to date and does not make clear that not 100 percent of each corridor has been surveyed. The table should be revised to reflect the percent of each route surveyed to date.

Response
The second and third paragraphs of Section 3.2.2.1.5 of the EIS, which reference the table, discuss the archaeological site file search results and the approximate percentage of each corridor. The incorporation of these data in the table itself would be redundant.

8.11.5 (9665)
Comment - EIS002074 / 0009
It appears that in looking at some of these sites, and, again, finding in my previous suggestion or finding here on the systematic ethnographic studies, that it appears that only a desktop review has been conducted of the corridors with respect to cultural resources. We were talking in here and just trying to imagine that if this project had to conduct

mechanical or geological studies or maybe even a site characterization study without doing any in-field analysis -- so we believe that it's been a bit shortsighted in that respect. And that, again, reinforces the need for those further kinds of studies. Also, with that when and if site selection is decided and transportation corridors are decided, that it's believed that there should be one monitor out there for any kind of activity going on.

Secondly, there should be preliminary cultural assessments being conducted leading to those systematic interviews that were recommended previously.

Response
DOE collected the cultural resource data presented in the EIS for the candidate rail corridors during a site file search for previous fieldwork and recording of archaeological and historic sites in the region of influence. In addition, in response to public comments, DOE reevaluated available information on archaeological, historic, and Native American cultural resources. The analyses of candidate rail corridors, routes for heavy-haul trucks, and sites for intermodal transfer stations include these reevaluations. The information used in the analyses is sufficient to enable DOE to assess the potential for impacts to cultural resources for each rail corridor, route for use by heavy-haul trucks, and site for construction of an intermodal transfer station.

DOE acknowledges that there have been no project area-specific cultural resource surveys for the proposed transportation corridors, routes, intermodal transfer station sites, and related project areas. The Department would complete archaeological surveys for all areas subject to ground-disturbing activities during transportation-related construction before such activities started. Federal regulations provide for phased identification and evaluation of cultural resources in projects in which alternatives under consideration consist of corridors or large land areas (36 CFR 800.4). Due to the overall length of the proposed rail and heavy-haul truck scenarios considered in the EIS, extensive field surveys prior to selection of the final mode of transportation and route would be impractical. Before the cultural resource surveys, DOE would identify the corridor centerline and right-of-way boundaries. Moreover, until selection of the final route was complete, the Department would be unable to complete related engineering studies to identify potential access needs and material sites. After these activities, DOE would complete cultural resource surveys consistent with the requirements of the National Historic Preservation Act and 36 CFR Part 800.

DOE recognizes that it is common practice to use qualified monitors (cultural resource observers) during construction activities in areas where buried cultural resources might occur. If such places existed along a selected corridor or route or at an intermodal transfer station site, DOE would use qualified monitors to ensure there was no inadvertent disturbance or destruction of cultural resources.

8.11.5.1 Archaeological and Historic Resources

8.11.5.1 (254)
Comment - 3 comments summarized
Commenters noted that the Draft EIS did not identify any direct or indirect impacts to historic sites due to the operations of heavy-haul trucks along any of the heavy-haul truck routes. Specifically, the commenters expressed disagreement because older historic buildings in Goldfield, Nevada, are within 10 feet of the highway. Commenters indicated that there is no room available to widen the highway through Goldfield and that it would be necessary to build a roadway around the business section of the town to address this impact.

Response
In response to these comments, DOE examined available literature on potential impacts from heavy-haul trucks on historic buildings. Based on current analyses, DOE believes that ground-level vibration would be well below that which could adversely affect such structures. Section 6.3 of the EIS now includes the results of this evaluation. DOE recognizes that if it selected a heavy-haul truck route that passed through a historic downtown district, such as that in the Town of Goldfield, additional evaluation of this situation could be necessary, including evaluation of the historic structures themselves. In addition, DOE continues to consider the use of bypass routes as an option.

8.11.5.1 (4294)
Comment - EIS001160 / 0103
Page 6-11, Section 6.1.2.5: The archeological impacts on the five rail corridors are essentially unassessed and unquantified. There is no information provided that would allow assessments to be made of the option to avoid

outstanding significant sites rather than to damage, destroy or treat through data recovery. Sites should be characterized by type and the constraints provided for avoidance rather than damage or data recovery by rail construction.

Response
DOE cannot completely delineate identification and assessment of the number of significant cultural resource properties, potential impacts, and mitigation options until it could complete field inventories for the selected corridor. At this time, however, DOE can make high-level comparisons on the relative "richness" of a corridor from a cultural resources standpoint based on existing information and the potential for cultural resources to occur due to knowledge about a corridor's characteristics, proximity to known sites, and an area's relationship to known historic events. If the site was recommended and approved, the Department would conduct additional field studies after selecting a preferred transportation corridor, which would occur only after the President and Congress, if necessary, agreed with any possible forthcoming recommendation that Yucca Mountain would be suitable for a repository. Therefore, it is impossible to incorporate such data in the EIS. However, DOE would complete all required cultural resource studies before making a decision on a specific alignment within a corridor.

8.11.5.1 (5152)
Comment - EIS001444 / 0004
Cultural Heritage Impacts

Section 3.2.2.1.5 Page 1-112, Paragraph 2
The state repository for cultural files for Lander and Eureka Counties is the Nevada State Museum in Carson City; the Harry Reid Center does not have the records for these counties. Any overview for projects in Lander or Eureka Counties that fails to check the Nevada State Museum records is inadequate. In addition, since the majority of the land that will be impacted by the transportation alternatives is managed by the Bureau of Land Management, records in the various BLM field offices should have also been checked.

1. Map submitted with EIS is too generalized. It doesn't provide enough geographic information. Proposed routes could impact any number of valleys and mountain ranges. Without specific geographic references it is difficult to determine the impacts.

2. While the plan generally describes proposed actions that will impact areas outside the Yucca Mountain Repository, the effected environment section of the EIS fails to discuss the resources and the potential impacts to resources outside area of Yucca Mountain. The "potential rail corridors" (Carlin and Caliente) and the "variations of potential rail corridors" go through some of the most culturally significant areas within the Tonopah Resource Area. Big Smokey, Monitor, Reveille, Hot Creek, and Oasis Valleys, all contain high concentrations of prehistoric sites. Additionally many of those sites and geographic locations are likely to be identified as TCP's [Traditional Cultural Properties]. South Stone Cabin and Ralston Valleys contain numerous historic sites related to WWII. Many of the known sites located in previously mentioned locations do meet the criteria for significance as defined in the National Historic Preservation Act.

Response
DOE reviewed archaeological site file records at the Nevada State Museum in Carson City to acquire information on known sites along corridors in Lander and Eureka Counties. DOE has revised Section 3.2.2.1.5 of the EIS to include this information. DOE has incorporated information from additional site file searches in the EIS, including relevant Bureau of Land Management District and Resource Area office records, and literature reviews for the areas that the candidate transportation corridors cross to support the comparative analysis of cultural resource issues between corridor alternatives.

8.11.5.1 (5168)
Comment - EIS001910 / 0007
The potential adverse impacts regarding transportation include cultural integrity, health, and economic considerations. The existing transportation routes and construction of new rail and highway infrastructure could destroy significant cultural sites. Even though mention is made that preconstruction surveys may occur, modification or relocation of these routes would not necessarily happen based on the Department's assessment of whether rerouting is "reasonable." Tribal importance of cultural integrity becomes secondary to the whims of DOE

archaeologists and anthropologists. It is an important point that the archaeologists and anthropologists conducting the studies and surveys are non-Indian and, it is our understanding, not from the Yucca Mountain region.

Response
It is premature to address detailed analyses of cultural resources along a candidate transportation route in Nevada, since a decision to select a route has not been made. If the Yucca Mountain site was found suitable for a nuclear waste repository, DOE would select a rail corridor for constructing and operating a branch rail line or select a location for an intermodal transfer station and an associated route for use by heavy-haul trucks. DOE then would conduct additional National Environmental Policy Act analyses that could be required to evaluate, avoid, or mitigate potential impacts of a specific rail alignment or specific location of an intermodal transfer station. Any new construction of transportation infrastructure in Nevada would include specific cultural resource surveys and Native American interactions.

For the EIS, DOE obtained cultural resource studies from the Desert Research Institute, which has principal offices in Las Vegas and Reno, Nevada. The research professionals involved at the Institute have direct experience in southern Nevada and Yucca Mountain area anthropology and archaeology. In addition, local Western Shoshone, Southern Paiute, and Owens Valley tribal representatives have worked closely with DOE cultural scientists for resource protection since the late 1980s.

8.11.5.1 (5576)
Comment - EIS001887 / 0203
Page 3-133; Section 3.2.2.2.5 - Cultural Resources

The State Historic Preservation Office [SHPO] comments on highway corridors and intermodal transfer stations are the same for rail corridors. Insufficient data is presented to determine the location and number of historic properties. DOE needs to consult with SHPO to identify consulting parties and define an APE [Area of Potential Effect]. DOE needs to prepare a new programmatic agreement that details how it will identify, evaluate, and treat historic properties and how the consultation process shall occur. In addition, the State requests responses to the following questions:

1. Has consultation with Native Americans proceeded regarding the highway systems and intermodal transfer stations?

2. Has DOE examined whether the use of highways has the potential to affect historic properties?

Response
DOE has begun preliminary interactions with the State Historic Preservation Office, the Advisory Council on Historic Preservation, and Native American tribes and organizations to complete a Programmatic Agreement covering repository construction and related activities.

DOE examined available literature on potential impacts from heavy-haul trucks on historic buildings. Based on current analyses, DOE believes that ground-level vibration would be less than levels that could adversely affect historic structures.

8.11.5.1 (5698)
Comment - EIS001887 / 0313
Page 6-11; Section 6.1.2.5 - Cultural Resources

Historic properties should be identified before effects are determined.

Response
In response to public comments, DOE reevaluated available information on archaeological, historic, and Native American cultural resources. The analyses of candidate rail corridors, routes for heavy-haul trucks, and sites for intermodal transfer stations in Chapter 6 of the EIS include these reevaluations. The information used in the analyses is sufficient to enable DOE to assess the potential for impacts to cultural resources for each rail corridor, route for use by heavy-haul trucks, and site for construction of an intermodal transfer station.

Following requirements and guidelines outlined in relevant historic preservation laws and regulations, DOE would identify and evaluate all historic properties along a selected transportation route before starting ground-disturbing activities. The Department would assess potential impacts to important properties and develop appropriate options for mitigation.

8.11.5.1 (6671)
Comment - EIS001878 / 0053
The DEIS fails to analyze impacts of the proposed action on archeological and ethnographic resources in Nevada and Eureka County. (pp. 6-11, -37, -47) Although the DEIS says that "Table 3-36 lists the cultural resource information currently available in each corridor," it lists only the number of recorded sites, of which there are approximately 110. The DEIS says that additional information is available for the Carlin corridor (p. 3-113), but does not say what it includes. Furthermore, the DEIS does not specify whether Table 3-36 applies to the candidate rail corridors, the variation of the potential corridor, or both. (See Figure 6-12, p. 6-59.)

Rather than saying that impacts could occur during construction but not during operations, (p. 6-48, -40) the DEIS must specifically disclose anticipated impacts upon archeological and ethnographic resources in the Carlin corridor and Eureka County. The analysis must consider the impacts of improved access to archeological and ethnographic sites. The additional surveys and studies needed to identify impacts (p. 6-11) must be completed prior to a decision on a transportation mode, route, or corridor.

Response
DOE is adopting a phased approach to the identification, evaluation, and assessment of impacts to cultural resources, including archaeological, historic, and Native American, for Nevada transportation. Under this approach, existing data sets were examined for relevant information on the known occurrence of cultural resource properties in the candidate corridors for the EIS. If DOE identified its preferred mode of transportation and routing, it would complete specific cultural resource and ethnographic field studies for the preferred route(s).

In this context, DOE reevaluated the adequacy of the existing baseline cultural resource data for the EIS. To strengthen the analysis for Nevada transportation, this Final EIS incorporates data from the evaluation of additional sources in the cultural resource site files and literature.

8.11.5.1 (7142)
Comment - EIS001337 / 0039
Lincoln County and the City of Caliente recommended that the repository EIS include field surveys of alternative rail corridors, material sites, and other areas where construction may occur to determine the location and significance of any archeological resources. The DEIS does not identify potential borrow pits and therefore has not included an assessment of the archaeologic resources at such sites. Such an omission makes the document less useful as a decision-support tool, particularly in choosing among transportation corridor alternatives.

Lincoln County and the City of Caliente recommended that the DEIS include an inventory of important historic resources within Lincoln County along transportation corridors and in the vicinity of construction material sites. The DEIS does not identify potential construction material or man Camp sites and therefor no inventory of historic resources in the vicinity of such areas is included within the DEIS. The absence of this information makes the document less useful as a tool for discriminating among alternative transportation corridors.

Response
In response to public comments, DOE reevaluated available information on archaeological, historic, and Native American cultural resources in the Final EIS. The information used in the analyses is sufficient to enable DOE to assess the potential for impacts to cultural resources for each rail corridor, route for use by heavy-haul trucks, and site for construction of an intermodal transfer station.

DOE acknowledges that there have been no project area-specific cultural resource surveys for the candidate transportation corridors, routes, intermodal transfer station sites, and related project areas. The Department would complete archaeological surveys for all areas subject to ground-disturbing activities during transportation-related construction before such activities started. Federal regulations provide for phased identification and evaluation of cultural resources for projects in which alternatives under consideration consist of corridors or large land areas

(36 CFR 800.4). Due to the overall length of the rail and heavy-haul truck scenarios considered in the EIS, extensive field surveys prior to selection of the final mode of transportation and route would be impractical. Before the cultural resource surveys, DOE would identify the corridor centerline and right-of-way boundaries. Moreover, until selection of the final route was complete, the Department would be unable to complete related engineering studies to identify potential access needs and material sites. After these activities, DOE would complete cultural resource surveys in accordance with the requirements of the National Historic Preservation Act and 36 CFR Part 800.

8.11.5.1 (7214)
Comment - EIS001337 / 0099
Page 3-133 Section 3.2.2.2.5. The fourth line of the 2nd paragraph of this section should reflect that archaeological sites are “at or near” sites. The Caliente site has been developed as the City of Caliente’s wastewater treatment facility. The site has been wholly disturbed. The significance of cultural resources as an issue at this site needs to be reconsidered within the DEIS.

Response
DOE has revised Section 3.2.2.2.5 of the EIS to include the disturbance of the area that includes the two candidate intermodal transfer station sites at Caliente due to the City’s wastewater treatment plant. Section 3.2.2.1 discusses the land disturbance in more detail. DOE believes that it has dealt with the significance of the cultural resources in this area in an appropriate manner.

8.11.5.1 (8360)
Comment - EIS001873 / 0044
P. 3-133. The rock art site is fairly close to the Caliente intermodal site.

Response
If the Caliente intermodal transfer station site was selected for development as part of the Nevada transportation system, additional field studies would be completed to identify all cultural resource properties that are situated within or adjacent to the station site. Further, the potential for direct or indirect impacts would be evaluated, and mitigation strategies would be developed, as necessary.

The archaeological site file search conducted for the Draft EIS identified this site as being close to the alternative intermodal transfer station site.

8.11.5.2 NATIVE AMERICAN INTERESTS

8.11.5.2 (5153)
Comment - EIS001444 / 0006
The Native American Consultation section of the EIS fails to address the possible concerns of the various tribes and groups in regard to the proposed transportation routes. It is probable that they will have a large number of concerns, since the proposed actions will pass through culturally important areas that not only contain a large number of conventionally recognizable sites, but also less obvious, yet traditionally important, trails, geographic locations, plants, animals, and minerals.

Response
Section 4.4 of DOE’s reference document *American Indian Perspectives on the Yucca Mountain Site Characterization Project and the Repository Environmental Impact Statement* (DIRS 102043-AIWS 1998) offers Native American views on transportation issues. This report correctly notes that DOE has not completed ethnographic studies involving Native American peoples along the candidate rail corridors.

In accordance with its Indian Tribal Government Policy, DOE, through the Native American Interaction Program, is committed to involving tribes and organizations in future studies to identify, evaluate, and protect cultural resources important to Native Americans that could occur along the route selected in the final analysis for Nevada transportation.

The Final EIS transportation analysis incorporates additional information on Native American issues for lands that the transportation corridors cross. This information is available in the general literature, and environmental reviews for adjacent projects – for example, Nellis Air Force Base, Nevada Test Site, and the recent DOE evaluation of Native American issues along proposed highway routes for the intermodal transportation of low-level radioactive waste to the Nevada Test Site. Many of the routes evaluated for the low-level waste transportation routing correspond to the repository heavy-haul truck scenarios.

8.11.5.2 (8379)
Comment - EIS001873 / 0064
P. 6-48. Under Cultural Resources the necessary systematic studies of Native American sites and resources should be included in the EIS.

Response
The comment refers to impact analyses associated with transportation corridors. DOE cannot delineate the identification and assessment of the number of Native American sites, potential impacts, and mitigation options until it has completed field inventories of a specific corridor, once it was selected. The Department would conduct the required field studies after selecting a preferred transportation corridor, which would occur only after the President and Congress agreed with any possible forthcoming recommendation that Yucca Mountain would be suitable for a repository. Therefore, it is impossible to incorporate such data in the EIS. However, DOE would conduct all required cultural resource studies and Native American interactions before initiating any corridor construction activities.

8.11.5.2 (9650)
Comment - EIS002074 / 0006
On the transportation portion is that the transportation model only considered portions within -- we have conflicting views -- of either a quarter or a half mile of the proposed transportation corridors. And, as we know, that because there's been the lack of systematic ethnographic studies in those areas, that there potentially may be other cultural considerations that should be given because of potential traditional cultural properties or other cultural resources sites that would be by areas or fall within those corridors.

Response
The region of influence for the archaeological site file search for the rail corridors includes a 0.25-mile (400-meter)-wide zone.

DOE is aware of the current lack of detailed site-specific cultural resource investigations along many of the candidate transportation corridors. If a selection was made regarding mode and routing of a corridor, intensive cultural resource and ethnographic studies would be conducted to identify and evaluate all cultural resources sites that could be affected by construction and operation of the corridor.

8.11.5.2 (9747)
Comment - EIS001888 / 0331
[Clark County summary of comments it has received from the public.]

Commenters requested that the EIS evaluate cultural resources nearby Yucca Mountain and along proposed regional rail/heavy haul corridors (Carlin and Jean routes, in Lincoln and Esmeralda counties, historic Palisade- Eureka route) given the proposal to construct and operate the repository system. More specifically, commenters indicated that the EIS should consider historical and prehistoric sites, paleontologic resources, and Native American land claims and religious freedom issues. Analyses must also be based on Class III field surveys, as well as other forms of research.

Response
In response to public comments, DOE reevaluated available information on archaeological, historic, and Native American cultural resources. The analyses of candidate rail corridors, routes for heavy-haul trucks, and sites for intermodal transfer stations in Chapter 6 of the EIS include these reevaluations. The information used in the analyses is sufficient to enable DOE to assess the potential for impacts to cultural resources for each rail corridor, route for use by heavy-haul trucks, and site for construction of an intermodal transfer station.

As stated in the sections of Chapter 6 of the EIS that address potential cultural resource impacts, DOE agrees that additional analyses of archaeological, historic, and Native American cultural resources along a selected transportation corridor or route for heavy-haul trucks and the selected site of an intermodal transfer station would be necessary. DOE disagrees, however, that Class III (intensive) field surveys of each candidate rail corridor, highway route for heavy-haul trucks, and site for an intermodal transfer station would be necessary to provide information to support possible transportation route decisions in Nevada. Such decisions would be to select a particular rail corridor for construction of a branch rail line or a particular route for use by heavy-haul trucks and a particular site for construction of an intermodal transfer station. However, once a decision was made on the transportation mode and route in Nevada, DOE would complete Class III field surveys before starting ground-disturbing activities.

8.11.5.2 (9748)
Comment - EIS001888 / 0332
[Clark County summary of comments it has received from the public.]

Commenters, representing Native Americans, requested more formal involvement in the overall NEPA [National Environmental Policy Act] process to ensure that tribal rights and concerns are considered prior to decision-making or Departmental action. Many commenters cited: (1) the DOE's Indian policy regarding government-to-government relations, (2) tribal sovereign rights to regulate tribal lands and resources, and (3) cultural resource laws (National Historic Preservation Act, Native American Graves Protection and Repatriation Act, Archaeological Resources and Protection Act) as appropriate justification for greater involvement. Specific involvement issues raised included routing decisions and transportation planning, development of alternatives, impacts to ancestral artifacts, ecosystem impacts, the development of a plan to ensure Native American review of the draft EIS, and financial assistance for consultation purposes.

Response
DOE will interact with the State of Nevada Historic Preservation Office, the Advisory Council on Historic Preservation, and Native American tribes and organizations to complete a Programmatic Agreement covering repository construction and operation and related activities. Interactions are ongoing with the Consolidated Group of Tribes and Organizations through the Yucca Mountain Project Native American Interaction Program. Under this program, DOE has informed tribal representatives of transportation implementing alternatives, including candidate heavy-haul truck highway routes and intermodal transfer station sites (DIRS 102043-AIWS 1998).

8.11.6 SOCIOECONOMICS

8.11.6 (44)
Comment - 3 comments summarized
Several commenters stated that the Draft EIS indicated new jobs will be created in the Caliente/Lincoln County areas as a result of intermodal activities. Commenters said the Final EIS should include an estimate of new residents by age and make a determination of how many school children will be in the school system and how new residents will impact the existing infrastructure.

Response
Section 3.1.7 of the EIS addresses the projected baseline conditions through 2035 for Lincoln County. Sections 6.3.2 and 6.3.3 provide an estimate of the changes in population and other economic measures for each relevant implementing alternative. The transportation analysis in the EIS includes a sensitivity analysis that assigns all potential impacts to Caliente. This analysis conservatively estimates impacts of potential transportation actions on a community level for what could be the most affected community in Nevada.

8.11.6 (740)
Comment - EIS000195 / 0004
The socioeconomic section discussing the impact of heavy haul of the large rail casks totally fails to address the impacts to the quality of life, to the residents of Goldfield and other rural communities resulting from four to five of these large trucks along with the remaining convoy coming through our community every weekday for twenty-four years.

There are residents and businesses within twelve feet of US 95. Also, the trucks will be returning along this route which makes it eight to ten per day. Along these lines, the noise impacts also need to be addressed.

Response
The EIS does assess potential land-use and noise impacts associated with each transportation scenario. Subsequent environmental studies would assess transportation scenarios in more detail to support decisions on preferred transportation alignments and any necessary mitigative actions.

8.11.6 (795)
Comment - EIS000197 / 0002
In the discussion of the socioeconomic impacts associated with construction of the Caliente ... and Carlin ... rail corridors, you identify the annual average number of construction workers to be 500 to 560, and that there would be five construction camps. It would seem that one of the camps would be in the vicinity of Goldfield and could have a significant impact in this small community. We feel that this impact also needs to be addressed in the socioeconomic section and how these impacts could be mitigated should be included.

Response
The EIS presents information for the counties within the designated region of influence (Clark, Nye, and Lincoln Counties) and the Rest of Nevada. The Rest of Nevada is an aggregate of the 14 remaining Nevada counties. The socioeconomic simulation model DOE used to estimate potential impacts indicated that the Rest of Nevada would experience direct economic effects from spending by construction workers for food and lodging.

The simulation accounts for workforce expenditures through the Eating and Drinking Sector and the Construction Sector of the Standard Industrial Code. A small fraction of the spending for food and lodging was allocated to the Rest of Nevada to account for the possibility that a few workers could or purchase food in Goldfield or other counties not in the region of influence.

The simulations assumed that construction camp development and water drilling would be contracted to firms in the counties where the camps were located. It was assumed that all railroad construction workers would commute weekly from Clark County to camps outside Clark County and eat in local restaurants 5 days per week, 50 weeks per year.

Subsequent environmental studies would further assess transportation scenarios in more detail to support decisions on preferred transportation corridor alignment and any necessary mitigative actions.

8.11.6 (1000)
Comment - EIS000235 / 0007
The Final EIS should include an evaluation of existing emergency medical capabilities in Lincoln County and provide recommendations for needed enhancements.

Response
Section 3.1.7.5 of the EIS provides information on health care and hospitals within the region of influence. Lincoln County has one hospital, in Caliente. Table 3-29 lists hospital use in the region.

However, DOE will not presume to speculate on what agencies feel that they might need to do to serve their citizenry. Section 116(c) of the NWPA states that "the Secretary shall provide financial and technical assistance to [an affected unit of local government or the State of Nevada]…to mitigate the impact on such [an affected unit of local government or the State of Nevada] of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

Under the NWPA, the Section 116 impact assistance review process and the EIS process are distinct from one another, and the implementation of one is not dependent on the implementation of the other. Thus, the provision of assistance under Section 116 would not necessarily be limited either by the impacts identified in this EIS or by its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of requests for assistance submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts. If the proposed repository was to become operational, DOE would enter into discussions with the State of Nevada and affected units of local government and consider appropriate support and mitigation measures.

After a decision was made regarding the proposed repository and transportation modes and routes, local jurisdictions would be better able to identify the likely economic, social, public health and safety, and environmental impacts that would be the basis for a request for economic assistance, which could include assistance in providing additional medical and emergency response facilities, under Section 116(c) of the Act.

Further, in the Final EIS, DOE has expanded its socioeconomic discussions in Chapter 3 to provide a clarified basis for understanding the magnitude of potential impacts described in Chapters 4 and 6. This discussion includes a projection of baseline parameters through 2035 based on the most recently available information and assumptions.

8.11.6 (1241)
Comment - EIS000226 / 0004
Page 30 of the County/City EIS Scoping Report provided a range of estimates of the population and demand for housing which would be induced by a range of new jobs. While the DEIS estimates the number of jobs which might be associated with intermodal activities in Caliente, rail line construction in the County and operation of heavy-haul trucks across Lincoln County, no estimate of induced population and related demands for housing and other public services (i.e., schools) is provided.

Response
The document cited in this comment is one of many DOE reviewed before preparing the Draft EIS. DOE estimates provided in the EIS for employment and population growth (including indirect population) in Lincoln County associated with the Yucca Mountain Project align most closely with the upper-case estimates in the scoping report (DIRS 104630-YMP 1997). The Department estimated about 237 total operations jobs for the Caliente-Chalk Mountain options. Of this total, DOE assumed that half the drivers and private escorts and other indirect employees (about 133 total) would work in Lincoln County. In the Final EIS DOE estimated a population increase of about 166 in Lincoln County. DOE does not believe, however, that this represents an impact that could stress local housing or infrastructure because it does not expect the need for in-migration to fill most of the jobs. DOE estimates of incremental changes in employment include direct and indirect jobs and population increases due to Yucca Mountain activities.

DOE has revised its socioeconomic estimates for Lincoln County to reflect population estimates from the Nevada State Demographer. The Department has reviewed pertinent information and revised its analyses of demands for public services and infrastructure in light of the identified repository-induced population changes.

8.11.6 (3145)
Comment - EIS000642 / 0002
Some issues that have not been addressed in the EIS properly. And these are to deal with the fact of socioeconomics for this part of the world. We rely on mining and ranching at this point in this part of the country for survival. This project that you are proposing threatens our way of life forever.

Response
DOE developed a list of assumptions to determine the projected economic and demographic changes in Nevada by construction and operation of the proposed repository. The REMI model used in these determinations is a four-region model. Three of the regions are Clark, Nye, and Lincoln Counties. The fourth region is the Rest of Nevada, an aggregation of the other 14 counties in Nevada (including Lander County).

DOE assumed, for railroad construction, workers would be nominally assigned to base camps according to an even split by the number of camps. All railroad construction workers would commute weekly from Clark County to the trailer camps outside Clark County and would eat in local restaurants 5 days per week, 50 weeks per year. Operations workers would live in the county where the branch rail line branched off the main line, with the exception of the Carlin routes, for which they would live in Elko, Nevada.

Given the above assumptions, the total estimated incremental population increase for the aggregated 14 counties in Nevada attributed to the Carlin Corridor would be about 115 individuals in the peak year. Total employment associated with the Carlin Corridor for the aggregated 14 counties of Nevada, including Lander County, for the peak year would be about 75. The Department does not believe there would, therefore, be any discernible direct or indirect impacts to the economy (including mining and ranching) or to the infrastructure (such as public safety or recreation) for any of the counties, including Lander County.

8.11.6 (3147)
Comment - EIS000642 / 0004
There are many people here in Nevada who are into ranching and that is their way of life and their only way of life, and we are all very concerned on this. Will the grazing allotments be cut up? How will the ranchers be compensated for the lost rangeland?

I want to expand on that a little bit. I am very concerned about the issue of water rights and the loss of land in our state.

Response
At this time, definitive information is not available on specific tracts of land that could be required for a given transportation alternative. For any land that would be required or otherwise affected, the Department would fairly compensate landowners under Federal acquisition procedures. Should DOE be required to exercise its right of eminent domain, it would do so pursuant to applicable laws and regulations.

8.11.6 (4216)
Comment - EIS001160 / 0033
The DEIS does not adequately address issues raised and substantiated by White Pine County during the scoping process. For example:

DOE is encouraged to make use of the White Pine County Economic Impact Model in preparation of the repository EIS. DOE did not utilize the White Pine County Economic Impact Model despite said model having been given to the Department. The DEIS does not include an assessment of economic or fiscal impacts in White Pine County.

Response
The EIS presents information for the counties in the defined region of influence (Clark, Nye, and Lincoln Counties) and for the Rest of Nevada, which is an aggregate of the 14 remaining Nevada counties (including White Pine County). Any economic impacts on White Pine County would be an indirect impact caused by DOE employment and expenditures in neighboring Lincoln County or in the Rest of Nevada. For example, Section 6.3.3.2.2 of the EIS discusses socioeconomic impacts of the construction and operation of an intermodal transfer facility in Caliente for the Caliente/Chalk Mountain heavy-haul truck route. The socioeconomic simulation model DOE used to estimate potential impacts indicated that the Rest of Nevada would experience relatively small direct economic effects from permit fees paid to the State for the operation of a facility such as an intermodal transfer station. The estimated total employment increase due to direct and indirect jobs for the entire Rest of Nevada for the Caliente and Caliente/Las Vegas heavy-haul truck route (14 counties) could be up to 38 jobs during construction and up to 26 jobs during operations. The impacts to White Pine County, if any, would be small.

8.11.6 (4239)
Comment - EIS001160 / 0054
White Pine County is concerned that there is no review of potential state-wide impacts, how changes in regional economic trends might impact neighboring counties, or impacts that could occur in counties along proposed transportation routes. It is not possible to suggest specific positive or negative impacts to White Pine County without initial analysis on anticipated state and regional impacts. In addition, the DEIS should include a separate review and analysis of impacts to communities along transportation routes once they have been selected. The FEIS should commit to such an analysis and the related identification of mitigation measures.

All communities with the state could be impacted by changes in the economic picture for the entire state because of the repository. The DEIS provides no assessment of the impacts to counties and cities from losses in state-level economic and fiscal activity. The State of Nevada Nuclear Waste Project Office has demonstrated the potential for statewide tourism related economic and fiscal impacts as a result of nuclear waste being transported throughout the state and stored at Yucca Mountain. State sales and gaming tax revenues could be reduced, and this would impact state services and funds available to counties and cities for local services. It is also possible that the fact that high level nuclear waste is being transported on Nevada highways may influence motor freight routes. Communities like Ely receive a significant economic benefit from the increasing amount of truck traffic over US Highway 93 and State Route 318. If trucking firms elected to use Interstate 15 instead to avoid the routes used for high level nuclear waste, then our communities and the state as a whole would feel an economic impacts. Each of these key issues needs to be addressed in the FEIS.

Positive and negative impacts in neighboring counties including Lincoln, Nye, and Eureka Counties could indirectly impact White Pine County. Moderate increases or decreases in population and economic strength in Eureka, northern Nye, and northern Lincoln Counties could impact White Pine. These areas currently depend, at least in part, on Ely as a commercial and professional center. Decreases in their economies could reduce White Pine County's economic activity from its neighboring counties. Increases in population and activity could increase the economic activity in White Pine County. If the increases in the neighboring areas were significant enough to support development of new commercial and professional activity, it could decrease the activity now coming to White Pine County. These connected actions or impacts have not been considered within the DEIS.

It is possible that selection of transportation routes through White Pine County could result in socioeconomic impacts for White Pine County. If the presence of trucks hauling high-level nuclear waste in White Pine County required new state and/or federal employees in the area, their households would generate revenue in the community. New private sector ventures could be warranted to provide parking areas or shuttle services between parking and motels. However, the negative impacts of the presence of high-level nuclear waste could include reduced tourist traffic to White Pine County attractions, reduced customers for businesses located along the transportation routes or near the parking areas, reluctance of lenders to finance projects located within the corridor because of potential environmental hazards or increased risk perceived for the area; and regulations governing the use of areas along the transportation route could deter future land use decisions on mining, grazing, or tourism/recreation projects. The identification and analysis of impacts to the local economy in White Pine County and the City of Ely need to be included within the DEIS. Absent such analyses and identification of appropriate measures to mitigate impacts, potential effects will go unmitigated. Such an outcome is inconsistent with the intent of NEPA [National Environmental Policy Act]. The limited discussion regarding Clark, Lincoln, Nye, Eureka, Lander, and Esmeralda Counties does not show the true picture of impacts White Pine County could expect from the development of Yucca Mountain to store high level nuclear waste.

Response

The economic and demographic simulations that DOE performed using the REMI EDFS-53 forecasting and simulation model derived fiscal changes to the economy from interindustry relationships (including the eating and drinking places and hotel sectors of the Standard Industrial Code), labor markets, and national and worldwide economic variables. The analyses considered the entire State of Nevada. DOE structured the information presented in the EIS into four regions – Clark, Nye, and, Lincoln Counties, and the Rest of Nevada. The Rest of Nevada comprises the 14 remaining Nevada counties (including White Pine County and the Ely Shoshone Tribe). DOE estimated the potential impacts of each alternative on the same economic parameters for each region. Economic impacts on White Pine County would be indirect, caused by DOE employment and expenditures in neighboring Lincoln County or in the Rest of Nevada. For example, Section 6.3.3.2.2 of the EIS discusses the socioeconomic impacts of the construction and operation of an intermodal transfer facility in Caliente for the Caliente/Chalk Mountain route. The socioeconomic simulation model that DOE used to estimate potential impacts indicated that the Rest of Nevada would experience relatively small direct economic effects from permit fees paid to the State for operation of an intermodal transfer facility. The estimated total employment increase in total jobs (direct and indirect) for the Rest of Nevada (all 14 other counties) could be up to 37 jobs during construction and up to 18 jobs during operations. Impacts to White Pine County, if any, would be small.

Assessing the perceived impact on quality-of-life variables or the impact of "stigma" is generally problematic because it does not necessarily depend on actual physical effects or risks of the proposed action, but on the negative perception of those effects or risks by the public. While DOE agrees stigmatization could result in adverse impacts under some scenarios, it is not inevitable or measurable and stigmatization would likely be an aftereffect of unpredictable future events. As a consequence, DOE addressed but did not attempt to quantify potential impacts from risk perceptions or stigma in the EIS. This issue is discussed in Section 2.5.4 and Appendix N of the EIS.

8.11.6 (4290)
Comment - EIS001160 / 0098
Page 4-88. The analysis on Section 4.1.15.4 should have considered the economic impacts of locating one or more cask manufacturing facilities at a greenfield site in Nevada, particularly, White Pine County. Such a facility might serve to mitigate potential negative economic impacts in the area.

Response
The EIS presents information for the counties in the defined region of influence (Clark, Nye, and Lincoln Counties) and the Rest of Nevada (including White Pine County). The Rest of Nevada comprises the 14 remaining counties. Economic impacts on White Pine County would be indirect, caused by DOE employment and expenditures in neighboring Lincoln County or in the Rest of Nevada. The socioeconomic simulation model DOE used to estimate potential impacts indicated that the Rest of Nevada would experience relatively small direct economic effects from permit fees paid to the State for operation of an intermodal transport facility. The estimated total employment increase in total jobs (direct and indirect) for the Rest of Nevada could be up to 38 jobs during construction and up to 26 jobs during operations. Impacts to White Pine County, if any, would be small.

While the details of cask manufacturing facilities are not known at present, they probably would not be DOE facilities. In all probability, private firms would manufacture the casks and, therefore, DOE would not control their location.

Section 4.1.15 of the EIS provides information on potential environmental impacts from manufacturing repository components.

8.11.6 (5483)
Comment - EIS001660 / 0019
Public services information is incorrect and incomplete (p. 3-115). Counties referenced only include 6 out of 10 affected units of local government. The DEIS implies all small communities in Nevada contain community water, sewer services, wells or septic tanks. Small communities may provide these services; however, have very limited access to sufficient quantities of water.

Response
DOE has expanded the discussions of public services in Sections 3.1.7.5 and 3.2.2.1.6 of the EIS. Results of the EIS analysis indicated that not all counties initially named as affected units of local government would experience impacts from the Proposed Action.

8.11.6 (5501)
Comment - EIS001660 / 0027
The DEIS does not adequately address specific community, local government, statewide, and regional impacts. Except for a discussion of the direct and indirect impacts from construction on disposable income and the Gross Regional Product, the DEIS fails to address the impacts of the proposed action on Mineral County's economy (pp. 6-l3,-l4,-37,-64). Mineral County's economy depends on mining, construction, military, transportation, agriculture and service industries (see "Hawthorne Facts at a Glance/Winter 1999" for more information about Mineral County's economy). The DEIS must address: (1) the anticipated impacts - positive and negative - upon the mining, construction, military transportation, agriculture and service industries, and (2) the anticipated impacts on the agricultural economy. The DEIS must address the anticipated economic impacts of shared use of alternative routes by the DOE and by other users, such as mines.

Response
DOE does not expect direct impacts of repository operations to Mineral County because none of the candidate transportation corridors are in the county. The closest candidate branch rail line would be in the Carlin Corridor, approximately 32 kilometers (20 miles) to the east in Nye County.

DOE estimated the incremental impacts at the county level for Clark, Lincoln, and Nye Counties, and for the remaining 14 Nevada counties together. The Department used the REMI EDFS-53 Forecasting and Simulation Model. The model segments age, ethnicity, and gender based on 600 cohorts to predict population. In addition, it calculates births, deaths, and aging. Employment and fiscal changes to the economy are derived from interindustry relationships, labor markets, and national and worldwide economic variables. Based on the results of the model outputs, DOE does not believe incremental increases in socioeconomic parameters represent large or widespread economic impacts.

DOE would consider sharing the selected transportation corridor with others such as mine operators and private freight shippers. This could benefit communities near the transportation route. Sections 8.2.1 and 8.4.2.1 of the EIS discuss the idea of shared branch rail lines.

8.11.6 (5513)
Comment - EIS001660 / 0031
The DEIS does not adequately address specific community, local government, statewide, and regional impacts. Also, it fails to address the fiscal impacts of the proposed action on Mineral County and other local governments (p. 6-37). Mineral County has a very limited property and sales tax base, and a volatile mining economy. For these reasons it is very difficult to provide essential services and infrastructure related to fire suppression, emergency response, water and sewer, law enforcement, education, etc.; and the County would have very limited resources to defend itself against any litigation which may arise. The DEIS must evaluate the projected local revenues and expenses associated with alternative routes, considering both direct and indirect effects. Other possible impacts include: (1) fiscal impacts to local emergency response agencies, including costs of training and maintaining personnel; and (2) the fiscal effects of potential litigation related to Mineral County's emergency first response, or lack thereof, to an accident involving transportation of SNF [spent nuclear fuel] and HLW [high-level radioactive waste] along the proposed alternate routes.

Response
DOE does not expect direct impacts of repository operations to Mineral County because none of the candidate transportation corridors are in the County. The closest candidate branch rail line would be in the Carlin Corridor, approximately 32 kilometers (20 miles) to the east in Nye County.

DOE estimated the incremental impacts at the county level for Clark, Lincoln, and Nye Counties, and for the remaining 14 Nevada counties together. The Department used the REMI EDFS-53 Forecasting and Simulation Model. The model segments age, ethnicity, and gender based on 600 cohorts to predict population. In addition, it calculates births, deaths, and aging. Employment and fiscal changes to the economy are derived from interindustry relationships, labor markets, and national and worldwide economic variables. Based on the results of the model outputs, DOE does not believe incremental increases in socioeconomic parameters represent large or widespread economic impacts.

As required by Section 180(c) of the NWPA would provide technical assistance and funds to states for training public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. This training would cover procedures required for safe routine transportation of these materials and for dealing with emergency response situations. In addition, Sections 116(A) and 117(c)(5) of the NWPA establish assistance guidelines covering a number of issues including emergency response, health baseline studies, and monitoring.

8.11.6 (5524)
Comment - EIS001660 / 0036
The DEIS does not adequately address the impacts of the proposed action on public services in Mineral County and other counties. Mineral County provides public services such as education, libraries, public health administration, police, fire protection, etc. The DEIS must analyze the direct and indirect impacts of the proposed action on education and other essential public services. Specifically, the DEIS must address the demand on public services and associated costs. The discussion of impacts on public services of the Nevada transportation alternatives, both rail and road, is particularly inadequate regarding emergency response services. The type, capability, and availability of such services, and local government attitudes toward response to radiological incidents vary widely in

the affected counties. Additional risks, costs, training, and management issues regarding emergency response must be included in the DEIS.

Response
DOE estimated the potential incremental changes to a projected baseline for a number of socioeconomic and transportation parameters. The estimates were based on a range of reasonable assumptions and input variables such as where transportation workers would live and the number of waste shipments required. In the Final EIS, the projected baseline is shown through 2035. DOE expects that most of the potential impacts would occur in Nye, Clark, and Lincoln Counties. In most cases, DOE does not believe the incremental changes in population and employment would appreciably influence the level of community services. However, DOE would monitor its activities and consider reasonable mitigation actions should it be required.

Section 116(c) of the NWPA provides a non-National Environmental Policy Act process by which DOE can provide compensation to the State of Nevada and affected units of local government from impacts of developing the proposal. Section 180(c) of the NWPA establishes a process by which DOE can provide technical and funds for training to states, local governments, and tribes for training in safe transport methods and emergency response.

8.11.6 (5616)
Comment - EIS001887 / 0242
Page 4-44; Section 4.1.6.2.5 - Impacts to Public Services

The analysis of impacts to public services in the Draft EIS is inadequate and incomplete. The Draft EIS fails entirely to examine the effects of the Proposed Action on State-level public services and State agencies. A June 1998 report prepared for the State of Nevada found that costs to State agencies alone for preparing for and responding to repository-related shipments of spent fuel and HLW [high-level radioactive waste] in Nevada would be almost $498 million for the first three years of the project.(33)

The Draft EIS also fails to adequately assess costs and impacts to local governments for preparing for nuclear waste shipments, training response and other emergency preparedness personnel, obtaining necessary equipment, and related activities. Interjurisdictional impacts resulting from the nature of the emergency response systems in Nevada, the existence of and need for inter County mutual support agreements, multi County training requirements, etc. would also occur. Such costs are direct impacts associated with the Proposed Action and should have been clearly identified and assessed in the Draft EIS.

Public service impacts should be calculated on a use/revenue basis for: (1) services provided to the Yucca Mountain project by state, local, and private utilities (subject to market and service regulation, e.g., electric, water, gas, etc.); (2) services provided to employees and their households; (3) services required by the indirect and multiplier effects of the project and project employees; and (4) services by state and local governments that are mandated by federal law or represent official responses by state and local officials and agencies to the activities of the Yucca Mountain project. The public services to be assessed should include:

- All state and local government services that contribute to the Yucca Mountain project. This would include services for health and safety, emergency management and response, transportation, regulation (e.g., permitting, licensing, and oversight), legal and judicial actions, and support for the public infrastructure.

- State and local public services to the direct, indirect, and induced population and households resulting from the Yucca Mountain project, including the proportional and marginal costs for education, police and public safety, criminal justice, libraries, recreation and parks, local transportation, welfare, and publicly mandated services such as economic development. The cost estimates should include expenses for all community services, facilities, equipment, infrastructure, and staff.

The assumption in the Draft EIS that public services impacts related to the Proposed Action would be small in comparison to the overall employment and population of the region of influence does not mean that impacts cannot or will not be significant. Without a complete assessment, the significance of these impacts cannot be known.

Because the State's tax and revenue systems rely on tourism/gaming revenues to pay for growth in other sectors, public services impacts associated with additional repository-related population growth would generate negative fiscal impacts for state and local jurisdictions. Although such negative fiscal impacts would result from any non-gaming industry economic development, there is a distinction between the state's willingness to subsidize desired economic diversification and its willingness to subsidize the fiscal effects of a repository. As such, public services impacts and costs must be identified under the provisions of NEPA [National Environmental Policy Act] and the NWPA.

(33) "The Fiscal Effects of Proposed Transportation of Spent Nuclear Fuel on Nevada State Agencies," by Planning Information Corp. and Alvin Mushkatel, Arizona State University (June, 1998).

Response
DOE did not assess potential fiscal impacts at an agency level. DOE does not believe this would provide meaningful or discriminating information for the decisionmaker. DOE did, however, estimate the potential impacts at the county level for Clark, Nye, and Lincoln Counties. The remaining 14 counties in Nevada were considered aggregately.

DOE estimated the potential impact of each alternative on the same economic parameters for each of the regions. The economic and demographic simulations performed by the Department, using the REMI EDFS-53 Forecasting and Simulation Model, derived fiscal changes to the economy from interindustry relationships (including the Eating and Drinking Places and Construction Sectors of the Standard Industrial Code), labor markets, and national and worldwide economic variables. The simulations included direct and induced impacts based on changes in employment and population. One of the parameters evaluated was change in State and local spending, which captures some of the issues raised in the comment. For example, security support from the State Highway Patrol is factored into the simulations for each rail corridor.

Regarding possible agency support or response to repository activity, DOE will not presume to speculate on what agencies feel that they might need to do to serve their citizenry, nor will DOE presume to comment on the State's preferred fiscal structure. DOE will, however, enter into discussions with potentially affected units of government and consider appropriate support and mitigation measures. As required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. In addition, Sections 116(A) and 117(c)(5) of the NWPA set forth assistance guidelines covering a number of issues including emergency preparedness and response, state liability arising from accidents, and necessary road upgrading.

In addition, Payments-Equal-to-Taxes (PETT) are made pursuant to Section 116(c)(3)(A) of the NWPA, which requires the Secretary of Energy to "... grant to the State of Nevada and any affected unit of government, an amount each fiscal year equal to the amount such State or affected unit of government, respectively, would receive if authorized to tax site characterization activities..." These payments, historically and for the future, are determined by estimating the amount of Yucca Mountain Project property, purchases (inside and outside the State of Nevada), and business activities (employees) within the jurisdiction of an affected unit of local government. Nye County and the State of Nevada have been eligible to receive PETT since commencement of site characterization activities in May 1986. The other affected units of government include Clark, Lincoln, Esmeralda, Eureka, White Pine, Churchill, Lander, and Mineral Counties in Nevada, and Inyo County, California. Potentially, they have been eligible to receive PETT since Congress passed the Nuclear Waste Policy Amendments Act of 1987.

For PETT relating to property taxes in Nye County, DOE and the County entered into a settlement agreement, amended in May 1999, whereby DOE would make specified payments on a fixed disbursement schedule. The current agreement runs through 2003.

8.11.6 (6053)
Comment - EIS001898 / 0014
Additional documentation or analysis should be provided in the FEIS to support the characterization of impacts and the description of environmental parameters in some areas of the FEIS.

Section 6.3.2.2.1 (Environmental Impacts of Transportation Caliente Rail Corridor Implementing Alternative-Socioeconomics) states “[t]he projected length of the corridor-513 kilometers is the most important factor for determining the number of workers (560) that would be required.” This statement is repeated for all corridors, but more specific information is needed to support this conclusion. Terrain and other factors might have significant impact, because productivity per worker (km/worker) varies considerably by route (e.g., 1.04km/worker on the Carlin route, 0.53km/worker on the Jean route).

Response
This comment takes issue with Section 6.3.2.2.1 of the EIS, which indicates “[t]he projected length of the corridor – 513 kilometers (319 miles) – is the most important factor for determining the number of workers [560] that would be required.” Because DOE based the identification of the alternative corridors on a range of factors including land ownership, engineering, and terrain or steepness of grade, the length of the corridor inherently reflects of the weighing and balancing of these other factors. As a consequence, the length of a branch rail line would influence the number of workers required and worker productivity because of the engineering requirements and possible routing constraints in the initial layout of the corridor.

With regard to the socioeconomic analyses in which the cited statement appears, the number of workers is the fundamental parameter for estimating other potential changes to the economy such as Gross Regional Product, disposable income, and State and local spending.

8.11.6 (6303)
Comment - EIS001727 / 0012
The DEIS doesn’t make any effort to assess the socioeconomic impacts of transportation other than the number of people that have to work on the trucks.

Response
The EIS assesses the socioeconomic impacts for each transportation scenario. Sections 6.3.2.2 and 6.3.3 provide socioeconomic impact estimates for each rail corridor and heavy-haul truck route, respectively.

The analysis for each alternative estimated the projected change in a number of socioeconomic parameters including employment, population, State and local spending, disposable income, and Gross Regional Product. It compared the changes associated with Yucca Mountain activities to projected baseline growth trends and economic activity for each potentially affected county (Clark, Lincoln, and Nye) and the Rest of Nevada (the 14 remaining Nevada counties).

8.11.6 (6380)
Comment - EIS001590 / 0005
It does not address properly socioeconomic impacts. For example, what would be the effect in communities along the transportation route of an accident of having the potential for an accident. This is something that my neighbors in the Rum Village Neighborhood Association along the route are very, very concerned about.

Response
DOE analyzed a range of accident scenarios related to proposed transportation activities and the accident risk would be very small. Accident scenarios analyzed in the EIS are based on probabilities with no definitive knowledge of when or where an accident could occur. As a consequence, to attempt to assess the potential impacts of an accident to a local economy would be highly speculative. The EIS does, however, address the potential socioeconomic impacts that could occur, directly or indirectly, as a result of the proposed siting, construction, operation and monitoring, and eventual closure of a geologic repository at Yucca Mountain, including transportation activities. The socioeconomic parameters considered in the EIS include quantitative estimates of changes to populations, employment, and income that could result from repository-related activities.

8.11.6 (6434)
Comment - EIS001828 / 0005
The population element in the DEIS should also include visitors to our county. More than 32 million tourists annually augment the population of the metro Las Vegas area, situated directly along the proposed truck route.

Response
Section 3.1.7.1 of the Draft EIS identified the annual number of visitors to Las Vegas. DOE has updated this number in the EIS and included it in the analysis of transportation accident health effects.

8.11.6 (6675)
Comment - EIS001878 / 0054
Except for a discussion of the direct and indirect impacts from construction on disposable income and the Gross Regional Product, the DEIS fails to address the impacts of the proposed action on the economy of Eureka County. (pp. 6-13, -14, -37, -64) The County's economy depends heavily on mining. Construction, agriculture, government, and services are the next largest sectors.

The statement (p. 3-115) that "[s]ocioeconomic effects from the construction of a rail line would be small and, for the most part, short-term," which the DEIS uses to justify the inclusion of less-detailed information for Esmeralda, Eureka, and Lander Counties, is unsupported by any evidence and does not allow an adequate analysis of the impacts of the rail alternatives.

Specifically, the DEIS must address: (1) the anticipated impacts--positive and negative--upon the mining, construction, government, and service sectors and (2) the anticipated impacts on the agricultural economy. The DEIS must address the anticipated economic impacts of shared use of the Carlin rail corridor by the DOE and by other users, such as mines.

Response
A relatively short section of the Carlin Corridor crosses Eureka County from Beowawe through Crescent Valley. DOE developed a list of assumptions to determine projected economic and demographic changes in Nevada from the construction and operation of the proposed repository. The REMI model that DOE used in these determinations is a four-region model. Three of the regions are Clark County, Nye County, and Lincoln County. The fourth region is the Rest of Nevada, which includes the other 14 counties (including Eureka County).

For railroad construction, DOE assumed that workers would be assigned to base camps according to an even split by the number of camps. Railroad construction workers would commute weekly from Clark County to the trailer camps outside Clark County and would eat in local restaurants 5 days a week, 50 weeks a year. Operations workers would live in the county where the route branched off the main line, with the exception of the Carlin routes, for which they would live in Elko County.

Given these assumptions, the total estimated population increase, as reported in the Draft EIS, for the aggregated 14 counties in Nevada attributed to the Carlin Corridor would be about 115 individuals in the peak year. DOE does not believe this would cause discernible direct or indirect impacts to the public services of any of the counties including Eureka.

In relation to possible benefits of the branch rail line, DOE would consider sharing transportation corridors with others such as mine operators and private freight shippers. This could benefit communities near the transportation routes. Sections 8.2.1 and 8.4.2.1 of the EIS discuss the idea of shared branch rail lines.

8.11.6 (6687)
Comment - EIS001878 / 0058
The DEIS fails to adequately address the impacts of the proposed action on housing in Eureka County. The housing data provided (p. 3-115) is 10 years old. Due to such factors as the high percentage of public land, the variability of the mining economy, and the high cost of raw materials, Eureka County has unique housing problems that could be aggravated by the proposed action, particularly during the construction phase. Construction would require an annual average of 500 workers (p. 6-63) in a county with only 820 housing units as of 1990 (p. 3-115). Thus, housing impacts could be quite severe.

The DEIS must disclose the anticipated impacts of the proposed action on Eureka County's housing stock. The disclosure must include direct impacts (e.g., housing of construction crews) and indirect impacts (e.g., increased demand for housing, short-term and long-term, resulting from the multiplier effect from rail corridor construction).

Response
A relatively short section of the Carlin Corridor crosses Eureka County from Beowawe through Crescent Valley. DOE developed a list of assumptions to determine projected economic and demographic changes in Nevada from the construction and operation of the proposed repository. The REMI computer model that DOE used in these determinations is a four-region model. Three of the regions are Clark County, Nye County, and Lincoln County. The fourth region is the Rest of Nevada, which includes the other 14 counties (including Eureka County).

For railroad construction, DOE assumed that workers would be assigned to base camps according to an even split by the number of camps, and that these base camps would be constructed by a local subcontractor and would include an adequate number of trailers to house the workforce. Railroad construction workers would commute weekly from Clark County to the trailer camps outside Clark County and would eat in local restaurants 5 days a week, 50 weeks a year. Operations workers would live in the county where the route branched off the main line, with the exception of the Carlin routes, for which they would live in Elko County.

Given these assumptions, the total estimated population increase, as reported in the Draft EIS, for the aggregated 14 counties in Nevada attributed to the Carlin Corridor would be about 115 individuals in the peak year. Total employment associated with the Carlin Corridor for the 14 counties, including Eureka, for the peak year would be about 75. DOE believes there would be no discernible direct or indirect impacts to housing for any of the counties including Eureka. The housing information in the EIS is based on the most current information available. The Bureau of the Census updates housing information on a county basis only every 10 years. DOE had modified this information as more timely data became available. Fifty households would represent about 4.8 percent of Eureka County's 2000 housing stock.

8.11.6 (6689)
Comment - EIS001878 / 0059
The DEIS fails to adequately address the impacts of the proposed actions on infrastructure in Eureka County. The County and its residents provide (and depend upon) roads, schools, drainage, water systems, aviation facilities, medical facilities, and public safety facilities that could be affected, directly or indirectly, by the proposed action.

The DEIS must disclose the anticipated impacts of the proposed action on Eureka County's infrastructure. The disclosure must include direct impacts (e.g., damage or displacement of infrastructure during construction) and indirect impacts (e.g., increased demand on infrastructure due to construction employment). Specifically, the DEIS must address the impact of the rail corridor on the Crescent Valley airport, which lies within the corridor.

Response
A relatively short section of the Carlin Corridor crosses Eureka County from Beowawe through Crescent Valley. DOE developed a list of assumptions to determine projected economic and demographic changes in Nevada from the construction and operation of the proposed repository. The REMI computer model that DOE used in these determinations is a four-region model. Three of the regions are Clark County, Nye County, and Lincoln County. The fourth region is the Rest of Nevada, which includes the other 14 counties (including Eureka County).

For railroad construction, DOE assumed that workers would be assigned to base camps according to an even split by the number of camps, and that these base camps would be constructed by a local subcontractor and would include an adequate number of trailers to house the workforce. Railroad construction workers would commute weekly from Clark County to the trailer camps outside Clark County and would eat in local restaurants 5 days a week, 50 weeks a year. Operations workers would live in the county where the route branched off the main line, with the exception of the Carlin routes, for which they would live in Elko County.

Given these assumptions, the total estimated population increase, as reported in the Final EIS, for the aggregated 14 counties in Nevada attributed to the Carlin Corridor would be about 115 individuals in the peak year. Total employment associated with the Carlin Corridor for the 14 counties, including Eureka, for the peak year would be about 75. DOE believes there would be no discernible direct or indirect impacts to housing for any of the counties, including Eureka.

At this time definitive information is not available on specific tracts of land that DOE could require for a particular transportation corridor. In relation to the commenter's concern about damage or displacement of infrastructure, the

Department would fairly compensate landowners under Federal acquisition procedures for land that would be required or otherwise affected. If DOE had to exercise its right of eminent domain, it would do consistent with applicable laws and regulations.

As indicated in Section 9.3.1 of the EIS, DOE would develop mitigation measures where construction and operation of transportation facilities would result in (1) impacts to publicly used lands, (2) direct and indirect land loss, and (3) displacement of capital improvements.

8.11.6 (6692)
Comment - EIS001878 / 0061
The DEIS fails to address the fiscal impacts of the proposed action on Eureka County and other local governments. (p. 6-37) With a very limited property tax base and sales tax base, and with a volatile mining economy, Eureka County and its residents must provide services and infrastructure related to fire suppression, emergency response, water and sewer, law enforcement, education, and others. The County must also defend itself in any litigation that may arise.

The DEIS must evaluate the projected local revenues and expenses associated with the Carlin corridor in Eureka County, considering both direct and indirect effects. Among other possible impacts, the DEIS must evaluate: (1) fiscal impacts to local emergency response agencies, including the costs of training and maintaining their personnel, and (2) the fiscal effects of potential litigation related to the County's emergency first response, or lack thereof, to an accident involving transportation of SNF [spent nuclear fuel] and HLW [high-level radioactive waste] along the Carlin corridor.

The estimates of local expenditures provided in the DEIS are so general that they are meaningless. They do not provide a viable basis for comparison, nor do they relate estimated expenditures to specific local government budgets. Thus, the information does not permit an examination of actual impacts on local governments and their budgets.

Response
A relatively short section of the Carlin Corridor crosses Eureka County from Beowawe through Crescent Valley. DOE developed a list of assumptions to determine projected economic and demographic changes in Nevada from construction and operation of the proposed repository.

As required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. In addition, Sections 116(A) and 117(c)(5) of the NWPA set forth assistance guidelines covering a number of issues including emergency response, health baseline studies, and monitoring.

8.11.6 (6694)
Comment - EIS001878 / 0062
The DEIS fails to evaluate the impacts of the proposed action on mining in Eureka County and neighboring counties. Mining is by far the largest sector of Eureka County's economy. The proposed Carlin corridor traverses an area potentially rich in mineral deposits, which may be needed to support the nation's economic development and national defense. According to testimony before the DOE at the Crescent Valley public hearing on December 9, 1999, the corridor would divide the existing Cortez mine, and cross a haul road that is in regular use.

The DEIS must evaluate the effects of the proposed action on mining, including: (1) possible restrictions on claimants' access to their mining claims, (2) division of mining claims, (3) possible physical and legal barriers to the exploitation of mineral deposits, and (4) potential benefits to mining from improved access to railroad service. The DEIS must also disclose whether restricted use of or access to mining claims and sites would be a taking of private property rights requiring compensation under the Constitution of the United States.

Response
DOE acknowledges that the Carlin Corridor passes near historic and established mining districts. In addition, the Department is aware of the Cortez Gold Mines operation in Crescent Valley. Sections 8.1.2.3 and 8.4.2 of the EIS discuss the Cortez Gold Mines and possible cumulative impacts.

As indicated in Section 9.3.1 of the EIS, DOE would develop mitigation measures where construction and operation of transportation facilities would result in (1) impacts to publicly used lands, (2) direct and indirect land loss, and (3) displacement of capital improvements. Such measures could most practically be developed after a single transportation corridor was selected and in conjunction with alignment of a route within the corridor.

In relation to possible benefits of a branch rail line, DOE would consider sharing transportation corridors with others such as mine operators and private freight shippers. This could benefit communities near the transportation routes. Sections 8.2.1 and 8.4.2.1 of the EIS discuss the idea of shared branch rail lines. In addition, DOE would evaluate the need for preserving access to land that a rail corridor could divide. The Department would try to minimize any restriction to or control over lands used for mining and would develop specific mitigation measures to alleviate impediments to the continued use of lands.

8.11.6 (6701)
Comment - EIS001878 / 0065
The DEIS does not adequately address the impacts of the proposed action on public services in Eureka County and other counties. Eureka County and the Eureka County School District provide public services including education, libraries, public health administration, police, fire protection, and others.

The DEIS must analyze the direct and indirect impacts of the proposed action on education and other essential public services. Specifically, the DEIS must address the demand on public services, and associated costs, that would be created by construction crews of 500 persons (annual average) and their families and support personnel.

Response
A relatively short section of the Carlin Corridor crosses Eureka County from Beowawe through Crescent Valley. DOE developed a list of assumptions to determine the projected economic and demographic changes in Nevada by construction and operation of the proposed repository. The REMI model used in these determinations is a four-region model. Three of the regions are Clark, Nye, and Lincoln Counties. The fourth region is the Rest of Nevada, an aggregation of the other 14 counties in Nevada.

DOE assumed, for railroad construction, each of the following: Workers would nominally be assigned to live in base camps according to an even split by the number of camps. All railroad construction workers would commute weekly from Clark County to the trailer camps outside Clark County and would eat in local restaurants 5 days per week, 50 weeks per year. Operations workers would live in the county where the route branched off the main line, with the exception of the Carlin routes in which case workers would live in Elko County.

Given the above assumptions, the total estimated population increase, as reported in the Draft EIS, for the aggregated 14 counties in Nevada attributed to the Carlin Corridor would be about 115 individuals in the peak year. The Department does not believe there would, therefore, be any discernible direct or indirect impacts to the public services of any of the counties, including Eureka.

8.11.6 (6705)
Comment - EIS001878 / 0067
The DEIS fails to consider the impacts of the proposed action on the quality of life now experienced by Eureka County's residents. The unique values of such communities as Crescent Valley include clean air, access to open space and recreation, active and passive enjoyment of fish and wildlife, quiet surroundings, enjoyment of nature, beautiful views and scenery, participation in the community life of a small town, the safety and security of a close-knit community, employment in agriculture and other outdoor occupations, and many others.

According to the written testimony of Jean Plummer, presented at the public hearing before the DOE on December 9, 1999, at Crescent Valley:

Beowawe and Crescent Valley, Nevada, might be considered townships with small populations, even if all the surrounding areas were included. Our land, though, has much natural beauty, good fishing, hunting, colorful spring flowers, canyons in the mountains, willows and cottonwood trees and streams winding through. Our children have a great school and a small community to grow up in. The Yucca Mountain project will destroy all of this within 25 years if not sooner.

The DEIS must consider the impacts of the proposed action on the quality of life in the communities in Eureka County and neighboring counties that would be affected--directly and indirectly--by the construction and operation of a rail line, access roads, fences, and supporting structures.

Response
The comment implies that actions associated with the proposed repository could negatively affect the quality of life in Eureka County. The EIS analysis in fact shows that expected impacts to Eureka County would be small.

While DOE agrees stigmatization could result in adverse impacts under some scenarios, it is not inevitable or measurable, and such stigmatization would likely be an aftereffect of unpredictable future events. As a consequence, DOE addressed but did not attempt to quantify potential impacts from risk perception or stigma in this Final EIS. See Section 2.5.4 and Appendix N of the EIS for additional information.

8.11.6 (6903)
Comment - EIS001539 / 0006
Current Data: The use of 1990 census data is inappropriate for the calculation of risks to Denver area residents. DOE should update their risk calculations with the most recent census data, as soon as they are available.

The DOE/EIS states that risks were calculated using 1990 census data. The Denver area has one of the fastest growing populations in the United States. As soon as possible, updated census data should be used in the calculation of risk estimates (e.g., population densities along each route, including railroads), and these data should be considered during the planning of waste shipment routes. The routes should be designed to minimize transport through areas of high population density.

Additionally, as the DOE/EIS states that potential risks from accidental release scenarios were calculated based on "state-specific accident rates" (pg. J-8), DEH [Denver Department of Environmental Health] encourages DOE to use the most recent data available, because the Denver area has recently experienced a large increase in automobile traffic.

Response
Based on comments received on the Draft EIS, DOE has revised the EIS to adjust transportation impacts for the Proposed Action to reflect projected changes in population from 1990 to 2035. For Modules 1 and 2, DOE adjusted the estimates for transportation impacts to incorporate projections made by the Bureau of the Census for populations in 2047.

In many instances DOE conducted special studies to collect additional data. For example, transportation accident and fatality rates were updated for the EIS in the report *State-Level Accident Rates of Surface Freight Transportation: A Reexamination* (DIRS 103455-Saricks and Tompkins 1999). These data represent the best available information for estimating transportation accident risks.

As required by the NWPA, DOE would comply with U.S. Department of Transportation regulations and requirements of the Nuclear Regulatory commission regarding routing of highway shipments of spent nuclear fuel and high-level radioactive waste. The Department of Transportation does not regulate routing of rail shipments. However, as required by the NWPA, DOE would use routes for rail shipments that are first approved for use by the Nuclear Regulatory Commission. DOE and its transportation contractors would work with railroad carriers to ensure that routes used were the safest and permitted expeditious transport of shipments of spent nuclear fuel and high-level radioactive waste.

8.11.6 (7205)
Comment - EIS001337 / 0090
Page 3-71 Section 3.1.7. The evaluation of impacts in Section 6 for transportation include impacts to real disposable income, gross regional product and government expenditures. In order to define magnitude of impact data for these parameters need to be included in the Affected Environment section of the DEIS.

Page 3-71 Section 3.1.7. The factors considered under socioeconomics is not adequate to enable a comprehensive assessment of impacts. At a minimum other factors needing to be included are age distribution of residents; other community services including water and waste water, solid waste, and emergency management and emergency medical services. Local government expenditures for these services needs to be considered. The baseline "without repository" projections of population, housing, employment, school enrollment, local government revenues and expenditures, and various community service capacities and demands should be at least through 2033 or better yet closure of the repository. Currently, the DEIS lacks sufficient information to enable a determination of the significance of impacts over projected without repository baseline to be determined.

Page 3-74 3rd paragraph. Text here indicates that Lincoln County had a 13 percent decline in employment between 1990 and 1995. The text should indicate what this was attributed to. This decline is inconsistent with the findings in Section 4, Environmental Consequences that a 1.9 to 5.8 percent increase in employment and population would be "within the range of historic changes in the county". Either the data in Section 3-74 in not accurate or the finding in Section 4 is inappropriate.

Page 3-76 Section 3.1.7.3. To enable a comparison with projected levels of PETT [Payments-Equal-to-Taxes] and to enable the reader to understand how past and future PETT levels were determined, the text here needs to explain how past PETT payment levels were derived, by County. The text should also identify any inconsistencies between derivation of PETT payments from one jurisdiction to another. Without such information any projection of PETT in Section is unsupported. (Section 4 does not provide any estimates of PETT payments and this is a deficiency in the DEIS.)

Page 3-77 Table 3-26. Because the text on Page 3-73 indicates that the population of Lincoln County will increase 2 to 4 percent per year during the next decade, an explanation is needed as to why school enrollments in Lincoln County are projected to decline between 1997 and 2001. These two trends appear inconsistent, unless there are extenuating factors (i.e. aging of the population, reduced birth rates, etc.). Because Section 3 includes school enrollment, Section 4 should include a projection of school age children resulting from population growth. In addition, Section 4 should consider the need for additional school facilities to accommodate enrollment growth.

Page 3-78 Table 3-27. The year 2000 population forecasts for Lincoln County are not consistent with those of the Nevada State Demographer (4,410).

Page 3-78 Health Care. The description of hospitals should indicate whether these facilities are currently capable of handling patients contaminated by radiation. In the case of the Grover C. Dils Medical Center in Caliente, that facility is currently not capable of effectively handling a patient contaminated with radiation.

Page 3-78 Law Enforcement. The description of law enforcement should indicate whether each police or sheriff department is currently trained and equipped to respond to emergencies involving radiation hazards. The Lincoln County Sheriff Department is not currently trained or equipped to respond to such a hazard.

Page 3-78 The description of fire protection and emergency management should indicate whether each department and/or jurisdiction is currently trained and equipped to respond to emergencies involving radiation hazards. None of the volunteer fire departments or emergency medical service providers in Lincoln are currently trained or equipped to respond to such a hazard.

Page 3-98 Section 3.2.1.1. The last sentence of this section indicates that population densities were derived to estimate health risks. The methodology used to estimate potentially impacted population as described on Page J-40 has resulted in an underestimation of population in rural areas such as Lincoln County. This results from the fact that population densities used were derived from Census Block data. In Lincoln County Census areas are very large relative to total population within the area. Most persons residing in the Census areas reside near to transportation infrastructure. As a result, it is necessary to adjust population densities prior to multiplying each by the 1.6 kilometer region of influence. Research completed by the University of Nevada, Las Vegas, Transportation Research Center has documented the need to make such an adjustment in population density.[19] [These comments also apply to Page 3-114, Section 3.2.2.1.6]

[19] Sathisan, Shasi et. al., Risk Analysis for Spent Nuclear Fuel Transportation Through Lincoln County Volume I: Rail Shipments, Volume IIA: Highway Shipments, Volume IIB: Technical Appendix, Transportation Research Center, Howard Hughes College of Engineering, University of Nevada, Las Vegas, February 1995.

Response

DOE appreciates the breadth of this comment. The Final EIS reflects some of the issues and the following response categories or groups the issues by topic to better capture some of the commenter's diverse but related concerns. DOE has expanded its socioeconomic discussions in Section 3.1.7 of the EIS to provide a clarified basis for understanding the potential impacts described in Chapter 4. This discussion includes a projection of baseline parameters through 2035 based on the most recently available information and assumptions. Information on Gross Regional Product, government spending, and real disposable income has been included. DOE incorporated State Demographer population information for Lincoln County in the Final EIS. DOE has revisited population estimates by age to determine potential impacts on specific services, particularly schools. In the Final EIS, DOE provides a quantified estimate, to the extent possible, of school changes in enrollment and the status of law enforcement and public service personnel requirements.

- Employment Decline

  Regarding Lincoln County employment, the decline between 1990 and 1995 is primarily attributed to the services sector possibly related to the Nevada Test Site employment reductions during that time period. The reference to a 1.9- to 5.8-percent increase in employment and population pertains to long-term trends going back to the 1980s and encompasses the identified employment declines of the 1990s. DOE has clarified the text in the EIS to make this distinction.

- Payments-Equal-To-Taxes

  Payments-Equal-To-Taxes (PETT) are made pursuant to Section 116(c)(3)(A) of the NWPA, which requires the Secretary of Energy to "…grant to the State of Nevada and any affected unit of government, an amount each fiscal year equal to the amount such State or affected unit of government, respectively, would receive if authorized to tax site characterization activities…." Nye County and the State of Nevada have been eligible to receive PETT since commencement of site characterization activities in May 1986. The other affected units of local government include Clark, Lincoln, Esmeralda, Eureka, White Pine, Churchill, Lander, and Mineral Counties in Nevada, and Inyo County, California. Potentially, they have been eligible to receive PETT since the enactment of the amendments to the Nuclear Waste Policy Act in 1987.

  DOE acquires data from the Yucca Mountain Site project organizations that purchase or acquire property for use in Nevada, have employees in Nevada, or use property in Nevada. These organizations include Federal agencies, national laboratories, and private firms. Not all of these organizations have Federal exemption status so they pay the appropriate taxes. The purchases (sales and use tax), employees (business tax), and property (property or possessory use taxes) of the Yucca Mountain Project organizations that exercise a Federal exemption are subject to the Payment-Equal-To-Taxes Program (DIRS 103412-NLCB 1996).

  The age group 6 to 18 estimate (school age) drops about 25 percent between 2002 to 2011 and rises again, reaching its 2002 level in about 2020. DOE believes the direct and indirect impacts of transportation activities would result in helping restore the school-age population back to its previous levels.

- Emergency Response

  Regarding possible agency support or emergency response to repository activities, DOE does not presume to speculate on what agencies feel that they might need to do to serve their citizenry. If the proposed repository was approved for development, DOE would, however, enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures. As required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. In addition, Sections 116(c) and 117(c)(5) of the NWPA set forth assistance guidelines covering a number of issues including emergency response, health baseline studies, and monitoring.

- Populations and Health Risk

  The EIS used U.S. Census data to estimate the number of people in the general population who would live near the highway and rail routes that were selected for analysis. However, it was not possible or practical to identify each special population that would be in each of the thousands of Census blocks crossed by the routes and analyzed. However, the use of Census data for population along real routes selected for the analysis ensured that estimated impacts would be calculated for the health and safety of real people—not generic populations along generic routes. Because populations resident in care facilities for the elderly are included in Census data, the analysis included the impacts to these populations. Furthermore, impacts to temporary occupants of schools and hospitals that would be near routes and whose temporary occupancy is not included in Census data were included in the analysis, because the analysis assumed that adults, children, and hospital patients would be present in their homes when every shipment passed. Thus, while it is certain that the approach of using Census data to estimate the number of people who would be exposed to passing shipments leaves some uncounted, it is also certain that the analysis counted some who would not be affected. For the purpose of estimating health and safety risks to populations along routes, the approach provides reasonable estimates and does not exclude special populations.

Comment - EIS001337 / 0116
Page 6-96 Socioeconomic Section discusses the impacts of heavy-haul of the large rail casks - This section fails to address potential impacts to the quality of life of residents living along highways in the rural communities resulting from 4-5 of these large trucks, along with their remaining convoy, traveling communities every day for 24 years. This area needs to be addressed by DOE. One method to mitigate this impact would be to construct heavy haul by-passes around these communities working with each community as to where by-pass should be located.

Response
If the repository was approved, subsequent environmental studies would assess route alignment in more detail to support decisions and identify possible mitigation measures.

8.11.6 (7633)
Comment - EIS001912 / 0085
Why not include other countries in the socioeconomic section? What makes Clark and Lincoln different except for the possibility of employment opportunities. How are the impacts from transportation different? The northern Nevada rail route crosses through several large urban areas. About 80 percent of Elko County's population lives within the Humboldt River corridor and adjacent to the existing rail line.

Response
All counties in Nevada were considered in the socioeconomic analysis. However, DOE defined the region of influence based on the distribution of the residences of current employees of the Department and its contractors who work on the Yucca Mountain Project or at the Nevada Test Site. The region of influence, therefore, consists of the counties where about 90 percent of the DOE workforce live (Clark, Nye, and Lincoln Counties). The Department used the residential distribution, which reflects existing commuting patterns, to estimate the future distribution of workers. The Draft EIS presented information for counties within the designated region of influence and then the Rest of Nevada. The Rest of Nevada is an aggregate of the 14 remaining Nevada counties. The socioeconomic simulation model DOE used to estimate potential impacts indicated that the Rest of Nevada (including Elko County) would experience some economic effects from spending by workers for food and lodging.

8.11.6 (8144)
Comment - EIS001653 / 0087
Pg. 6-37 needs to discuss socioeconomic impacts related to land values, recreation use, and the cost to implement and manage emergency response training at the local level.

Response
DOE did not address potential changes in property values because of the dynamic nature of real estate and the uncontrollable factors that can influence property values. Assessing perceived impacts to property values or the impacts of "stigma" is generally problematic because it does not necessarily depend on the actual physical effects or risks of the proposed action, but on the negative perception of those effects or risks by the public. While DOE agrees stigmatization could result in adverse impacts under some scenarios, it is not inevitable or measurable and such stigmatization would likely be an aftereffect of unpredictable future events. As a consequence, DOE addressed but did not attempt to quantify potential impacts from risk perceptions or stigma in this Final EIS. Dollars spent on recreation activities in Nevada are inherent in the economic forecasts and are part of the estimated incremental change in economic parameters.

Costs associated with the implementation and management of emergency response training are not part of the socioeconomic impacts identified for Yucca Mountain activities. However, Sections M.6 and M.7 of the EIS describe the implementation of Section 180(c) of the NWPA. Under these requirements, DOE would provide technical assistance and funds to states for training public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures for safe routine transportation of these materials and for dealing with emergency response situations. DOE would institute this training before beginning shipments to the repository.

8.11.6 (8300)
Comment - EIS001873 / 0040
P. 3-72. The map of the socioeconomic region does not show Pioche, the county seat of Lincoln County. Alamo, Hiko, Panaca, and Rachel should also be shown since they are on potential haul routes.

Response
DOE has added Pioche to Figure 3-23 of the EIS. Figure 6-13 and related figures depicting transportation corridors in Lincoln County show Alamo, Hiko, Panaca, and Rachel. DOE has also added Pioche to those figures.

8.11.6 (8384)
Comment - EIS001873 / 0067
P. 6-97. DOE assumes socioeconomic impacts would occur mainly in Clark County. It seems likely that the construction could cause a short boom and bust cycle in a town like Caliente.

Response
DOE estimated that Lincoln County employment associated with repository construction and operations would be very small (see Section 4.1.6.2.1 of the EIS). The greater potential increase in Yucca Mountain-related jobs and population growth would be associated with transportation activities. The estimated peak total operational employment for Lincoln County would be about 167 if DOE selected the Caliente/Chalk Mountain heavy-haul truck route.

The construction-related workforce for Lincoln County would be very small comparatively. DOE assumed operations employees would live in Lincoln County and construction employees would live in Clark County and commute to the job site. Estimated total incremental population increases over a 25-year period would be about 166 people per year, on average, from the Caliente/Chalk Mountain route. The peak year for population increases associated with heavy-haul truck operations would be about 241 individuals, approximately 2.4 percent of the estimated County population.

DOE does not believe a boom-or-bust situation would occur because increases would be marginal and would be sustained over a long period and because of the County's proximity to a large metropolitan area. In general, if population growth associated with a proposed action was less than 5 percent of the study area's total population, potential impacts would be small.

8.11.6 (9986)
Comment - EIS001888 / 0492
[Clark County summary of comments it has received from the public.]

One commenter believed that the EIS, in reaching a decision for selection of transportation routes, should consider the potential socioeconomic impacts.

Response
The potential socioeconomic impacts associated with the transportation of spent nuclear fuel and high-level radioactive waste comprise one of the factors decisionmakers would weigh and balance in determining a preferred transportation mode and route.

Sections 6.3.2.2 and 6.3.3 of the EIS provide socioeconomic impact estimates for each rail corridor and heavy-haul truck route, respectively. The analysis for each alternative estimated the projected changes in a number of socioeconomic parameters including employment, population, State and local spending, disposable income, and Gross Regional Product. It compared the changes associated with Yucca Mountain activities to projected baseline growth trends and economic activity for each potentially affected county (Clark, Lincoln, and Nye) and the Rest of Nevada (the 14 remaining Nevada counties).

8.11.6 (10037)
Comment - EIS001888 / 0524
[Clark County summary of comments it has received from the public.]

Traffic volumes and shipments of hazardous wastes have increased dramatically since 1980. If trucks are used 44 accidents are likely from transport of HLW [high-level radioactive waste] to the repository. Even if minor, this could hurt economically.

Response
DOE analyzed a range of accident scenarios related to proposed transportation activities. It based these scenarios on probabilities with no definitive knowledge of when or where an accident could occur. As a consequence, attempting to assess the potential impacts of an accident on a local economy would be highly speculative.

8.11.6 (10038)
Comment - EIS001888 / 0525
[Clark County summary of comments it has received from the public.]

A serious accident with HLW [high-level radioactive waste] combined with limited alternate routes and limited ER [emergency response] capability could shut down commerce and damage economy.

Response
DOE analyzed a range of accident scenarios related to proposed transportation activities. Accident scenarios are based on probabilities with no definitive knowledge of when or where an accident could occur. As a consequence, to attempt to assess the potential impacts of an accident to a local economy would be highly speculative. The EIS does, however, address the socioeconomic impacts that could occur, directly or indirectly, as a result of the proposed siting, construction, operation and monitoring, and eventual closure of a geologic repository at Yucca Mountain, including transportation activities. The socioeconomic parameters considered in the EIS include quantitative estimates of changes to populations, employment, and income that could result from repository-related activities.

With regard to emergency response, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures. As required by Section 180(c) of the NWPA, DOE would provide technical assistance funds to states for training for public safety officials of appropriate units of government and Native American tribes through whose jurisdictions it would transport spent-nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe, routine transportation of these materials, as well as procedures for dealing with emergency response situations. A discussion of Section 180(c) can be found in Appendix M of the EIS. In addition, Section 116(c)(2)(A) of the NWPA sets forth assistance guidelines covering a number of issues including emergency preparedness and response and Section 117(c) sets forth requirements for written assistance agreements. In the event of an incident or accident involving radioactive materials, states, tribes, and local governments can request assistance from the Federal Government under the Federal Radiological Emergency Response Plan. Assistance is available from 17 different agencies. In addition, DOE maintains eight Regional Coordinating Offices, which are ready at all times to provide assistance. Information concerning these resources can be found in Appendix M. Regional Servicing Contractors that DOE could use would be required to provide drivers and crews with specific written procedures that clearly define detailed actions to be taken in the event of an emergency or incident. The Draft Request for Proposals, *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153847-DOE 1998), focuses on these responsibilities, as well as on other related responsibilities. Carrier and shipper responsibilities regarding emergency situations are discussed in Appendix M.

8.11.6 (10194)
Comment - EIS001888 / 0565
[Clark County summary of comments it has received from the public.]

Commenters stated that the EIS should evaluate the economic impacts of transportation accidents.

Response
Accident scenarios are based upon probabilities with no definitive knowledge of when or where an accident could occur. As a consequence, any attempt to assess the potential impacts of an accident to a local economy would be highly speculative.

8.11.6 (10935)
Comment - EIS000463 / 0010
Nevada also believes that there would be significant adverse economic impacts (from a transportation accident), which, unfortunately, DOE chooses not to address in the draft DEIS.

Response
Risks to health and safety would be small because the risks of releases of radioactive materials in accidents would be small. Because the risks of releasing radioactive materials in transportation accidents would be small, the risk of detrimental economic consequences would also be small, although such risks would be different for each location and community along the routes used. The Federal Government would compensate for economic consequences of releases of radioactive materials in transportation accidents under provisions of the Price-Anderson Act (see Section M.8 of the EIS.) In response to public comments, Section J.1.4.2.5 contains a review of analyses of potential environmental and economic impacts from releases of radioactive materials.

8.11.6 (12069)
Comment - EIS000226 / 0023
Page 32 of the County/City EIS Scoping Report presented evidence that a transportation accident characterized by extensive media reporting might result in stigmatization of tourist destinations in Lincoln County (including five state parks). A loss of tourism during peak season could pose significant economic and fiscal consequences in Lincoln County. Mitigation of such a potential impact might include a contingent tourism marketing plan which is ready to implement the instant an accident occurs.

Response
Assessing the perceived impact of stigma is generally problematic because it does not necessarily depend on actual physical effects or risks of the proposed action, but on the negative perception of those effects or risks by the public. While DOE agrees stigmatization could result in adverse impacts under some scenarios, it is not inevitable or measurable and stigmatization would likely be an aftereffect of unpredictable future events, such as a serious accident. As a consequence, DOE addressed but did not attempt to quantify potential impacts from risk perceptions or stigma in the Final EIS. Section 2.5.4 and Appendix N of the EIS discuss this issue.

8.11.7 HUMAN HEALTH AND SAFETY

8.11.7 (801)
Comment - EIS000164 / 0004
Human error and systems errors happen. If one transports thousands of shipments over cumulative millions of miles, risks that are only one-in-a-million become virtually guaranteed. We must make our government keep waste transportation and power companies from making profits at our considerable peril. The classic textbook Public Health and Preventive Medicine states that "radiation protection has developed from using basic principles of protection against external irradiation in occupational settings: shielding, distance, time, and training." We must take those basic principles, especially that of shielding, distance, and time to heart.

Response
The commenter points out four principles—shielding, distance, time, and training—that are at the heart of radiation protection. DOE agrees with these principles and has incorporated them into the planning and design of all operations associated with the transportation of radioactive materials to the proposed repository.

The EIS addresses the radiological impacts of incident-free transportation and transportation accidents in Chapter 6 and Appendix J. The analyses take into consideration the distance and number of shipments to estimate the number of accidents that would be expected for each of the transportation alternatives. The spent nuclear fuel and high-level radioactive waste transportation casks are sufficiently robust that in more than 99.99 percent of accidents, no release of radioactive materials from the casks would be expected. Additional information on cask safety and testing is provided in Section M.4.

8.11.7 (927)
Comment - EIS000122 / 0002
What are the level of dosages allowed by the DOE on each of the radioactive elements that are known to cause cancer in the one hundred million people that these canisters will pass by in transport?

Response
The requirements listed in the U.S. Department of Transportation Hazardous Materials Packaging and Transportation Regulations (49 CFR Subchapter C – Hazardous Materials Regulations, Parts 171 through 180) specify a maximum allowable dose rate of 10 millirem per hour at 2 meters (6.6 feet) from the surface of the cask. This is total radiation from the cask and its contents, not the radiation for each individual radionuclide. The analysis in Chapter 6 of the EIS assumed the maximum allowable dose rate for all routine, incident-free transportation exposures. Estimated doses to individual members of the public would be far below those known to have reasonable probability of causing cancer. Considering national legal-weight truck transportation of spent nuclear fuel and high-level radioactive waste for 24 years, Section 6.2.3.1 of the EIS states that in a population of about 10 million people living along the roads, one would expect about 12.6 latent cancer fatalities. An individual resident would receive a dose of about 6 millirem. Background radiation for those 24 years would be about 7,200 millirem (about 300 millirem per year).

8.11.7 (2226)
Comment - EIS000622 / 0010
My questions earlier about exposure, accumulative exposure. If this panel cannot address them, then I think that's extremely important. If we have rules and regulations for transporting materials that specify they need to be moved in 48 hours, then why isn't this addressed in this book more adequately so that our questions can be answered?

We're talking about materials that are extremely deadly, and all of us are very concerned and want factual information. We want to know about cumulative effects. People who live along rail lines and have herds and growth materials, farms, who raise alfalfa and family foods, people who go out and harvest natural medicines and so forth need this kind of information.

Response
Section 8.4 of the EIS presents the past, present, and reasonably foreseeable future actions that would be additive to actions related to the transportation of spent nuclear fuel and high-level radioactive waste to a proposed repository. These actions include activities of the Nevada Test Site, Nellis Air Force Base, management of low-level radioactive

waste, Native American activities, other DOE waste management, and regional mining activities and enterprises, among others. For each action, the Department has presented the radiological impacts and vehicular accident impacts. There would be no cumulative effect of radiation on crops and farm animals grown in the vicinity of the transport routes since no radioactive material would be released from the cask during incident free transportation.

8.11.7 (3967)

Comment - EIS002239 / 0003

The EIS understates the potential health consequences of a very severe rail accident. We ran these same models, using different but credible inputs. They say 31 latent cancer fatalities, and we say the same accident could generate up to 1,380 latent cancer fatalities. A range of outputs results from a range of inputs; that's a bounding scenario that DOE uses, or they would like to in the document.

But in other areas they give you this sense of specificity; and they can tell you exactly what the impact would be. You have to define it broadly, and it could be significantly larger.

Response

The shipping casks used to transport spent nuclear fuel and high-level radioactive waste would be massive and tough with design features that comply with strict regulatory requirements that ensure the casks perform their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials. The consequences of rail accidents ranged from 0.7 to 130 latent cancer fatalities; even the most severe accident, which had a probability of 8×10^{-19} per year, did not yield 1,380 latent cancer fatalities.

8.11.7 (4486)

Comment - EIS001409 / 0003

"5.6 cancer deaths" is unacceptable; even saying the number sounds nutty.

Response

The EIS addresses the radiological impacts of incident-free transportation and transportation accidents in Chapter 6 and Appendix J of the EIS. The analyses take into consideration the distance and number of shipments to estimate the number of accidents that would be expected for each of the transportation alternatives.

The spent nuclear fuel and high-level radioactive waste transportation casks are sufficiently robust that in more than 99.99 percent of accidents, no release of radioactive materials from the casks would be expected. Additional information on cask safety and testing is provided in Section M.4 of the EIS.

Safety is DOE's primary concern when shipping all types of radioactive material, including spent nuclear fuel and high-level radioactive waste. U.S. Department of Transportation and Nuclear Regulatory Commission regulations strictly regulate all aspects of radioactive material transportation, including packaging, transporting, and handling radioactive materials for all modes of transportation, and include standards for labeling, shipping papers, placarding, loading and unloading, allowable radiation levels, and limits for contamination of packages and vehicles, among other requirements. In addition, the regulations specify training for personnel who perform handling and transport of hazardous materials, liability insurance requirements for carriers, and safety requirements for vehicles and transport operations. More details on transportation regulations can be found in Section M.2 of the EIS.

The estimated number of latent cancer fatalities associated with incident-free transportation has been revised. As discussed in Section 6.1.1 of the EIS, the estimated number of latent cancer fatalities among the several million people along the transportation routes would be 2.5 for mostly legal-weight truck transportation over 24 years and 1 for mostly rail. Also as discussed in Section 6.1.1, the estimated number of latent cancer fatalities for workers would be 5.6 for mostly legal-weight truck transportation over 24 years and 1.8 for mostly rail. At this time, it is not possible to know if a specific cancer would be caused by radiation; however, for perspective, there would be about 220,000 cancer fatalities in a population of 1 million along the transport routes from other causes besides the transport of spent nuclear fuel and high-level radioactive waste over the same period.

8.11.7 (6908)
Comment - EIS001539 / 0009
Acceptable Risks: Cancer risks of 1 x 10^{-3} are unacceptable to Denver residents and workers.

While DEH [Denver Department of Environmental Health] understands that the maximally exposed service station worker scenario is unlikely (service station worker exposed to 430 truck shipments per year for 24 years), DEH takes exception to a characterization of "very low" risk for the calculated probability of 1.2 x 10^{-3}, for a latent fatal cancer. Individual cancer risk estimates in the range of 1 x 10^{-3} are unacceptable for Denver residents and workers, and are recognized as unacceptable in environmental regulation.

Response
As indicated in Section J.1.3.2 of the EIS, the maximally exposed individual scenario cited by the commenter is meant to be a conservative estimate of potential exposures, not an expected exposure. A more realistic estimate of the radiation dose to people along transportation routes is about 0.2 millirem per year. This is equivalent to a latent cancer fatality risk of about 1×10^{-7}. For perspective, risks in the range of 1×10^{-4} to 1×10^{-6} are generally regarded as acceptable in environmental regulations.

8.11.7 (7620)
Comment - EIS001912 / 0079
Pg. 6-23. Needs to describe the numbers in Table 6-5 and discuss their implications.

Response
The implications of the results of the transportation analyses are discussed in Section 6.2.3.1 and Section S.4.2 in the EIS. Additional information on the basis for these calculations is provided in Appendix J.

8.11.7 (7950)
Comment - EIS001903 / 0013
Paragraph 1 on page J-45 states the baseline likelihood of fatal cancer is 23 percent. Paragraph 3 on page J-45 and paragraph 2 on page J-47 (citing the same reference) states the baseline likelihood of fatal cancer is 22 percent. This inconsistency should be corrected. Also, paragraph 3 on page J-45 incorrectly indicates that 8 percent plus 22 percent is 32 percent.

Response
Appendix J of the EIS has been revised to make these estimates consistent.

8.11.7 (8123)
Comment - EIS001653 / 0077
Pg. 6-23 Needs to describe the numbers in Table 6-5 [population doses and impacts from legal weight truck] and discuss their implications.

Response
The implications of the results of the transportation analyses are discussed in Section 6.2.3.1 and Section S.4.2 in the EIS Summary. Additional information on the basis for these calculations is provided in Appendix J.

8.11.7 (9625)
Comment - EIS001888 / 0295
A careful review of the DEIS leaves the reader unclear as to what the report is about and why the report recommends the Proposed Action. If the decision to ship waste to Yucca Mountain is made, that decision cannot be

supported on the basis of the human health risks presented in the DEIS. Based on the DEIS, the risk to human health when transporting the waste far exceeds the risk of leaving the waste in place.

This aspect of the report highlights the uncertain role risk assessment plays in the decision making process. In a 1995 report, a DOE contractor described a process for choosing a route through Nevada to Yucca Mountain. Nowhere in that report did the contractor mention human health risk as a criterion. Part of the uncertainty about the role of probabilistic risk assessment in the decision-making process is due to the inconsistent way in which PRA is performed. The differences between the DEIS produced by the DOE and the Generic EIS (GEIS) produced by the Nuclear Regulatory Commission for the relicensing of nuclear power plants are inconsistent. The differences in methodologies used to prepare transportation risk analysis are substantial and effect the results of the analysis.

Response
As discussed in the EIS Summary, the impacts from the Proposed Action would range from 22 to 50 fatalities. For the No-Action alternative, the impacts would range from 33 fatalities for Scenario 1 to 3,300 fatalities for Scenario 2. The impacts of the Proposed Action would be about the same as the impacts of Scenario 1 and less than the impacts of Scenario 2. Therefore, the risk to human health when transporting the waste would not far exceed the risk of leaving the waste in place.

Human health risk does play a role in transportation routing. For example, in the U.S. Department of Transportation guidelines for selecting preferred highway routes for spent nuclear fuel shipments, two of the primary criteria are normal radiation exposure and public health risks from accidents. These criteria are directly related to human health risks.

The Nuclear Regulatory Commission *Generic Environmental Impact Statement for License Renewal of Nuclear Plants* (DIRS 101899-NRC 1996) estimated about 3 fatalities for transport of spent nuclear fuel in Nevada. The EIS analysis estimated that as many as 1.5 fatalities could occur in Nevada, which is about half the number of fatalities for transport of spent nuclear fuel estimated by the Nuclear Regulatory Commission. The difference between the two analysis results is not substantial.

8.11.7 (9871)
Comment - EIS002150 / 0001
I heard in the evening news that the Department of Energy has the public safety for most in mind when considering trucking nuclear waste. However, I read in the Draft EIS that [the] Department of Energy estimates that 29 people will die from cancer as a result of using legal weight trucks. Eleven workers will die and 178 of the general public.

In signing 29 Americans to death through the horrors and pain of cancer does not indicate to me the Department of Energy really is concerned about public safety. Who decides which 29 will die as the Department of Energy estimated how many Americans will suffer the ravages of cancer and not die?

Response
Safety is DOE's primary concern when shipping all types of radioactive material, including spent nuclear fuel and high-level radioactive waste. U.S. Department of Transportation and Nuclear Regulatory Commission regulations strictly regulate all aspects of radioactive material transportation, including packaging, transporting, and handling radioactive materials for all modes of transportation, and include standards for labeling, shipping papers, placarding, loading and unloading, allowable radiation levels, and limits for contamination of packages and vehicles, among other requirements. In addition, the regulations specify training for personnel who perform handling and transport of hazardous materials, liability insurance requirements for carriers, and safety requirements for vehicles and transport operations. More details on transportation regulations can be found in Section M.2 of the EIS.

The estimated number of latent cancer fatalities associated with incident-free transportation has been revised. As discussed in Section 6.1.1 of the EIS, the estimated number of latent cancer fatalities among the several million people along the transportation routes would be 2.5 for mostly legal-weight truck transportation over 24 years and 1 for mostly rail. Also as discussed in Section 6.1.1, the estimated number of latent cancer fatalities for workers would be 5.6 for mostly legal-weight truck transportation over 24 years and 1.8 for mostly rail. At this time, it is not possible to know if a specific cancer is caused by radiation; however, for perspective, there would be about 220,000 cancer fatalities in a population of 1 million along the transport routes from other causes besides the transport of spent nuclear fuel and high-level radioactive waste over the same period.

8.11.7 (11679)
Comment - EIS002293 / 0001
The radiation allowed to reach the surface from the underground Yucca Mountain Nuclear Waste repository is less than a tenth of that which we receive from nature; and data now indicates that such extra low-level radiation, like that in Denver, may be healthy. But, what about the transportation of wastes to Yucca Mountain? Considering the real transportation dangers we face from such common carriers as gasoline trucks, and the 50,000 deaths each year from automobile accidents, why has there been such concern over nuclear waste transportation. Nuclear waste shipments are required to have such strong packaging and containment requirements that even in an accident the probability of significant radiation leakage is negligibly small. For the past 45 years, there have been some 3,000 shipments of nuclear fuel wastes without any effects on the public from nuclear radiation. The normal public radiation exposures from the transportation of wastes are orders of magnitude less than our radiation exposures from nature.

Response
The analyses in the EIS of transporting spent nuclear fuel and high-level radioactive waste indicate that the impacts would be negligible.

8.11.8 NOISE

8.11.8 (10)
Comment - 6 comments summarized
Commenters expressed concern about the proximity of public buildings and residences to proposed heavy-haul truck routes and rail lines in the State of Nevada. Some expressed concern about impacts to the quality of life due to noise during construction and operation of transportation facilities. Others expressed concern about impacts to structures from ground vibration associated with intermodal transfer stations and operation of heavy-haul trucks. Specific concern was expressed regarding the 640-meter (2,100-foot) region of influence established at the 45-decibel (dBA) level as it applies to Goldfield in Esmeralda County. Similar concerns were expressed regarding the assessment of noise associated with a railroad, an intermodal transfer station, and heavy-haul truck traffic in Caliente.

Response
Because of the need to differentiate among implementing alternatives (for example, among corridors), the noise analysis applied to the alternative rail corridors and heavy-haul truck routes was a reconnaissance-level screening analysis, rather than an examination of individual noise receptors or baseline levels of noise and traffic. As discussed in the introduction to Chapter 6 of the EIS, follow-on implementing decisions, such as the selection of a specific rail alignment within a rail corridor, would require additional field surveys, State. Local, and tribal government consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews. Buildings of historic significance, as well as public exposure to noise and vibration for example, would be addressed at that time.

Nevada does not have noise regulations. DOE used 45 dBA for the EIS analyses to establish conservatively a region of influence that would include most receptors. For comparison, residential noise standards in many other states generally use a level of 60 dBA for residential zones and 65 dBA for commercial zones. Residences located near highways along heavy-haul truck routes would be exposed to instantaneous levels of noise exceeding 60 dBA, which could elicit complaints that the noise was annoying. Annoyance levels are below levels that would be unsafe or could cause hearing damage. DOE has modified Section 3.1.9.2 of the EIS to include a discussion of noise levels that are potentially unsafe or that could cause hearing damage compared to levels that merely result in annoyance.

8.11.8 (7217)
Comment - EIS001337 / 0100
Page 3-134 Section 3.2.2.2.7. 3rd paragraph. The Caliente Route is located several miles from the community of Hiko. Reference to Hiko in this paragraph should be deleted.

Response
DOE has deleted the reference to Hiko.

8.11.9 AESTHETICS

8.11.9 (47)
Comment - 3 comments summarized
Commenters stated that the beauty and serenity of Crescent Valley, Nevada, would be destroyed if the valley were to become a rail or truck route for nuclear waste. A commenter indicated that the project would destroy everything in the valley within 25 years because of radioactivity in the air and water.

Response
The Carlin Corridor, part of which passes through Crescent Valley, is but one of five alternative rail corridors DOE considered in Section 6.3 of the EIS. Similarly, the Carlin heavy-haul truck route is only one of five alternative heavy-haul truck routes under consideration (see Section 6.3). See Sections 6.3.2.1 and 6.3.3.1 for discussions of the impacts from noise and to aesthetics in rail and heavy-haul truck corridors, respectively.

Crescent Valley has already been altered by man. There are houses, ranches, roads, and businesses in the valley, most of which are along State Route 306 between the Cortez area and Beowawe. There are historic and present-day mining operations in the vicinity of Cortez, and the effects of these operations are evident in the valley. Tailing piles, access roads, and mining facilities are evident. South of the Cortez area, there are fewer disturbances to the valley, consisting primarily of farming operations.

DOE recognizes that additional, site-specific information would be needed before it constructed either a branch rail line or upgraded roads to support heavy-haul truck shipping. DOE believes, however, that sufficient information on impacts to visual resources is provided in Chapter 6 of the EIS to help make a decision about the transportation mode (rail or truck) and the specific corridor or heavy-haul truck route (see Section 1.1 of the EIS). More detailed field surveys, government consultations, and appropriate National Environmental Policy Act reviews would be conducted if DOE made a decision to select either a specific rail alignment within a corridor or an intermodal transfer station and associated heavy-haul truck route. These additional reviews could include more detailed analyses of impacts to visual resources, as well as the identification of possible mitigation measures to minimize any impacts identified.

Sections 6.2.3 and 6.2.4 of the EIS summarize the radiological impacts of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Appendix J describes these impacts in more detail. The radiation dose from routine transportation would not be likely to harm plant or animal life within the area. Sections 4.1.4 and 5.9 discuss radiation impacts to biological resources.

8.11.9 (5699)
Comment - EIS001887 / 0314
Page 6-14; Section 6.1.2.9 - Aesthetics

This transportation impacts overview section admits that the Caliente intermodal transfer station site “could cause impacts on the Class II lands of Kershaw-Ryan State Park” in terms of aesthetics. However, it goes on to imply that, because the character of the Meadow Valley Wash has already been modified by the existence of a rail line, the City of Caliente’s water treatment facility and agricultural uses, the impact would be slight, if not negligible. No other potential impacts were even acknowledged in the overview. We find this cursory analysis inadequate.

Response
As discussed in Section 6.1.2.9 of the EIS, routes originating in Caliente could adversely affect the Class-II visual designation of lands in and around Kershaw-Ryan State Park, the entrance of which is on the east site of Meadow Valley Wash across from the potential location of an intermodal transfer station. Section 6.3.3.1 of the Draft EIS stated that more stringent management requirements would be necessary to retain the existing visual character of Class-II lands. Nevertheless, DOE has included additional discussion in Sections 6.3.2.2 and 6.3.3.2 of potential impacts to selected views from outside and inside each alternative rail corridor, and the visual impacts associated with the alternative sites for an intermodal transfer station.

8.11.9 (5700)
Comment - EIS001887 / 0315
Page 6-14; Section 6.1.2.9 - Aesthetics

No mention is made of the fact that the Apex/Dry Lake intermodal transfer station sites are in close proximity to the Valley of Fire State Park exit off I-15. Furthermore, no attempt is made to quantify any impacts that may occur as a result of this proximity.

Response
The entrance to Valley of Fire State Park is approximately 19 kilometers (12 miles) east of Interstate-15. The site of the Apex/Dry Lake intermodal transfer station would be another 18 kilometers (11 miles) south on Interstate-15 near its interchange with U.S. 93. Because of the distances between these locations, construction or operation of an intermodal transfer station at Apex/Dry Lake would not have any impacts on Valley of Fire State Park.

8.11.9 (7139)
Comment - EIS001337 / 0036
Lincoln County and the City of Caliente recommended that the DEIS, to facilitate an assessment of impacts upon viewshed, include an analysis of existing visual quality within basins potentially impacted by rail construction and operation. The County and City noted that such information can be used in developing measures for mitigation of impacts to viewshed within Lincoln County. The DEIS does assess existing visual quality along rail corridors in Lincoln County. There is however, no description of measures to mitigate visual impacts of rail corridors within Section 9.3 of the EIS.

Response
Section 9.3.8 of the EIS has been modified to include several possible measures to mitigate visual impacts from a branch rail line. Potential mitigation measures could include (1) removing or contouring spoil piles from construction activities to mimic the existing landscape; (2) minimizing the height of spoil piles if they could not be removed or recontoured; (3) planting native seedlings and other vegetation in specific locations to screen or reduce texture and color contrasts from key observation points; and (4) implementing a water spraying program during construction to minimize emissions of fugitive dust.

8.11.9 (7221)
Comment - EIS001337 / 0096
Page 3-116 Section 3.2.2.1.8. This section needs to describe BLM [Bureau of Land Management] designated wilderness study areas (WSA) proximate to transportation corridors. Section 4, environmental consequence needs to consider visual impacts to and from designated WSA's.

Response
Section 4.1.10 of the EIS describes potential aesthetic impacts of the proposed repository. There are no Wilderness Study Areas near Yucca Mountain. Therefore, construction and operation of a repository at Yucca Mountain would not affect existing Wilderness Study Areas.

The Caliente Corridor passes near Weepah Springs Wilderness Study Area in the Kawich and Reveille Mountains, and the Valley Modified Corridor passes near two Wilderness Study Areas near the Sheep Range Mountains, the Desert National Wildlife Refuge, and the Nellis Air Force Range. The Steiner Creek Alternate of the Carlin Corridor potentially encroaches on the Simpson Park Wilderness Study Area. DOE has modified Section 6.3.2.1 of EIS to include additional discussion of the visual impacts to these Wilderness Study Areas from construction and operation of a branch rail line.

8.11.9 (8141)
Comment - EIS001653 / 0085
Pg. 6-14 There is no discussion of aesthetic or visual impacts along the proposed rail corridors. Simply showing the VRM [Visual Resource Management] classifications for public lands is not acceptable. More importantly it is the views from surrounding mountains and inhabited areas of the proposed rail line, which are impacted. There are numerous high quality well used recreation areas along the proposed route. DOE needs to consider visual impacts from surrounding lands and prepare a full visual resource analysis.

Response
DOE described the potential aesthetic impacts of constructing and operating a branch rail line in Section 6.3.2.1 of the Draft EIS. Because these corridors cross mostly public land administered by the Bureau of Land Management, DOE used the Visual Resource Management classifications developed by the Bureau to assess each corridor's scenic sensitivity. DOE incorporated this approach into the EIS for consistency with the Bureau's approach and to facilitate comparison with previous assessments conducted by the Bureau.

DOE agrees that factors other than the Visual Resource Management classifications are pertinent to assessing visual impacts. Therefore, DOE has included additional discussion in Sections 6.3.2.2 and 6.3.3.2 of the Final EIS of potential impacts to selected views from outside and inside each alternative rail corridor, and the visual impacts associated with the alternative sites for an intermodal transfer station.

8.11.9 (8361)
Comment - EIS001873 / 0045
P. 3-135. The Kershaw Ryan State Park should be mentioned here as a resource. On the following page BLM [Bureau of Land Management] Visual Resource classes are displayed as if they included all the aesthetic resources of the area. Important areas not shown as resources, because they are not BLM lands apparently, should include the Pahranagat Lakes and Groom Mountain.

Response
Section 6.1.2.9 of the EIS notes that routes originating in Caliente could adversely affect the Class-II visual designation of lands in and around Kershaw-Ryan State Park, the entrance of which is on the east side of Meadow Valley Wash across from the potential location of an intermodal transfer station.

Pahranagat Lakes, located west of U.S. 93 along a section of road, is a natural area. However, since the lakes are along a highway that is being considered as a heavy-haul truck route (Caliente/Las Vegas Route) and a legal-weight truck route and not as a possible rail route, impacts to the area would not be likely.

Groom Mountain, located in the northeast portion of the Nellis Air Force Range, has already been removed from public use with the exception of several mining claims. The mountain previously was managed by the Nevada Test Site and used by the Air Force. Management of the mountain was transferred to the Air Force by the Test Site during the same time Pahute Mesa management was transferred from the Air Force to the Test Site.

DOE used the Visual Resource Management classifications developed by the Bureau of Land Management to assess each corridor's scenic sensitivity because the rail corridors cross mostly public land administered by the Bureau. The Bureau has prepared many environmental documents that use this visual-assessment classification. DOE incorporated this approach into the EIS for consistency with the Bureau's approach and to facilitate comparison with previous assessments conducted by the Bureau.

DOE agrees that factors other than the Visual Resource Management classifications are pertinent to assessing visual impacts. Therefore, DOE has included additional discussion in Sections 6.3.2.2 and 6.3.3.2 of the EIS of potential impacts to selected views from outside and inside each alternative rail corridor, and the visual impacts associated with the alternative sites for an intermodal transfer station.

8.11.9 (8387)
Comment - EIS001873 / 0068
P. 6-98. Even the BLM [Bureau of Land Management] Visual Resource map shows the Caliente intermodal site as being in a Class II area. Meeting Class III objectives is not satisfactory.

Response
As discussed in Section 6.1.2.9 of the EIS, routes originating in Caliente could adversely affect the Class-II visual designation of lands in and around Kershaw-Ryan State Park, the entrance of which is on the east side of Meadow Valley Wash across from the potential location of an intermodal transfer station. Section 6.3.3.1 of the EIS states that more stringent management requirements would be necessary to retain the existing visual character of Class-II lands.

8.11.9 (8388)
Comment - EIS001873 / 0069
P. 6-98. The impacts to aesthetics and cultural resources would be greater at Caliente than at the other sites.

Response
Only the Caliente intermodal transfer station and immediately adjacent routes would adversely affect the Class-II visual designation. Section 6.1.2.9 of the EIS states that routes originating in Caliente could adversely affect the Class-II visual designation of lands in and around Kershaw-Ryan State Park, the entrance of which is on the east side of Meadow Valley Wash across from the potential location of an intermodal transfer station. Section 6.3.3.1 describes the aesthetic impacts associated with this intermodal transfer station.

Section 6.3.3.1 of the EIS indicates that limited cultural resources surveys have been performed along the candidate heavy-haul truck routes. For this reason, specific impacts to culturally important sites, areas, or resources cannot be determined. If, however, DOE selected heavy-haul truck for the transportation of spent nuclear fuel and high-level radioactive waste, along with a site for an intermodal transfer station in Meadow Valley Wash, the Department would conduct additional field studies to identify cultural resource properties in or adjacent to the intermodal transfer station site (see Section 6.3.3.1).

8.11.9 (9807)
Comment - EIS001888 / 0394
[Clark County summary of comments it has received from the public.]

Commenters requested that the EIS include an analysis of existing visual quality within basins in Lincoln County and in the Elko region, and a description of the visual impact from rail construction and operation.

Response
DOE has included additional discussion in Sections 6.3.2.2 and 6.3.3.2 of the EIS of potential impacts to selected views from outside and inside each alternative rail corridor, and the visual impacts associated with the alternative sites for an intermodal transfer station.

8.11.9 (9868)
Comment - EIS002158 / 0013
Ryan Park is not sufficiently identified as a resource. It's within a half a mile of the proposed intermodal facility. This is one of our state parks in Lincoln County where people go for the scenery. Of course the facility's known, Rainbow Canyon and the name speaks for itself. It's a scenic area. The EIS simply says that it's a BLM [Bureau of Land Management] Class 3 area or something and leave it at that. Well, BLM visual impact categories are absolutely meaningless to the people that live in this area, where it's an aesthetic resource and a recreation resource that has deep significance for the community.

Response
Figure 3-29 of the EIS shows selected features along the alternative rail corridors, including Kershaw-Ryan State Park near Caliente. As discussed in Section 6.1.2.9 of the EIS, routes originating in Caliente could adversely affect the Class-II visual designation of lands in and around Kershaw-Ryan State Park, the entrance of which is on the east side of Meadow Valley Wash across from the potential location of an intermodal transfer station. Section 6.3.3.1 of the Draft EIS stated that more stringent management requirements would be necessary to retain the existing visual character of these Class-II lands.

DOE agrees that factors other than the Bureau of Land Management Visual Resource Management classifications are pertinent in assessing visual impacts. Therefore, DOE has included additional discussion in Sections 6.3.2.2 and 6.3.3.2 of the EIS of potential impacts to selected views from outside and inside each alternative rail corridor, and the visual impacts associated with the alternative sites for an intermodal transfer station.

8.11.9 (11937)
Comment - EIS001878 / 0069
The DEIS fails to adequately address the impacts of the proposed action on the scenic resources of Eureka County and Nevada's other rural counties. Nevada's rural areas provide increasingly rare unspoiled views of the basin and

range region, and include numerous scenic resources, none of which are identified in the DEIS. Scenic resources that could be affected by the proposed Carlin corridor include such areas as Monitor Valley and Grass Valley, and such features as stage stops, hot springs, graveyards, historic mines, historic ranches, historic railroads, the Humboldt River, and unique geological formations. The statement on p. 6-50, "The greatest impact on visual resources from the construction of a rail line would be the presence of workers, camps, vehicles, large earth-moving equipment, lay down yards, and dust generation" is self-serving and unsupported by any evidence. The statement completely ignores the long-term scenic impacts of new permanent linear facilities (i.e., rail lines and access roads) and the associated land disturbance.

The DEIS must analyze the anticipated impacts of the proposed action on views and scenery, particularly in areas now in a natural or nearly-natural condition. The DEIS must consider, at a minimum, the long-term scenic impacts of the railroad bed, access roads, excavations and pits, fences, and supporting infrastructure.

Response
DOE agrees with this comment and has included additional discussion in Sections 6.3.2.2 and 6.3.3.2 of the EIS of potential impacts to selected views from outside and inside each alternative rail corridor, and the visual impacts associated with the alternative sites for an intermodal transfer station.

8.11.10 WASTE MANAGEMENT

8.11.10 (112)
Comment - 2 comments summarized
Commenters stated that the Draft EIS provided insufficient information regarding the expected wastes that would be generated during the construction and operation of a rail line in Nevada (or intermodal transfer station and heavy-haul truck routes) and where such wastes would be disposed of. Commenters noted the remoteness of the proposed activities and the limited capacity of existing disposal facilities in those areas.

Response
Waste generated from the construction of a branch rail line or intermodal transfer station would fall into several categories: waste soil and rock material; general construction waste, such as wood, excess rebar, rail ties, and track material; solid waste generated by workers indirect to construction, such as trash; hazardous wastes, such as certain used paints, resins and lubricants; and sanitary waste. For all waste types, DOE likely would use the nearest available authorized disposal facilities having sufficient capacity. In some instances, DOE recognizes that wastes might need to be transported either by use of a partially completed branch rail line or by truck. DOE would identify disposal facilities during final design and construction of a branch rail line or intermodal transfer facility.

8.11.11 ENVIRONMENTAL JUSTICE/NATIVE AMERICAN ISSUES

8.11.11 (3084)
Comment - EIS000735 / 0012
The area of environmental justice addresses primarily Native-American issues. Other minority groups in urban areas may be effected just as much and should be considered.

Response
As discussed in Section 3.1.13 of the EIS, DOE defined minority as "Hispanic, Black, Asian/Pacific Islander, American Indian/Eskimo, Aleut, and other non-white person." To identify minority and low-income communities in the region of influence, DOE analyzed Bureau of the Census block groups. Those block groups where the percentage of minority or low-income residents was meaningfully greater than average were identified as minority or low-income communities for purposes of the environmental justice analysis. This EIS considers whether activities at Yucca Mountain could cause disproportionately high and adverse human health or environmental effects to those communities. The results of the analysis are throughout the EIS (for example, Section 6.2.5 for national transportation and Section 6.1.2.12 for Nevada transportation). The analysis determined that the potential impacts to public health and safety would be small on all populations during all phases of the repository program, and that no subsection of the population, including minority or low-income populations, would receive disproportionately high and adverse impacts.

8.11.11 (5147)
Comment - EIS001911 / 0006
We know that nuclear waste from Northern States Power will be transported through and adjacent to our reservation to a federal storage facility. Other jurisdictions may not be aware that they might be impacted by shipments. The DOE must begin conducting field workshops in these areas to begin educating people about these shipments and to answer the many questions people have regarding safety and emergency preparedness arrangements.

Response
Section 180(c) of the NWPA requires DOE to provide technical and financial assistance to states for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions the Department planned to transport spent nuclear fuel or high-level radioactive waste. The training of public safety officials would cover procedures required for safe routine transportation of these materials and for dealing with emergency response situations.

DOE plans to fully implement these requirements, but implementation would not begin until closer to the time that actual shipments would occur. Section M.6 of the EIS describes how Section 180(c) of the NWPA would be implemented. DOE anticipates knowing at least 4 years before shipments occurred the states or tribal jurisdictions through which the shipments would travel, even if exact routes had not been selected. Using this information, DOE would notify those jurisdictions about their potential eligibility for the Section 180(c) program. DOE published a Notice of Revised Proposed Policy and Procedures in the *Federal Register* (63 *FR* 23753 to 23766, April 30, 1998) that sets forth its plan for implementing a program of technical and financial assistance for training public safety officials of appropriate units of local government and tribes through whose jurisdictions the Department would transport spent nuclear fuel or high-level radioactive waste.

8.11.11 (5502)
Comment - EIS001660 / 0028
The DEIS inadequately analyzes the project impacts in relation to environmental justice. Rural communities are dispersed, rather than concentrated. Given the limited political power of rural communities, they are often targeted for unwanted projects. The Yucca Mountain repository is an excellent example of this type of “justice”. The DOE’s risk models are based on avoiding urban areas, and presume that risks from the project should be borne by individuals in rural communities. The DEIS should consider the effects of past programs and policies on communities, as well as additional impacts of the Yucca Mountain Project.

Response
An environmental justice analysis considers the potential for disproportionately high and adverse impacts to minority and low-income populations. Executive Order 12898, issued by the President, gives the environmental justice analysis this exclusive focus. An environmental justice analysis does not consider the potential for impacts on the general population. The EIS as a whole, however, does.

The EIS brings together the results of analyses from different technical disciplines that focus on consequences to certain resources that could affect human health or the environment. The EIS analyzes the demographic characteristics of the population in the immediate vicinity of the Yucca Mountain site and along transportation routes. Chapter 8 of the EIS addresses cumulative impacts, which consider the effects of past programs and policies on communities. The discussion focuses on past, present, and reasonably foreseeable future projects together with the potential impact from implementing the Yucca Mountain proposal. Section 8.1.2.2 discusses the other Federal actions in the vicinity of Yucca Mountain (including those conducted at the Nellis Air Force Range and the Nevada Test Site). Section 8.2 discusses cumulative impacts on human health and environmental resources. Section 8.2.5 discusses cumulative impacts to cultural resources. Section 8.2.6 discusses socioeconomic indicators associated with construction, operation, and closure of the repository.

8.11.11 (6382)
Comment - EIS001590 / 0006
There are questions about environmental justice. There’s been no analysis along the specific routes regarding the impact on minority communities. Half of Rum Village is minority, not to mention Native American communities, black and Hispanic communities. Note that the waste would end up in land, which, by the treaty of Ruby Valley, is the property of Western Shoshone nation.

Response
Section 6.2.5 of the EIS discusses environmental justice aspects of national transportation of spent nuclear fuel and high-level radioactive waste. DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

Section 3.1.13 of the EIS describes the minority or low-income populations in Nevada in relation to Yucca Mountain and the alternative rail and heavy-haul truck corridors. Section 6.3.4 addresses environmental justice impacts in Nevada as a result of the shipment of spent nuclear fuel and high-level radioactive waste to the proposed repository. These sections contain maps that show the locations of minority or low-income populations in relation to the site and the transportation corridors.

This comment raises the question of whether disproportionately high and adverse health and safety impacts (as the term is used in Executive Order 12898) exist whenever minorities and low-income individuals reside along transportation routes for radioactive materials. The EIS considers air emissions and doses from exposure to radioactive materials during routine transport and shows that the impact from air emissions to be 1 emissions-related fatality. The EIS estimates that the 24-year national transportation campaign would cause fewer than about 3 latent cancer fatalities among the general public, and fewer under the preferred, mostly rail scenario. Although many people would be exposed nationwide over a long campaign, the radiation dose to any exposed individual would be very low. In this context, DOE does not consider such impacts to be high. DOE does not know of a plausible mechanism under these circumstances whereby low-income or minority populations could incur high and adverse impacts when the general public would not.

Section 3.1.1.4 of the EIS acknowledges the issue over the Ruby Valley Treaty of 1863. At this time, the Federal Government owns the land encompassing the Yucca Mountain site. A 1985 U.S. Supreme Court decision held that the Western Shoshone claim to land associated with the Ruby Valley Treaty has been extinguished. Although DOE recognizes the sensitivity of this issue, it believes that the Supreme Court case settles these issues [United States v. Dann, 470 U. S. 39 (1985)].

DOE believes that the EIS adequately analyzes the level of potential transportation-related disproportionate impacts to minority and low-income populations, including Native American tribes.

8.11.11 (8799)
Comment - EIS001907 / 0026
The DOE states in the DEIS that it believed there would be no disproportionately high and adverse impacts to minority or low-income populations as a result of the Proposed Action, including national transportation. This claim is obviously false, since already heavy-weight truck and rail routes throughout this country are placed in low-income, people of color communities. That this environmental racism would change with this proposed action, is as likely flying toads (although with continued accidents throughout the country, I'm sure that flying toads caused by radioactive mutation are getting closer and closer).

Response
Thank you for your comment.

8.11.11 (8853)
Comment - EIS002087 / 0003
On page J-110, under environmental justice, section J.3.6.4, it says, "In addition to the nearly random nature of accidents that would involve the transportation of materials and people, the probability of such an accident would be small in any location, minimizing the risk at a specific location. Furthermore, because the potential accidents would be nearly random, impacts to minorities in low income populations and to Native Americans along the routes in Nevada, it would be unlikely to be disproportionately high and adverse."

And with that particular statement, we would then disagree with that, because if there was an accident near a reservation, clearly being an Indian population there, we believe that would be higher and more disproportionate. I would also – with that close proximity due to the subsistence patterns of Native Americans that that, again, would be a disproportionately high something to the Indian people, whatever the word is.

Response
The likelihood of a transportation accident that resulted in a considerable release of radioactivity affecting Native Americans along the shipping routes is extremely remote. The shipping casks used to transport spent nuclear fuel and high-level radioactive waste would be massive and robust, with design features that complied with strict regulatory requirements that ensure they were fault-tolerant. That is, the casks would perform their safety functions if damaged. Tests and analyses using the most advanced methods have demonstrated that the casks would provide containment and shielding even under the most severe accidents that could occur. A study by Sandia National Laboratories for the Nuclear Regulatory Commission concluded that the casks would continue to contain spent nuclear fuel completely in more than 99.99 percent of all accidents (DIRS 152476-Sprung et al. 2000). This means that there would be much less than a 1-percent chance of an accident that could result in a release of radioactive material from a cask over 24 years of spent nuclear fuel and high-level radioactive waste shipments to Yucca Mountain by truck. The chance of a rail accident that would cause release from a cask is even lower. The chance that an accident would occur in a specific locale would be much less than 1 percent.

8.11.11 (9342)
Comment - EIS001888 / 0058
In the DEIS minority and low-income populations are identified along possible transportation routes and in the vicinity of the proposed disposal site for the high-level nuclear wastes. This is accomplished by identifying census tracts and determining whether the proportion of these groups within those census tracts is higher than in other tracts. Because in the Yucca Mountain DEIS it is concluded that there is very little or no risk of adverse impacts from the government actions in question, it is also concluded that these groups will not be significantly affected.

There are several inadequacies in the methods that lead to these conclusions. These are listed below along with corresponding recommendations.

The DEIS treats minority and low-income populations as the vulnerable populations of interest (DEIS, pg. 3-94). These groups are specifically mentioned in all government documents considering environmental justice, because they have historically been politically vulnerable to government actions with adverse effects. But these are not the only groups that are disproportionately vulnerable to such actions. Guidance documents for interpreting Executive Order 12898 emphasize that fair treatment means that no group of people should bear a disproportionate share of negative environmental consequences of government actions. Other groups, for example, would be disproportionately vulnerable to such consequences because of impaired health or immature immunological systems.(1)

In view of this, we recommend that other vulnerable populations, including the aged, the infirm, pregnant women, and children, be included in the DEIS and other environmental justice analyses.

The DEIS sections on environmental justice use census and demographic information from 1990 (pp. 3-94, 3-96). The population of Clark County has changed dramatically in the ten years since the 1990 census. The Council on Environmental Quality (CEQ) Final Guidance Document notes the limitations of census data and proposes using multiple sources of information on potentially affected populations.(2) Clark County recommends that data on current populations and projections of population changes into the foreseeable future should be used to correct, supplement or replace 1990 Census data.

(1)Section 2. 1, *CEQ Final Guidance for Incorporating Environmental Justice Concerns in EPA's NEPA Compliance Analyses*, April 1998.

(2)Section 5. 1, *CEQ Final Guidance for Incorporating Environmental Justice Concerns in EPA's NEPA Compliance Analyses*, April 1998.

Response
DOE implements its responsibilities to environmental justice through the DOE Environmental Justice Strategy [of] Executive Order 12898, April 1995. This strategy lists four goals: (1) identify and address DOE programs, policies,

and activities that might have disproportionately high and adverse human health or environmental effects on minority populations and low-income populations; (2) enhance the credibility and public trust of DOE by making public participation a fundamental component of all program operations, planning activities, and decisionmaking; (3) improve research and data collection methods related to human health and the environment of minority and low-income populations by incorporating full characterizations of risks, including the identification of differential patterns of subsistence consumption of natural resources among such populations; and (4) further Departmental leadership by integrating environmental justice criteria, as appropriate, with activities and processes related to human health and the environment. The DOE environmental justice methodology brings together results of analyses from technical disciplines that focus on consequences to certain resources that could affect human health or the environment to determine disproportionately high and adverse effects on minority and low-income populations.

The DOE implementation of environmental justice in identifying minority and low-income populations for closer analysis is consistent with Executive Order 12898. Health effects modeling includes all persons, including vulnerable populations identified by the comment.

The Final EIS uses Nevada population data that are consistent across technical areas and that directly reflect data developed by and received from county and State officials.

The Regional Economic Models, Inc. (REMI), Economic and Demographic Forecasting System (EDFS) 53-sector model incorporates population estimates from recent years (1998 to 1999) provided by Nye and Clark Counties for the socioeconomic baseline. For Lincoln County and the rest of Nevada, the REMI model used State Demographer estimates for the same period. DOE compared these locally derived estimates to the 2000 data provided by the Bureau of the Census.

The Final EIS baseline used REMI model projections of population totals for each county until 2035. The DOE Clark County projections correspond to those used by the University of Nevada, Las Vegas (DIRS 136698-Riddel and Schwer 1999), which also used the REMI model. Inputs to the Nye County projections for the Final EIS are based on data identified in Nye County documents (DIRS 150996-Williams 2000; DIRS 148140-PIC 1998). The Nye County projections are based in part on a REMI 14-sector model. Lincoln County and Rest of Nevada projections through 2018 from the Nevada State Demographer's Office (DIRS 107195-NSD 1999) were inputs to population projections for these areas. DOE used the county projections and Nye County source documents to project population distribution within the 80-kilometer (50-mile) radiological monitoring grid. California Department of Finance projections (DIRS 150294-California State Department of Finance 1998) for Inyo County were the basis for projecting population distributions for Inyo County sections of the radiological monitoring grid.

For analysis of accidents near transportation corridors and for health effects modeling in Nye, Clark, and Lincoln Counties, DOE used county population estimates as the basis for extrapolating estimated impacts. Thus, for example, if the estimated county population would double from 1990 to the year of analysis, the analysis generally assumed that the population in the block groups along transportation routes would also double. As appropriate, DOE based estimates of population changes in some areas (for example, the vicinity of the Las Vegas Beltway) on assumptions or information other than a simple percentage change.

For other Nevada counties, DOE used Nevada State Demographer projections (DIRS 107195-NSD 1999) as the basis for population projections in analyses of accidents near transportation corridors and for health effects modeling. The Department obtained estimates of historic populations of towns and cities in Nevada from the State Demographer's Office or from county documents.

Finally, as discussed in Section 5.2.4.1 of the EIS, DOE accepts the position of the National Academy of Sciences that it is not possible to predict future human behavior accurately. As stated in that section, the Draft EIS used a default position of today's conditions. For the Final EIS, DOE projected baseline population and other economic measures to 2035. Projections for periods further in the future would be substantially less credible.

However, while totals of populations would be forecast for block group levels, the 1990 Census remains the best readily available, consistent identification of the percentage of minority and low-income populations for small geographic areas such as block groups.

8.11.11 (9475)
Comment - EIS001888 / 0144
DEIS Statement (pg. 6-8) 6.1 - Nationwide, during the 24 years of the Proposed Action transportation activities, about four fatalities could result from traffic accidents under the mostly legal-weight truck scenario. For the same time period, about four fatalities could also result from traffic accidents under the mostly rail scenario. These fatalities would all be related to physical injuries associated with traffic accidents, not radiological impacts.

Clark County Comment - Under the transportation accident scenario for either rail or truck, four fatalities are forecast over 24 years. Without route identification, it is impossible to ascertain whether low-income or minority communities may be unduly burdened at the local scale. NEPA [National Environmental Policy Act] Regulation: Sec. 1502.22.

Response
Chapters 2, 3, and 6 and Appendix J of the EIS identify potential national and Nevada transportation routes for rail and heavy-haul-truck shipments. Further, Section 3.1.13 describes the minority and low-income populations in Nevada in relation to Yucca Mountain and the alternative rail and heavy-haul truck corridors. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use. Before such shipments began, states or tribes could designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified. Therefore, for the analysis in this EIS, DOE selected potential highway routes in accordance with U. S. Department of Transportation regulations, which require the use of preferred routes (typically highways and bypasses that are part of the Interstate Highway System). The Department based its selection of potential rail routes on current rail practices, because there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials. In response to public comments, DOE included maps of highway routes and rail lines it used for analysis in the EIS. It also included potential health and safety impacts associated with shipments for each state through which shipments could pass.

In the EIS, DOE used the census block data to identify minority populations that the selection of a particular rail corridor or route for heavy-haul trucks could affect. Census block data are not available to identify low-income populations. DOE has updated and refined information germane to its environmental justice analysis. The EIS now includes, for example, additional and more detailed mapping of minority populations, and additional mapping and information that describes the proximity of tribal lands and cultural and ceremonial areas to candidate rail corridors in Nevada. DOE conducted a statistical analysis for Nevada and the Nation to determine potential accident fatalities using accident statistics for states and applying these to large numbers of shipments across multiple routes and over long distances. Thus, the analysis cannot specify the location of a specific accident or the identification of the specific people involved.

In response to comments received on the Draft EIS, DOE considered locations at which individuals could reside nearer to the candidate rail corridors and heavy-haul truck routes in Nevada as a way of representing conditions that could exist anywhere in potentially affected communities. For example, DOE assumed that a maximally exposed individual could reside or work as close as 4.9 meters (16 feet) to a candidate heavy-haul truck route. During the 24-year period of repository operations, a maximally exposed individual would receive an estimated dose about 29 millirem, resulting in an increased fatal cancer probability of 2 in 100,000.

These exposures would be well below those received from natural background radiation, would not be discernible, even if corresponding doses could be measured, and would not add measurably to other impacts that an individual could incur. For comparison, the lifetime likelihood of an individual incurring a fatal cancer from all other causes is about 1 in 4.

If DOE made a decision on a specific mode and route of transportation through Nevada to the repository site, it would perform additional engineering and environmental studies to support detailed designs and appropriate National Environmental Policy Act reviews that included potential impacts to minority and low-income populations. Along with these studies, the Department would initiate consultations with responsible Federal, State, tribal, and local agencies to gather information and address potential mitigation of impacts.

DOE believes that the EIS adequately analyzes the potential environmental impacts of transportation accidents and the potential for disproportionate impacts to minority and low-income populations.

8.11.11 (9652)
Comment - EIS001888 / 0315
The environmental justice section of the DEIS clearly demonstrates the failings in the DOE's approach to impact assessment. The DEIS indicates that because there are no impacts on the population at large, therefore, there can be no impact on minority populations. This violates the DOE's own directives for implementing environmental Justice programs and is at variance with the best practice in the field. The DOE failed to make a serious effort in this area. In order for the DOE to have credibly analyzed environmental justice along pertinent transportation routes, the DOE must produce a new DEIS that contains documentary evidence of the DOE's outreach efforts and their effectiveness in engaging minority communities along the transportation corridors. It is vital that these communities be part of a meaningful dialogue about the risks of the program.

Response
DOE recognizes its obligation to identify potential impacts to minority or low-income populations. Section 1.5.1 of the EIS describes the outreach activities that DOE has undertaken to involve all members of affected communities. Section 3.1.13 describes the minority and low-income populations in Nevada in relation to Yucca Mountain and the candidate rail and heavy-haul truck corridors. Section 6.3.4 addresses environmental justice impacts in Nevada as a result of the shipment of spent nuclear fuel and high-level radioactive waste to the proposed repository. These sections contain maps that show the locations of minority or low-income populations in relation to the site and the transportation corridors. DOE generated these maps using census block group data. Only block group data are available for low-income populations, although a more detailed data set (blocks) is available for minority populations. In response to comments, DOE has updated its population estimates in the regions of influence to reflect the most recent State and local information, as well as the U.S. Census Bureau 2000 population summary data for Nevada. For the repository- and transportation-related regions of influence, DOE performed REMI simulations to establish an updated population baseline by accounting for population estimates and projections provided by county governments.

In the EIS, DOE used the census block data to identify minority populations that the selection of a particular rail corridor or route for heavy-haul trucks could affect. As noted above, block data are not available to help identify low-income populations. Based on these data, the EIS contains maps for each candidate corridor, route and intermodal transfer station location that identify more precisely the extent to which transportation activities could affect. However, for Nevada and the Nation, DOE conducted a statistical analysis to determine potential fatalities using accident statistics for states and applying these to large numbers of shipments across multiple routes and over long distances. Thus, the analysis cannot specify the location of a specific accident or the identification of the specific people involved.

If DOE made a decision on a specific mode and route of transportation through Nevada to the repository site, it would perform additional engineering and environmental studies to support detailed designs and appropriate National Environmental Policy Act reviews that included potential impacts to minority and low-income populations. Along with these studies, the Department would initiate consultations with responsible Federal, State, tribal, and local agencies to gather information and address potential mitigation of impacts.

DOE believes that its outreach activities and its efforts to identify potential impacts of the proposed repository, including transportation, are consistent with the objectives of Executive Order 12898 (*Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*), relevant agency guidance, and National Environmental Policy Act best practices. DOE also believes that the EIS adequately analyzes the potential environmental impacts of transportation accidents and the potential for disproportionate impacts to minority and low-income populations.

8.11.11 (10236)
Comment - EIS001888 / 0585
The Department of Energy was one of the first federal agencies to develop an Environmental Justice policy. It is unfortunate, then, that the evaluation of effects on minority, low-income and Native-American groups is totally ignored in the DEIS. For example, U.S. 95, a major or proposed routing option bisects the Las Vegas Paiute

reservation. No statement is made of potential impacts. Other routes through the Las Vegas metropolitan area are adjacent to minority and low-income populations. However, there is no recognition of potential impacts to these populations in the DEIS.

Response
Section 6.3.4 of the EIS addresses environmental justice impacts in Nevada from shipping spent nuclear fuel and high-level radioactive waste to the proposed repository. These sections include maps that show the locations of minority or low-income populations with respect to the site and potential transportation routes. The EIS acknowledges that a 1.6-kilometer (1-mile) section of U.S. 95 would cross the southwest corner of the Las Vegas Paiute Indian Reservation that could be used by legal-weight trucks as well as either the Caliente-Las Vegas or Apex/Dry Lake heavy-haul truck route. In addition, the EIS notes a branch rail line in the Valley Modified Corridor would pass near the Las Vegas Paiute Reservation. As noted in Section 6.3.4, public health and safety impacts to all populations in Nevada would be small (less than 0 to 2 latent fatalities from cancer and other causes for incident-free transportation and 0.0005 latent cancer fatality for accidents over 24 years). The public health and safety impacts to minority and low-income populations along the routes of travel would also be small. Because the probability would be small at any single location, the risk of an accident at a specific location would also be small. Thus, impacts to minority or low-income populations or to Native Americans in small communities along the routes would also be small and, therefore, unlikely to be disproportionately high and adverse.

8.11.11 (10404)
Comment - EIS001927 / 0022
Using a groundless piece of circular logic, this DEIS holds that because the Proposed Action poses no impact anyway, it thus cannot impact low income communities or people of color. As shown above, this finding of no impact is flawed, as is this weak attempt to claim that principles of environmental justice are not being violated.

Who is most likely to live along the railroad tracks and the highway? In a place like Chicago, it would be people of color and the poor. Sometimes train cars sit on the tracks for up to 48 hours before moving on. If that car happens to hold an irradiated nuclear fuel cask, then the family sleeping in the house right next to the switch yard could receive a significant dose of gamma radiation. In certain sections of south Chicago, where thousands of high-level waste transport are targeted to go through, many residents are exclusively Spanish speaking. The same is probably true along transportation routes in Colorado, New Mexico, Arizona, and southern California. Has the DEIS been translated into Spanish? Why not? Why are these significantly impacted communities being excluded from the public comment process just because they don't speak English?

Response
The approach to environmental justice in the Draft EIS and Final EIS is consistent with Council on Environmental Quality guidance. The goal of this approach is to identify whether any high and adverse impacts would fall disproportionately on minority and low-income populations. The approach first analyzes the potential impacts on the general population as a basis for comparison. Second, based on available information, the approach assesses whether there are unique exposure pathways, sensitivities, or cultural practices that would result in high and adverse impacts on minority and low-income populations. If such potential impacts would be high and adverse, the approach then compares the impacts on minority and low-income populations to those on the general population to determine whether any high and adverse impacts fall disproportionately on minority and low-income populations. In other words, if high and adverse impacts on minority or low-income population would not appreciably exceed the same type of impacts on the general population, no disproportionately high and adverse impacts would be expected.

The Nuclear Regulatory Commission and U.S. Department of Transportation regulate the transportation of spent nuclear fuel. Although spent nuclear fuel emits gamma radiation and neutrons, these would be largely absorbed by the massive cask in which the fuel was transported. The regulations require that at 2 meters (6.6 feet) from the edge of the transport vehicle, the dose rate from the cask can be no higher than 10 millirem per hour. The EIS evaluated the dose to a "maximally exposed individual" resident who was assumed to live within 200 meters (660 feet) of a railroad switchyard at an exposure of 20 hours for each occurrence. The EIS also evaluated a resident living 30 meters (100 feet) from a point where all truck shipments would pass. The analysis of exposure for this maximally exposed individual conservatively assumed that the same resident would be exposed to all rail shipments to the repository over 24 years. Table 6-12 of the EIS indicates that a resident near a rail stop would receive a dose of 0.3 rem over 24 years of operation. The probability of a latent fatal cancer from this exposure would be 0.0001.

The maximally exposed individual would receive a dose of about 6 millirem from exposure to all truck shipments (6 millirem represents an increased probability of contracting a fatal cancer of 3 in 1 million).

During the public comment period for the Draft EIS, DOE encouraged stakeholders to offer comments on the document during the public hearings and by mail, facsimile, and the Internet. Before each hearing, DOE placed advertisements in local newspapers, including Spanish-language newspapers, and distributed public service announcements and press releases to more than 175 local and national stakeholders and media outlets to publicize information that would be accessible to the general public and to minority and low-income communities. In addition, in concert with the publication of the Draft EIS, DOE made available Spanish-language fact sheets about Yucca Mountain and the proposed repository.

8.11.11 (10635)
Comment - EIS001906 / 0016
The DEIS also fails to analyze nuclear waste transportation impacts for the proposed Timbisha Shoshone Trust Land Parcel at Scotty's Junction along U.S. 95 in Nevada. The DEIS does state that the Carlin and Caliente rail corridors implementing alternatives as well as the Caliente heavy-haul truck implementing alternative would pass through, overlap, or be located along the edge of the proposed Scotty's Junction Parcel (DEIS, p. 8-13). A high-level nuclear waste transportation route located on a proposed trust land parcel is an extremely negative impact for the Timbisha Shoshone Tribe. However, there is absolutely no mention of any impact to the Timbisha Shoshone by the above proposed routes in the DEIS. The DOE needs to fully analyze the impacts to the Timbisha Shoshone Tribe, including its Environmental Justice implications.

Response
DOE has updated and refined information germane to its environmental justice analysis and is aware of the potential conflict between the Carlin and Caliente Corridors, the Caliente heavy-haul truck route, and the Timbisha Shoshone Trust Lands. The Final EIS acknowledges that the Bonnie Claire variation of the Caliente and Carlin Corridors would pass through 4.5 kilometers (2.8 miles) covering 1.8 square kilometers (450 acres) of the Scottys Junction portion of the newly designated Timbisha Shoshone Trust Lands planned for residential and tourist uses.

8.11.11.1 Environmental Justice Issues

8.11.11.1 (2390)
Comment - EIS000713 / 0002
It is possible that the decision to haul the nation's nuclear waste across the country may affect more neighborhoods than any other decision by the Department of Energy indeed it will affect over 100 communities with populations of more than 100,000 people. Yet, the DOE refuses to name the mode of transportation (rail or truck) or the routes that it will use to transport 77,000 metric tons of nuclear waste across the country. Further, it has failed to hold hearings in key areas such as Chicago, Cleveland, Hartford, Indianapolis, Los Angeles, and other major cities that are likely to lie along those transportation routes, thereby ignoring the goals set forth in the Environmental Justice Strategy.

Response
The Final EIS identifies rail as the preferred mode of transportation. DOE assessed the health and safety impacts to people living near transportation routes along which spent nuclear fuel and high-level radioactive waste could be transported. This analysis examined the impacts using actual routes that DOE could select. DOE evaluated the impacts to an individual, the maximally exposed individual, who resided 200 meters (660 feet) from a point where all rail shipments, would pass. Under these circumstances, the maximally exposed individual would receive a dose of about 2 millirem from exposure to all rail shipments (6 millirem represents an increased probability of contracting a fatal cancer of 3 in 1 million). DOE estimated the average lifetime impact for an individual who lived along a route for 24 years of the Proposed Action. Although it can be argued that individuals could live closer to these shipments, it is highly unlikely that an individual would be exposed to all shipments over the 24-year period of shipments to the repository, even though DOE incorporated this highly conservative assumption into the analysis. These impacts are so low that they would not be discernible and would not add measurably to or compound other impacts that individuals or communities might incur.

DOE believes that its public involvement process during the development of the EIS is consistent with the Council on Environmental Quality and DOE regulations on implementing the National Environmental Policy Act, and DOE guidance on public participation during the preparation of EISs. In 1995, DOE held 15 public scoping meetings across the country during a 120-day public scoping period (August 13, 1999, through February 28, 2000). After publishing the Draft EIS, DOE held public hearings at 21 locations in Nevada and across the country during a 199-day comment period to receive comments from interested parties. Given the impracticality of holding hearings at every location potentially affected by the transportation of spent nuclear fuel and high-level radioactive waste, DOE selected national hearing locations in the major metropolitan areas most likely to experience large numbers of shipments or locations close to nuclear powerplants.

8.11.11.1 (2612)
Comment - EIS000692 / 0001
I think most basically a definition of minority is numbers. In terms of numbers, votes, representation in the government process, Nevada residents should be viewed as a minority.

I don't think people in the East realize what it means to have ninety-eight percent of your county under public domain, or eighty-seven percent of your state publicly owned. Growth, both in population and economic growth, is curtailed.

In terms of low income populations, taken as an entity, Lincoln County is about as low income as it's possible to get.

It seems like taking advantage of the economically disadvantaged to have three of the five possible sites for intermodal transfer facilities located in Caliente, Nevada.

Response
DOE implements its responsibilities to environmental justice through its Environmental Justice Strategy [of] Executive Order 12898, April 1995. The first goal of this strategy is to identify and address DOE programs, policies, and activities that might have disproportionately high and adverse human health or environmental effects on minority and low-income populations. The procedure for implementing this goal and Executive Order 12898, *Environmental Justice*, is to identify minority and low-income communities by analyzing the Bureau of the Census population designation called "block groups." DOE pinpoints block groups where the percentages of minority or low-income residents are meaningfully greater than average. For environmental justice purposes, the pinpointed block groups are minority and low-income communities. DOE identifies low-income communities based on a determination of percentages of persons in poverty.

8.11.11.1 (4367)
Comment - EIS001157 / 0013
The DEIS is not clear as to what census blocks with high minority populations or high levels of poverty would be affected by the proposed routings. The DEIS refers to "City of Las Vegas" and "Las Vegas area" interchangeably. The area of concern needs to be clarified to make the environmental justice findings understandable.

Response
Figures 3-27 and 3-28 identify minority and low-income census block groups in Nevada, with potential transportation corridors (rail and heavy-haul truck) shown in relation to these block groups..

8.11.11.1 (6677)
Comment - EIS001878 / 0055
As discussed in the general comments, the DEIS inadequately analyzes the project impacts in relation to environmental justice. Because of the nature of rural life, communities are dispersed, rather than concentrated. Given the limited political power of rural communities, they are often targeted for unwanted projects. The Yucca Mountain repository is an excellent example of this type of "justice." The DOE's risk models are based on avoiding urban areas, and presume that risks from the project should be borne by rural people.

The DOE should consider the effects of past programs and policies on communities, as well as the additional impacts of the Yucca Mountain project. Rural low income populations received damaging doses of radiation in the 1950s and 1960s from above-ground and underground nuclear weapons tests conducted by the Atomic Energy

Commission. The DOE must take these disproportionately high adverse health and environmental impacts of its programs, policies, and activities into consideration.

Response
DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offers the most appropriate means to arrive at conservative estimates of transportation-related impacts. However, in response to comments, DOE has considered locations at which individuals could reside nearer to the candidate rail corridors and heavy-haul truck routes in Nevada as a way of representing conditions that could exist anywhere in potentially affected communities. For example, DOE assumed that a maximally exposed individual could reside as close as 4.9 meters (16 feet) to a candidate heavy-haul truck route. During the 24-year period of repository operations, the maximally exposed individual would receive an estimated dose of about 29 millirem, resulting in an increased fatal cancer probability of 2 in 100,000.

These exposures would be well below those received from natural background radiation, would not be discernible even if corresponding doses could be measured, and would not add measurably to other impacts that an individual could incur. For comparison, the lifetime likelihood of an individual incurring a fatal cancer from all other causes is about 1 in 4.

The analysis of cumulative impacts in Chapter 8 of the EIS did consider the impacts of past programs and policies in addition to those of the Yucca Mountain Project. The analysis evaluated impacts of repository activities coupled with those of other Federal, non-Federal, and private actions. The evaluation included past DOE activities at the Nevada Test Site (such as nuclear weapons testing) and past disposal of low-level radioactive waste at the Beatty Disposal Area.

8.11.11.1 (9136)
Comment - EIS001860 / 0005
Environmental justice/transportation considerations - The project proposes to transport waste by rail, road or both from 77 sites all over the U.S. to Yucca Mountain yet fails to provide any information about proposed routes outside the state of Nevada. Note that the bulk of the waste is proposed to be transported from reactors on the east coast to Yucca Mountain nearest the west coast of the country.

I live in the First District of San Bernardino County in southeastern California through which a portion or all of the waste produced at the five Southwestern commercial reactor sites might be transported to Yucca Mountain. The people in my community and neighboring communities rely upon State Route 247 as one of only three access roads to our Morongo Basin. Our community groups and cities are in constant communication with the state and the county transportation departments regarding the poor condition and inadequate maintenance on SR 247 and our major thoroughfare, SR 62. We have even considered formation of assessment districts to tax ourselves to improve our roads in this area for our use.

We are a moderate to low income area dependent upon Joshua Tree National Park tourism for our economic future. Most residents have to commute at least an hour a day to work in other places. Six dumps have been proposed for within 200 miles of Joshua Tree National Park. This is an environmental injustice which sacrifices our area to the profits of the waste industry and we have organized to oppose it, including changing our political representation and encouraging our elected representatives in their now-well-known efforts to stamp out corruption in our county and prevent our desert from being used as the nation’s waste repository.

If the people who will be affected by the transportation of these wastes were to be allowed to vote on the issue, they would vote no as they have voted on other proposed projects in this area.

Implementing Yucca Mountain means transporting 800,000 cubic feet of high-level radioactive waste through our desert, 80 times more waste than would have been scheduled for the Low Level Radioactive Waste site proposed for Ward Valley near Needles. Why would we put up with this if we won’t put up with Ward Valley?

It would be an environmental injustice to expect the citizens of San Bernardino County's First District to bear the brunt of DOE traffic on our already inadequate roads and we should be able to expect the DOE to advise us which of our roads are being considered for alternate waste transportation routes.

Response
DOE has not determined the specific routes it would use to ship spent nuclear fuel and high-level radioactive waste to the proposed repository. Nonetheless, the EIS analysis used current regulations governing highway shipments and historic rail industry practices to select existing highway and rail routes to estimate potential environmental impacts of national transportation. Routing for shipments of spent nuclear fuel and high-level radioactive waste to the proposed repository would comply with applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission in effect at the time the shipments occurred.

These regulations, which were developed to promote public safety and reduce radiological risk for transport of Highway Route Controlled Quantities of Radioactive Materials, require shipments of radioactive material to be on state or tribal designated preferred routes to reduce the time in transit. The State of California would have the opportunity to designate alternative preferred routes in accordance with U.S. Department of Transportation regulations. Consultation with local jurisdictions and tribes would be necessary.

8.11.11.1 (9826)
Comment - EIS001888 / 0403
[Clark County summary of comments it has received from the public.]

County feels EIS must seriously consider federal directives regarding environmental justice. 24% of county is minority (11% Hispanic/ 9% Black) and 38% along UP rail line. Native Americans live in areas adjacent to I-15 and US 95.

Response
The analysis of environmental justice impacts in Nevada considered existing highways and railroads that DOE would use in Nevada - Interstate-15, the proposed Las Vegas Beltway; U.S. 95; five possible highway routes for heavy-haul trucks; the Union Pacific Railroad's mainlines in northern and southern Nevada; and five corridor alignments with variations for a possible branch rail line in five rail corridors in the State. Section 6.3.4 of the EIS discusses the environmental justice impacts from transportation options being considered in Nevada. The EIS acknowledges that the Union Pacific Railroad's mainline tracks pass through the center of the Moapa Reservation and through the center of Las Vegas, crossing census block groups with high fractions of minority and low-income populations.

8.11.11.1 (10012)
Comment - EIS001444 / 0005
Section 3.1.13, Page 3-94 - 3-96
Esmeralda County needs to be included in the discussion on Environmental Justice.

Response
Esmeralda County is included in the environmental justice discussions on the transportation options in Section 3.2.2.1.10 of the EIS, which addresses candidate rail corridors and in Section 3.2.2.2.10, which addresses candidate heavy-haul truck routes.

8.11.11.1 (10655)
Comment - EIS001888 / 0402
[Clark County summary of comments it has received from the public.]

Populations at risk include: residents; peak and average daily visitors; workplace employment population; institutional populations. Are some populations, for example, African Americans at greater risk than the general resident population?

Response
The DOE analysis showed that the Proposed Action would not result in significant environmental or health and safety impacts to any segment of the population. Using available information, DOE evaluated the likelihood that circumstances unique to minority and low-income populations could create a potential for these populations to be exposed to disproportionately high and adverse impacts. For example, DOE assessed the health and safety impacts to people living near actual transportation routes along which spent nuclear fuel and high-level radioactive waste could be transported. The analysis showed that even if an individual lived along the same route for 24 years, this would increase the likelihood of a latent fatal cancer for this individual by about 1 in 1 million for rail shipments to about 29 millirem (increased fatal cancer probability of 2 in 100,000). These exposures would be well below those received from natural background radiation, would not be discernible even if corresponding doses could be measured, and would not add measurably to other impacts that an individual could incur. For comparison, the lifetime likelihood for an individual fatal cancer from all other causes is about 1 in 4.

8.11.11.2 Native American Issues

8.11.11.2 (5377)
Comment - EIS001887 / 0093
Pages 2-41 and 2-42; Figures 2-26 and 2-27 - Highway and Rail System Maps

The maps do not show the locations of potentially affected Native American tribes in relation to the Interstate Highway and rail systems. Even in the absence of identified shipping routes (a major shortcoming of the Draft EIS that is discussed in detail elsewhere in these comments), the document should have provided some indication of Native American lands that are traversed by, or are located in proximity to, highway and rail routes. Numerous Native American lands/communities outside Nevada will be impacted by spent fuel and HLW [high-level radioactive waste] shipments including: Gila Bend, Navajo, San Xavier, and Salt River in Arizona; Umatilla and Cow Creek in Oregon; Miccosukee in Florida; Fort Hall in Idaho; Winnebago in Nebraska; Cattaraugus in New York; Quapau, Ottawa, Modoc, Sac Fox, in Oklahoma; and others. The failure to identify Native lands and communities along transportation routes and to assess impacts of the Proposed Action on those entities is another indication of the inadequate and superficial treatment of transportation impacts in the Draft EIS.

Response
In response to public comments, Figures 2-25 and 2-26 of the EIS have been revised to show Federally recognized tribal lands located along highway and rail routes that could be used for national transportation.

8.11.11.2 (5573)
Comment - EIS001887 / 0199
Page 3-113; Section 3.2.2.1.5 - Cultural Resources

Native American Interests: The Draft EIS states that, "...while transportation issues are of extreme importance to [Native Americans], at present they cannot provide specific comments on any of the Nevada transportation alternatives... due to the absence of systematic ethnographic studies for any of the proposed project areas." Since the Draft EIS acknowledges at least the potential for significant impacts to Native American cultural resources, it is incumbent upon DOE to carry out the needed ethnographic studies as part of its work in preparation of the Draft EIS. DOE has had almost 17 years to do this work, and failure to do it should not exempt DOE from its obligations under NEPA [National Environmental Policy Act]. In addition, a considerable body of information exists as a result of research carried out by the State of Nevada between 1986 and 1998. This research was available to DOE at the time it was preparing the Draft EIS. Summaries of the State's Native American studies reports are found in Appendix II of these comments.

Response
DOE had not conducted comprehensive and systematic ethnographic studies of lands along candidate transportation corridors at the time it published the Draft EIS. The Department reviewed Appendix II to the above-referenced comments with respect to ethnographic information. Since the publication of the Draft EIS, DOE has gathered ethnographic information along the transportation corridors and included it in Section 3.2.2.1.5 of the EIS. The cultural resources sections of Chapter 6 include analyses of this information. Ethnographic information gathering is

not yet complete. DOE would conduct additional surveys in the course of evaluating any final corridor selection and before route construction began to identify cultural resources and to design avoidance or other mitigation measures to minimize the potential for harm to such resources.

Section 9.3.5 of the EIS acknowledges that land clearing, excavation, and construction activities have the potential to disturb or cause the relocation of cultural artifacts, and identifies actions that DOE would take to mitigate adverse impacts to cultural resources along transportation routes. These actions include those required by law or regulation and those built into the project to reduce such impacts.

8.11.11.2 (5606)
Comment - EIS001887 / 0232
Page 4-38; Section 4.1.5.2 - Impacts to Cultural Resources from Construction, Operation and Monitoring, and Closure

Native American Viewpoints: The 1986 Environmental Assessment (EA) for Yucca Mountain stipulated that, "[i]f the Yucca Mountain site is approved for site characterization, [Native American impacts] will receive appropriately detailed treatment in research to be performed during the Environmental Impact Statement process."(26) The EA also made special note of the "potential for impacts on Native American cultures from [SNF (spent nuclear fuel) and HLW (high-level radioactive waste)] transportation activities" and stated that "[t]his aspect will receive appropriately detailed treatment ... if Yucca Mountain is approved for site characterization."(27) The Draft EIS, however, fails to specifically address potential impacts to Native American communities in Nevada (and in states through which SNF and HLW will be shipped to a Yucca Mountain repository). Such impacts include effects on Native culture, economics, infrastructures, emergency response/preparedness requirements, state-tribe relationship effects that may be caused by state routing or risk management decisions, implications for tribal sovereignty, Native land claim issues and impacts, and other areas potentially impacting Native peoples and communities. The Draft EIS should have contained a detailed description of the activities undertaken, the data collected, and the analyses done to adequately evaluate potential effects of the Yucca Mountain program on Native peoples and communities across the country. The Draft EIS should also have included an analysis of the impacts of the transportation of spent fuel and high-level waste.

(26) U.S. Department of Energy. Environmental Assessment Yucca Mountain Site, Nevada Research and Development Area, Nevada, May, 1986, pp. C.4-30.

(27) Ibid, pp. C.7-42.

Response
DOE determined that it is not necessary to examine the composition of the general population residing along existing spent nuclear fuel and high-level radioactive waste transportation corridors before DOE can reasonably conclude that there would be no disproportionately high and adverse impacts to minority and low-income populations from the transportation of radioactive materials. In addition, as described in Chapter 6 of the EIS, incident-free transportation and the risks from transportation accidents (the maximum reasonably foreseeable accident scenario would have 2.3 chances in 10 million of occurring per year) would not present a large health and safety risk to the population as a whole, or to workers or individuals along national transportation routes. The low effect on the population as a whole would be likely for any segment of the population, including minorities, low-income groups, and members of Native American tribes.

However, the Final EIS examines the composition of the population along newly proposed transportation rail corridors in Nevada. Selecting among alternative new routes could offer opportunities to avoid high and adverse impacts that would fall disproportionately on low-income or minority populations in relation to the general population that would not be present when considering existing transportation corridors. Therefore, even though the health effects from exposure to radioactive materials from transportation activities would not implicate environmental justice concerns in selecting new routes, other factors such as the impacts of the construction and use of a newly created route on land use, socioeconomics, noise, air quality, and esthetics could vary by location. Section 6.3.4 of the EIS presents the analysis of environmental justice impacts in Nevada.

8.11.11.2 (5717)
Comment - EIS001887 / 0328
Page 6-34; Section 6.2.5 - Environmental Justice

The Draft EIS refers only to Native Americans affected by national transportation in Idaho. Proper identification of the national highway and rail routes used in the Section 6 analysis would have revealed additional impacts on Native American populations in other states. Analyses prepared for the State of Nevada by Planning Information Corporation identified the following potentially affected Indian Reservations:

Arizona: Hualapai and Navajo (I-10, I-40; BNSF/UPRR);

California: Agua Calientes, Cabazon, Chemehuevi Valley, Ft. Mojave, Ft. Yuma, Morongo, Torres Martinez, and Hoopa Valley (I-10, I-40/I-15; BNSF/UPRR);

Florida: Hollywood (I-95, FECR);

Iowa: Mesquakie (Sac & Fox) (UPRR);

Kansas: Potawotamie (UPRR);

Minnesota Prairie Island (CP/Soo);

Nebraska: Omaha and Winnebago (UPRR);

New Mexico: Acoma, Canoncito, Isleta, Laguna, Navajo, and Zuni (I-10, I-40; BNSF/UPRR);

New York: Cataraugas and Tonawanda (I-90, Conrail)

North Carolina: Cherokee (I-40)

Oklahoma: Choctaw, E. Shawnee, Kialegee Creek, Kickapoo, Miami, Modoc, Osage, Ottawa, Peoria, Quapaw, Sac & Fox, and Thlopthlocco Creek (I-35, I-40; BNSF/UPRR);

Oregon: Umatilla (I-84; UPRR);

Utah: Goshute, Ouray, Skull Valley, and Unitah (I-84/I-15/I-80/US93A; UPRR)

Washington: Yakima (I-84; UPRR)

Wisconsin: Oneida (WCRR)

The Draft EIS does not attempt to define transportation-affected and potentially-affected Indian lands and resources. Nevada defines affected lands and resources to include the following: (1) reservations crossed by potential shipping routes; (2) off-reservation ceded lands, where Tribes retain treaty rights or other legally recognized user rights crossed by potential shipping routes; (3) reservation lands and off-reservation lands within transportation emergency evacuation zones along potential shipping routes; (4) reservation and off-reservation lands which could be contaminated by air or water transport of radioactive materials released in a severe transportation accident or terrorist incident (generally within 50 miles down-wind, down-stream, or down-gradient of a potential shipping route); (5) reservations whose highway access would be disrupted by a nuclear waste transportation emergency; and (6) off-reservation lands along potential shipping routes where Tribal personnel would likely be involved in transportation emergency response.

The Draft EIS gives insufficient consideration to the major concerns identified by potentially affected Indian Tribes and by the National Congress of American Indians. These concerns include: (1) Tribal authority to regulate shipments across reservations; (2) emergency response planning and training for Tribal personnel; (3) advance notification of shipments and shipment monitoring; (4) protection of Native American religious and cultural sites, plants, and animals, both on and off reservations; (5) cultural implications of potential radiological contamination of Indian lands and the cultural implications of cleanup activities involving non-tribal personnel; and (6) adverse economic impacts of public perception of risk, especially adverse impacts on tribal tourism and recreation businesses. Moreover, except for tribes in Idaho, DOE failed to identify potential Indian reservations and communities in the Draft EIS and in the public hearing notices, and failed to provide financial assistance to facilitate independent technical review of the Draft EIS by potentially affected Indian Tribes.

Response

In response to public comments, DOE has revised the EIS to show the locations of Federally recognized tribal lands along highway and rail routes the Department could use for transportation. DOE recognizes that tribal governments have a unique legal and political relationship with the Government of the United States. For this reason, DOE will continue to interact with tribal governments and work with representatives of the Consolidated Group of Tribes and Organizations to ensure that it considers tribal rights and concerns before making decisions or implementing programs that could affect tribes.

With regard to emergency response planning and training, DOE would provide technical and financial assistance to states to assess the need for and training of public safety officials of units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste, as required by Section 180(c) of the NWPA. Section M.6 of the EIS discusses these requirements in detail. In addition, the Federal Radiological Program includes plans that outline the policies, procedures, roles, and responsibilities of Federal, tribal, state, and local agencies in planning for and responding to emergencies involving releases or suspected releases of radiological materials from Government facilities or operations. Training would cover procedures for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. In the event of an incident involving spent nuclear fuel or high-level radioactive waste, the transportation vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities, if requested, to mitigate such an incident.

DOE would comply with applicable Federal regulations for notification of spent nuclear fuel shipments and would follow the same procedures for shipments of high-level radioactive waste and for unclassified shipments of DOE-owned material. Nuclear Regulatory Commission regulations require notification of the governor of the affected state or the governor’s designee of pending shipments. In addition, DOE would notify potentially affected tribes of pending shipments. The governor would notify state and local safety officials, as appropriate.

With respect to the Proposed Action, DOE has implemented worker education programs on the protection of cultural resources to limit direct impacts to such resources, especially inadvertent damage and illicit artifact collecting. If significant data recovery (artifact collection) was required during construction and operation, DOE would initiate additional involvement of Native American tribes to determine appropriate costs. If DOE made a decision about the transportation of spent nuclear fuel and high-level radioactive waste in Nevada, it would conduct additional engineering and environmental studies for the selected mode and route to provide the basis for detailed design. In addition, DOE would initiate consultations and interactions with responsible Federal, state, tribal, and local agencies to gather additional location- and community-specific information, assess potential impacts, consider mitigation measures, and conduct appropriate National Environmental Policy Act reviews.

A system of financial protection established by the Price-Anderson Act covers the costs of state and tribal actions associated with a nuclear accident, such as a transportation accident in which there was a suspected release of radioactive material. In response to public comments, Appendix M of the EIS discusses Federal radiological emergency response programs.

The EIS addresses potential risks to human health and the environment from the proposed siting, construction, operation and monitoring, and closure of a repository at Yucca Mountain. The socioeconomic impacts discussed in the EIS include quantitative effects on populations, employment, and income that would result from a decision on whether to proceed with development of the repository. However, the manner in which particular individuals might perceive risks and modify their behavior is speculative and subject to debate.

8.11.11.2 (6621)
Comment - EIS001632 / 0068
The draft EIS (Figures 2-26 and 2-27) depicts U.S. interstate and rail routes which are potential corridors for waste proposed for disposal at Yucca Mountain. We recommend that the final EIS provide a modified overlay of these two figures to depict Tribal lands through which waste bound for disposal at Yucca Mountain may pass via road or rail. The Bureau of Indian Affairs (BIA) has a 1993 map for Indian Land Areas in the lower 48 states. This map depicts the location of tribal lands in relationship to the Federal highway network, and may be useful for this effort.

Response
In response to public comments, DOE has revised Figures 2-25 and 2-26 of the EIS to show Federally recognized tribal lands located along highway and rail routes that could be used for national transportation.

8.11.11.2 (10764)
Comment - EIS002144 / 0001
I'm a member of the tribe the Paiutes, been here since forever. Our people, we're not going anywhere. We can't, because this is our land. This is where we come from. That's a real short, quick history. We are located fifty-five miles from here with the rail line and the interstate running across our lands.

Response
DOE has been interacting with representatives of the Moapa Paiute Tribe as part of the Native American Interaction Program since the late 1980s. The Department appreciates the tribe's involvement to help better understand Native American issues associated with the repository program.

8.11.11.2 (10768)
Comment - EIS002144 / 0005
There have been no studies of our lands and our people and we are the ones that are to lose the most. The studies that they have, transportation studies that they have is for big places like Las Vegas. Well, to some of you guys in Las Vegas, that's not even a drop in the bucket, but if somebody dies on a reservation where we only have approximately 290 enrolled members, that's a big drop. If a truck was going down the road and our tribal council a lot of time travel together in a van, if they were to knock that van off the road and kill everyone, that's six people. That's a whole government that is gone and can't be revived. There is no way you could pay us any amount of money to get those people back because they are no longer here. They no longer exist. The only way they exist is to us, our -- the people of Moapa because they come back and they tell us how we should be doing things, how -- what we should say.

Response
The transportation analyses in the EIS evaluated impacts to all people along the transportation routes, including Native Americans. DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For example, DOE assumed that an individual, the "maximally exposed individual," would be a resident living 30 meters (100 feet) from a point where all truck shipments, or 200 meters (660 feet) from a point where all rail shipments, would pass. Under these circumstances, the maximally exposed individual would receive a dose of about 6 millirem from exposure to all truck shipments, and a dose of about 2 millirem from exposure to all rail shipments (6 millirem represents an increased probability of contracting a fatal cancer of 3 in 1 million).

Although it can be argued that individuals could live closer to these shipments, it is highly unlikely that an individual would be exposed to all shipments over the 24-year period of shipments to the repository, even though DOE incorporated this highly conservative assumption into the analysis.

8.11.11.2 (11352)
Comment - EIS002271 / 0002
For example, the DOE's lack of proactive procedures put communities at a high level of risk by failing to establish MOU's [Memorandums of Understanding] in a timely manner with Affected Units of Tribal Governments along the nuclear waste transportation routes for the New Mexico, WIPP [Waste Isolation Pilot Project] site.

The DOE's refusal to act in such a proactive manner demonstrated the department's willingness to allow a back-up of nuclear waste on major highways and rail thoroughfares putting citizens at an unnecessary level of risk along those routes. This would not have occurred had MOU's been established with the Affected Units of Tribal Government.

In this scenario, affected tribes may shut down a rail transportation route and file lawsuits against the DOE, severely limiting safe transportation of nuclear waste. When the MOU's were finally established, the language within the MOU's recognized and addressed the concerns and rights of the affected tribes. Similar tribal actions and lawsuits could impede the effective and safe transportation of nuclear wastes.

Response
The Final EIS identifies rail as the preferred mode of transportation. If the Yucca Mountain site received approval, DOE would implement the requirements of Section 180(c) of the NWPA, which requires it to provide technical and financial assistance to states to train public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel or high-level radioactive waste. Training would cover procedures for safe transportation and for dealing with emergency response situations.

DOE has not yet acted to implement Section 180(c) of the NWPA because such action could only occur after the Yucca Mountain site was been determined to be suitable as a nuclear waste repository. As stated in Appendix M of the EIS, about 4 years prior to the beginning of shipments, DOE would notify affected states and tribes of preliminary routes that shipments could use. Because shipments are not expected to occur prior to 2010, DOE anticipates that the notifications would occur after 2005. At that time, affected states and tribes that had been notified could present proposals to DOE for grants to determine their respective needs for training of safety officials.

Backups on rail lines due to additional rail transport would be unlikely. Spent nuclear fuel and high-level radioactive waste transportation would represent a very small fraction of the total railroad traffic (0.007 percent of railcar kilometers).

8.11.11.2 (11353)
Comment - EIS002271 / 0003
My concern is that within close proximity to the Yucca Mountain site, the Timbisha-Shoshone people are in the process of acquiring surplus federal lands both outside and within the boundaries of the Death Valley National Park. The tribe will be directly affected by the transportation of nuclear wastes within Inyo County and the additional transportation routes to the proposed Yucca Mountain repository. Such transportation routes will affect their pursuit of economic development and physical well-being.

To reiterate, tribal governments need assistance now. Now, not at the time the Yucca Mountain site may be approved or disapproved, or when an alternative site is considered. Such assistance would include funds to establish nuclear waste spill and contamination response teams to address accidents within proximity to tribal ancestral homelands, developed lands, watershed, affected aquifers, and affected atmospheric use areas.

Response
The Timbisha Shoshone Trust Lands are discussed in Section 8.1.2.2 of the EIS. The EIS acknowledges that, because of the proximity of some of the proposed transportation corridors, there would be potential cumulative impacts between their use and the proposed repository with regard to land use, regional water use, and transportation impacts. The analysis found that construction and operation of a branch rail line in the Bonnie Claire variation of the Caliente or Carlin Corridor would restrict access across the Scottys Junction parcel of the Timbisha Shoshone Trust Lands. If the Yucca Mountain site received approval, DOE would implement the requirements of Section 180(c) of the NWPA, which requires it to provide technical and financial assistance to states to train public safety officials of appropriate units of government and Native American tribes through whose jurisdictions it would

transport spent nuclear fuel or high-level radioactive waste. The training would cover procedures for safe transportation and for dealing with emergency response situations.

DOE has not implemented Section 180(c) of the NWPA because such action could occur only after a determination that the Yucca Mountain site is suitable as a nuclear waste repository. As stated in Appendix M of the EIS, about 5 years before shipments began DOE would notify affected states and tribes of preliminary routes the shipments could use. Because shipments would not start before 2010, DOE anticipates that such notifications would occur after 2005.

8.11.11.2 (12509)
Comment - EIS001887 / 0342
Page 6-137; Section 6.3.4 - Environmental Justice Impacts in Nevada

The Draft EIS fails to acknowledge the full range of nuclear waste transportation impacts on Native American communities, lands, and cultural resources in Nevada.

The State of Nevada considers the following Indian Reservations and Colonies in Nevada to be potentially affected by rail and truck routes identified in the Draft EIS:

-Moapa Reservation (UPRR, I-15)

-Las Vegas Reservation (Valley Rail Spur, US95)

-Ely Colony (US93)

-Duckwater Reservation (US6)

-Walker River Reservation (UPRR)

-Pyramid Lake Reservation (UPRR)

-Reno-Sparks Colony (UPRR)

-Lovelock Colony (UPRR)

-Winnemucca Colony (UPRR)

-Te-Moak Reservations [Battle Mountain, Elko, South Fork, Te-Moak, Wells] (Carlin Rail Spur, UPRR)

The Draft EIS does not define transportation-affected and potentially-affected Indian lands and resources. Nevada defines affected lands and resources to include the following: (1) reservations crossed by potential shipping routes; (2) off-reservation ceded lands, where Tribes retain treaty rights or other legally-recognized user rights, crossed by potential shipping routes; (3) reservation lands and off-reservation lands within transportation emergency evacuation zones along potential shipping routes; (4) reservation and off-reservation lands which could be contaminated by air or water transport of radioactive materials released in a severe transportation accident or terrorist incident (generally within 50 miles down-wind, down-stream, or down-gradient of a potential shipping route); (5) reservations whose highway access would be disrupted by a nuclear waste transportation emergency; and (6) off-reservation lands along potential shipping routes where Tribal personnel would likely be involved in transportation emergency response.

The Draft EIS gives insufficient consideration to the major concerns identified by potentially affected Indian Tribes in Nevada, the Western Shoshone National Council, and organizations such as the Nevada Indian Environmental Coalition and the Inter-Tribal Council of Nevada. These concerns include: (1) Tribal authority to regulate shipments across reservations; (2) emergency response planning and training for Tribal personnel; (3) advance notification of shipments and shipment monitoring; (4) protection of Native American religious and cultural sites, plants, and animals, both on and off reservations; (5) cultural implications of potential radiological contamination of Indian lands, and the cultural implications of cleanup activities involving non-tribal personnel; and (6) adverse economic impacts of public perception of risk, especially adverse impacts on tribal tourism and recreation businesses. DOE's proposal to construct a rail spur to Yucca Mountain creates special concerns about right-of-way acquisition implications for Western Shoshone land claims (Ruby Valley Treaty) and about protection of graves, religious sites, and other cultural resources within the candidate rail corridors identified in the Draft EIS. Moreover, DOE failed to provide financial assistance to facilitate independent technical review of the Draft EIS by potentially affected Indian Tribes in Nevada.

Response

In response to public comments, DOE has revised the EIS to show the locations of Native American reservations that could be affected by transportation routes. The Department recognizes that Native American tribal governments have a unique legal and political relationship with the Government of the United States. For this reason, DOE will continue to consult and interact with tribal governments and work with representatives of the Consolidated Group of Tribes and Organizations to ensure that it considers tribal rights and concerns before making decisions or implementing programs that could affect tribes.

With regard to emergency response planning and training, DOE would provide technical and financial assistance to states to assess the need for and training of public safety officials of units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste, as required by Section 180(c) of the NWPA. Section M.6 of the EIS discusses these requirements in detail. In addition, the Federal Radiological Program includes plans that outline the policies, procedures, roles, and responsibilities of Federal, tribal, state, and local agencies in planning for and responding to emergencies involving releases or suspected releases of radiological materials from Government facilities or operations. Training would cover procedures for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. In the event of an incident involving spent nuclear fuel or high-level radioactive waste, the transportation vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities, if requested, to mitigate such an incident.

DOE would comply with applicable Federal regulations for notification of spent nuclear fuel shipments and would follow the same procedures for shipments of high-level radioactive waste and for unclassified shipments of DOE-owned material. Nuclear Regulatory Commission regulations require notification of the governor of the affected state or the governor's designee of pending shipments. In addition, DOE would notify potentially affected tribes of pending shipments. The governor would notify state and local safety officials, as appropriate.

With respect to the Proposed Action, DOE has implemented worker education programs on the protection of cultural resources to limit direct impacts to such resources, especially inadvertent damage and illicit artifact collecting. If significant data recovery (artifact collection) was required during construction and operation, DOE would initiate additional involvement of Native American tribes to determine appropriate costs. If DOE made a decision about the transportation of spent nuclear fuel and high-level radioactive waste in Nevada, it would conduct additional engineering and environmental studies for the selected mode and route to provide the basis for detailed design. In addition, DOE would initiate consultations and interactions with responsible Federal, state, tribal, and local agencies to gather additional location- and community-specific information, assess potential impacts, consider mitigation measures, and conduct appropriate National Environmental Policy Act reviews.

A system of financial protection established by the Price-Anderson Act covers the costs of state and tribal actions associated with a nuclear accident, such as a transportation accident in which there was a suspected release of radioactive material. In response to public comments, Appendix M of the EIS discusses Federal radiological emergency response programs.

The EIS addresses potential risks to human health and the environment from the proposed siting, construction, operation and monitoring, and closure of a repository at Yucca Mountain. The socioeconomic impacts discussed in the EIS include quantitative effects on populations, employment, and income that would result from a decision on whether to proceed with development of the repository. However, the manner in which particular individuals might perceive risks and modify their behavior is speculative and subject to debate.

8.12 Transportation-Related Comments on the Supplement to the Draft EIS

8.12 (224)
Comment - 11 comments summarized
Commenters stated that the flexible design includes the capability for handling younger, hotter fuel, and questioned whether the transportation impacts of fuel blending were adequately addressed in the Supplement to the Draft EIS. They believe shipping hotter fuel would cause increased radiation exposure to those along transportation routes, to workers, and to those exposed to an accident. Commenters stated that shipping younger fuel would invalidate accident analyses in the Draft EIS and that the Supplement should have contained a risk assessment for this fuel.

Commenters stated that the Supplement should have contained a description of the shipping campaign, including the specific timing, number, and composition of the shipments, and a description of the national routes DOE would use to transport the material. Commenters expressed concern that fuel blending and shipping younger fuel could eliminate the advantages of using rail transportation.

Response
If DOE shipped younger (and therefore hotter) spent nuclear fuel than that assumed for the analysis in the Draft EIS, estimates of public and occupational health and safety impacts would be greater than those reported in the Draft. However, DOE developed the flexible design for the repository to allow flexibility in the emplacement of spent nuclear fuel and high-level radioactive waste that DOE projects it would receive, not to promote or accommodate receipt of younger, hotter spent nuclear fuel. The estimated quantities and characteristics (for example, years following discharge from a reactor) of receipts were based on DOE projections of actions that would be taken by utilities to deliver spent nuclear fuel for disposal. The projections are independent of the repository design. Rather, they are based on the terms of DOE's Standard Contract for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste contained in 10 CFR Part 961 and the generation and storage characteristics of each generator site (see discussion of CALVIN computer code in Section J.1.1.1 of the EIS). DOE does not anticipate that the flexible design would have any effect on the characteristics of spent nuclear fuel that would be shipped to a Yucca Mountain Repository or, consequently, on the casks and modes of transport that would be used for shipment. Therefore, DOE does not expect that the health and safety risks of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain, or the consequences of maximum reasonably foreseeable transportation accidents would be different for the flexible design from those associated with the design presented in the Draft EIS.

Nevertheless, in response to public comments on the Draft EIS concerning the age and burnup assumed for spent nuclear fuel used in accident analyses, DOE reevaluated the characteristics of spent nuclear fuel that it would receive. As a result of this reevaluation, DOE determined that the accident hazard for spent nuclear fuel with a cooling time of 15 years for pressurized-water reactor fuel assemblies and 14 years for boiling-water reactor fuel assemblies represents the midpoint of the cumulative hazard of all spent nuclear fuel that would be shipped. As a consequence, analyses of accidents presented in the EIS use the characteristics of "representative" spent nuclear fuel described in Appendix A of the EIS. The projected average age of spent nuclear fuel delivered to a repository would be that described for "typical" spent nuclear fuel in Appendix A.

The Draft EIS discussed ongoing site characterization activities and design evaluations, and the potential for resulting changes to the design. Since the publication of that document, DOE acquired an improved understanding of the interactions of repository features with the natural environment, and the advantages of a number of design features (such as titanium drip shields) to enhance containment and isolation. DOE published the Supplement to the Draft EIS to provide the updated information to the public. While aspects of the design evolved from those in the Draft EIS, the basic elements of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain (such as transportation of spent nuclear fuel and high-level radioactive waste) remain unchanged. For this reason, the Supplement focused on the most recent design enhancements, including various repository operating modes to manage heat generated by emplaced spent nuclear fuel and high-level radioactive waste.

If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and NWPA Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, states or tribes could designate alternative preferred highway routes, and highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highways, beltways, or bypasses, and state or tribal designated alternate routes) that reduce time in transit. Rail lines were identified based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials.

Because the Yucca Mountain site has not been approved for construction and operation of a geologic repository, DOE has not developed operations plans for transportation. However, a Draft Request for Proposals for *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153487-DOE 1999) describes the Department's schedules and plans for acquiring services to transport spent nuclear fuel and high-level radioactive waste to a Yucca Mountain Repository (see Appendix M of the EIS).

In response to public comments, DOE has included in the EIS maps of representative highway routes and rail lines that were used for analysis. In addition, potential health and safety impacts associated with shipments are provided for each state through which shipments would pass.

8.12 (251)
Comment - 10 comments summarized
Commenters recognized that, because of the flexible design, the Supplement to the Draft EIS indicates an increased number of worker- and material-related transportation fatalities. Some commenters questioned the validity of the analytical results, and others asked that the analyses be incorporated into the Final EIS along with mitigation strategies. Several commenters expressed concern that the short-duration campaign to ship drip shields to the repository, currently planned for the time near repository closure, is not adequately addressed.

Response
To estimate the number of traffic-related fatalities that would occur in the course of worker commuting and transportation of materials, supplies, and wastes to and from a Yucca Mountain Repository, DOE used the latest reasonably available information compiled from U.S. Department of Transportation statistics. For example, the Bureau of Transportation Statistics reports that about 1 traffic fatality occurs for each 100 million kilometers (62 million miles) of travel on U.S. highways. A fatality rate of 1.4 fatalities per 100 million kilometers is the average of state-specific values used in the EIS for heavy-haul trucks. This value was compiled from data from the Department of Transportation.

The impacts of transporting drip shields to Yucca Mountain are included in analyses of impacts of transporting other materials and personnel in Section J.3.6 of the EIS. Estimated transportation impacts would be the same whether the drip shields were transported for emplacement over the full duration of the emplacement phase or over a period of 1 or 2 years near the end of emplacement, because:

1. The number of railcar and truck shipments and the distance shipped would be the same.

2. The analysis of transportation impacts is based on rate data (per kilometer of travel) for accidents and fatalities. These data were derived from national transportation statistics. Shipments of drip shields, even if compressed into 1 or 2 years, would not be discernible from the total transportation of all commodities on U.S. highways and railroads and, therefore, would not be expected to affect accident or fatality rates.

In addition, because shipments of drip shields from manufacturers to Yucca Mountain would use commercial transportation carriers operating under U.S. Department of Transportation and applicable state safety regulations, the expected rate for involvement in accidents would be the same as for other commodities.

8.12 (10971)
Comment - EIS010158 / 0007
As other people have said, the SDEIS doesn't present qualitative or quantitative studies of the various accident scenarios. Studies must be conducted and presented to the public. How would a crack in the fuel column, accidents

along transportation routes, mislabeling, as people have said of packages, of the waste packages, how the Alloy 22, which is my age, how are all these things going to play out in the long run?

Response
The Draft EIS discussed ongoing site characterization activities and design evaluations, and the potential for resulting changes to the design. Since DOE issued the Draft EIS, it has acquired an improved understanding of the interactions of repository features with the natural environment, and the advantages of a number of design features (such as titanium drip shields) to enhance waste containment and isolation. DOE published the Supplement to the Draft EIS to provide the updated information to the public. While aspects of the design have evolved from those in the Draft EIS, the basic elements of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain (such as transportation of spent nuclear fuel and high-level radioactive waste) remain unchanged. For this reason, the Supplement focused on the most recent design enhancements, including various operating modes to manage heat generated by emplaced spent nuclear fuel and high-level radioactive waste.

In the Draft EIS DOE considered six categories of increasingly severe and increasingly unlikely accident scenarios. The analyses hypothesized one accident scenario to represent each category, along with a corresponding projection of the amount of radioactive material that could be released from a transportation cask. The analyses estimated impacts of postulated releases in three population zones – urban, suburban, and rural – and under two weather conditions – slowly dispersing conditions and moving-air conditions. The analyses also estimated the impacts from an unlikely but severe accident scenario called a maximum reasonably foreseeable accident. In response to public comments and to clarify this discussion for the reader, DOE has revised the EIS to describe the maximum reasonably foreseeable accident in terms of cask failure mechanisms, range of impact velocities, and temperature range for the accident.

Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

Section 2.3.4.1 of the Supplement to the Draft EIS discusses the construction of the flexible design waste package, which includes an Alloy-22 shell. This package would contain the waste for emplacement within the proposed repository and is not the cask that would be used for transportation to the Yucca Mountain site. The NWPA requires DOE to use transportation casks certified by the Nuclear Regulatory Commission when transporting spent nuclear fuel and high-level radioactive waste to a repository.

8.12 (12708)
Comment - EIS010485 / 0007
While, according to the Supplement, "Transportation of spent nuclear fuel and high-level radioactive waste to the repository would not be affected by the repository design evolution and is not evaluated in this Supplement," the DOE should disclose the growing resistance to shipping nuclear waste throughout the country in the Supplement.

Response
DOE published the *Supplement to the Draft Environmental Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada* to provide the updated design information to the public. While aspects of the design evolved from those in the Draft EIS, the basic elements of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain (including transportation of spent nuclear fuel and high-level radioactive waste) remain unchanged. For this reason, the Supplement focused on the most recent design enhancements, including various operating modes to manage heat generated by emplaced spent nuclear fuel and high-level radioactive waste.

Chapter 6 and Appendix J of the EIS contain information on transportation-related impacts that could result from the Proposed Action. These analyses used widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions that offer the most appropriate means to arrive at conservative estimates of transportation-related impacts. In addition, because of the public's interest in transportation in general and in the related information and analyses, the Department has included in the EIS descriptive information such as a new Appendix M and maps and tables that show the analyzed routes and estimated health and safety impacts for each state through which the shipments would pass. Appendix M provides general background information about transportation-related topics, such as transportation operations, cask testing requirements, and emergency response.

DOE has considered all comments received on the Draft EIS, as well as all comments received on the Supplement to the Draft EIS, and responded to them in this Comment-Response Document, including those that address concerns with shipping spent nuclear fuel and high-level radioactive waste. The Secretary of Energy will make a determination on whether to recommend the site to the President on the basis of a number of different types of information, including that contained in the Final EIS. Any recommendation of the site to the President by the Secretary of Energy would be accompanied by the Final EIS.

8.12 (13080)
Comment - EIS010230 / 0006
The low-temperature scenario is intended to improve the long-term performance of the repository and reduce geologic uncertainties, but would result in greater transportation risks, including a higher traffic fatality rate, due to an increased distance/number of shipments to the repository. The SDEIS should offer mitigation measures to help minimize the increased transportation risk.

Response
DOE believes that the risks of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain would be very small for the Proposed Action, regardless of the eventual repository design. The transportation activities under the lower-temperature repository operating mode would be similar to the other repository scenarios. The distances and number of shipments to the repository would not change. Therefore transportation risks would not be greatly different. If the Yucca Mountain site was selected, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

8.12 (13082)
Comment - EIS010230 / 0008
In Section 3.1.14, "Transportation," the SDEIS states that "transportation of spent nuclear fuel and high-level radioactive waste to the repository would not be affected by the repository design evolution." It is impossible to predict whether transportation would be affected because the design has not been finalized. Therefore, the relationship of design evolution to transportation parameters is unknown.

Response
The Draft EIS discussed ongoing site characterization activities and design evaluations, and the potential for resulting changes to repository design. Since DOE issued the Draft EIS, it has acquired an improved understanding of the interactions of repository features with the natural environment, and the advantages of a number of design features (such as titanium drip shields) to enhance waste containment and isolation. DOE issued the Supplement to the Draft EIS to provide the updated information to the public. While aspects of the design have evolved, the basic elements of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain (such as transportation of spent nuclear fuel and high-level radioactive waste) remain unchanged. For this reason, the Supplement focused on the most recent design enhancements, including various operating modes to manage heat generated by emplaced spent nuclear fuel and high-level radioactive waste.

DOE believes, however, that the EIS adequately analyzes the potential environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

8.12 (13225)
Comment - EIS010244 / 0024
Figure 2-4 of the SDEIS refers only to direct rail access and heavy-haul access to the site. The text on page 2-12 refers to legal weight trucks. It is not clear if DOE anticipates legal-weight trucks being used to transport waste directly to the Yucca Mountain site.

Response
DOE has incorporated Figure 2-4 of the Supplement to the Draft EIS into the Final EIS and modified it to clarify that legal-weight trucks and either railcars or heavy-haul trucks would have access to the site.

8.12 (13277)
Comment - EIS10231 / 0011
Page 3-17, Section 3.1.14. Transportation. We note that the transportation impacts are increased for the flexible design over the draft EIS design. These increased impacts, as well as those noted in other areas, should be incorporated into the final EIS analysis.

Response
The flexible design presented in the Supplement to the Draft EIS was carried forward to the Final EIS analyses.

No-Action Alternative

9. NO-ACTION ALTERNATIVE

9.1 Technical Issues

9.1 (138)
Comment - 13 comments summarized
Commenters said that the No-Action analysis is inadequate and does not provide a basis for comparison with the Proposed Action. Some of the reasons stated include: the existence of large uncertainties, lack of information, and failure of DOE to quantify how uncertainties could affect the outcome of the analysis; the use of a regional approach instead of a site-by-site approach, without providing data that shows it is truly representative; the use of different assumptions related to conservatism between the analysis of the Proposed Action and the No-Action Alternative; the need to look at a scenario that includes some redistribution or centralizing of the waste as a possible outcome of no action on the repository; and failure to consider the potential value of the waste.

Several commenters stated that a more comprehensive analysis on a site-by-site basis would demonstrate that a geologic repository would be favorable.

Response
DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress, with the Department's recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository (Chapter 1 identifies the process and alternative sites previously selected by DOE for technical study as potential repository locations), the development of new technologies (for example, transmutation), or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed in other contexts in other documents to varying degrees.

The No-Action Alternative did not consider redistribution or centralizing of spent nuclear fuel. However, the introduction to Chapter 7 of the EIS lists several references to documents that have evaluated potential environmental impacts of away-from-reactor spent nuclear fuel consolidation facilities. In addition, because the Department believes that it is a reasonably foreseeable future action although still uncertain, the Final EIS includes an evaluation of potential cumulative transportation impacts associated with the shipment of 40,000 metric tons of heavy metal (MTHM) of commercial spent nuclear fuel to a proposed privately owned centralized storage facility at Skull Valley in Utah (see Chapter 7 and Section 8.4 for details).

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios—long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

In addition, because the purpose of the No-Action Alternative is to provide a basis for comparison with the Proposed Action, DOE has tried to be consistent with the analyses of the Proposed Action, as appropriate. Regarding long-term analyses, for example, Section K.1 of the EIS notes that DOE did not want to influence the results to favor the

Proposed Action, and thus used assumptions for the No-Action Alternative that minimized predicted impacts. The Department believes that the avoidance of overstatement of impacts is the conservative approach for evaluation of potential impacts from the No-Action Alternative. Section K.4 discusses examples of these assumptions and their effects on the outcome of the impact analyses. Based on the above, DOE believes that the environmental impacts of the No-Action Alternative discussed in Chapter 7 and Appendix K are not overstated.

In Section K.4.4 of the EIS, DOE acknowledges that the No-Action Alternative impacts presented in Chapter 7 and Appendix K could be much larger or smaller than those estimated for the EIS. DOE believes that these estimates (with their uncertainties) adequately describe the potential environmental impacts that could occur from continued storage of high-level radioactive waste and spent nuclear fuel at or near existing facilities, and are valuable to the decisionmaking process.

Chapter 7 and Appendix K of the EIS provide information related to the No-Action Alternative. In addition, the 16 references cited in the No-Action impact analysis provide additional detailed information.

DOE analyzed five “regionalized” sites based on regional environmental parameters. DOE selected and weighted these parameters based on each site’s potential for human health impacts (that is, inventory, facility failure rates, canister corrosion rates, surface-water pathways to humans, and downstream populations). DOE evaluated site-specific environmental conditions, such as freeze-thaw cycles, precipitation frequency and quantities, precipitation chemistry, and relative humidity, at the 77 storage locations to determine failure times for the primary weather protection barriers (see Section K.2.1.1 of the EIS). For above-ground concrete storage facilities, these failure times ranged from fewer than 75 years for areas with many freeze-thaw cycles and abundant precipitation, such as the Northeast, to more than 600 years in dry, warm areas, such as the desert Southwest. For the below-grade storage facilities (such as those at the Savannah River Site and Hanford), the Department assumed that the primary weather protection would fail at 50 years after maintenance ended because, unlike the reinforced concrete structures used in above-ground facilities, the below-grade facilities use sheet-metal buildings. Release of radioactive materials would not begin with the loss of weather protection but only after the weather protection was lost and the storage canister and or cladding failed (see Section K.2.1). In addition, DOE gathered operational data obtained from facilities currently in operation or planned for the near future (see Appendix K of the EIS). The analysis constructed and evaluated the five hypothetical sites in a manner such that the total collective impacts estimated for a given region would be essentially equal to those that would have been estimated using individual, site-specific analyses.

Because the potential value of spent nuclear fuel and high-level radioactive waste would be the same under the Proposed Action and the No-Action Alternative, DOE does not consider it to be an important discriminator in the decisionmaking process and, therefore, did not include the value in either analysis.

9.1 (162)
Comment - 2 comments summarized
Commenters stated that a reliance on the Nuclear Regulatory Commission’s prior analysis conducted for independent spent fuel storage installations as a basis for characterizing long-term at-reactor storage is not appropriate.

Response
The Nuclear Regulatory Commission (DIRS 101899-NRC 1996) has stated, “The overall conclusion for on-site storage of spent fuel during the term of a renewed license is that the environmental impacts will be small for each plant.” Although this finding is applicable only to the continued storage of existing spent nuclear fuel and spent nuclear fuel generated during the 20-year license renewal period for a nuclear powerplant, for purposes of analysis, DOE assumed that potential environmental and radiological impacts for the storage facility would remain small for much longer periods assuming effective institutional controls are maintained. Environmental impacts would remain small because no additional fuel would be generated beyond the operation of the nuclear powerplant (plants are assumed to be closed after the first 20-year license renewal period), and radiological impacts would remain within regulatory limits specified in the storage facility license (10 CFR Part 72).

9.1 (250)
Comment - 20 comments summarized
Commenters suggested that the Supplement to the Draft EIS should have considered aging spent nuclear fuel and high-level radioactive at the generator sites rather than at the repository site. The commenters suggested several benefits of generator-site aging which included reduced transportation risks (incident-free and accidents), reduced health and safety risks (for both routine operations as well as accident consequences) and expenses related to the proposed repository spent nuclear fuel aging facility, and providing additional time for development of new management technologies as well as scientific research and review of currently proposed disposal technologies. Other commenters suggested that storage of fuel at existing sites for up to 100 years for the purpose of cooling would be a more realistic No-Action Alternative than abandoning the spent nuclear fuel at the reactor sites for 10,000 years. Commenters suggested that the interim storage facilities could be used to age the spent nuclear waste.

Response
The commenters are correct in saying that, as spent nuclear fuel and high-level radioactive waste age, their radioactivity decreases. DOE recognizes that delaying the shipment of these materials for 50 years could reduce radiation exposures to transportation workers (truck drivers and handlers) and the public living along the transportation routes. However, because of the generally higher population densities near the generator sites, delaying shipment to the proposed repository and allowing the material to accumulate at generator sites or nearby interim storage facilities could increase potential overall impacts to current and future generations of individuals living and working in and around the storage facilities. Section 7.2.1.7.3 of the EIS contains information on the effects of delayed shipment indicating that most short-term impacts from the continued storage of spent nuclear fuel and high-level radioactive waste (about 15 latent cancer fatalities) would result from exposure to noninvolved workers working near the storage facilities during the first 50 years of storage. Implementation of the Proposed Action would avoid much of this exposure. Under a delayed shipping scenario, such exposures would be additive to the somewhat reduced exposures to workers and the public resulting from the later transportation of spent nuclear fuel and high-level radioactive waste to the repository. Thus, a significant reduction in collective impacts, including those resulting from a smaller repository surface aging facility, under a delayed shipping scenario or near-site interim storage would be unlikely.

Similarly, reductions in potential impacts resulting from transportation (both accidents and incident-free transport) of "representative" fuel (see Appendix A) evaluated in Chapter 6 of the EIS or for routine operations or accidents at the repository evaluated in Chapter 4 would not be offset by the potential impacts of 50 to 100 years of additional storage at the generator sites of more than 16 latent cancer fatalities (see Section 7.2.1.7.3).

Socioeconomic impacts related to extended emplacement periods are discussed in Section 3.1.6 of the Supplement to the Draft EIS and 4.1.6 of the Final EIS. However, as discussed in Section 5.2.4.1 of the Draft EIS, DOE accepts the position of the National Academy of Sciences that it is not possible to make accurate predictions of future human behavior. As stated in Section 5.2.4.1 of the Draft EIS, DOE used a default position of today's conditions. For the Final EIS, DOE has projected baseline population and other economic measures to 2035. Because much of the aging process occurs outside of the timeframe for which socioeconomic impacts can reasonably be predicted (2035), the estimated impacts are generalized and confined to direct employment estimates. In addition, projections for periods further in the future would be substantially less credible and for this reason, have not been included in the analysis.

With regard to comments suggesting that onsite aging would be a more realistic No-Action Alternative, although not specifically evaluated, DOE believes that potential impacts related to onsite aging would be similar to the short-term impacts estimated for the No-Action Alternative, which assumes that the spent nuclear fuel would remain on the site for 100 years (see Section 7.2.1.7.3). DOE believes that licensed onsite dry storage facilities demonstrate the practicality and feasibility, and thus the reasonableness, of the No-Action scenarios. In addition, DOE believes the two No-Action Alternative scenarios evaluated in this EIS reflect a range of impacts that could occur and, therefore, provide an adequate basis for comparison of impacts resulting from the Proposed Action.

The Proposed Action includes a lengthy program of monitoring and testing that would continue for perhaps more than 300 years after waste emplacement ended (through closure of the repository, as described in Section 2.1.2 of the EIS). It would give future decisionmakers the ability to take advantage of technological advances, implement corrective actions, if required, and make societal choices on closing the repository or retrieving the wastes.

However, even if new technologies become feasible sometime in the future, the Department believes that a repository would continue to be an essential element of the nuclear fuel cycle because significant quantities of highly radioactive, long-lived materials would remain unsuitable for treatment. Therefore, the Department does not recommend abandoning the Nation's current waste management strategies.

9.1 (292)
Comment - EIS000026 / 0003
Under the No-Action Alternative, if the Department of Energy decides not to proceed with the development of a repository at Yucca Mountain, one alternative will be the continued storage of the materials at their present locations. The EIS considered two scenarios in this event: long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years and long-term storage with no institutional controls after approximately 100 years. A number of considerations were taken into account under these scenarios. However, from Florida's standpoint, the risks from possible hurricanes on stored spent nuclear fuel and high-level radioactive waste were not considered appropriately in either scenario.

Response
The Nuclear Regulatory Commission licenses spent nuclear fuel storage facilities at commercial nuclear generating sites (such as those in Florida) under 10 CFR Part 72. License requirements include extensive safety analyses that consider the impacts of plausible accident-initiating events (including natural phenomenon such as earthquakes, tornadoes, lightning, hurricanes, floods, tsunami, and seiches). These analyses must demonstrate that the facilities can withstand the most severe wind loading (tornado winds and tornado-generated missiles) and flooding from the Probable Maximum Hurricane with minimal release of radioactive material. DOE has revised Section 7.2.1.8 of the EIS to reflect these requirements.

Chapter 7 of the EIS describes an analysis DOE performed to identify types of events (natural and manmade) that could lead to the release of radioactive material to the environment. The analysis found no such events. However, it did determine that two events would be the most challenging to the integrity of a licensed and maintained storage facility -- the crash of an aircraft and a severe seismic event (see Section 7.2.2.7).

The analysis assumed that the facilities would be licensed and maintained during the period of active institutional control (the first 100 years of Scenarios 1 and 2 and the remaining 9,900 years of Scenario 1) and, therefore, that they would be able to withstand maximum postulated hurricanes. Under Scenario 2, during the period without institutional control (100 to 10,000 years), there would be no maintenance so the facilities would eventually degrade to a point where protection from hurricanes would not be effective. If a hurricane struck a degraded facility, a release of radioactive materials could occur earlier than predicted (see Section K.2 of the EIS) because of damage to the engineered barriers (concrete storage modules, dry storage canisters, material cladding, etc.). Section K.4 describes the potential effect of early loss of these barriers, which could result in significantly greater collective impacts than those discussed in Sections 7.2.1.7.3 and 7.2.2.5.3. However, because of the large uncertainties involved with trying to predict the outcome, and because DOE did not want to overestimate the impacts of the No-Action Alternative, the analysis made no attempt to quantify potential impacts from future severe weather phenomena.

9.1 (2043)
Comment - EIS001660 / 0006
The DEIS is confusing and misleading with regards to future generation of SNF [spent nuclear fuel] and HLW [high-level radioactive waste]. When discussing the no-action alternative, the DEIS says that all nuclear power plants will be closed by 2116 (p. 7-28), that decommissioning will occur in 2052 (p. 7-29), and that nuclear power plants would be closed after the first 20-year licensing renewal period (pp. 7-43 and -44). The cumulative impact analysis considers SNF generated until the year 2046, and says that Modules 1 and 2 represent "all" projected SNF and HLW (p. 8-5). No such statements are made regarding the proposed action.

If the DOE proposes to close all commercial nuclear power plants by a certain year, this must be explicitly stated as part of the proposed action. If not, both the proposed action and the no-[action] alternative must consider SNF and HLW generated after that year. Presently, the analysis of the proposed action does not account for 35,000 tons of SNF and HLW generated through 2046, over and above 70,000 tons that would be placed at Yucca Mountain. Nor does the DEIS account for SNF and HLW generated after 2046. Because of these errors, the DEIS greatly underestimates the costs of the proposed action. (See Table 2-5.)

Response
DOE recognizes that some existing nuclear facilities could be shut down prematurely and that others could be relicensed more than once. However, for purposes of analysis, the Department used certain simplifying assumptions to evaluate potential impacts of the No-Action Alternative. Important among these are the assumption that the No-Action Alternative would begin in 2002 (Sections 2.2.2 and 7.2 of the EIS), that some commercial nuclear powerplants would continue to operate through the first 20-year licensing renewal period (Section 7.3), and that noninvolved workers (powerplant workers) would remain at the generating facilities until 2052 (Section 7.2.1.7.3). These assumptions established a basis for analysis of the No-Action Alternative and are not predictions of actual events or proposals for future action.

The NWPA specifically restricts the capacity of the Nation's first repository to no more than 70,000 metric tons of heavy metal of spent nuclear fuel and high-level radioactive waste. Therefore, DOE limited the impact evaluation of the Proposed Action to those that could result from the emplacement of 70,000 metric tons of heavy metal. However, disposing of all commercial and DOE spent nuclear fuel and all high-level radioactive waste projected through 2046 (Module 1) as well as Greater-Than-Class-C low-level radioactive waste and Special-Performance-Assessment-Required waste (Module 2) in the repository represents a reasonably foreseeable future action. For this reason, DOE analyzed the potential impacts for these actions as potential cumulative impacts (Chapter 8).

For consistency, the No-Action Alternative analysis also evaluated the potential environmental impacts from continued onsite storage of all commercial and DOE spent nuclear fuel and all high-level radioactive waste projected through 2046. Section 7.3 of the EIS discusses the results of these analyses.

Regarding evaluation of commercial spent nuclear fuel generated after 2046, DOE believes that generation rates after the first licensing renewal period are too speculative to predict. Therefore, the analyses did not evaluate these potential impacts for either the Proposed Action or the No-Action Alternative.

9.1 (3637)
Comment - EIS001105 / 0001
While it is recognized that the no-action alternative be addressed, it is acknowledged that the judged consequences are highly speculative and that the actual impact of no action could well be many times greater than that presented in the draft. A particular example is the "sealed source" waste described in Appendix A Section A.2.5.3. The assumption that this material will always be placed in standard waste packages is unrealistic. Thus, the no-action case underestimates the potential for its deterioration, with resultant releases of actinides. Such releases would seriously multiply the consequences of the no-action case to both human mortality and environmental contamination throughout the DOE/commercial sites and their environments across the entire country.

Response
The assumption that DOE would place sealed-source waste in standard waste packages applies only to disposal of these wastes at the proposed Yucca Mountain Repository, as discussed in Chapter 8 of the EIS.

As stated in Section 7.3 of the EIS, DOE did not include a quantitative evaluation of Module 2 inventory potential impacts under the No-Action Alternative because not enough information is available about the long-term storage configuration of the sealed sources under that alternative.

9.1 (3959)
Comment - EIS001486 / 0001
Missing under the No-Action Alternative is No-Generation. This would cut loses due to the predicted increment in waste as well as to an accidental increment as aging generators become short-timers.

Response
DOE has no authority over the operation of the Nation's commercial nuclear powerplants. As mandated by the Atomic Energy Act, the Nuclear Regulatory Commission has jurisdictional authority for commercial uses of nuclear

materials, including the operation of reactors to produce electricity; this includes the production of electricity from nuclear energy and the interim storage of spent nuclear fuel at the reactor sites.

9.1 (4101)
Comment - EIS001375 / 0005
The "No Action" alternative leaves the waste in storage facilities at reactor sites that were never intended to become permanent storage sites. Although on-site dry cask storage has been determined by the NRC to be safe for a limited amount of time, waste should not be stored on-site indefinitely. There are 11 active commercial nuclear reactors in Illinois and 3 retired commercial reactors. These sites are all near major population centers and/or Illinois waterways.

Response
By including long-term onsite storage as part of the No-Action Alternative, DOE is not predicting conditions that would actually occur. In fact, the Department recognizes that both No-Action Alternative scenarios are unlikely (see Section 2.2 and the introduction to Chapter 7 of the EIS). However, the Department selected these scenarios to provide a basis for comparison to the Proposed Action and because they reflect a range of potential impacts that could occur from the continued storage of material at these sites.

If the Yucca Mountain site was not approved, DOE would discontinue the development of a repository at Yucca Mountain and, as directed by Section 113(c)(3) of the NWPA, would prepare a report to Congress with its recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Based on Nuclear Regulatory Commission regulations and DOE directives that govern the safe and secure storage of spent nuclear fuel and high-level radioactive waste, commercial and DOE sites have an obligation to continue to manage these materials in a manner that protects public health and safety and the environment.

9.1 (4260)
Comment - EIS001160 / 0075
Page 1-20. Failure to provide institutional control over this sensitive and potentially dangerous material (provided governmental agencies concerned with this still exist) is poor logic. Perhaps the DOE could consider alternatives in the range between 100 and 10,000 years. Other parts of the document discuss permanent closure after 300 years. This appears inconsistent with other statements in the document.

Response
DOE recognizes that maintaining effective institutional control for 10,000 years is unlikely, as is losing effective institutional control after 100 years (see Section 2.2 and Chapter 7 of the EIS). The Department selected these scenarios because it did not want to speculate on actions that Congress, DOE, and the utilities could take if Yucca Mountain was not approved as a repository site and because predicting a date for a loss of institutional control would be speculative. The Nuclear Regulatory Commission and the Environmental Protection Agency have recognized this and, although they encourage the maintenance of monitoring and physical oversight for as long as possible, they recognize that projecting society's willingness and ability to provide such a function for more than 100 years into the future is not reasonable. DOE selected these scenarios to provide a basis for comparison of impacts from the Proposed Action and to reflect a range of impacts that could occur if spent nuclear fuel and high-level radioactive waste were left where they are currently stored.

DOE believes that efforts to perform additional analyses, such as institutional control for 300 years, probably would yield results that contained some combination of the environmental and human health effects postulated for the two scenarios evaluated in the EIS and, therefore, would not provide substantive additional information for the decisionmakers.

9.1 (4272)
Comment - EIS001160 / 0080
Page 2-1: The second paragraph notes that the No Action Alternative is intended to serve as a baseline against which the Proposed Action can be evaluated. Because waste managed on-site at generator locations has institutional controls, the No Action assumption of loss of institutional controls is not a true reflection of baseline conditions.

Response
Because the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain did not receive a recommendation as a repository site is uncertain (see the introduction to Chapter 7 of the EIS), DOE decided to illustrate one set of possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios: long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no institutional control after approximately 100 years (Scenario 2). DOE recognizes that neither of these scenarios would be likely to occur but selected them for analysis because they reflect a range of potential impacts that could occur. The Department evaluated Scenario 1 to estimate potential impacts under the status quo: continuing to store spent nuclear fuel and high-level radioactive waste with institutional control. Scenario 2 provides another set of potential impacts if the responsible organizations became unable or unwilling to continue to fund surveillance and maintenance of the storage facilities. DOE selected Scenario 2 to parallel that part of the Proposed Action analysis in which long-term performance does not include institutional controls.

9.1 (4279)
Comment - EIS001160 / 0087
Page 2-59: The No-Action Alternative should be recognized as more than simply "providing a baseline for comparison." In fact, DOE can choose the No-Action Alternative and the Secretary of Energy could do so in a subsequent Record of Decision. The DEIS must provide analytical evidence as to why whichever alternative is selected.

Response
DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress, with the Department's recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios – long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

As discussed in Section 2.6 of the EIS, the Secretary of Energy would consider not only the potential environmental impacts and public comments on the EIS, but also other factors in determining whether to recommend the Yucca Mountain site to the President. Factors could include those identified through public input, but others as well, including:

- Ability to obtain necessary approvals, license, and permits
- Ability to fulfill stakeholder agreements
- Consistency with DOE mission
- Assurance of safety facility construction and operations flexibility
- Cost of implementation
- Ability to mitigate impacts

9.1 (4407)
Comment - EIS001555 / 0004
So as far as where this nuclear waste can go, who knows, there is no safe place.

Leaving it on site is the worst place to put it, short of dumping it in the middle of Lake Erie. And the reason why is every nuclear power plant in the United States is sited on a river, a lake, or around the ocean coast. The reason being they need all that water for their operations, you know, millions of gallons. And yet if you leave the waste on Lake Erie, on a river, on an ocean coast, if there is a tornado, whatever, the Nuclear Regulatory Commission has stated in a hearing they had in Lake County about the Perry Nuclear Power Plant that low level radioactive waste, if stored in a special radioactive waste storage building, that CEI was going to do there, but now apparently doesn't have to, could destroy the building and spread radioactive waste around the community, according to testimony that was in the transcript from an official at the NRC. So a tornado can pick up a car, it can pick up a cow, can a tornado pick up a dry cask of radioactive waste and throw it in to Lake Erie, sure, why not?

Response
DOE believes that the Federal policy to dispose of such wastes underground in a mined geologic repository continues to be the most promising method to provide reasonable expectation of adequate protection of public health and the environment from potential radiation impacts.

The Nuclear Regulatory Commission licenses spent nuclear fuel storage facilities at commercial nuclear generating sites under 10 CFR Part 72. License requirements for such facilities include extensive safety analyses that consider the impacts of plausible manmade and natural phenomenon accident-initiating events (including earthquakes, tornadoes, lightening, hurricanes, floods, tsunami, and seiches). These safety analyses must demonstrate that the facilities are able to withstand the most severe wind loadings (tornado winds and tornado-generated missiles) and flooding from the Probable Maximum Hurricane with minimal release of radioactive material. Therefore, it is highly unlikely that a tornado could pick up a dry cask of spent nuclear fuel and carry it into Lake Erie.

However, because of lower hazard and shorter storage times, these requirements might not exist under the 10 CFR Part 50 license used for storing low-level radioactive waste. DOE did not evaluate potential impacts associated with onsite storage of low-level radioactive waste because these wastes are not candidates for disposal at Yucca Mountain under the Proposed Action.

9.1 (4482)
Comment - EIS001376 / 0008
The DEIS states (at S.3.2) that neither No-Action Scenario would be likely, ostensibly because the Nation could pursue one of numerous other alternatives to manage SNF [spent nuclear fuel] and HLW [high-level radioactive waste] if Yucca Mountain is not licensed. However, history has shown that the Nation and the federal government have failed to implement any of those other alternatives and have also failed to identify and implement a viable permanent storage option. If there are other scenarios which are considered viable, they should be analyzed as part of the EIS.

The No-Action Scenarios emphasize the problems created by temporary, consolidated storage facilities, which are also not considered in the DEIS, e.g., a temporary facility at Yucca Mountain and/or the proposed PFS [the Private Fuel Storage] facility in Skull Valley, Utah. Moving SNF to temporary facilities, which would not be constructed but for the status of a permanent facility, transfer the risk of storage to new sites.

The federal government should not license or operate any consolidated, temporary SNF storage facilities at Yucca Mountain or in Utah. Under any Scenario other than No-Action, such facilities would not be needed, based on the evaluation in the DEIS.

On the other hand, if temporary, consolidated SNF storage facilities are licensed at Yucca Mountain or Skull Valley, but permanent storage at Yucca Mountain ultimately is not licensed, the risks (as defined in the No-Action Scenarios) will have been shifted from existing nuclear power plant facilities to new sites for which there is currently no risk or responsibility for management of high-level nuclear waste. That impact, as indicated above, is not adequately addressed for Skull Valley, Utah or Yucca Mountain, Nevada in this DEIS.

Response
DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress, with the Department's recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository (Chapter 1 identifies the process and alternative sites previously selected by DOE for technical study as potential geologic repository locations), the development of new technologies (for example, transmutation), or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed in other contexts in other documents to varying degrees.

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios – long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

9.1 (4850)
Comment - EIS001215 / 0001
The draft EIS does not adequately address the potential impacts of various forms of "no action" on Hanford. Substantial quantities of high-level waste and spent fuel would remain in storage at Hanford. The impact of this indefinite long-term storage must be considered.

The EIS states that different and less conservative parameters were used in evaluating the No Action Alternative as compared to those used for the repository analysis so as not to unduly influence the results in favor of the repository. As a result, the standards of the analysis become a comparison of apples and oranges. It is abundantly clear from the current extensive contamination of soils and groundwater at Hanford that these wastes are mobile and they will spread in the surface and near-surface environment. There are also additional unique driving forces including burrowing animals, insects and plants that increase these problems. The No Action Alternative analysis must be conducted with equal rigor and protection in its general assumptions for the comparison to have any real meaning.

Response
DOE agrees that potential impacts at the Hanford Site could be greater than the estimates in this EIS. Section K.4.4 of the EIS acknowledges that the No-Action Alternative impacts in Chapter 7 and Appendix K could be much larger or smaller than those estimated because of uncertainties associated with the numerical values used in the calculations. However, such uncertainties are typical of predictions of the outcome of complex physical and biological phenomena over long periods (such as the 10,000-year analysis period). DOE believes that these estimates (with their uncertainties) adequately describe the potential environmental impacts that could occur from continued storage at or near existing facilities, and are valuable to the decisionmaking process.

DOE notes that potential impacts associated with onsite management of spent nuclear fuel and high-level radioactive waste have been analyzed in greater detail in other EISs, such as the *Final Environmental Impact Statement for the Tank Waste Remediation System, Hanford Site, Richland, Washington* (DIRS 103214-DOE 1996), and *Addendum (Final Environmental Impact Statement): Management of Spent Nuclear Fuel from the K-Basins at the Hanford Site, Richland, Washington* (DIRS 103213-DOE 1996).

9.1 (4852)
Comment - EIS001215 / 0003
The selection of wastes to send to the High Level Waste repository creates orphan wastes. This has serious repercussions. One such example is the spent nuclear fuel stored at Hanford. If some small part of this material is left at Hanford, nearly the full costs of continuing to operate the storage facilities for these wastes will continue for the indefinite future. It makes more sense to include all of the spent nuclear fuel from Hanford as a single unit for disposal. On the other hand, if the waste is not sent for disposal, it has no other path forward and additional work will be needed in the next 50 years to remove the fuel from storage and process it into a form that can either be safely maintained for the long term, or disposed elsewhere. It is not safe for storage in its currently planned form for more than about 50 years. Questions also remain unanswered about the ultimate status of "Greater than Class C" and "Special Case" wastes and other spent fuel waste forms, such as spent fuel from the Fast Flux Test Facility currently stored at Hanford.

Response
The two No-Action scenarios in the EIS include an evaluation of continued storage of the entire foreseeable inventory of spent nuclear fuel and high-level radioactive waste. However, as the commenter notes, under the DOE Proposed Action of disposal of 70,000 MTHM, some spent nuclear fuel and high-level radioactive waste would not be part of that capacity allocation and would require continued management. Its emplacement at Yucca Mountain would require legislative action by Congress unless a second repository was in operation. A separate National Environmental Policy Act evaluation, as well as legislative action, would have to occur before a second repository could be licensed for the disposal of the remaining inventory. The continued management of these materials at the Hanford Site are not within the scope of this EIS; they are already addressed in two other DOE documents: *Department of Energy Programmatic Spent Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (DIRS 101802-DOE 1995) and *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (DIRS 101816-DOE 1997).

The No-Action analysis evaluated the DOE spent nuclear fuel and high-level radioactive waste at existing sites or at sites where existing Records of Decisions have placed or will place these materials. For example, the Record of Decision (60 *FR* 18589, April 12, 1995) for the *Final Supplemental Environmental Impact Statement, Defense Waste Processing Facility* (DIRS 103191-DOE 1994) decided to complete construction and operate the Defense Waste Processing Facility and associated facilities at the Savannah River Site to pretreat, immobilize, and store high-level radioactive waste. Similarly, the *Site Final Environmental Impact Statement for the Tank Waste Remediation System, Hanford Site, Richland, Washington* (DIRS 103214-DOE 1996) identified ex situ vitrification of high-level radioactive waste with onsite storage until final disposition in a geologic repository as the preferred alternative. For DOE spent nuclear fuel, the Record of Decision (60 *FR* 28680, June 1, 1995) for the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (DIRS 101802-DOE 1995) decided that Hanford production reactor fuel would remain at the Hanford Site; aluminum-clad fuel would be consolidated at the Savannah River Site; and non-aluminum-clad fuels (including spent nuclear fuel from the Fort St. Vrain reactor and naval spent nuclear fuel) would be transferred to the Idaho National Engineering and Environmental Laboratory.

The decisions on the types and quantities of materials that will be moved as well as the timeframe for these activities have been and are continuing to be made in programmatic documents (for example, DIRS 101802-DOE 1995). Therefore, the evaluation of impacts related to these decisions are in those documents and are beyond the scope of the Yucca Mountain EIS.

9.1 (4853)
Comment - EIS001215 / 0004
In addition to the serious discrepancies with the No Action Alternative noted by Washington, another major problem involves the potential failure and release mechanisms if the waste is processed into glass intended for repository disposal and which is instead left in near surface storage. The alloys planned for the containers may not be suitable for long term surface or near surface storage. The glass waste form is likewise not designed to withstand the corrosive effects of surface waters containing erosive organic vegetative decay products such as humic and fulvic

acids. These materials corrode glass far more rapidly than their low acidity would indicate. They do not exist in waters that would be encountered in a repository setting, but they are always present in surface waters.

Response
Under No-Action Scenario 2, the failure and release models used to evaluate the long-term impacts of onsite storage of high-level radioactive waste assumed that corrosion of the stainless-steel canisters and dissolution of the waste matrix would result from contact with precipitation–not surface water (see Section K.2 of the EIS). Therefore, vegetative decay products should not be an important consideration. However, the estimated Region 5 impacts attributable to high-level radioactive waste (135 person-rem) are less than 0.04 percent of those from spent nuclear fuel (382,000 person-rem), assuming the Proposed Action inventory (70,000 metric tons of heavy metal). Over the 10,000-year analysis period, these impacts would result from an estimated 1-percent dissolution of approximately 2,000 canisters of high-level radioactive waste and 100-percent dissolution of 2,300 metric tons of heavy metal of DOE spent nuclear fuel. In view of these estimates, even if the Department significantly underestimated the corrosion rate for the high-level radioactive waste containers or the dissolution rate for the waste matrix, the maximum additional dose could increase by a factor of 100 (assuming 100-percent dissolution) resulting in an additional dose of about 13,000 person-rem or 3 percent of the dose attributable to the DOE spent nuclear fuel. This additional dose could result in an additional 7 latent cancer fatalities over the 10,000-year analysis period. This increase would be a small fraction of the 230 latent cancer fatalities predicted for Region 5 (see Section K.3.1) and is well within the overall uncertainties that DOE acknowledges in Section K.4.

9.1 (4874)
Comment - EIS000337 / 0012
Pg. 2-65, High-Level Radioactive Waste Storage Facilities, 2nd par.: "the canister cavities are galvanized steel...." Why not stainless steel?

Response
The primary purpose of the canister cavities is to direct cooling air around the high-level radioactive waste. Because the high-level radioactive waste, which would be in welded stainless-steel canisters, would never come in direct contact with the wall of the canister cavity, DOE elected to use galvanized steel to reduce the overall cost.

9.1 (4894)
Comment - EIS000337 / 0034
Pg. 9-13, Long-Term Performance Measures Under Consideration: The referenced studies are useful for the No-Action Alternative. The implementation of the noted measures would be very germane to the dry storage facilities.

Response
The barrier measures described in Section 9.2.8 of the EIS would be appropriate for reducing package corrosion, delaying or reducing water transport, retarding radionuclide movement and release rates, and reducing potential damage to canisters from factors in the subsurface environment such as rockfall. These measures would be appropriate for a subsurface environment when human intervention is not possible or practicable (that is, loss of institutional control after repository closure).

The No-Action Alternative includes two hypothetical scenarios: (1) Scenario 1, which assumes the maintenance of institutional controls at the 77 storage facilities for the entire 10,000-year analysis and (2) Scenario 2, which assumes no credit for institutional controls after the first 100 years.

Under Scenario 1, the barrier measures described in Section 9.2.8 of the EIS would not be necessary or appropriate because continuous surveillance and maintenance of the facilities and storage canisters would ensure the timely identification and repair of environmental degradation of these structures and canisters, thereby ensuring containment of radioactive materials. Although DOE considers both scenarios unlikely (see Section 2.2 and the introduction to Chapter 7 of the EIS), if long-term onsite storage became a reality, storage facilities and canisters probably would undergo some design evolution to increase their useful lifetimes and to enhance the long-term integrity and corrosion resistance of the canister. However, because institutional control would remain in effect, design enhancements would probably not differ greatly from today's designs.

Because Scenario 2 takes no credit for institutional control after the first 100 years, it would not be appropriate to assume funding to construct long-term, surface storage facilities that could benefit from the barrier measures discussed in Section 9.2.8 of the EIS because of their high cost.

9.1 (5040)
Comment - EIS001520 / 0008
The Board believes that neither of the no-action scenarios evaluated in the draft EIS is likely to occur, but the two scenarios do appear to represent the extremes of a spectrum of possible futures. Because the no-action alternative is hypothetical, there may be little merit in attempting analyses of this alternative more sophisticated than those presented in the draft EIS.

Response
DOE agrees that neither of these scenarios would be likely if there was a decision not to develop a repository at Yucca Mountain. Because DOE did not want to influence the analysis results to favor the repository, it used assumptions that generally resulted in lower predicted impacts rather than applying the conservative assumptions used in many of the repository impact analyses.

9.1 (5426)
Comment - EIS001887 / 0125
Page 2-61; Section 2.2.2.1 - Storage Packages and Facilities at Commercial and DOE Sites

It is beyond the scope of this Draft EIS to assume, without further DOE commitment, how DOE spent fuel and high-level radioactive waste would be stored at DOE facilities. Most of the high-level waste is currently in liquid form in underground storage tanks and will still be in 2002, when the No-Action Alternative is assumed to start.

Response
The Department agrees that it is beyond the scope of this EIS to specify how DOE spent nuclear fuel and high-level radioactive waste would be stored at DOE facilities. Therefore, as discussed in Section 7.2 of the EIS, the No-Action analysis evaluated the impacts from continued storage assuming that the DOE materials were at the sites specified in existing DOE Records of Decision for prior environmental documentation. For example, the Hanford Site *Final Environmental Impact Statement for the Tank Waste Remediation System* (DIRS 103214-DOE 1996) identified ex situ vitrification of high-level radioactive waste with onsite storage until final disposition in a geologic repository as the preferred alternative. For DOE spent nuclear fuel, the Record of Decision (60 *FR* 28680, June 1, 1995) for the *U.S. Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (DIRS 101802-DOE 1995) decided that Hanford production reactor fuel would remain at the Hanford Site, aluminum-clad fuel would be consolidated at the Savannah River Site, and non-aluminum-clad fuels (including spent nuclear fuel from the Fort St. Vrain reactor and naval spent nuclear fuel) would be transferred to the Idaho National Engineering and Environmental Laboratory. Therefore, the analysis evaluated DOE aluminum-clad spent nuclear fuel at the Savannah River Site, DOE non-aluminum-clad fuels at the Idaho National Engineering and Environmental Laboratory, most of the Fort St. Vrain spent nuclear fuel at the Colorado generating site, and high-level radioactive waste at the generating sites (the West Valley Demonstration Project, the Idaho National Engineering and Environmental Laboratory, the Hanford Site, and the Savannah River Site).

In addition to assigning various materials to specific DOE facilities, the National Environmental Policy Act documents citied above also evaluate potential environmental impacts of various storage options for DOE spent nuclear fuel and high-level radioactive waste including, under the No-Action Alternative, continued storage of high-level radioactive waste in underground tanks. These documents also describe facilities used for long-term storage of processed waste (for example, borosilicate glass), most of which have been designed and are either completed (Savannah River Site Glass Storage Facility) or under construction.

Because the cited National Environmental Policy Act documents have addressed the environmental impacts associated with the processing and storage of DOE spent nuclear fuel and high-level radioactive waste, and to simplify the analyses, DOE limited the No-Action Alternative impact analyses to those resulting from long-term storage of processed, road-ready materials. These analyses assumed that these materials would be stored in the structures described in the cited National Environmental Policy Act documents.

Comment - EIS001887 / 0126
Page 2-67; Section 2.2.2.3 - No-Action Scenario 2

This paragraph conflicts with the third paragraph on page 2-59 that describes the two scenarios for the No-Action Alternative. The information should be consistent.

Response
DOE can find no inconsistencies between the sections cited.

9.1 (5445)
Comment - EIS001660 / 0007
The DEIS must include a realistic no-action alternative. It repeatedly says that the no-action scenarios are unlikely and unreasonable; however, it says these scenarios provide a baseline for comparison. The no-action alternative is only the absence of the proposed action. It must be analyzed fairly using consistent assumptions regarding institutional controls and all other relevant factors.

According to the DEIS (p. 3-140), the description of the affected environment for the no-action alternative "describes the affected environment that reflect (sic) the average or mean conditions of the sites." Thus, "average" conditions mean nothing and provide no information that one could use to evaluate the no-action alternative. The DOE presumably knows, and must disclose the existing conditions in the vicinity of the sites that generate SNF and HLW. Without a description of the affected environment, no meaningful analysis of anticipated impacts is possible.

Response
DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress with the Department's recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not recommended and approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository (Chapter 1 identifies the process and alternative sites previously selected by DOE for technical study as potential geologic repository locations), the development of new technologies (for example, transmutation), or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed in other contexts in other documents to varying degrees.

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios – long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

DOE agrees that Chapter 3 of the EIS should include additional baseline information for the 77 storage locations to enable for a comparative evaluation of potential impacts of the No-Action Alternative. Accordingly, Section 3.3 now contains additional information on No-Action site conditions.

9.1 (5546)
Comment - EIS001660 / 0044
Unreasonable "No-action" alternatives - Two no-action alternatives were provided. One would have the radioactive waste stay where it is under institutional control for just 100 years. The second would have the waste stay under institutional control for 10,000 years. DOE acknowledges that neither is likely to occur but says that other scenarios would be too speculative. Reasonable alternatives should be analyzed and included in the DEIS. Mineral County accepts Eureka County's analysis for its own comments. See Attachment D (page 21 of 26 of Eureka County's comments.) [Following is text from reference.]

Analysis of no-action alternative inconsistent and biased. Despite statements to the contrary, the analysis of the proposed action and the no-action alternative is not consistent. (See pp. 7-9,-16) The statement on p. 7-9 that Chapter 3, section 3.3, discusses the conditions at the sites that formed the basis for identifying impacts of the no-action alternative is not true. The statement on p. 7-11 that the Yucca Mountain workforce would lose their jobs under the no-action alternative is unsupported and alarmist; it reflects bias. The statement on p. 7-12 that payments in lieu of taxes would be diminished under the no-action alternative is unsupported. The analysis of in-lieu payments should address both costs and revenues. The statement on p. 7-46 that concentrations and areas affected by radiation from Module 1 would be impossible to estimate is untrue on its face.

Response
DOE recognizes that neither No-Action Alternative scenario is likely to occur (see Section 2.2 and the introduction to Chapter 7 of the EIS). To enable a comparison of the impacts between the Proposed Action and the No-Action Alternative, DOE took care, for example, to maintain consistency, where possible, with the assumptions used to evaluate the proposed repository. In pursuit of this goal, the Department structured the Scenario 2 analysis to facilitate an impact comparison with the repository impact analysis. Section K.1 of the EIS describes these important consistencies.

Scenario 1, which includes an analysis of impacts under effective institutional control for at least 10,000 years, is consistent with the portion of the analysis of the Proposed Action that includes an analysis of effective institutional control at the repository for the first 100 years after closure. Scenario 2, in which the analysis does not consider institutional control after approximately 100 years, is parallel to the portion of the Proposed Action analysis in which long-term performance after 100 years also does not include institutional control.

Section 3.3 of the Final EIS contains more information on the No-Action site conditions.

Under the No-Action Alternative, DOE would not proceed with the development of a repository at Yucca Mountain. Following any reclamation actions, workers assigned to the repository would have no remaining work. Unless the workforce was reassigned or new missions were identified, the workforce would be reduced. This assumption is based on the fact the Department cannot use tax receipts or the Nuclear Waste Fund to support workers for whom there is no identified mission.

Payments-Equal-To-Taxes are made pursuant to Section 116(c)(3)(A) of the NWPA, which requires the Secretary of Energy to "...grant to the State of Nevada and any affected unit of government, an amount each fiscal year equal to the amount such State or affected unit of government, respectively, would receive if authorized to tax site characterization activities..." These payments, historically and for the future, are determined by estimating the amount of Yucca Mountain Project property, purchases (in and out of the State of Nevada), and business activities (employees) within the jurisdiction of an affected unit of local government. Under the No-Action Alternative for the repository, the number of employees and purchases would be significantly lower. As a consequence, it is accurate to state that Payments-Equal-To-Taxes would be correspondingly lower, and could even be eliminated in the long term.

Through Fiscal Year 1999, DOE has paid over $41 million to the State of Nevada and other affected units of local government. Estimated payments for Fiscal Years 2000 through 2003 would be about $44 million, for a total of about $85 million. Most of these payments are made to Nye County; for example, DOE's Fiscal Year 2001 budget and proposed Fiscal Year 2002 funding for Payments-Equal-To-Taxes for Nye County alone are $10 million each. [May 2, 2001, presentation by Victor Trebules to the meeting of the affected units of local government.)

DOE has not estimated Payments-Equal-To-Taxes beyond 2003 and does not intend to make long-term Payments-Equal-To-Taxes estimates. While the Nuclear Waste Policy Act requires Payments-Equal-To-Taxes, they are not discriminating factors in the EIS decisionmaking process.

DOE agrees with the commenter that the statement in Section 7.3.2.1 of the Draft EIS, "...concentrations and areas affected by radiation from Module 1 would be impossible to estimate..." is untrue. The statement in the EIS now reads "...concentrations and areas affected by radiation from Module 1 would be difficult to estimate with any level of accuracy...."

Comment - EIS001887 / 0381
APPENDIX K. LONG-TERM RADIOLOGICAL IMPACT ANALYSIS FOR THE NO-ACTION ALTERNATIVE

Two No-Action Alternatives are considered by DOE, both involving long-term storage at present locations: (1) Long-term storage at present locations with effective institutional control for at least 10,000 years; and (2) Long-term storage at present locations with no effective institutional control after 100 years. Another alternative, perhaps more likely, is storage at a centralized location, such as the proposed PFS [Private Fuel Storage] facility in Skull Valley, Utah. The environmental impact of this alternative should be seriously investigated by DOE.

While DOE researchers have attempted to construct the impact analysis of the No-Action Alternative in parallel to the analysis conducted for the proposed Yucca Mountain repository, in several respects, researchers have not been successful.

For decentralized storage at reactor sites where spent fuel is presently stored, a major concern over the long-term is the freeze-thaw cycle. As DOE researchers note, freeze-thaw cycles lead to concrete spalling and weakening of the concrete overpacks around spent fuel canisters (page K-4). In addition, storage canisters can degrade due to corrosion caused by acidity and chloride concentration. This can be followed by water infiltration (page K-8). The final barriers to radionuclide release are the fuel cladding and the fuel matrix (page K-9).

According to DOE, degradation appears to begin at about 7,000 to 8,000 years. In year 10,000, less than 1% of the cladding has degraded. This is primarily the stainless steel clad fuel. For zirconium, degradation begins about 10,000 years (page K-11).

Table K-4 [Section K.2.2] lists radionuclides important to dose for this decentralized storage scenario: Am [americium]-241, Am-243, Np [neptunium]-237, Pu [plutonium]-238, Pu-239, Pu-240 and Tc [technetium]-99. (p. K-14) These radionuclides are important, but they are not the radionuclides considered in the repository analysis. Of these, only Np-237 is directly considered in the repository analysis. Pu-239 (49%) and Pu-240 (47%) contribute most of the dose, followed by Am-241 (3.2%).

Response
The scenario for possibly moving the spent nuclear fuel and high-level radioactive waste to a centralized interim storage or monitored retrievable storage site has been evaluated by others, and the Private Fuel Storage facility at Skull Valley, Utah, is currently under study by the Nuclear Regulatory Commission (see the introduction to Chapter 7 of the EIS for details). However, DOE recognizes interim storage at the Private Fuel Storage facility to be a reasonably foreseeable future action and has included this action as part of the cumulative impacts analysis in Chapter 8.

For the No-Action Alternative, DOE evaluated more than 200 radionuclides for potential human health impacts including all of the radionuclides considered in the repository analysis. Some of the radionuclides important to the repository analysis do not appear in the table in Section K.2.2 because they are not important contributors to radioactive dose in the No-Action case. However, the listed radionuclides are those determined to contribute more than 99.5 percent of the total dose under Scenario 2 of the No-Action Alternative.

9.1 (6016)
Comment - EIS001879 / 0041
The no action alternative scenarios are, even by the Department's admission, speculative in nature, and the assumptions for institutional control have no technical or historical basis. Such is the baseline “No action alternative” which the Department has examined in great detail. Yet, on-going NRC [Nuclear Regulatory Commission] licensing activities that would directly influence the implementation of the NWPA [Nuclear Waste Policy Act] (connected actions), and could also affect the need for a repository, are not even evaluated.

Response
DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress, with the Department’s recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository (Chapter 1 identifies the process and alternative sites previously selected by DOE for technical study as potential geologic repository locations), the development of new technologies (for example, transmutation), or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed in other contexts in other documents to varying degrees.

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios – long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

9.1 (6076)
Comment - EIS001469 / 0002
I challenge the conclusion a little bit in terms of no action. While the Department of Energy states that both no-action alternatives are not feasible and wouldn’t be done, nevertheless, the actual health impacts from the long-term scenario 2 would actually be less than the Yucca Mountain repository by their own calculations, even though I suppose it’s not considered reasonable. So that implies to me that there must be something in between there that’s much more reasonable and much better for the health and safety and should be addressed.

Response
DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress, with the Department’s recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository (Chapter 1 identifies the process and alternative sites previously selected by DOE for technical study as potential geologic repository locations), the development of new technologies (for example, transmutation), or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed in other contexts in other documents to varying degrees.

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios–long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

The EIS does not indicate that the impacts for No-Action Scenario 2 would be smaller than those for Scenario 1. Section 2.4 indicates that overall public health and safety impact estimates would be greater for Scenario 2 and cost impacts would be greater for Scenario 1.

9.1 (6146)
Comment - EIS001654 / 0036
Page S-64. DEIS Findings Clearly Support the Conclusion that the Proposed Action is Far Superior to No Action

The first two sentences of the first paragraph summarize well what the 1,400 page DEIS demonstrates: the impacts of the Proposed Action to develop the repository at Yucca Mountain are minor. Conversely, we simply repeat the third paragraph:

“There could be **large public health and environmental consequences** under the No-Action Alternative if there were no effective institutional control, causing storage facilities and containers to deteriorate and radioactive contaminant from spent nuclear fuel to enter the environment. In such circumstances, there would be *widespread* contamination at the 72 commercial and 5 DOE sites across the United States, with resulting human health impacts.” (emphasis added.)

Anyone who attended the 21 public hearings certainly heard numerous public expressions of fear over the perceived harmful radiological effects of either the repository itself or transportation of waste to it. That testimony, while sincerely stated, was often unrelated to the information in the DEIS. The harmful effects of the No-Action Alternatives, though greater by orders of magnitude and more certain, drew less attention, even though the DEIS does provide demonstrable quantification of the aggregate risk. That may be because:

- DOE is not actually proposing to leave the waste in those 77 locations for 10,000 years, and

- No analysis was provided for the long-term effects in a specific or typical temporary storage site, nor was a public hearing held at such a location.

We share the conclusion of Section S.11. We would restate it ourselves that there is simply no comparison of the certain and far more harmful impacts of either of the No-Action Alternatives with the relatively minor and manageable impacts of the Proposed Action.

Response
As discussed in the Foreword, the purpose of the EIS is to provide information on the environmental impacts that could result from the Proposed Action, as well as a basis for comparison of the two No-Action scenarios. DOE has developed this information for the Secretary of Energy’s consideration, along with other factors required by the NWPA, in making a determination whether to recommend Yucca Mountain as the site for the Nation’s first monitored geologic repository.

For this reason, and in accordance with the National Environmental Policy Act process, DOE has presented this environmental information without conclusions as to the level of environmental impacts that could be acceptably small or unacceptably large. These are in essence policy decisions that would ultimately be made by the President and Congress, if necessary.

9.1 (6474)
Comment - EIS001632 / 0032
Page 3-142, Section 3.3.3: This section states that, "DOE calculated the river flow past each population center ... and used this number in the calculation to determine dose to the population." The final EIS should provide the dose calculation used.

Response
Appendix K of the EIS cites reference documents that include the details of the dose calculations. Information on these documents is available at DOE Reading Rooms and on the DOE Internet site (*http://www.ymp.gov*).

9.1 (6573)
Comment - EIS001632 / 0059
Page 7-38, end of the first partial paragraph: EPA appreciates that for comparison purposes and to avoid the appearance of bias toward the preferred alternative, "DOE did not want to overestimate the impacts from Scenario 2." However, the document should provide an estimate or a range of impacts for the reader.

Response
As is typical for deterministic analyses such as those performed to evaluate No-Action Scenarios 1 and 2, the EIS analysis used best estimate single-input values to produce a best estimate result. As is also typical with these analyses, a separate analysis (semi-quantitative) addressed the uncertainty associated with the input values and assumptions and provided an assessment of the effects these uncertainties could have on the model results (see Section K.4 of the EIS for details).

However, for Scenario 2 the analysis provided a range of best estimate impact values between regions for collective, as well as individual, impacts (see the tables in Section K.3.1 of the EIS). This was done to illustrate the importance of environmental transport human exposure (exposed population) parameters. Also under this scenario, a range of accident impacts was provided for high and low populations. Under Scenario 1, impact ranges were not developed because all collective and individual impacts were extrapolated from information provided by the Nuclear Regulatory Commission's environmental assessment of the Calvert Cliffs Independent Spent Fuel Storage Installation (DIRS 101898-NRC 1991).

As stated in Section K.4 of the EIS, DOE attempted to quantify a range of uncertainties associated with mathematical models and input data, and estimated the potential effect these uncertainties could have on collective human health impacts. By summing the uncertainties discussed in Sections K.4.1, K.4.2, and K.4.3 of the EIS where appropriate, DOE estimated that total collective impacts over 10,000 years could have been underestimated by as much as 3 or 4 orders of magnitude. However, because there are large uncertainties in the models used for quantifying the relationship between low doses (that is, less than 10 rem) and the accompanying health impacts, especially under conditions in which the majority of the populations would be exposed at a very low dose rate, the actual collective impact could be zero.

On the other hand, impacts to individuals (human intruders) who could move to the storage sites and live close to the degraded facilities could be severe. During the early period (200 to 400 years after the assumed loss of institutional control), acute exposures to external radiation from the spent nuclear fuel and high-level radioactive waste material could result in prompt fatalities. In addition, after a few thousand years onsite shallow aquifers could become contaminated to such a degree that consumption of water from these aquifers could result in severe adverse health effects, including premature death. Uncertainties associated with these localized impacts relate primarily to the inability to predict accurately how many individuals could be affected at each of the 77 sites over the 10,000-year analysis period. In addition, the uncertainties associated with localized impacts would exist for potential consequences resulting from unusual events, both manmade and natural. Therefore, as discussed in Section K.4 of the EIS, uncertainties resulting from future changes in natural phenomena and human behavior that cannot be predicted, process model uncertainties, and dose-effect relationships, when taken together, could result in overestimating or underestimating the impacts by as much as several orders of magnitude relative to the values listed in Section K.3.

9.1 (6680)
Comment - EIS001632 / 0082
Page 14-19, definition of "inadvertent intrusion": The word "unintended" needs to be inserted before "disturbance," i.e., "The unintended disturbance of a disposal facility..." As currently written, the definition would include purposeful intrusions.

Response
DOE agrees with this recommendation and has included this change in the EIS Glossary.

9.1 (6683)
Comment - EIS001632 / 0083
Page 14-19, definition of "institutional control": This definition should distinguish between "active institutional control," which requires the presence of humans to take actions to safeguard and repair the repository, and "passive institutional control," which also includes controls such as permanent markers and land records to warn future generations of dangers from the disposal site.

Response
In the EIS Glossary, DOE has modified the definition of institutional control to include the distinction between active and passive control.

9.1 (6695)
Comment - EIS001632 / 0088
Page K-7, Figure K-3: This map shows failure times for above-ground concrete storage modules. The no-action impact analysis looked at a 100-year time frame, yet Figure K-3 indicates that in some areas of the country, failure could be expected in less than 75 years and, in other areas, between 75-100 years. The final EIS should evaluate the premature failure potential for those areas of the country where such could be expected in less than 100 years.

Response
Both No-Action scenarios assume that the onsite storage facilities would remain under effective institutional control for the first 100 years. This means that they would be monitored and maintained with repairs being made as necessary to ensure the integrity of the dry storage canisters. DOE recognizes that the weather-protection structures (metal buildings for DOE below-grade storage vaults and reinforced concrete storage modules for commercial spent nuclear fuel), as currently constructed, would not likely remain intact for the 100-year institutional control period without major repairs. Therefore, the Department assumed that a major repair effort would occur 50 years into the 100-year period (see the figure in the introduction to Chapter 7 of the EIS). For purposes of analysis, DOE assumed this major repair effort to require 50 percent of the manpower and materials required to completely replace the facilities. Collective occupational radiation doses were estimated to be 72 and 118 person-rem for the Proposed Action and Module 1 scenarios, respectively (see DIRS 104596-Orthen 1999). Although not reported separately, these impacts have been included in the short-term (first 100 years) impacts for both scenarios, as discussed in Sections 7.2.1 and 7.3.2 of the EIS.

Although the analysis assumed that under institutional control the storage facilities would be maintained and repaired as necessary, Sections K.4.1.1 and K.4.3.1 of the EIS discuss the uncertainties associated with maintenance of institutional control and uncertainties associated with environmental degradation and corrosion rates along with their potential impacts on the reported results. As stated in Section K.4.1.1, premature failure of effective institutional controls could result in an earlier release of radioactive materials to the accessible environment. However, this scenario would probably increase overall impacts by no more than a factor of 2.

9.1 (6724)
Comment - EIS001878 / 0076
Limitation on scope of analysis inappropriate. Although the DEIS says that the same spectrum of environmental impacts was considered for the no-action alternative as for the proposed action, it also says (in the same paragraph) that DOE decided to focus the no-action analysis on the health and safety of workers and members of the public.

(p. 7-6) This limitation on the scope of the no-action analysis is inappropriate. It rules out any meaningful comparison with the impacts of the proposed action.

Also, the implication (p. 7-7) that the proposed action does not affect the 72 commercial and 5 DOE facilities and their surrounding environments, but the no-action alternative does, is not true. Obviously, both alternatives would result in environmental impacts at all the sites.

Response
As the commenter noted, DOE considered the same spectrum of impacts for the Proposed Action and the No-Action Alternative. In accordance with Council on Environmental Quality regulations [40 CFR 1501.7 (a)], as part of the scoping process DOE identified the important issues to be analyzed in detail in the EIS. In addition, the Department was able to identify and eliminate from detailed study the issues that were either unimportant or had been covered by prior environmental review (40 CFR 1506.3). Thus, DOE focused the discussion on what it believes are the important issues.

DOE then identified the environmental impact areas with potential impacts common to both the Proposed Action and the No-Action Alternative. These common areas (occupational, public health and safety, and hydrology) received detailed evaluation under the No-Action Alternative.

DOE recognized that there would be potential for environmental impacts at the generator sites as part of the Proposed Action. The principal impacts identified were those associated with the loading of the spent nuclear fuel and high-level radioactive waste at the generator sites, and those associated with accidents that could occur during the loading operations. Section 6.2.2 of the EIS discusses the results of the impact analysis for the loading operations at the generator sites (specifically, radiological impacts and impacts from industrial hazards). Section 6.2.4.1 discusses potential impacts from accidents occurring during loading operations at the generator sites.

9.1 (7192)
Comment - EIS001337 / 0083
Page 2-74 Section 2.4.1. The use of the word "small" to describe impacts is not consistent with NEPA [National Environmental Policy Act] terminology. Although DOE considers impacts to be small they may yet be significant. For example, a small absolute change might represent a 50 percent increase or decrease in given parameter. The DEIS must evaluate impacts and risks on the basis of their significance not their absolute value. Further, NEPA requires that impacts, even if "small", be mitigated.

Response
The Council on Environmental Quality regulations require consideration of all impacts (large and small) and of both "context" and "intensity" when assessing the significance of a proposed action (40 CFR 1508.27). Consistent with the regulations, DOE quantifies impact estimates in most cases. The regulations also require that EISs be written in plain language so that the widest audience can readily understand them. To be consistent with the regulations, the Department has used descriptive terms, such as "small," to help convey the relative impacts of various actions on the environment.

Moreover, consistent with these requirements and the standards established by the Nuclear Regulatory Commission (DIRS 101899-NRC 1996; DIRS 101900-NRC 1996), the Department has determined, in general, that "small" means potential environmental effects (with or without mitigation) that are not detectable or are so minor that they would neither destabilize nor noticeably alter any important attribute of the resource. For example, human health impacts that do not exceed permissible levels as defined in Federal or state regulations are generally considered small because adverse health effects would not be expected for exposure to these levels.

The Department is committed to identifying mitigation measures. Potential mitigation measures are discussed in Chapter 9 of the EIS. However, the commenter's assertion that the National Environmental Policy Act requires mitigation of impacts (large or small) is incorrect.

9.1 (7379)
Comment - EIS001832 / 0010
The Draft Environmental Impact Statement's evaluation of two No Action Alternative (NAA) scenarios adequately bounds the complete spectrum of no action possibilities.

DOE included the two No Action Alternative (NAA) "to provide a baseline for comparison with the Proposed Action." The comparison provided demonstrates the tremendous societal benefit associated with the proposed action as opposed to doing nothing. These two scenarios adequately describe both ends of the full spectrum of "no action" possibilities. The NAA scenarios are comprehensive in describing the cost and environmental and human health impacts of the no action possibilities. NAA 1 sets the lower bound on environmental and human health impacts and the upper bound on the potential costs for the NAA. NAA 2 sets the upper bound on the environmental and human health impacts and the lower bound on the potential costs for the NAA. The human health impacts of the proposed action are shown to be lower than the lowest possible health impacts of "no action" (NAA 1) and the cost impacts of the proposed action are shown to be lower than the least costly "no action" possibility (NAA 2).

As part of the public hearing process, we understand that DOE has received some criticism for not constructing more realistic NAA scenarios. At the heart of much of this criticism is the realization that, in reality, society is unlikely to actually chose to take no action and simply leave spent fuel where it is over the long term. If the repository at Yucca Mountain does not go forward, society will "take some action" to manage spent nuclear fuel. DOE has recognized this in stating, regarding NAA Scenario 1 and 2, that "neither scenario would be likely if there were a decision not to develop a repository at Yucca Mountain, however they are part of the EIS to provide a baseline for comparison to the Proposed Action." In providing a basis for comparison through a bounding analysis, it is not necessary for DOE to address the likelihood of any specific "no action" possibilities or to attempt to identify the most likely outcomes. Any effort to be more specific within these bounds would only yield results that contain some combination of the costs and human health effects postulated for the two bounding scenarios, the net result of which will inevitably be higher impacts than for the proposed repository.

A true "no action" alternative means that no actions are taken beyond what is currently being done at reactor and DOE sites to store spent nuclear fuel. To assume, for DOE's purposes herein, that some action would be taken on the part of utilities or DOE, would not be consistent with the "no action" alternative concept. In short, in the case of used nuclear fuel management, there is an irreconcilable conflict between undertaking "no action" and being realistic. Therefore, DOE's bounding approach is a sound, complete and effective way to address the "no action" concept.

Rather than conducting additional "no action" analyses, a more valuable perspective would be provided for the public and decision-makers if DOE were to relate the risks and impacts of Yucca Mountain to other real risks and impacts that society already accepts.

Response
DOE agrees that the two No-Action scenarios provide a range of cost, environmental, and human health impacts that could result from a decision to abandon plans for the proposed Yucca Mountain Repository and that additional effort to perform more specific analyses would likely yield similar results and not provide substantive additional information. However, because DOE did not want to overestimate potential impacts and influence a decision in favor of the repository, neither of the No-Action scenarios was developed to provide the most pessimistic outcome based on the assumptions. In addition, DOE believes that the two No-Action scenarios provide an adequate basis for comparison to the Proposed Action.

DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress, with the Department's recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository (Chapter 1 identifies the process and alternative sites previously selected by DOE for technical study as potential geologic repository locations), the development of new technologies (for example, transmutation), or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed in other contexts in other documents to varying degrees.

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios–long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

Discussions in the EIS relate the impacts from Yucca Mountain operations to other real risks and impacts that exist in society. Specific examples are the comparisons of radiological health impacts to workers and the public to the radiological impacts these same people receive from natural background radiation, to which they are continually exposed (see the last paragraph of Section 4.1.7 of the EIS). Another example is the discussion of fatalities from spent nuclear fuel and high-level radioactive waste shipping operations in relation to impacts from overall transportation activities (Section 6.2.4.2.2).

DOE has added a discussion of relative risks to Appendix F of the EIS, which includes a discussion of radiation and other common risk factors.

9.1 (7647)
Comment - EIS001912 / 0099
The no-action alternative provides more details about specific proposals than the action alternative does. Why?

Response
DOE believes that both the Proposed Action and the No-Action Alternative contain the level of detail appropriate for the evaluation of potential environmental impacts. Without further detail, DOE is unable to determine the precise nature of the commenter's concern.

9.1 (7981)
Comment - EIS001577 / 0003
The no action scenario number two is absolutely irresponsible but a highly likely scenario given the nature of the nuclear industry and the regulating community. It is important that the people of the United States, their government, the DOE and the commercial utilities not allow this scenario to develop in a de facto manner. We all have the responsibility to monitor their actions so as to not allow it to develop. Collectively, the world population and the more responsible governments of the world have a responsibility to prevent this scenario from developing within this country and elsewhere on our planet.

Response
DOE has stated that it believes that neither No-Action Alternative scenario is likely. Continued storage of high-level radioactive waste and spent nuclear fuel at existing sites could be required for some time in the future if the Yucca Mountain site was not approved for a geologic repository. However, if such events occurred, DOE, consistent with the NWPA [Section 113(c)(3)], would prepare a report to Congress with its recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Until Congress provides additional direction for future actions, under current regulations and DOE directives, commercial and DOE sites have an obligation to continue to manage

the spent nuclear fuel and high-level radioactive waste in a manner that protects public health and safety and the environment.

No-Action Scenario 2 does not assume that there would be a decision to halt institutional control after 100 years. Rather, for purposes of long-term analysis, this scenario assumes no effective institutional control after approximately 100 years. DOE based its choice of 100 years on a review of the generally applicable Environmental Protection Agency regulations for the disposal of spent nuclear fuel and high-level radioactive waste (40 CFR Part 191) and Public Health and Environmental Radiation Protection Standards for Yucca Mountain, Nevada (40 CFR Part 197); Nuclear Regulatory Commission regulations for the disposal of low-level radioactive material (10 CFR Part 61); and the National Research Council report on standards for the proposed Yucca Mountain Repository (DIRS 100018-National Research Council 1995), all of which generally discount the consideration of institutional control for longer periods in performance assessments for geologic repositories. The assumption of no effective institutional controls after 100 years provides a consistent analytical basis for comparing the No-Action Alternative and the Proposed Action.

9.1 (8027)
<u>Comment</u> - EIS000817 / 0071
"No Action Alternative" -- why don't you evaluate creating no more spent fuel? If Yucca Mountain were found inadequate, certainly it would be prudent to stop spent fuel creation. It only makes sense. Yet DOE evaluates "no effective institutional control after 100 years" -- why? Of what value is that? Certainly the waste would be controlled and certainly less waste would be easier to control. Why is the assumption that we have to create 70,000 MTHM valid? It should not be.

<u>Response</u>
The No-Action scenarios were constructed to provide a basis for comparison with the Proposed Action (Section 2.2 of the EIS). Under the Proposed Action, as discussed in Section 2.1, DOE would dispose of 70,000 metric tons of heavy metal in the repository. Therefore, the amount of spent nuclear fuel and high-level radioactive waste considered in the No-Action analysis is also 70,000 metric tons of heavy metal. DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress, with the Department's recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository (Chapter 1 identifies the process and alternative sites previously selected by DOE for technical study as potential geologic repository locations), the development of new technologies (for example, transmutation), or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed in other contexts in other documents to varying degrees.

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios–long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

Comment - EIS001023 / 0002
The Department of Energy claims that the commercial and Department of Energy sites would remain under effective institutional control for at least 10,000 years. I honestly cannot believe the pretentiousness of the claim.

Response
DOE recognizes that both No-Action scenarios are unlikely. However, the Department selected these scenarios because it did not want to speculate on future actions that Congress could take if there was no recommendation of Yucca Mountain as a repository. DOE selected these scenarios to provide a basis for comparison of impacts from the Proposed Action and to reflect a range of impacts that could occur.

Comment - EIS000817 / 0152
P. 7-16. What do you mean, “The No-Action Alternative assumes that the spent nuclear fuel and high level waste could be treated, packaged, and stored in a condition ready for shipment to a repository”? -- Do you mean it should all be in shipping casks? Then “storage only” casks should be unloaded and put in transport casks now. Not left on the pads. The concern is that we don’t know what to expect for sure when we open these casks in 20, 40 years. Can the fuel actually be transported after long term storage at a reactor? Maybe its “condition” will no longer allow it to travel on our roads and rails.

Response
The term “ready for shipment” means that the spent nuclear fuel and high-level radioactive waste would have been treated (in the case of high-level radioactive waste), processed (in the case of some DOE spent nuclear fuel), and packaged in a stable configuration in dry, stainless-steel storage canisters until it was time to transport them to a repository. Section 7.2 of the EIS describes these storage configurations. The No-Action Alternative assumes that the dry storage canisters would be loaded in shipping casks just before transport to the repository.

Licensed spent nuclear fuel dry storage systems are in operation at more than 10 nuclear powerplants across the United States, and are planned at others. The systems assumed for this analysis include stainless-steel canisters loaded with spent nuclear fuel in large structures designed to withstand environmental conditions for 40 years or longer without change in their safety and operational characteristics. With the exception of reductions in temperature and the radioactivity of the spent nuclear fuel over time, DOE does not expect that the storage canisters or their contents would change measurably. DOE assumes that the canisters could be handled and loaded directly into transportation casks – thus, in a condition ready for shipment.

Regarding knowledge necessary to handle and unload storage canisters after long-term storage, along with other information that must be provided to the Nuclear Regulatory Commission, licensees must demonstrate, as a condition of licensing, procedures they can use for handling, loading, and unloading the canisters. The Commission has addressed potential environmental impacts for dry storage systems (DIRS 147915-NRC 1991; DIRS 101899-NRC 1996) and concluded that long-term effects to nearby environments, including effects of direct radiation and skyshine (radiation scattered off air molecules), would be small. Nevertheless, to support their applications for licenses to store spent nuclear fuel, applicants must provide to the Commission technical information demonstrating that no gross degradation would occur while spent nuclear fuel is in storage.

Based on the information discussed above, DOE is confident that the integrity of spent nuclear fuel stored at commercial nuclear reactor sites for long periods would be satisfactory for transportation to a repository at Yucca Mountain and, if required, temporary storage prior to disposal.

9.1 (8488)
Comment - EIS000817 / 0154
P. 7-17. I’m not so very sure as you are that dry storage is the preferred answer. We may need to revert back to pools. The rosy picture you paint of dry storage safety, etc. may not prove to be accurate over time. Dry storage is only in its infancy. No utility has really had to deal with numerous full cask arrays on pads yet -- especially in bad weather. Surrey, I suppose, has the most. There are concerns about snow and ice at Trojan -- the VSC-24 [Ventilated Storage Cask, Model No. 24] was originally designed with a snow shield, but the shield blocked inlets too much, so the shield was eliminated. But snow can block inlets, and icicles can cover outlets (that happened once

at Pt. Beach and at Ft. St. Vrain). Imagine a blizzard and then melting icecaps on each cask in several pads full of casks -- those outlets and inlets need to be open. Outlets will not work as inlets if inlets are blocked. These are things to think about in the future too.

Are fuel rods, as you say, really “likely” to be environmentally “secure” for long periods of time? Is dry storage really “safe”? “Economical”? Is low level waste generated really “minimal”? Is dry storage really “simple” and “easy” to maintain? Better take a closer look at what really is happening with dry storage right now -- the repeated blunders cost money. Is having to UT [ultrasonically test] casks on the pad simple? Easy? No way. Think again. Dry cask storage could maybe be all those things -- but so far the track record is a mess. Make sure you know what NRC [Nuclear Regulatory Commission] is doing. What happens to that spent fuel at reactors now will affect the DOE program. You know it will, yet I think there is certainly not enough communication or interest in this issue between NRC, DOE, and NWTRB [Nuclear Waste Technical Review Board]. You have got to include dry cask storage issues at reactors now, and in the future, in your analysis. Look at reality. Studies predict -- they don’t tell you the actual situation. DOE needs to know what’s going on.

Response
At present, most commercial nuclear powerplant sites store their spent nuclear fuel in water-filled basins (fuel pools) at the reactors. However, because they have inadequate storage space, some of the sites have built independent spent fuel storage installations, in which they store spent nuclear fuel dry in above-ground metal casks or welded canisters inside reinforced concrete storage modules. Other commercial sites plan to build independent spent fuel storage installations so they can proceed with the decommissioning of their nuclear plants and termination of their operating licenses (for example, the Rancho Seco and Trojan plants). Because commercial sites could elect to continue operations until their fuel pools became full and then cease operations, the EIS analysis initially considered ongoing wet storage in existing fuel pools to be a potentially viable option for spent nuclear fuel storage. However, dry storage is almost certainly the preferred option among regulators and the industry for long-term spent nuclear fuel storage at commercial sites for the following reasons (see Section 7.2 of the EIS):

- Dry storage is a safe, economical method of storage.
- Fuel rods in dry storage are likely to be environmentally secure for long periods.
- Dry storage generates minimal, if any, low-level radioactive waste.
- Dry storage units are simpler and easier to maintain.

As licensees under 10 CFR Part 72, the commercial utilities are responsible for assuring that quality assurance programs (including vendor programs) and technical specifications comply with the site-specific license conditions. DOE believes that the most likely option for long-term storage at reactor sites would be dry storage and, thus, that is the scenario evaluated for the No-Action Alternative.

9.1 (8494)
Comment - EIS000817 / 0156
P. 7-28. The top paragraph is of interest -- DOE did not want to overestimate impacts from repackaging -- I don’t even know what you would base this on anyway as it hasn’t been done.

Response
In Section 7.2.1.7.3 of the EIS, DOE acknowledges that there is no experience on which to base an analysis of potential air quality impacts resulting from repackaging material removed from dry storage canisters. The Department did not want to speculate on the rate and extent of canister degradation because the rates are likely to be very site-specific. In addition, DOE did not want to overestimate the impacts for the No-Action scenarios. However, DOE believes that any impacts to air quality from repackaging are likely to be small.

9.1 (8608)
Comment - EIS001256 / 0007
The DEIS calculates the maximum potential dose from the underground testing inventory to be 0.2 millirem per year at 20 kilometers. (Section 8.3, page 8-76). We question how this dose was arrived at. How did the Yucca Mountain project get access to the underground testing radiological source term inventory, when the information is classified and not available yet to the UGTA [Underground Testing Area] program? Did you take each nuclear test

inventory separately or did you group the Pahute Mesa inventory together and take the summary? This calculation is inadequate because it seems to base on mostly speculation.

The DEIS states that no radioactive contamination attributable to underground tests has been detected in monitoring wells off the Nevada Test Site [NTS]. (Section 8.3, page 8-76). Absence of evidence is not evidence of absence. There is no state of the art monitoring system on or off the NTS, because no one has constructed one. This statement should be regarded as more of a belief and subject to change as more data is collected over the next decade.

It is highly likely that underground test contamination is past the NTS boundary, because that is exactly what personnel from the DOE UGTA program said at a Community Advisory Board meeting almost four years ago in June 1996. The phenomenon of prompt injection has probably blown the radionuclides past the NTS boundary, in a manner similar to the way it probably blew Europium 0.8 miles at Benham with a colloidal boost. DOE cannot afford to prove or disprove that contamination is past the NTS boundary, but Yucca Mountain could fund a well program to help make this statement more factual.

Response
In 1996, DOE published the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996). This document provided an estimate of the underground testing radionuclide source term that is the best available, unclassified, source-term information currently available. This data was used in a simplified calculation to provide a reasonably conservative estimate of potential long-term cumulative impacts resulting from the underground testing activities at the Nevada Test Site. Because of ongoing studies and the current uncertainty surrounding groundwater transport models, the Department did not attempt to estimate actual groundwater transport characteristics for the Nevada Test Site. Rather, the estimates of potential Nevada Test Site groundwater impacts provided in Section 8.3 of the Draft EIS were based simply on the ratio of inventories of radionuclides available for transport at the repository and the Nevada Test Site.

For the Final EIS, the Department has refined the Nevada Test Site groundwater impact analysis to consider not only the total inventories of radionuclides but also the relative source-term radionuclide concentrations and dilution factors for the repository and the Nevada Test Site. However, because of the large uncertainties remaining, the refined analysis did not attempt to model actual groundwater transport at the Nevada Test Site. Instead, the refined analysis assumed that the radionuclide constituents in the groundwater at the Nevada Test Site would be transported in an identical manner to those from the repository (that is, the repository groundwater transport model was applied to the Nevada Test Site source term). In doing so, the Department believes that the resulting estimates of the potential cumulative impacts from underground testing activities at the Nevada Test Site represent a reasonable upper bound of the actual impacts.

With regard to the commenter's concern about the adequacy of the Nevada Test Site Underground Testing Area groundwater characterization program, DOE continues to evaluate, outside of this EIS, the extent of contamination due to past underground testing and refine the monitoring network based on the results of this evaluation. This will provide a better understanding of the current distribution and extent of contaminated groundwater as well as the transport characteristics (including colloidal behavior) of the unsaturated soils and underlying aquifers. As new information becomes available, the Department will update impact estimates as appropriate.

Comment - EIS000817 / 0196
P. K-25. The freeze-thaw cycle effect on dry cask storage needs more evaluation. We have been concerned about it for years.

Response
While the freeze-thaw cycle is a potential concern for the longevity of dry storage casks made of reinforced concrete and exposed to the elements, there would be no effect on the contents of the casks because they would be dry and emit large amounts of heat. Thus the casks would not experience the freezing and thawing. Nevertheless, the cladding integrity of spent nuclear fuel in these types of storage environments is being and would continue to be evaluated.

9.1 (8882)
Comment - EIS001834 / 0023
The “No-Action Alternative” is unrealistic and does not provide a baseline to which the proposed action can be compared. This section should either be entirely deleted from the DEIS, or a real no-action alternative should be described.

The “No-Action” alternative presented is not truly a no-action scenario. It would require action by the federal government to take control of the nuclear waste on the reactor sites and monitor it for at least one hundred years. The true no-action alternative would be to require the utilities to be responsible for safe storage of the waste on the reactor sites until an alternate sound solution is discovered. Although this scenario would raise some safety and environment concerns, it would be a truly “no-action” alternative, and would provide a better comparison model than the scenarios currently described in the DEIS.

Further, it would be possible for the DOE to propose other alternatives that would not be “no-action” alternatives (i.e., other actions). It is clear that the DOE is legally prohibited from looking at other repository sites, but it is not prohibited from looking at alternatives to repository sites. Although Public Citizen does not currently endorse any proposals currently in circulation, we do support continued research in this area and focused efforts to find a true solution.

Response
DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress, with the Department’s recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository (Chapter 1 identifies the process and alternative sites previously selected by DOE for technical study as potential geologic repository locations), the development of new technologies (for example, transmutation), or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed in other contexts in other documents to varying degrees.

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios–long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

Based on regulations and directives that govern the safe and secure storage of spent nuclear fuel and high-level radioactive waste, under the No-Action Alternative commercial utilities and DOE sites would have to continue to manage these materials in a manner that protects public health and safety and the environment (that is, maintain the status quo). This is the assumption DOE used to evaluate Scenario 1 and the first 100 years of Scenario 2.

The NWPA directs DOE to perform detailed evaluations of the Yucca Mountain site and states that the Department need not consider alternatives to a Yucca Mountain Repository [Section 114 (f)(2)]. However, if the site was not approved, DOE would not proceed with development activities at Yucca Mountain. Rather, as directed by the NWPA [Section 113(c)(3)], the Department would prepare a report to Congress with its recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority.

Comment - EIS001971 / 0005
OTHER PROBLEMATIC ASSUMPTIONS (appendix K, & section 7): The structure of the analysis of the no-action alternative is built upon a series of hypothetical 'assumptions' for 'consistency' or 'purpose of analysis'. While this is an understandable strategy, it cannot be used to entirely evade analysis of the situation that the no-action alternative would actually create, which is 72 de-facto, at reactor storage sites with high exposures to water and people for an indeterminate period of time. Nor is it likely that other assumptions of the no-action analysis will be met (e.g.) "1) that the spent fuel and high level radioactive waste would be treated, packaged and stored in a condition ready for shipment to a repository" and that 2) a double barrier of cask and concrete storage module.

Response
DOE recognizes that the No-Action Alternative does not represent actual conditions at each of the 77 sites, but believes that the two scenarios present a range of impacts that could occur and represent an adequate basis for comparison to the impacts of the Proposed Action.

The No-Action Alternative analysis evaluated environmental impacts for the 77 sites based on National Environmental Policy Act documents prepared by DOE and the Nuclear Regulatory Commission that describe site-specific and "typical" storage configurations for facilities in operation or planned for the near future (DIRS 101898-NRC 1991; DIRS 101899-NRC 1996; DIRS 103191-DOE 1994; DIRS 103214-DOE 1996; DIRS 101802-DOE 1995; DIRS 155929-Jason 1999).

These documents, in addition to describing likely storage configurations (which DOE used to evaluate the No-Action Alternative), evaluated and discussed environmental impacts associated with stabilizing waste materials in preparation for onsite storage. In most cases, the stabilized waste forms are "road ready." Therefore, in accordance with Council on Environmental Quality regulations (40 CFR 1502.20 and 1502.21), DOE decided not to include impacts from stabilization of waste forms except by reference.

This dual-barrier concrete storage modular design is currently licensed by the Nuclear Regulatory Commission and employed at several sites.

9.1 (9229)
Comment - EIS001971 / 0006
The assumption that 10,000 years of institutional control is even a possibility is vain and vacuous; the D.E.I.S. does not even attempt to explain how it might be possible. And an analysis where "the long term impact analysis used recent climate and meteorological data, assuming they would remain constant throughout the evaluation period," is completely incredible. The D.E.I.S. offers this rejoinder:

"DOE recognizes that there could be considerable changes in the climate over 10,000 years (precipitation patterns, ice ages, global warming, etc.) but, to simplify the analysis, did not attempt to quantify climate changes" (at K-3)

Response
DOE recognizes that both No-Action scenarios are unlikely, just as losing effective institutional control after 100 years is unlikely (Section 2.2 and the introduction to Chapter 7 of the EIS). The Department selected these scenarios because it did not want to speculate on future actions that Congress could take if there was no recommendation of Yucca Mountain as a repository and because predicting a date for loss of institutional control would be speculative. The Nuclear Regulatory Commission and the Environmental Protection Agency have recognized this fact and, although they encourage the maintenance of monitoring and physical oversight for as long as possible, they recognize that projecting society's willingness and ability to provide such a function for more than 100 years into the future is not reasonable (see 40 CFR Part 197 and 10 CFR Part 63).

DOE selected these scenarios to provide a basis for comparison of impacts from the Proposed Action and to reflect a range of impacts that could occur. DOE does not believe either scenario is likely to occur. Scenario 1, which includes an analysis of impacts under effective institutional control for at least 10,000 years, is consistent with the portion of the analysis of the Proposed Action that includes an analysis of effective institutional control for the first 100 years after closure. Scenario 2, in which the analysis does not consider effective institutional control after approximately 100 years, is parallel to the portion of the Proposed Action analysis in which long-term performance after 100 years does not include effective institutional control.

For consistency with the repository analysis in the *Viability Assessment for a Repository at Yucca Mountain* (DIRS 101779-DOE 1998), the No-Action Alternative assumed constant climatology during the 10,000-year analysis period. This is consistent with climate studies that show the Yucca Mountain area is at most 35,000 years into a fluctuation between a cold glacial climate and a warm interglacial climate (similar to the present), which occurs about every 100,000 years (DIRS 101779-DOE 1998). DOE discusses the difficulties of modeling these changes and the potential effect on outcomes resulting from uncertainties associated with predicting future climatic conditions in Section K.4.1.2 of the EIS.

9.1 (9284)
Comment - EIS001971 / 0017
As the 'test of common sense' illustrates, the most difficult aspect of trying to respond formally to the no-action alternative in the context of the draft E.I.S for Yucca Mountain is that it really does not 'make sense.' The conclusion of 'no impact' for the no-action alternative simply eluded my most tenacious attempts to understand the process by which this conclusion was reached. Internal contradictions are fundamental; assumptions evade both the current reality of the no-action alternative and the very scenarios that are posited by the alternative.

The 'belief' of the drafters of the E.I.S., given to frame the no-action alternative, is perhaps the most problematic of all: that neither of the no-action alternatives is likely to happen. From the perspective of those of us living in the vicinity of ad hoc interim at-reactor-site storage, which would become defacto permanent storage under either an official no-action alternative or simply by continued failure on the part of DOE to fulfill its contract, this 'belief' is nonsense. It makes sense ONLY if the structure of the no-action alternative is entirely disingenuous: if what the drafters mean is that it is not likely that a 100 year storage period will be without institutional oversight, and that institutional oversight throughout a 10,000 year period is not likely. This would, of course, be true. But then, the whole structure of the alternative would have been set up to undermine itself. I do not choose to 'believe' that this was the intention – even if it was. I prefer to attribute the disjunction to the human capacity for denial – which has proved to be one of the most abiding factors of nuclear waste policy and politics. This is the fundamental dynamic that we must change.

Response
DOE prepared the EIS to provide information on environmental impacts that could result from the Proposed Action and a basis for comparison in the two No-Action scenarios. As such, the EIS provides estimates of environmental impacts without conclusions on their significance (that is, the EIS has not concluded that the No-Action Alternative would result in "no impacts"). In fact, the EIS presents local impact estimates under Scenario 2 that many would consider quite severe (see Section K.3.1 of the EIS).

DOE believes that both No-Action scenarios are unlikely as a permanent solution even though continued onsite storage of spent nuclear fuel and high-level radioactive waste would be necessary for some time if the site was not approved. If the Secretary of Energy did not recommend Yucca Mountain as a repository, DOE would, in accordance with the NWPA [Section 113(c)(3)], prepare a report to Congress, with the Department's recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository, the development of new technologies, or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed to varying degrees in other contexts in other documents (see the introduction to Chapter 7).

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios – long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years, and long-term storage with no effective institutional control after about 100 years. Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

9.1 (9321)
Comment - EIS001888 / 0051
EIS Statement (pg. 2-65) 2.2.2.2 - In No-Action Scenario 1, DOE would continue to manage its spent nuclear fuel and high-level radioactive waste in above- or-below-grade dry storage facilities at five sites around the country. Commercial utilities would continue to manage their spent nuclear fuel at 72 sites. The commercial and DOE sites would remain under effective institutional control for at least 10,000 years. DOE based the 10,000-year analysis period on the generally applicable Environmental Protection Agency regulation for the disposal of spent fuel and high-level radioactive waste (40 CFR Part 191), even though the regulation would not apply to disposal at Yucca Mountain.

Clark County Comment - This alternative is not authentic since it posits that institutional controls would remain for 10,000 years at 77 facilities that currently store spent fuel. DOE's alternative for institutional controls should be reasonably comparable. It is not reasonable to compare relaxed standards of the Nuclear Waste Policy Act with a more restricted national standard. Further, under this scenario, storage facilities would be completely replaced every 100 years. This artificially distorts the cost of a "realistic" on site storage for an interim period of 20-50 years while a fair search for an appropriate disposal solution is sought. Further, HLW [high-level radioactive waste] at DOE facilities throughout the country are the responsibility, in perpetuity, of the DOE. Replacement of buildings at these facilities should not be factored into the costs of the No-Action alternative. The spirit of NEPA [National Environmental Policy Act] requires the formulation of realistic scenarios in order to identify alternatives, impacts and potential mitigation strategies. The DEIS fails to meet the spirit and letter of NEPA in this regard. NEPA Regulation: Sec. 1502.14 Alternatives including the proposed action; Sec. 1502.16 Environmental consequences.

Response
DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress, with the Department's recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository (Chapter 1 identifies the process and alternative sites previously selected by DOE for technical study as potential geologic repository locations), the development of new technologies (for example, transmutation), or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed in other contexts in other documents to varying degrees.

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios – long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

DOE also believes that any additional effort to perform more specific analyses probably would yield results that contain some combination of the costs and human health effects postulated for the two scenarios evaluated in the EIS and, therefore, would not provide substantive additional information for the decisionmakers.

DOE also believes that the assumptions made about facility replacement every 100 years could, if anything, underestimate the costs because current Nuclear Regulatory Commission regulations (10 CFR Part 72) allow only a 20-year license period for independent spent fuel storage installations.

DOE does not understand the reference to comparison of "relaxed standards of the Nuclear Waste Policy Act with a more restricted national standard." DOE believes that the NWPA and regulatory standards issued by the Environmental Protection Agency and Nuclear Regulatory Commission (40 CFR Part 197 and 10 CFR Part 63, respectively) are at least equivalent to and in many ways more demanding than current standards for independent spent fuel storage installations. In addition, DOE notes that 40 CFR Part 197 specifies a 10,000-year compliance period.

Comment - EIS002149 / 0006
In the no action alternative, there's been a lot of talk about how well, we can't keep the stuff on-site because of all the potential dangers with on-site storage, which -- the on-site no action alternative in this document is -- is not very well addressed, and one of the issues that keeps coming up is oh, there's all this problem with flooding. I looked in this thing and I looked in volume 2 and I didn't really see a flood analysis in there, and I would be happy if you want to point it out to me if it's in there. So if it's such a big problem, then explain how it's a big problem, why it's going to be such a big problem to have on-site storage in areas which are relatively near to water, to water facilities, which is what one of the big arguments I've been hearing. So I'd like to see that addressed in this document, as well.

Response
Chapter 7 of the EIS provides quantitative estimates of environmental impacts from two No-Action scenarios without conclusions as to their significance. In Scenario 1, the spent nuclear fuel and high-level radioactive waste would be maintained for at least 10,000 years. The environmental impacts associated with this scenario would be predominantly to workers associated with ongoing monitoring and maintenance of the storage facilities. The analysis assumed that the storage facilities would be built at existing nuclear facility sites, where flooding is not an issue.

In Scenario 2, the storage facilities would again be at existing nuclear facility sites, but there would be no institutional control (ongoing monitoring and maintenance) after 100 years. As the concrete storage facilities, storage canisters, and spent nuclear fuel and high-level radioactive waste materials deteriorated, contaminants would enter surface waters from stormwater runoff from failed facilities and storage containers and exposed radioactive materials. Sections 2.2.2, 7.2.1, and 7.2.2 of the EIS describe the scenarios further. DOE is unaware of any implication of flooding as an issue for the No-Action scenarios unless the reference is to eventual widespread contamination of surface-water bodies from the stormwater runoff mentioned above.

Comment - EIS001888 / 0339
[Clark County summary of comments it has received from the public.]

The No Action Alternative should include activities in addition to stopping work at Yucca Mountain and Continued storage of SNF [spent nuclear fuel] and HLW [high-level radioactive waste] at the generator sites. Other activities to be evaluated include: (1) long term storage and maintenance of SNF and HLW (also Greater than Class C), (2) the development and use of dry cask storage, (3) phaseout and replacement of nuclear power with alternative sources, (4) all SNF and HLW (not limited to 70,000 MTHM [metric tons of heavy metal]), and (5) site-specific activities (e.g., closure dates, handling options, onsite storage, SNF/HLW inventory). Several commenters stated that the No Action Alternative should not include discussions of the future of the nuclear energy industry, including future construction and operation. Some commenters stated that the No Action Alternative must be part of the EIS, while other commenters stated that the No Action Alternative should not be part of the EIS because it was not part of Congress's intent. One commenter stated that the No Action Alternative should be the only alternative evaluated in the EIS.

Response

Responses to the various points in this comment are numbered in accordance with the numbers in the comment.

Items 1 and 4. Section 7.3.2 of the EIS evaluates continued storage at the 77 existing sites of all spent nuclear fuel and high-level radioactive waste (called Inventory Module 1; see Table 7-9 in Section 7.3). Section 7.3.2 describes short- and long-term impacts at commercial and DOE sites. DOE has not included Module 2 in its consideration of potential impacts under the No-Action Alternative because not enough information about Module 2 wastes is available to enable a meaningful analysis. For example, materials such as sealed radioactive sources, calibration, medical, and well-logging sources are used and stored by private industry at hundreds of locations in the United States (DIRS 101798-DOE 1994). Environmental information at the hundreds of sites at which Greater-Than-Class-C and Special-Performance-Assessment-Required low-level radioactive wastes are used and stored is not readily available. Although specific analysis is not possible, DOE believes short-term impacts such as those to socioeconomics and land use would not increase appreciably, but health effects could increase over the long term because workers and the public could be exposed to these waste types.

Item 2. Regarding the development and use of dry cask storage at the 72 commercial storage sites, DOE points to the Nuclear Regulatory Commission's findings in its *Generic Environmental Impact Statement for License Renewal of Nuclear Plants* (DIRS 101899-NRC 1996). The Commission stated: "Within the context of a license renewal review and determination, the Commission finds that there is ample basis to conclude that continued storage of existing spent fuel and storage of spent fuel generated during the license renewal period can be accomplished safely and without significant environmental impacts." Although applicable only to the continued storage of spent nuclear fuel generated up to and through the 20-year license renewal period for the nuclear powerplants, DOE believes the conclusions remain valid for much longer periods assuming that current institutional controls and regulatory frameworks (for example, 10 CFR Part 72) continue. Dry cask storage is and will continue to be an option for nuclear utilities to safely manage spent nuclear fuel until ultimate disposal.

Item 3. Speculation regarding the phaseout of nuclear power and replacement with alternative energy sources is beyond the scope of this EIS. DOE has revised the introduction to Chapter 7 of the EIS to discuss some of the potential impacts that could result from the phaseout of nuclear powerplants. This section also identifies the actions required of DOE by the NWPA to determine alternative means to ensure safe, permanent disposal of spent nuclear fuel and high-level radioactive waste if a decision was made not to proceed with the development of a repository at Yucca Mountain. The NWPA does not contain provisions concerning any phaseout of nuclear power.

Item 5. Section 2.2 of the EIS describes the No-Action Alternative and rationale for selection of scenarios for analysis. Chapter 7 and Appendix K contain the details of the analysis and results.

9.1 (10124)

Comment - EIS001295 / 0005

Section 7.2.1.13 on environmental justice effects of the so called "no-action" scenario is also severely lacking in attention to the justice issues which are involved in NOT moving this waste. If Yucca Mountain is not used, yet the DOE requires that the waste be moved away from the sites where it has been generated, someone, somewhere will have to become the new, probably unwilling host to an HLRW [high-level radioactive waste] disposal facility. The "no-action" scenario #1 attributes no positive aspect to the justice exhibited when those communities which have been responsible for creating the waste are the same communities which stand guard over the waste into the foreseeable future and beyond.

No positive aspect of the "no-action" scenario #1 is attributed to the salvation of possible transportation accidents, unplanned exposures, diminished land values along transportation routes and the most unfortunate ruining of the Yucca Mountain location and surrounding urban areas at Las Vegas, Los Angeles and elsewhere by the placement of this waste there. The negative impacts in terms of environmental justice issues are much greater in fact if the waste is removed from where it is currently located, shipped through urban, often poor communities next to railroad tracks and highways, and dumped into a hole out back on the Indian reservation as planned at Yucca Mountain. The "no-action" scenario #2 is absolutely irresponsible, but a highly likely scenario given the nature of the nuclear industry and the regulating community. It is important that the people of the United States, their government, the DOE and the commercial utilities not allow this scenario to develop in a de facto manner. We all have a responsibility to monitor their actions so as not to allow it to develop. Collectively, the world population and the more responsible governments of the world have a responsibility to prevent this scenario from developing within this country and elsewhere on our planet.

Section 7.3.2.7 claims that the employment of personnel involved with construction and maintenance of 77 facilities is the only contributing factor in socioeconomic impacts due to on site storage. I would comment that the potential of collective public responsibility for the safeguarding of these wastes for the time period considered would allow the creation of much greater socioeconomic impact. Participation in the activity of oversight, construction and maintenance of the storage facilities beyond the previously mentioned 100-year planned obsolescence, the possibility of tourism and pilgrimages; and educational and interpretational opportunities to understand and contemplate the profoundly deep social and economic commitment that human ancestors made to nuclear technology and the ongoing efforts of current generations to keep its waste products from contaminating the planet could have enormous social, economic and political impacts which are not even alluded to in the DEIS. Furthermore, the actual economic impact of the "no action" scenario #2 (basically ignoring the problem and burying the waste onsite) is not elaborated upon, and would include immediate short term economic benefit to the DOE, the public and the commercial utilities - this aspect of the problem, the potential unprofitability of dealing with this waste, contributes to the notion that Yucca Mountain is the only answer, because the utilities and waste handling contractors are already lined up at the trough like pigs. To address this waste problem involves huge economic subsidies by the people through their government, which would employ at great expense large nuclear industry contractors to hire low-cost workforces who would then build railroads, drive trucks and engineer casks and carriages and shuffle the waste around the country. The potential for local economic development in finding ways to collectively and democratically secure and isolate these wastes well into the future is great, yet the DEIS fails completely to explore it.

In summary, I do not think that the two scenarios for so-called "no action" are at all similar, and are not developed adequately to fully understand what the impact of long-term population-wide maintenance of the isolation of these wastes mean. I think that this failure to create a reasonable scenario for long term on site storage allows no adequate comparison to the environmental impact of transportation and storage of this waste at Yucca Mountain and I would request that more investigation be done on the possibility of long-term on site or near on site storage where the population as a whole is involved in the process of maintaining the isolation of these wastes from the environment.

Response

DOE does not believe that this alternative would result in beneficial impacts to the Nation as a whole. On the contrary, the No-Action Alternative would have potentially severe detrimental environmental consequences.

The National Environmental Policy Act process defines the No-Action Alternative as providing a benchmark, enabling decisionmakers to compare the magnitude of environmental effects on the action alternatives ["Forty Most Asked Questions Concerning National Environmental Policy Act Regulations" (46 *FR* 18026, March 21, 1981), Question and Answer No. 3]. The Council on Environmental Quality defines the No-Action Alternative as "no change" from current direction (that is, conditions that would result if the Proposed Action did not happen). Using the example of nationwide transportation, the No-Action impact assessment would compare potential transportation impacts (adverse or beneficial) to existing impacts. Because no transportation activities are under way related to the disposal of spent nuclear fuel and high-level radioactive waste and the No-Action Alternative assumed no transportation would occur, the net transportation impacts associated with the No-Action Alternative would be zero. The analysis captured transportation impacts for the Proposed Action by comparing them to the benchmark provided by the No-Action Alternative (that is, zero). Chapter 6 of the EIS discusses transportation impacts from the Proposed Action.

DOE believes that both No-Action scenarios are unlikely, even though continued onsite storage of high-level radioactive waste and spent nuclear fuel would be necessary for some time if the Yucca Mountain site was not approved. If DOE did not recommend Yucca Mountain, it would, as directed by the NWPA [Section 113(c)(3)], prepare a report to Congress with its recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority.

As noted by the comment, DOE estimated the workforce impacts associated with the No-Action Alternative. This estimate included construction, oversight, and maintenance activities. On the other hand, the Department cannot speculate on the possible role of generator sites as tourism or educational destinations. Commercial utilities, as nuclear plant operators under Nuclear Regulatory Commission regulations, determine the scope of public outreach and interpretive programs provided at their nuclear facilities. DOE believes that this level of activity does not provide discriminating information for the decisionmakers.

The costs associated with the Proposed Action would be greater during the first 100 years; the ongoing costs associated with continued storage under Scenario 1 would be far greater. Most of the funding for repository investigation and development comes from ratepayers who benefit directly from the use of nuclear power. In addition, ratepayers would fund continued storage of spent nuclear fuel at generator sites. The EIS analysis assumed that facilities would require replacement every 100 years, and that there would be a major facility repair halfway through the first 100-year cycle. Under Scenario 2, the projected economic impacts would be the same as those for Scenario 1 for the first 100 years, but after that approximately 800 jobs would be lost.

9.1 (10431)
Comment - EIS001927 / 0036
How about the "No Action Alternative" of phasing out nuclear power?

Response
In accordance with the NWPA, the EIS evaluates the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at the proposed Yucca Mountain Repository. The No-Action Alternative evaluated in the EIS is continued storage of spent nuclear fuel and high-level radioactive waste at generator sites, or maintenance of the status quo.

Speculation on the phaseout of nuclear power and replacement with alternative energy sources is beyond the scope of this EIS. DOE has revised the introduction to Chapter 7 of the EIS to discuss some of the potential impacts that could result from the phaseout of nuclear powerplants. This section also identifies the actions required of DOE by the NWPA to determine alternative means to ensure safe, permanent disposal of spent nuclear fuel and high-level radioactive waste if a decision was made not to proceed with the development of a repository at Yucca Mountain. The NWPA does not contain provisions concerning any phaseout of nuclear power.

9.1 (10662)
Comment - EIS001966 / 0002
In the No Action Alternative section, there is the statement that the drafters of the EIS do not believe either of the No Action Alternatives are likely to happen. However, the drafters give no reasons for this assumption. If this assumption is going to be made, it must be substantiated. In my opinion, this is the most likely event because thus far, there has been no DOE action and Secretary Richardson has recommended that the DOE take title on site, relieving the federal government of its duty and relieving the utilities of their potential liability.

Response
DOE analyzed the No-Action Alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. Under the No-Action Alternative, and consistent with the NWPA, DOE would terminate activities at Yucca Mountain and undertake site reclamation to mitigate any significant adverse environmental impacts. In addition, DOE would prepare a report to Congress, with the Department's recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Under any future course that would include continued storage at the generator sites, commercial utilities and DOE would have to continue managing spent nuclear fuel and high-level radioactive waste in a manner that protected public health and safety and the environment. However, the future course that Congress, DOE, and the commercial utilities would take if Yucca Mountain was not approved is uncertain.

DOE recognizes that a number of possibilities could be pursued, including continued storage of spent nuclear fuel and high-level radioactive waste at existing sites and/or one or more centralized locations, study and selection of another location for a deep geologic repository (Chapter 1 identifies the process and alternative sites previously selected by DOE for technical study as potential repository locations), the development of new technologies (for example, transmutation), or reconsideration of alternatives to geologic disposal. The environmental considerations of these possibilities have been analyzed in other contexts in other documents to varying degrees.

In light of these uncertainties, DOE decided to illustrate the possibilities by focusing the analysis of the No-Action Alternative on the potential impacts of two scenarios–long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no effective institutional control after about 100 years (Scenario 2). Although the Department agrees that neither of these scenarios is likely, it selected them for analysis because they provide a basis for comparison to the impacts of the Proposed Action and because they reflect a range of the impacts that could occur.

9.1 (10669)
Comment - EIS001966 / 0009
Because the siting guidelines require consideration of many factors in siting a repository, including natural resources, hydrology, geophysics, seismic activity, population characteristics, socioeconomic factors, and transportation, under NEPA these specific factors must also be considered in the "No Action Alternative," where on-site storage at nuclear generation plants is said to be an Alternative.

Response
Although the same degree of rigor was not comparable for all areas of environmental impacts, the same spectrum of impacts was considered for the Proposed Action and the No-Action Alternative. In accordance with Council on Environmental Quality regulations [Section 1501.7(a)], as part of the scoping process DOE identified the significant issues to be analyzed in detail in the EIS. DOE was also able to identify and eliminate from detailed study the issues that were not significant or that have been covered by prior environmental review (Section 1506.3). In doing so, it narrowed the discussion of these issues in the EIS to a qualitative or semi-quantitative presentation, including a statement of why they would not be expected to adversely affect the human environment.

DOE then identified the environmental impact areas associated with important issues that were common to both the Proposed Action and the No-Action Alternative. These common areas (occupational and public health and safety, and hydrology) received detailed evaluation under the No-Action Alternative.

9.1 (11152)
Comment - EIS000278 / 0002
The DEIS evaluates two scenarios of what is called the no-action alternative, which it says provides a baseline for comparison with proposed action. In both scenarios, storing waste at the plant sites for 10,000 years, scenario one; and storing waste at the plant sites for 100 years, scenario two, the spent fuel remains at the plant sites. Currently more than 38,500 metric tons of uranium are stored on site at 72 commercial nuclear power plants in 36 states. Additional high-level radioactive waste is stored at five DOE sites. In scenario one, the waste remains at the current sites under institutional controls for 10,000 years with repackaging approximately every 100 years. Nearly five trillion dollars would be required for canister replacement. According to the cost estimates in the DEIS, this scenario is double the cost of storing the waste on site for 100 years under institutional controls, scenario two. In human terms, an additional three latent cancer deaths would occur in the exposed population and 28 additional latent cancer deaths in the population of on-site workers. This is substantially more radiation-related cancer deaths than occur if the repository is completed in the Yucca Mountain site.

Scenario two is not as financially burdensome. Waste remains at the plant sites under institutional controls for only 100 years, but the waste still remains at the plant sites for 10,000 years. For the first 100 years, the costs of scenario one and two are the same. However, the number of people who would be affected by the migration of radioactive materials is far greater. In scenario two, additional latent cancer deaths in the exposed population increase to 3,300 with 12 additional latent cancer deaths in the on-site worker population. Such high numbers of latent cancer deaths are unacceptable.

Response
This comment accurately summarizes the estimated impacts for the No-Action Alternative. The Secretary will consider all information, including the estimated number of latent cancer fatalities, for both the Proposed Action and the No-Acton Alternative in determining whether to recommend the Yucca Mountain site to the President for further development.

9.1 (11607)
Comment - EIS001654 / 0037
Page S-66. Table S-1 Needs More Clarity of the Meaning of the Data it Displays

Just as we felt the major findings of the EIS in S.11 needed more emphasis, Table S-1 needs some improvement because it is the summary display of the supporting evidence that led to the findings.

For example, the impact on hydrology for the Scenario 2 is more than just "Potential for radiological contamination of groundwater around 72 commercial and 5 DOE sites." Is it not a certainty that there will be contamination in that scenario if the spent fuel and other waste are left unmanaged over the 9,900 years after institutional controls no longer exist?

We find some difficulty (and assume others do) in interpreting the data displayed to represent the long-term consequences in occupational health and safety for the Proposed Action and the Scenario 2 No-Action Alternative. The Latent Cancer Fatalities (LCF) for the Maximally Exposed Individual (MEI) and population are 4.4×10^{-5} and 5.3×10^{-4} for the Proposed Action compared to death within a few months for MEI and a population of 3,300 for Scenario 2 with a footnote that "downstream exposed population of approximately 3.9 *billion* over 10,0.90 years." (emphasis added) We conclude that there is a very slight radiological risk over 10,000 years under the Proposed Action. That compares with thousands of deaths with No-Action Scenario 2 and billions of people potentially exposed "downstream." If we have interpreted that even correctly, it should be presented more boldly in the Summary. If we have drawn an incorrect conclusion, then maybe others will and the table should be revised to prevent misinterpretation.

Response
DOE believes that contamination would probably occur at most of the 77 sites if they were left unmanaged for 9,900 years. However, excluding possible damage from manmade external events or severe natural phenomena, the Department's evaluations of environmental concrete degradation for some regions of the United States predict that the above-ground storage modules could maintain their integrity longer than 10,000 years, thus preventing the release of radioactive material to the accessible environment during the period of evaluation.

Regarding the presentation of the latent cancer fatalities in Table S-1 in Section S.11.1 of the EIS, the Department believes the presentation is sufficient and has made no related changes to the table.

9.1 (12711)
Comment - EIS001337 / 0084
Page 2-75 Table 2-7 [Section 2.4.1]. This table should be revised to include a comparison of the population likely to accrue the risks associated with the No Action and Preferred alternatives. For example, what is the number of persons potentially exposed to risks associated with the No Action Alternative (ie., population near on-site storage and transportation routes). This information would be helpful in evaluating the extent to which the alternatives tend to concentrate risks among persons exposed to them. This concentration of risk is an important impact, which must be considered for mitigation or compensation.

Page 2-76 Table 2-7. Under No Action Alternative estimates of Radiological Latent Cancer Fatalities why is not a range of estimates given similar to estimates for the Preferred Alternative. Absent a range, does this imply a lack of uncertainty in the estimates under the No Action alternative, which is not available for the Preferred Alternative. The presentation of comparative data in Table 2-7 for each parameter for each alternative should be consistent.

Page 2-76 Table 2-7. As the analysis in Table 1 of these comments illustrates, the number of fatalities associated with the Proposed Action [and] No Action alternatives. This is due to the fact that transportation is the key source of risk during the first 100 years. This analysis suggests that for at least 100 years the No Action serves to better protect public health and safety. The analysis in Table 1 also suggests that if the Preferred Action is implemented that during the first 100 years there will be a disequitable distribution of risk from existing storage sites to primarily Nevada, and in particular, communities located along transportation routes. The DEIS must consider the temporal and geographic distributions of risk associated with the Preferred and No Action alternatives. The DEIS must consider methods to mitigate risks transferred to Nevada. The DEIS must recognize that the Preferred Action does not minimize risk during the first 100 years of repository operation.

Table 1.
Draft Yucca Mountain Environmental Impact Statement
Comparison of Proposed Action to No Action Alternatives Total Fatalities Per Year
(derived from data in Table 2-7 of Yucca Mtn. DEIS)

Alternative	0-24yrs.	24 yr. Total	25-100yrs.	75 yr. Total	100yr. Total	101-10,000yrs.	9,900yr. Total
Proposed	.75-2.69	18.70-67.13	.04-.06	3.01-4.53	12.70-71.66	5 X 10^{-8}-5.3 X 10^{-8}	5 X 10^{-5}-5.3 X 10^{-4}
No Action #1	.25	6.35	.25	19.06	25.4	.11	1,095
No Action #2	.25	6.35	.25	19.06	25.4	.33	3,300

Table Conclusions[1]

1. During the period 0-24 years Proposed Action is 3-10 times riskier that the No Action alternatives.
2. During the period 25-100 year No Action #1 is 4-6 times riskier than the Proposed Action.
3. During the first 100 years Proposed Action is a little less to nearly three times riskier than No Action alternatives.
4. During the period 101 - 10,000 years No Action Alternative is 1,000 to 3,000 times riskier than the Proposed Action.
5. During first 24 years of repository operation, transportation is the source of over 95 percent of all fatalities, with most being from highway accidents rather than exposure to radiation.

1/ Proposed Action - disposal at Yucca Mountain
No Action Alternative #1 - on-site storage of wastes with long-term institutional controls
No Action Alternative #2 - on-site storage of wastes without long-term institutional controls

Response
DOE agrees that detailed affected population information is important. However, because of space considerations in Chapter 2 of the EIS, this detailed information is in later chapters and technical appendixes (principally Chapter 4 for short-term impacts for the Proposed Action, Chapter 5 for long-term impacts of the Proposed Action, Chapter 6 for transportation impacts, and Chapter 7 for impacts from the No-Action Alternative) rather than in the summary table in Section 2.4.1, which provides a broad overview of impacts.

The range of impacts to which the commenter refers in Table 2-7 was not meant to reflect uncertainty in the estimates, but rather to show the range of impacts of various implementation scenarios. For example, the range of radiological impacts for the repository given in the Draft EIS reflects the differences between the high, intermediate, and low thermal load scenarios. Similarly, the range for transportation impacts reflects the range of impacts for accidents that could occur in areas with low and high population densities.

For the No-Action Alternative, impacts for each of the scenarios evaluated are in separate columns (that is, Short-term, Scenario 1, and Scenario 2), and ranges are, therefore, not shown. However, Section K.4 of the EIS discusses the uncertainties associated with the No-Action Alternative in detail.

The purpose of the EIS is to provide information on the potential environmental impacts that could result from the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at the Yucca Mountain site. The repository and transportation analyses have captured the geographic shift of risks, as discussed in Chapters 4 and 6, respectively. Chapter 9 discusses the potential for mitigation of these risks. The EIS also provides information on potential environmental impacts resulting from a No-Action Alternative that assumes that the spent nuclear fuel and high-level radioactive waste would continue to be stored at the generator sites for some time into the future. The EIS does not, however, make judgments on whether the temporal and geographic distribution of impacts is equitable.

9.1 (13109)
Comment - EIS010227 / 0027
The SDEIS indicates that there could be a need for more surface cooling of the fuel assemblies, and suggests building an on-site above ground monitored retrievable storage area. What's the rush to move the fuel if it's just

going to sit in dry casks at Yucca Mountain? Why doesn't the DOE assume responsibility for putting the waste into dry casks at the reactor sites?

Response
The Nuclear Waste Policy Act of 1982 affirms the need and establishes a process for the siting, construction, and operation of a repository that will provide reasonable assurance that the public and the environment will be adequately protected. DOE is obligated to construct, operate and monitor, and eventually close a repository in accord with the provisions of this Act.

If the Secretary of Energy decided not to recommend Yucca Mountain for a repository DOE would prepare a report to Congress with its recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Such legislative authority could include DOE involvement in at-reactor storage activities only if approved and directed by Congress.

9.1 (13371)
Comment - EIS010296 / 0016
Section S-1 S&ER Flexible Design (p.S-2): The DOE proposed [land] surface cooling/aging of waste at the repository site prior to loading may constitute "interim storage." The DOE does not specify how much waste might be aging/cooling at any one time, and that this aging process could be accomplished at the nuclear reactor sites.

Response
Although the flexible design described in the Supplement to the Draft EIS, and carried forward in this Final EIS, includes a surface aging facility for storage of as much as 40,000 metric tons of heavy metal (MTHM) over 50 years, this facility has been proposed as a repository operational option that could provide a cost-effective method of achieving a lower-temperature repository. DOE does not believe that the siting limitations for interim storage facilities contained in the NWPA constrain the operational flexibility of the repository or ultimately the long-term performance of the repository. Therefore, DOE believes that the surface aging facility option constitutes a potential operational element of a proposed repository.

DOE has indicated that 40,000 MTHM would be the maximum size of a surface aging facility at the Yucca Mountain site. Accordingly, the 40,000-MTHM facility was analyzed for the EIS to ensure that the impacts covered the total range possible. However, a surface aging facility as large as 40,000 MTHM might not be required after all aspects of the shipping scenarios, such as the age of the spent nuclear fuel to be shipped first, had been defined.

As discussed in Section 7.3 of the EIS, DOE believes (as does the Nuclear Regulatory Commission), that continued onsite storage of spent nuclear fuel can be accomplished safely and without significant environmental impacts (DIRS 101900-NRC 1996). Therefore, the Department believes that if necessary, utilities could continue to safely store spent nuclear fuel at their sites and the impacts of such storage would be similar to the short-term (100-year) impacts evaluated for the No-Action Alternative (see Table 7-6).

9.2 Accidents

9.2 (6698)
Comment - EIS001632 / 0089
Page K-26, Section K.2.5.2: This section discusses the potential for criticality involving stored spent fuel. EPA agrees with the assessment that criticality for high-level nuclear waste is impossible, but believes the EIS should expand the assessment of low probability for criticality in stored spent fuel canisters. The text states that only water entry, and its retention in the canisters, would allow a criticality to develop; and, the discussion further acknowledges the possibility of degradation of the concrete storage facilities, allowing water entry. Yet, the text does not assess the probability that dripping water could corrode the fuel containers, allowing water to enter and remain there for some time, potentially causing a criticality.

The text discusses three types of criticality events, but does not connect them to more explicit container corrosion failures scenarios or evaluate the relative probabilities of each failure type. DOE should more explicitly analyze corrosion failures (penetration of the container and corrosion of the internal components) from water entering the storage container and the potential for various criticalities. It is plausible that dripping water could corrode a storage container, allowing water to collect and fill the container (a scenario similar to NRC's performance scenario for a breached waste package in the repository).

Response

DOE agrees that there is some limited potential for a criticality event to occur in degraded spent nuclear fuel canisters. However, DOE believes the discussion in Section K.2.5.2 of the EIS includes the appropriate level of analysis and qualitative description of probability. There are many uncertainties and speculative processes involved in the hypothetical scenario that assumes no effective institutional control after approximately 100 years, as well as the sequence of events that could occur within that scenario. DOE does not believe it is possible to establish defensible probabilities for this No-Action accident scenario or the components of the scenario described in this comment that could lead to potential criticality during extended periods of dry storage with no institutional control (Scenario 2 of the No-Action analysis). Other factors that the analysis would have to quantify to estimate those probabilities would be different climatic conditions around the country, the different types of commercially available dry storage configurations, the range of burnup in the spent nuclear fuel, and the initial enrichment of the fuel.

Rather than specific probability analyses of the impacts associated with this No-Action scenario, the EIS provides qualitative descriptions of the relative likelihood of criticality events. First, the EIS states that criticality could be possible (in degraded storage canisters) if other conditions were met simultaneously. Those other conditions are a configuration that would allow water to enter but not drain out of the storage canister and fuel containing sufficient fissionable atoms to allow criticality. The second condition would depend on initial enrichment and burnup of the fuel. The EIS also states that a small amount of the spent nuclear fuel would be likely to have the appropriate enrichment burnup combinations, which could enable criticality to occur. Three types of criticality events were acknowledged as possible with only the most energetic type having potential to produce large impacts. That event is possible, but highly unlikely. It could happen only if sufficient amounts of fissionable material were brought together suddenly into a critical configuration. The more likely possibility would be for water to build up around degraded fuel elements. If fissions began to occur, the water would boil away and the criticality would stop. As noted in Section K.2.5.2 of the EIS, even the most energetic criticality would be unlikely to exceed the impacts associated with an aircraft crash onto a degraded dry storage module as evaluated in Section K.2.5.1. Therefore, DOE believes that further quantification of the probability of such an event would not provide useful information or be defensible.

9.2 (7769)

Comment - EIS000817 / 0029

Your radiological impact from scenario 1 (no-action) is based on a postulated aircraft crash it says. However I do not see this airplane crash (with fuel fire from the plane) into a full cask array in most safety analysis reports for dry cask designs. Has DOE looked carefully at what NRC and cask vendors are evaluating here? Just what is the scenario? It should be a full cask array and a large jet crash with a full fuel tank fire, and probably a cask pushed into another cask or tipped over, etc. Just what could happen here?

Response

In evaluating existing information on dry cask storage accidents, DOE did not find any reference to aircraft crashes on dry cask storage arrays. However, as noted in Section K.2.5.1 of the EIS, an aircraft crash into a nondegraded concrete storage module would not result in a significant release because the limiting aircraft missiles (engines and engine shafts) would not be able to penetrate the concrete modules and the storage casks. For degraded storage modules (Scenario 2), such penetration would be possible after significant degradation occurred. Section K.2.5.1 evaluates this scenario and provides a reference for details of the accident analysis, including estimated consequences.

9.2 (8495)

Comment - EIS000817 / 0157

P. 7-31. This airplane crash postulated accident -- what kind of airplane? How much airplane fuel in the fire? What kind of cask? One with flammable materials in it? These variables need more site specific evaluation. I have always been very concerned about the simplified analysis of airplane crashes into a full cask array -- it needs more evaluation. It is one of the big concerns. Seems to me several casks analyze only the fuel from the transporter in their fire analysis -- a plane with full fuel load should be analyzed for a cask design.

Response
Section K.2.5.1 of the EIS and the references cited in that section contain details about the postulated airplane crash onto dry storage modules. The jet selected for the crash analysis would be a midsize commercial jet with a significant fuel load. The analysis assumed that the storage array would be 100 concrete modules, each containing a typical steel storage cask with 24 pressurized-water reactor fuel assemblies. It also assumed there would be no flammable materials in the casks because DOE would not use the casks to store such materials. Based on the spacing of the storage modules and the size of the aircraft, the analysis assumed that the crash would destroy two full casks and release all the pellets from the fuel rods in the assemblies. The jet fuel from the aircraft would burn and oxidize the exposed fuel pellets into a powder. The analysis predicted the release and dispersal of a fraction of the powder to the environment. It computed impacts from the released material for a high-population site and a low-population site, including doses to human receptors as far as 80 kilometers (50 miles) from the release point. Section K.3.2.1 describes the consequences of the accident.

9.2 (11950)
Comment - EIS000817 / 0155
P. 7-21 [high-level radioactive waste storage facility figure in Section 7.2]. What are the canister supports? I'm always very interested in any supporting structures for the casks. They can be a real hazard. Basket designs and spacers can be a real problem too in drop and lift analysis -- tip-overs and surfaces the casks can hit.

Response
The canister supports in the high-level radioactive waste storage building shown in the relevant figure in Section 7.2 of the EIS would be large-diameter galvanized-steel pipe sections arranged in a grid and supported by a concrete base mat. Each pipe would hold one high-level radioactive waste canister. The space between the pipes would be filled with overlapping horizontally steel plates designed to direct most of the ventilation air through the storage cavities to remove heat generated by the waste canister.

9.3 Socioeconomics

9.3 (7985)
Comment - EIS001577 / 0005
Furthermore, the actual economic impact of the no action scenario number two, and this is basically ignoring the problem and burying the waste on site, is not elaborated upon and would include immediate short-term economic benefit to the DOE, public and the commercial utilities. This aspect of the problem, the potential unprofitability of dealing with this waste contributes to the notion that Yucca Mountain is the only answer because the utilities and waste handling contractors are already lined up at the trough like pigs. To address this problem involves huge economic subsidies by the people through their government which would employ at great expense large nuclear industry contractors to hire low cost work forces, who would then build railroads, drive trucks and engineer cask carriages to shuffle the waste around the country. The potential for local economic development in finding ways to collectively and democratically secure and isolate these wastes well into the future is great, yet the DEIS fails completely to explore it.

Response
DOE has stated that it believes that neither No-Action scenario is likely, even though continued storage of spent nuclear fuel and high-level radioactive waste would be required for some time in the future. If DOE decided not to recommend Yucca Mountain for a repository, DOE would prepare a report to Congress with recommendations for further action, including the need for new legislation in compliance with Section 113(c)(3) of the NWPA.
The future course that Congress, DOE, and the commercial nuclear power utilities could take if the Secretary of Energy did not recommend Yucca Mountain as a repository site is uncertain. The continued storage scenarios analyzed in the EIS, although reasonable for analytical purposes, do not necessarily represent a likely action. Therefore, DOE believes that Congress, DOE, and the commercial utilities would identify a permanent disposal solution even if the Secretary of Energy did not recommend the Yucca Mountain site.

Section 2.1.5 of the EIS presents cost estimates for a Yucca Mountain Repository (including costs for transportation, repository development, construction, operation and monitoring, and closure). It also includes costs of waste acceptance, storage, and national transportation; Nevada transportation; program integration (quality assurance, human resources and administration, Nuclear Regulatory Commission fees, and Nuclear Waste Technical Review Board funding); and program institutional costs (Payments-Equal-To-Taxes, benefits payments to the State of Nevada, transportation training assistance, and other financial assistance payments). Section 2.2.3 of the EIS presents cost estimates for the No-Action Alternative. DOE based these estimates on the best available data and standard cost estimating techniques.

DOE developed these estimates for comparative purposes and to aid decision-makers in discriminating between the No-Action Alternative and the Proposed Action discussed in the EIS. The estimates do not include costs before early 2002, when DOE anticipates a decision on repository development, or the costs for siting and characterization of Yucca Mountain. The No-Action estimate includes only costs that differ from those of the Proposed Action estimate. For example, it does not include storage costs until 2010 when a repository would first accept spent nuclear fuel and high-level radioactive waste because storage would be necessary until then under both the Proposed Action and the No-Action Alternative. The No-Action estimate is based on, and consistent with, industry experience for dry storage of spent nuclear fuel and high-level radioactive waste.

Concerning economics, the costs associated with the Proposed Action would be greater during the first 100 years; the ongoing costs associated with continued storage under the institutional control scenario would be far greater. Most of the funding for repository investigation and ultimately development, should the project proceed to that stage, would come from commercial utilities and their ratepayers who benefit directly from the use of nuclear power. Continued storage of spent nuclear fuel at generator sites would also be ratepayer-funded. The analysis assumed that continued storage facilities would require replacement every 100 years, and there would be a major facility repair halfway through the first 100-year cycle. Under Scenario 2, loss of institutional control, the projected economic impacts would be the same as those for Scenario 1 for the first 100 years, but after that approximately 800 jobs would be lost.

9.4 Human Health and Safety

9.4 (1537)
Comment - EIS000456 / 0002
We didn't ask for this nuclear neighbor. The plant was forced on us more than 30 years ago. In 1994, the utility company was given permission to build a pad to hold up to 48 casks on Prairie Island. As of today, they have 17 casks sitting and they will need, I think, three or four more to reach the year 2012 when they are going to go for their relicensing.

Today we face a real threat that how it's been called a temporary storage facility while in fact its permanent. Our children, our children's children will be forced to live with this, which to us is a very real health and safety threat.

Response
The Nuclear Regulatory Commission has stated, "The overall conclusion for on-site storage of spent fuel during the term of a renewed license is that the environmental impacts will be small for each plant" (DIRS 101899-NRC 1996). Although this finding is applicable only to the continued storage of existing spent nuclear fuel and spent nuclear fuel generated during the 20-year license renewal period for the nuclear powerplant, for purposes of analysis, DOE assumed that potential environmental and radiological impacts for the storage facility would remain small for much longer periods assuming effective institutional controls are maintained. Environmental impacts would remain small because no additional fuel would be generated beyond the operation of the nuclear powerplant (plants are assumed to be closed after the first 20-year license renewal period), and radiological impacts would remain within regulatory limits specified in the storage facility license (10 CFR Part 172).

9.4 (6136)
Comment - EIS001654 / 0038
Page S-65. The Proposed Action Poses Some Small Health Risks in the Short-term While No Action Alternatives Pose Either Far Greater Health Risks or Unimaginable Financial Costs Based on S.11.3.

The impacts can be summarized as follows:

Impact Type	Proposed Action	No-Action Scenario 1	No-Action Scenario 2
Socio-Economic	2,400 jobs	Jobs lost	Jobs lost
Health (Latent Cancer Fatalities)			
Transportation	6-28	0	0
Construction-Pre-closure	3-4	16	16
First 100 years[a]	22-50	25	25
Long-term (100-10,000yrs)	<1	15	3,300

a. Includes non-radiological fatalities in all scenarios

It would be irresponsible to suggest that the Scenario 2 No-Action Alternative is acceptable in terms of long-term public health. Further, it does not fulfill the objective of the Nuclear Waste Policy Act, namely that it not only does not provide for geologic disposal of nuclear waste, it also does not isolate the waste from the environment.

Response
DOE agrees that the No-Action Alternative fails to fulfill the objectives of the NWPA to develop a repository for the disposal of spent nuclear fuel and high-level radioactive waste. The No-Action Alternative provides a basis for comparison of the potential environmental impacts of no action with those of the Proposed Action.

9.4 (9873)
Comment - EIS002150 / 0002
Has the department figured out how many latent cancer deaths there will be if the future waste is left in storage on-site? Why is it necessary to drag it across the country and put so many Americans at risk?

Response
Congress enacted the Nuclear Waste Policy Act of 1982, which acknowledges the Federal Government's responsibility to provide permanent disposal of the Nation's spent nuclear fuel and high-level radioactive waste. In 1987, Congress significantly amended the Act to identify Yucca Mountain as the only site to be studied as a potential location for a geologic repository. The NWPA establishes a process leading to a decision by the Secretary of Energy on whether to recommend that the President approve Yucca Mountain for development of a geologic repository. The NWPA requires that DOE submit a Final EIS along with any site recommendation to the President of the United States. The purpose of the EIS is to provide information on the potential environmental impacts that could result from the Proposed Action and provide a basis for comparison in the two No-Action scenarios.

In Chapter 7 of the EIS, DOE evaluated potential human health impacts that could result from continued long-term storage of spent nuclear fuel and high-level radioactive waste at the generator sites. This No-Action Alternative evaluated two scenarios: long-term storage of spent nuclear fuel and high-level radioactive waste at the current sites with effective institutional control for at least 10,000 years (Scenario 1), and long-term storage with no institutional control after approximately 100 years (Scenario 2). Although DOE does not consider either of these scenarios to be likely, they were selected for analysis because they provide a basis for comparison to the impacts of the Proposed Action. The EIS presents information about the potential radiological impacts to workers and members of the public from both No-Action scenarios, including potential latent cancer fatalities (see Chapter 7 of the EIS).

9.5 Native American Issues

9.5 (7631)
Comment - EIS001928 / 0003
While we recognize that the Nuclear Waste Policy Act prevents the DOE from considering the need for the repository or alternatives to geologic disposal, and the no-action alternative was considered to provide a baseline for comparison with the proposed action, we believe that it is necessary to point out that the No-Action alternative has serious ramifications for our Tribal community. The [Shoshone-Bannock] Tribes have consistently taken the position that the waste has remained too long in the aboriginal area of the Tribes. To even suggest that the spent fuel

will remain on site at INEEL [Idaho National Engineering and Environmental Laboratory], either with institutional controls or unimaginably, without controls, is not acceptable to our people.

As discussed in the draft EIS, if the spent fuel is left on-site in dry storage, eventually the radioactive material would escape to the environment, contaminating the atmosphere, soil, surface water and groundwater. Although there is no mention of what would happen to the people living near these sites, we assume that they would either be removed or face contamination. Such federal action as the Supreme Court succinctly stated in Lane v. Pueblo of Santa Rosa, 249 U.S. 110 (1919), "would not be an exercise of guardianship, but an act of confiscation" or "spoilation" as Justice Cardozo tartly stated in Shoshone Tribe v. United States, 299 U.S. 470, 498 (1937).

The DOE must recognize that tribal lands play a different role than in the non-Indian context. And, any federal action affecting such tribal lands must evaluate using the trust doctrine. First, the Tribal land base is the sine quo non of tribal sovereignty. Surrounded by a majority non-Indian society of a vastly different orientation, a distinct tribal territory remains essential to fulfilling the federal promise of native separatism envisioned in the treaty-making era. The vast cessions of land by tribal peoples through the treaty process were premised on federal promises that native people could continue their way of life on homelands of smaller size, free from intrusions of the majority society. The dominant tenet which emerges from these origins is that the Indians' best interests lie in preserving the tribes' sovereign nation status, resisting assimilation forces, and preserving homelands. Today, most fundamentally, the modern form of the trust obligation is the federal government's duty to protect this separatism by protecting tribal lands, resources and way of life, and shielding Indian lands from environmental threats. See e.g., United States v. Creek Nation, 295 U.S. 103, 110 (1935); Northern Arapahoe Tribe v. Hodel, 808 F.2d 741, 750 (10th Cir. 1987) (finding trust responsibility to protect tribe's wildlife resources); Joint Passamaquoddy Tribal Council v. Morton, 528 F.2d 370, 379 (1st Cir. 1975) (noting that the federal government's fiduciary duty to protect tribal lands is "beyond question"); Northern Cheyenne Tribe v. Hodel, 12 Indian L. Rep. 3065, 3070 9D.Mont, May 28, 1985) (mem.) (noting trust duty extends to off-reservation federal activities that impact tribes).

Second, intergenerational habitation is unquestionably a dominant feature of tribal land tenure. We have no intention of leaving our permanent homeland, land that was reserved by Treaty for present and future generations. The Tribes have justifiable expectations of a perpetual and stable land base. This stands in marked contrast to non-Indian owned lands, which [are] typically held by individuals for transitory habitation or business for investment.

Third, Indian land is essentially irreplaceable. This is due in part to the unavailability of alternate consolidated tracts of land, but also these lands form the basis for cultural and economic survival of the Tribes. Loss of a tribal land base because of contamination would be devastating to tribes and would lead to irreversible cultural extinction for some tribes. Moreover, if tribal lands are contaminated and damaged, habitation is restricted or eliminated which will result in the tribe losing its political powers to control and regulate the activities occurring on its homelands. Finally, the tribe may be unable to adequately preserve or protect its members' general health, welfare and safety through the loss of contaminated lands.

The concept of a secure usable tribal homeland for future generations must guide the trust analysis in the DOE's decisionmaking regarding the no-action alternative. Accordingly, relocating a tribe in a manner similar to the relocation of the non-Indian residents of Times Beach or Love Canal would be disastrous to the Tribe's well being, and inconsistent with the federal government' trust obligations to the tribe. See, e.g., Continental Insurance Co. v. Northeastern Pharmaceutical & Chem. Co., Inc., 811 F.2d 1180, 1182 n.1 (8th Cir. 1987) (noting high levels of the hazardous substance dioxin resulted in the government purchasing the entire town of Times Beach, Missouri with its population of approximately 2,200 people for $37 million); Smith v. Reagan, 842 F.2d 28 (2d Cir. 1988) (residents of Love Canal, New York received relocation assistance when 21,000 tons of chemical waste dumped by Hooker Chemical & Plastics Corp. in the Love Canal landfill leaked out and made many residences uninhabitable).

Response

The purpose of the EIS is to provide information on the potential environmental impacts that could result from the Proposed Action to construct, operate and monitor, and eventually close a repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain. DOE analyzed the No-Action alternative to serve as a basis for comparing the magnitude of potential environmental impacts of the Proposed Action. In making a determination on whether to recommend Yucca Mountain, the Secretary will consider not only the potential environmental impacts identified in the EIS, but other factors such as technology, economics, and national policy.

DOE acknowledges the Federal Government's trust responsibilities to Native Americans, but analysis of these obligations or issues associated with securing tribal homelands for future generations is beyond the scope of this EIS. If the Yucca Mountain site was not approved, DOE would not proceed with the development of a repository there and, as directed by Section 113(c)(3) of the NWPA, would prepare a report to Congress with its recommendations for further action to ensure the safe permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. DOE has stated that it believes that both No-Action Alternative scenarios are unlikely even though continued onsite storage of high-level radioactive waste and spent nuclear fuel would be necessary for some time in the event that the Yucca Mountain site was not approved.

Cumulative Impacts

10. CUMULATIVE IMPACTS

10 (3)
Comment - 16 comments summarized
Commenters said that the EIS did not adequately account for the cumulative impacts from past, present, and future transport of all radioactive and hazardous materials to the repository, to the Nevada Test Site, and to the Waste Isolation Pilot Plant in New Mexico. Some said that the cumulative impacts from all these waste shipments should have been integrated into one risk model, especially considering that the Nevada Test Site is a preferred alternative for the disposal of the Nation's low-level and mixed low-level radioactive waste and other hazardous materials. Commenters stated the routes that would be used to transport waste to Yucca Mountain are the same routes being used to carry transuranic wastes to the Waste Isolation Pilot Plant in New Mexico. Others said that all this waste transport is a violation of the principle of informed consent for citizens traveling the Nation's highways. Some said that DOE has also failed to inform emergency responders and state transportation departments of potential problems by not integrating accident and risk data from the Waste Isolation Pilot Plant and Yucca Mountain. Some said that the cumulative impacts from waste transport would be particularly adverse to residents of Nye and Clark Counties, Nevada.

Response
Section 8.4 of the EIS describes the cumulative impacts of past, present, and reasonably foreseeable shipments of radioactive materials throughout the nation and in Nevada. Table 8-58 lists the collective worker-dose and general-population dose (in person-rem), and traffic fatalities, from these actions between 1943 and 2047 (including mixed low-level radioactive waste). The table includes shipments of low-level waste to the Nevada Test Site (this includes the designation of the Nevada Test Site as a regional DOE low-level waste disposal site); shipments of transuranic waste to the Waste Isolation Pilot Plant in New Mexico; and shipments of spent nuclear fuel and high-level radioactive waste to various storage and disposal sites throughout the nation.

The Department is not aware of the specific "informed consent" principle to which the commenters refer. Transportation of hazardous materials requires informing the appropriate government agencies and adhering to requirements of the Federal Government and affected state governments, which act to protect the public. Further, transport vehicles must have special placards to identify hazards that might be on board the transport vehicle; these placards are visible to other drivers on the highways. In addition, public documents, such as this EIS, inform the public of potential risks that might accompany transportation activities.

Section 180(c) of the Nuclear Waste Policy Act, as amended (this EIS refers to the amended Act as the NWPA), requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions the Department would transport spent nuclear fuel and high-level radioactive waste. The training shall cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified approximately 5 years before shipments begin and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

The Price-Anderson Act establishes a system of financial protection (compensation for personal injury and property damage, including loss of use of property) for the public in a nuclear accident, regardless of who causes the damage. See Section M.8 of the EIS for a discussion of the Price-Anderson Act.

10 (91)
Comment - 12 comments summarized
Commenters said that the EIS did not examine (or did not examine adequately) the cumulative impacts to groundwater from the repository and from past, present, and future activities at the Nevada Test Site. Some noted that DOE had detonated nuclear explosions below the water table and that plutonium had migrated more than a mile from these detonations via colloids. According to some, plutonium migration might be more extensive, but DOE has gathered little information about groundwater conditions on the Nevada Test Site and groundwater flow between

the Test Site and Yucca Mountain. Some wanted to know why DOE has not examined the groundwater system on the Test Site with the same vigor that it has examined groundwater conditions at Yucca Mountain.

Response

Chapter 8 of the EIS discusses the cumulative impacts from the repository, along with the impacts of past, present, and reasonably foreseeable activities in the region. Section 8.3.2.1 describes the impacts to groundwater from past underground testing at the Nevada Test Site. Section 8.3.2.1 also discusses the movement of plutonium from underground test sites by binding with colloids, which is believed to account for this movement. Since issuing the Draft EIS, the Department has revised the analyses of impacts associated with the Nevada Test Site. Section 8.3 of the Final EIS includes updated estimates of future impacts to groundwater from activities on the Test Site. These estimates indicate that the potential dose to a receptor from groundwater from the Nevada Test Site is much less than 1 millirem per year, and the Department does not believe that adverse impacts would result from this small dose alone or combined with long-term releases from a repository at Yucca Mountain.

When DOE prepared the Draft EIS, it used the best available information to estimate cumulative impacts. While some data were available for the groundwater system at the Nevada Test Site, these data were not as complete as those available for the groundwater system between the repository and populated areas to the south. This is why the EIS analysis could not apply the same rigor to areas on the Nevada Test Site north of the repository compared to areas south of the repository. To compensate for this imbalance in available information, the EIS used a very conservative approach to bound estimated impacts. In other words, the Department believes that potential impacts associated with the Nevada Test Site were overestimated. This type of conservative analysis is designed to account for uncertainties by assuming very conservative values for parameters and not taking credit for possible mitigating effects. For example, the regional groundwater flow model developed by the U.S. Geological Survey for the repository program (DIRS 100131-D'Agnese et al. 1997) indicates that some groundwater from the Nevada Test Site flows southward toward the Amargosa Desert in the vicinity of Yucca Mountain. However, the actual transport times and groundwater pathways from potential radionuclide contaminants on the Test Site are not clearly known. Although very unlikely to occur, the Department assumed, for purposes of analysis in the Draft and Final EIS, that contaminants from the Nevada Test Site would move through identical pathways and have identical transport times as the material from the repository because this would provide an upper, bounding estimate of the possible impact to groundwater from the repository and the Nevada Test Site.

The qualitative calculation of the cumulative groundwater impacts from the Nevada Test Site and from a repository at Yucca Mountain indicates that the potential cumulative peak dose would be well below the regulatory limits in 40 CFR Part 197 (see Section 8.3.2.1.1). Moreover, this cumulative peak-dose would occur only in the unlikely event that the peak radiological concentrations from the Nevada Test Site and from Yucca Mountain occurred at the same time in the future and in the same location, which is unlikely.

Comment - 20 comments summarized

Commenters said that the EIS did not examine the cumulative impacts from all Federal and non-Federal actions and policies in the affected area. Agencies and organizations cited included the DOE, the Department of Defense, the Forest Service, the U.S. Fish and Wildlife Service, the Bureau of Land Management, the National Park Service, the Timbisha-Shoshone Tribe (with regard to the acquisition of trust lands), and the Clark County/Las Vegas Valley Water District. Others focused specifically on Nye County, stating that the EIS did not consider the cumulative impacts from the repository withdrawal, along with the millions of acres of Federal land already withdrawn for national parks, forests, wildlife refuges, and defense purposes in and near Nye County. Some said that the many separate resource-planning documents prepared by these and other agencies have not been coordinated among the agencies and have had, and will continue to have, cumulative impacts on the residents of Nye County through a variety of lost opportunities. Others said that residents of Nye County have been disproportionately affected by these Federal actions, citing lost opportunities due to the many land-use restrictions that have been imposed in Nye County, including what some commenters contend is a stated policy of the National Park Service and the Bureau of Land Management to protest local water-right applications in southern Nye County.

Response

Chapter 8 of the EIS discusses the potential impacts of the proposed repository, along with the impacts from past, present, and reasonably foreseeable future actions in the affected area. In preparing this chapter, the Department reviewed many documents to determine where there was potential for cumulative impacts. These documents included resource plans by land management agencies, EISs, environmental assessments, strategic plans, records of tribal meetings, and other documents prepared by Federal, state, local, and private organizations. The analyses and results described in Chapter 8 considered only those impacts from activities that have the potential to coincide in time and space with impacts from the repository. Based on some of the comments received by the Department on the Draft EIS and the Supplement to the Draft EIS and more recent information on activities at the Nevada Test Site, DOE modified several analyses in the Final EIS. DOE believes that the Final EIS analyzes the appropriate range of past, present, and reasonably foreseeable future actions that could contribute to cumulative impacts.

The Department understands that large tracts of land have been withdrawn from public use in southern Nevada and adjoining parts of California for reasons of national defense and environmental protection. Section 8.2.1 of the Final EIS includes a more detailed discussion of potential cumulative impacts from these land withdrawals. While it is true that land in Nevada has been withdrawn for national defense and environmental protection, other lands have passed out of the public domain. For instance, the Southern Nevada Public Land Management Act allows the Bureau of Land Management to sell public lands to promote responsible and orderly development.

The opposition to a water-appropriation application by an agency is not an environmental impact associated with the availability of water resources. This is because the filing of a protest does not determine the outcome of the water-application process. The Nevada State Engineer is independent of the Federal Government.

Comment - 3 comments summarized
Commenters said that nuclear weapons are still being tested at the Nevada Test Site and that this needs to be included in the cumulative impacts assessment. Others cited a high likelihood for a resumption of nuclear weapons testing at the Nevada Test Site, citing the recent failure of the Comprehensive Test Ban Treaty in Congress. Some stated that the Draft EIS did not contemplate a resumption of weapons testing, but that the 1986 environmental assessment of Yucca Mountain did, stating that workers would not be allowed in the underground repository during planned weapons tests for safety reasons.

Response
Since 1992, there has been a moratorium on nuclear testing. Even though the Nevada Test Site must maintain the ability to resume testing, the Department does not believe that a resumption of testing is a reasonably foreseeable action. Therefore, it was not included in the analyses in Chapter 8 of the EIS. Nevertheless, a recent evaluation of impacts from a resumption of underground testing at the Nevada Test Site (DIRS 103273-Walck 1996) concluded that the only impact such testing would pose on the repository would be ground motion from the energy released by the detonations. DOE has determined that such effects would not exceed the seismic design criteria for the repository. In other words, the design-basis earthquake for the repository would generate stronger ground motions than would underground nuclear detonations on the Nevada Test Site. Because DOE has designed the repository to survive the design-basis earthquake with minimal damage, ground motion from the resumption of underground testing would be unlikely to result in substantial damage to the surface or underground facilities at Yucca Mountain.

Section 8.3.2.1.1 of the EIS describes the cumulative impacts of past nuclear weapons testing based on information in the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996). As stated in that EIS, DOE continues to perform tests at the Nevada Test Site including dynamic, hydrodynamic, and other tests as well as a small number of subcritical experiments using special nuclear materials. The Department has revised Chapter 8 to include a more complete description of these activities so the public and decisionmakers have a clear understanding of the potential cumulative impacts.

Comment - 27 comments summarized
Commenters said that the EIS failed to examine the cumulative health effects to people in Nevada from all past, present, and future exposures to radiation. Some said that residents of counties in eastern Nevada have been repeatedly exposed to radiation, beginning with fallout from above-ground nuclear testing and from DOE's failure to contain atmospheric releases during underground testing. Others said that residents are still being exposed through hiking, hunting, farming, and continuing fallout. Commenters said that DOE must evaluate the cumulative health effects (higher risk of latent cancers) of weapons testing, along with the health effects from the transport of all

radioactive materials through communities in eastern Nevada, including the effects of accidents. Others wanted to know what the impacts would be to current residents who were exposed to these past sources, as well as to residents who are genetically related to people who have been repeatedly exposed to radiation. Others wanted to know whether DOE examined the cumulative health effects to selected groups of people (pregnant women, children, elderly people, ethnic groups, etc.) from repeated exposure to radiation from all manmade and natural sources of radiation.

Response
As part of its analysis of cumulative impacts in Chapter 8, the Department quantified, where possible, the total radiation dose that local residents have received. The Department calculated the total risk to the population based on the conservative assumption that radiation risks from different exposures are additive.

With respect to person-specific exposures, the Department cannot account for each resident's past exposure to radiation. To do so would require accounting for person-specific lifestyles and habits, such as the frequency of cross-country airline flights, past residences in locations that might have substantially higher or lower cosmic radiation, and the frequency and nature of medical diagnostic tests and treatments. Instead, the Department used population risk factors (5×10^{-4} latent cancer fatality per person-rem for the public and 4×10^{-4} latent cancer fatality per person-rem for workers) based on the recommendations of the International Commission on Radiological Protection (DIRS 101836-ICRP 1991). These factors account for the variety of individuals in the population, including differences in risk due to age. An estimate of impacts to specific groups of people (such as pregnant women, children, the elderly, and certain ethnic groups) was not made because such estimates would have greater uncertainty. The doses that have been calculated thus far for downwind residents have uncertainty associated with them that would tend to overshadow differences in risk to the various groups cited. The use of the average risk factors adequately covers all groups within the population and gives a reasonable estimate of the risk to the group as a whole.

Section 8.3.2.1 of the EIS describes the activities on the Nevada Test Site that could contribute to cumulative impacts with the proposed repository. Section 3.1.8.2 estimates the annual radiation dose to a hypothetical individual in Springdale, Nevada (located eight miles north of Beatty), from airborne radioactive materials released during past testing of nuclear weapons at the Nevada Test Site. Since issuing the Draft EIS, DOE has revised the analyses of impacts associated with the Nevada Test Site. Sections and 8.2.2.2 and 8.4.2.7 now include information on radiation exposure from past nuclear weapons testing, and Section 8.3 includes updated estimates of future impacts to groundwater and air resources from activities on the Test Site. In addition, Section 8.4.2.7 incorporates the human health impacts from the transportation activities discussed in Section 8.4 (for example, Table 8-58 describes radiological and nonradiological impacts from waste transport between 1943 and 2047). Section 8.3 estimates the long-term future impacts to groundwater from potential migration of radiological and hazardous contaminants from the repository, the Nevada Test Site, and the Beatty low-level waste site.

As indicated in Section 3.1.8.2, DOE made quantitative estimates of the offsite doses from releases from past weapons testing at the Nevada Test Site. In response to public comments, Appendix J of the Final EIS contains maps showing routes used in analyzing impacts, and estimates radiological and nonradiological impacts for each state. This is in addition to the route maps that were in the Draft EIS (see Section 2.1.3.2 for national maps and Section 2.1.3.3 for Nevada maps).

Readers interested in more information about the effects of past testing of nuclear weapons should refer to the *National Cancer Institute Study Estimating Thyroid Doses of I-131 Received by Americans From Nevada Atmospheric Nuclear Bomb Tests* (DIRS 152469-Institute of Medicine and National Research Council 1999).

Comment - EIS000056 / 0001
The proposed repository is predicted to leak additional radioactive contamination into the aquifers in the southwestern portion of the Nevada Test Site...water that is currently potable will be contaminated if the DOE's Performance Assessment is correct. This will result in a significant adverse impact on the water resources that must be mitigated.

Response
DOE recognizes that some radionuclides or potentially toxic chemicals would eventually enter the environment outside the repository. However, modeling of the long-term performance of the repository shows that the combination of natural and engineered barriers at the site would keep such a release small enough to pose no serious impact to the health and safety of people or the environment. The releases would be well below the radiation protection standards established by the Environmental Protection Agency for a repository at Yucca Mountain [40 CFR Part 197].

The U.S. Geological Survey regional flow model (DIRS 100131-D'Agnese et al. 1997) suggests that some of the water from the Nevada Test Site flows southward toward the Amargosa Valley in the vicinity of Yucca Mountain. However, the actual transport times and groundwater pathways from potential radionuclide contaminants on the Site are not clearly known at this time. A "qualitative" calculation of the combined impact from the Nevada Test Site and Yucca Mountain in Section 8.3.2.1.1 indicates that the potential cumulative peak dose would be well below the Environmental Protection Agency's regulatory limits. This combined peak dose would occur only in the unlikely event that the peak concentrations from the Test Site and Yucca Mountain occurred at the same time and same location. See Sections 3.1.4.2.1, 5.4, and 8.3.2.1.1 of the EIS for more information.

Comment - EIS000044 / 0002
The results of Nye County's water resource evaluations found that the direct impacts of water withdrawals for the proposed repository will be limited to a localized lowering of water levels that was not deemed to be significant. However, the evaluation did find that the predicted leakage from the repository and the cumulative impacts of the proposed repository will indeed be significant and that mitigating measures must be implemented. The Draft Yucca Mountain EIS is inadequate with regard to its evaluation of impacts on water resources and corresponding mitigation and must be revised extensively.

The cumulative impacts on water resources will include the direct and indirect impacts of 1) the total radiological burden that will be imposed on Nye County; 2) the impacts of federal land withdrawals on water resource availability: 3) the impacts of federal policies regarding nuclear weapons testing, waste disposal, and environmental protection; and 4) the water resource use and management practices on both private and federal lands in the County.

The Department of Energy, through their selection of a reduced region of influence, limited their analysis to only the direct impacts of their water withdrawals from a single basin while ignoring documented impacts that occur over a much broader region. Further, the Department ignored other federally prepared reports that detailed the direct, indirect, and cumulative impacts of Department of Defense, Energy, and the Interior actions over the same region. This approach is inconsistent with the CEQ [Council on Environmental Quality] guidance for considering cumulative impact assessment under NEPA [National Environmental Policy Act] and with 40 CFR 1508.25.

All the Yucca Mountain EIS says with regard to cumulative impacts is that the potential impacts to groundwater would be small and limited to the immediate vicinity of the land disturbances associated with the action and that some minor incremental risk would occur from drinking the groundwater down gradient of the repository at some distant time in the future.

This approach is inconsistent with statements in the Draft EIS:

"The general path of water that infiltrates through Yucca Mountain is south toward Lathrop Wells, into and through the area around Death Valley Junction in the lower Amargosa Valley. Natural discharge of groundwater from beneath Yucca Mountain probably occurs farther south at Franklin Lake Playa." Vol. I, p. 5-23.

"The implementation of the proposed action could potentially affect the water supply in Death Valley National Park, which is downgradient from Yucca Mountain" Vol. II, Appendix C, page C-9.

The region of influence evaluated for cumulative impacts cannot be smaller than the region over which impacts are expected to occur. Thus, the Department's approach is inconsistent with the letter and intent of NEPA, CEQ guidance, and other federal documents including the EIS for the Nevada Test Site, and the Special Nevada Report.

If the Department of Energy chooses to continue to ignore the local perspective by not evaluating the impacts identified in the Nye County document and by other federal agencies, then it is imperative that Nye County's perspective be clearly documented in the EIS as an opposing viewpoint.

Response
Chapter 8 of the EIS analyzes reasonably foreseeable cumulative impacts to water resources from a repository at Yucca Mountain. The region in which the cumulative impacts could occur includes the entire groundwater flow system south of Yucca Mountain described in Section 3.1.4.2.1 of the EIS, as well as areas to the north on the Nevada Test Site that could contribute impacts to this groundwater flow system. In other words, the region examined for cumulative impacts is larger than the region examined for impacts from just the repository. In relation to short-term impacts to water resources, Section 8.2.3 describes the cumulative impacts from the Proposed Action and from additional inventories of nuclear waste. As stated in Section 8.2.3.2.2, no other Federal, non-Federal, or private actions in the affected area during the short term would have cumulative impacts with the Proposed Action, with one exception; cumulative impacts to groundwater resources from water demands of the Yucca Mountain Repository, along with groundwater demands from activities on the Nevada Test Site. Impacts to downgradient users in the Amargosa Desert from cumulative water demands for the repository and the Test Site, however, would be small compared to impacts from local pumping in the Amargosa Desert. With regard to long-term cumulative impacts to groundwater resources (those that could occur 10,000 years after closure of the repository), the Department limited the scope to cumulative impacts from the repository along with impacts from the Nevada Test Site and the Beatty low-level radioactive waste site (see Section 8.3).

The first cited quote in the comment, from Section 5.3 of the EIS, is accurate. A fraction of the groundwater might flow through fractures in the relatively impermeable Precambrian rocks in the southeastern end of the Funeral Mountains toward spring discharge points in the Furnace Creek area of Death Valley. Sparse potentiometric data indicate that a divide could exist in the Funeral Mountains between the Amargosa Desert and Death Valley. Such a divide would limit discharge from the shallow flow system, but not necessarily affect the deeper carbonate flow system that might contribute discharge to the Furnace Creek area. Even if part of the flow from Yucca Mountain mixed into the carbonate pathway that supplies the Furnace Creek springs, it would be too little to have a noticeable effect on the chemistry of the springs. Considering the small fraction of water that would infiltrate though the repository area (approximately 0.3 percent or less) compared to the total amount of water flowing through the basin and the large distances involved [more than 60 kilometers (37 miles) from the source], any component of the flow from Yucca Mountain in this very long and complicated flowpath would be diluted to such an extent that it would be indistinguishable.

The second quote in the comment is consistent with the Department's conclusion that some minor incremental risk would occur from ingesting groundwater downgradient of the repository at some distant time in the future. The main point of Appendix C is to summarize interactions with organizations that have an interest in, or authority over, land that the Proposed Action could affect, such as the National Park Service, which manages the Devils Hole Protective Withdrawal and Death Valley National Park. DOE and National Park Service officials held discussions during which time the Department addressed Park Service concerns about water use for repository construction and operation.

Finally, DOE did consider planning and other documents from Federal, state, and local agencies in determining future actions that are reasonably foreseeable that could have impacts that are cumulative with the Proposed Action. With regard to the *Special Nevada Report* (DIRS 153277-SAIC 1991), Section 8.2 of the Final EIS describes this report and the reasons why DOE did not use the analysis in that report.

Comment - EIS000071 / 0019
Nye County, by virtue of its location, characteristics and overwhelming federal presence has been disproportionately impacted by past, present and continuing federal action.

Nye County must receive just equity offsets, mitigation and compensation from the United States to mitigate the cumulative impacts of these past, present actions and the proposed repository should it go forward.

Nye County's analysis and evaluations arrange direct, indirect cumulative and direct cumulative have been identified in areas of land use, water resources, lost economic opportunity, perceived risks, stigma and others.

Nye County believes that these impacts, although adverse and significant, can be mitigated through various measures.

Response
Impacts of the Proposed Action, along with other past, present, and reasonably foreseeable actions that are spatially and temporally related to impacts of the proposed repository, are discussed throughout Chapter 8 of the EIS. These other actions include, among others, activities at the Nevada Test Site, the Beatty waste-disposal site, and Nellis Air Force Range (now called the Nevada Test and Training Range).

Based on its method of analysis in Chapter 8, the Department believes that it has accounted for all past, present, and reasonably foreseeable actions in Nye County that could meaningfully contribute to cumulative impacts with the repository.

After the Draft EIS was published, the Department reviewed the activities in the region of influence that could contribute to cumulative impacts. Chapter 8 of the Final EIS includes a more detailed discussion of cumulative impacts related to projected water use for the repository and water availability and water rights issues in Nye and surrounding counties.

The Department is not considering mitigation of cumulative impacts that are unrelated to the proposed repository.

Section 116 (c) of the NWPA establishes a procedure, unrelated to this EIS, by which affected units of local government, such as Nye County, can report effects from the proposed repository to DOE. Affected units of local government can receive impact assistance upon agreement with DOE on the nature and severity of the impacts. Section 116(c) commits DOE to participate in this procedure and to provide assistance consistent with direction from Congress.

Comment - EIS000080 / 0008
You're looking at radioactivity and the risks associated with exposure to radioactivity. There's a little thing out here called toxicity and you only look at the toxicity of the non-radioactive constituents.

The radioactive constituents also have a toxicity and a risk associated with that toxicity, so if you want to look at the total risk to Amargosa Valley over the coming decades, you've got one, the risk of the naturally occurring uranium in the water up north of [U.S.] 95; two, the risk of the migration of tritium and other contamination off of the Nevada Test Site; three, the toxicity of the materials on the Test Site; four, any contributions from radionuclides coming from Yucca Mountain; and five, the toxicity of those.

The EIS does not cover all of those. It only looks at the radioactivity from Yucca Mountain and it needs to be revised to incorporate the entire suite of what is out there.

Response
The five items mentioned in the comment are characterized in Section 3.1.8.2 of the EIS and various sections in Chapter 8, particularly Section 8.3.2.

DOE realizes that radionuclides have chemical properties that could present an additional toxicity risk. For this reason, the Department considered the chemical toxicity of radionuclides in the screening criteria used for the long-term performance assessment, as discussed in Section I.3.2 of the EIS. Section 8.3 discusses the cumulative impact to groundwater of long-term releases from the Nevada Test Site and the proposed repository.

Comment - EIS000069 / 0007
Once this material arrives, we will have it here forever. We suggest that this document does not adequately address the issue of cumulative impacts that this county, Nye County has had to bear from a number of federal agencies; not

just a nuclear community, but we have huge presence with federal land management agencies, national parks, National Fish and Wildlife, Bureau of Indian Affairs and other federal agencies, all of them wanting to come to Nye County and manage the resources and none of them talking to each other. The United States must deal with this issue in a fair and equitable way and must deal effectively with the actual as well as the perceived risks.

Response
Based on available information, DOE analyzed the potential cumulative impacts to current and future populations surrounding the proposed repository at Yucca Mountain. Chapter 8 of the EIS contains this information. The Department realizes that, as in other communities in our country, many activities take place in Nye County. Not all of these activities, however, have had or would have cumulative impacts with the proposed repository.

During scoping for the EIS, DOE received comments on the need to address perception-based and stigma-related impacts that could arise from the construction and operation of a repository, and from the transportation of spent nuclear fuel and high-level radioactive waste. In considering these comments, DOE recognized that nuclear facilities could be perceived to be either positive or negative, depending on the underlying value systems of the individual forming the perception. Perception-based impacts would not necessarily depend on the actual physical impacts or risks from repository operations or transportation. Further, people do not consistently act in accordance with negative perceptions, so the connection between public perception of risk and future behavior would be uncertain or speculative at best. For these reasons, DOE determined that including analyses of perception-based and stigma-related impacts in the Draft EIS would not provide meaningful information.

However, in light of the comments received on the Draft EIS on this subject, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state of the science in predicting future behavior based on perceptions had advanced sufficiently since scoping to enable DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities. Of particular interest were those scientific and social studies carried out in the past few years that relate directly to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE also reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods by which such impacts could be predicted with any degree of certainty.

- Much of the uncertainty is irreducible.

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as a serious accident, which might not occur. As a consequence, DOE addressed but did not attempt to quantify the potential for impacts from risk perceptions or stigma in this Final EIS. See Section 2.5.4 and Appendix N for more information.

10 (524)
Comment - EIS000105 / 0001
The cumulative impacts on water resources will include the direct and indirect impacts of the total radiological burden that will be imposed on Nye County, the impacts of federal land withdrawals on water resource availability, the impacts of federal policies regarding nuclear weapons testing, waste disposal and environmental protection and the water resource use and management practices on both private and federal land in the county.

The Department of Energy limited their cumulative analysis to the Jackass Flats hydrographic basin and limited their analysis to only the direct impacts of their water withdrawals from that basin.

This approach is inconsistent with the CEQ [Council on Environmental Quality] guidance for considering cumulative impact assessment under NEPA [National Environmental Policy Act].

Response
In general, the analysis of cumulative impacts in Chapter 8 followed the process recommended in the Council on Environmental Quality's handbook *Considering Cumulative Effects Under the National Environmental Policy Act* (DIRS 103162-CEQ 1997). This process included the identification, through research and consultation, of Federal, non-Federal, and private actions with possible effects that would be coincident with those of the Proposed Action on resources, ecosystems, and human communities.

Chapter 8 of the EIS analyzes reasonably foreseeable cumulative impacts to water resources. In relation to short-term impacts to water resources, Section 8.2.3 describes the cumulative impacts from the Proposed Action and from additional inventories of nuclear waste. As stated in Section 8.2.3.2.2, no other Federal, non-Federal, or private actions in the affected area during the short term would have cumulative impacts with the Proposed Action, with one exception; cumulative impacts to groundwater resources from water demands by the Yucca Mountain Repository, along with groundwater demands from activities on the Nevada Test Site. Impacts to downgradient users in the Amargosa Desert from cumulative water demands for the repository and the Nevada Test Site, however, would be small compared to impacts from local pumping in the Amargosa Desert.

In relation to long-term cumulative impacts to groundwater resources (those that could occur 10,000 years after closure of the repository), the Department determined that the analysis of cumulative impacts from the repository should include impacts from the Nevada Test Site and the Beatty low-level radioactive waste site (see Section 8.3). In addition to considering cumulative radiological impacts to the Jackass Flats hydrographic basin, DOE also considered the primary discharge point for groundwater flowing beneath Yucca Mountain, which it believes to be Franklin Lake Playa. Groundwater reaching this area could, over the long term, contain small amounts of radioactive and hazardous materials from the repository, the Nevada Test Site, and the Beatty low-level waste site, as described in Section 8.3.2 of the EIS. Furthermore, the EIS recognizes that some groundwater reaching this far might bypass Franklin Lake Playa and continue to Death Valley, and that a very small amount of this groundwater beneath the Amargosa Desert might flow toward springs in the Furnace Creek Wash area of Death Valley. DOE expects that impacts to people and the environment of Death Valley would be negligible.

DOE has revised Sections 8.2.1 and 8.2.3.2 of the EIS to further explain potential cumulative impacts of land withdrawals on water resources. In relation to policies on weapons testing, the EIS uses information from the Expanded Use Alternative in the Nevada Test Site EIS (DIRS 101811-DOE 1996), which allows for weapons testing under a "supreme national interest." Several sections of the EIS discuss the impacts of waste management; for example, Section 8.2.12 discusses the management of waste generated at the repository, and Section 8.4 discusses impacts of waste transportation.

10 (893)
Comment - EIS000410 / 0001
I do not believe that a reasonable conclusion can be drawn from a study which does not include a comparison study of the radiation which already exists. While I am no physicist, it would be hard to convince me that the radiation from over 110 above-ground tests and 1,100 underground tests (+/- a few hundred) set off in shafts which were 5,000 to 15,000 feet deep over a period of 30 years has not already contaminated the ground and the water in unimaginable proportions for miles around.

I believe that the following questions need to be answered before your department can come to a reasonable conclusion - and inform the public of what already exists at Yucca Mountain and surrounding area:

1. Exactly how many nuclear tests were conducted, both above and below ground, and their exact proximity to population and water.

2. The depth of underground tests, and how they have already affected the water table.

3. Quantify the radiation which exists there now, both above and below ground, its potential life expectancy, comparing it to the proposed waste dump.

4. Conditions which exist from the testing which would affect workers at the project.

5. A complete public airing of all information concerning the detonations at the site, including any information considered classified by the military, insofar as radioactive contamination is concerned - I do not believe the military or DOE has the right to keep that sort of information secret.

Response
DOE described past activities at the Nevada Test Site in the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996). Chapter 8 of the repository EIS discusses the cumulative impacts of the repository along with past, present, and reasonably foreseeable future actions at the Nevada Test Site, Nellis Air Force Base, the Beatty low-level radioactive waste disposal site, and other non-Federal actions in the affected area (see Table 8-1). Section 8.3.2.1 describes possible impacts to groundwater quality from activities on the Nevada Test Site, including past weapons testing.

The five specific questions raised by the commenter are addressed to varying degrees in DIRS 101811-DOE (1996) and in Section 8.3.2.1 of the EIS. In brief, 821 underground and 100 atmospheric detonations have been conducted at the Nevada Test Site. The areas where these tests were conducted are shown on Figure 3-2 of the EIS and Figure 4-22 of DIRS 101811-DOE (1996). Many underground tests were conducted near and below the water table; contaminant migration from these points of detonation has been negligible. Total radioactivity is estimated to be more than 300 million curies, as cited in Table 8-55 of the EIS. Some of this material is long-lived, some is short-lived, but it will be there for the long term, not unlike the material that would be placed in the proposed repository. There are no known "conditions" caused by weapons testing that would affect workers at Yucca Mountain. Finally, DOE is obligated to comply with laws of the United States regarding the release of classified information.

10 (981)
Comment - EIS000242 / 0002
Nye County has found that the Department of Energy has not adequately addressed the cumulative impacts, that the proposed repository on the resources, ecosystems, or the human communities of Nye County.

The impacts of past federal actions, including the existing residual contamination from the conduction of more than 900 nuclear tests at the Nevada Test Site, have sacrificed the groundwater resources under more than 250 square miles of Nye County.

The withdrawal of lands from public use for the Nevada Test Site for the Nevada test and training range, part of the Nellis Range Complex, and the federal management of millions of acres of national parks, forests, and wildlife refuges have resulted in lost opportunities from those lands for the residents of the county.

Because of its location and characteristics, Nye County and its residents have been disproportionately impacted by past and present federal actions. Yucca Mountain will significantly add to these impacts, yet this draft EIS portrays to the decision maker that the Yucca Mountain Project is just another casual federal action with no more impact than clearing a road through a forest. Nothing could be further from the truth.

Response
Chapter 8 of the EIS analyzes a reasonable range of past, present, and reasonably foreseeable future actions that could contribute to cumulative impacts. In preparing this chapter, DOE reviewed many documents to determine where there was potential for cumulative impacts. These documents included resource plans, EISs, environmental assessments, tribal meeting records, and other documents prepared by Federal, state, local, and private organizations.

Section 8.3.2.1.1 of the EIS discusses the potential long-term impacts on groundwater from past weapons testing at the Nevada Test Site. This analysis does not show that groundwater resources have been sacrificed underneath Nye County.

The Department understands that large tracts of land have been withdrawn from public use in southern Nevada and adjoining parts of California for reasons of national defense and environmental protection. Section 8.2.1 now includes a more detailed discussion of potential cumulative impacts from land withdrawals by Federal agencies.

10 (1119)
Comment - EIS000225 / 0005
The document fails to address the broad scope of impacts on the 1,500 people who live spread over 200 square miles in the area. There needs to be further examination of cumulative impacts such as existing subsurface contamination at the nearby Nevada Test Site, disposal of low-level radioactive waste in the county and other federal uses of land by such agencies as the Defense Department, the U.S. Forest Service and the Bureau of Land Management.

Response
Chapter 8 of the EIS discusses the impacts of the repository along with the impacts from past, present, and reasonably foreseeable future actions that could affect this area. In preparing this chapter, DOE reviewed many documents to determine where there was potential for cumulative impacts. These documents included resource plans, EISs, environmental assessments, strategic plans, consultation documents, tribal meeting records, and other documents prepared by Federal, local, and private organizations. The analyses and results described in Chapter 8 consider only those activities with a potential for cumulative impacts with the repository.

10 (1135)
Comment - EIS000270 / 0020
Factors that give rise to public concerns about and opposition to approval of the Yucca Mountain site include:

Failure to account for additive sources of contamination from nearby areas, including but not limited to spread of radioactivity and hazardous materials or wastes from the Nevada Test Site and Nellis Air Force Base, or for future potential additional pollution sources in adjoining areas.

Response
Chapter 8 of the EIS describes the cumulative impacts from a repository, along with past, present, and reasonably foreseeable future actions at the Nevada Test Site, Nellis Air Force Base, the Beatty low-level radioactive waste disposal site, and other non-Federal actions in the affected area (see Table 8-1). In preparing Chapter 8, DOE reviewed many documents to determine the potential for cumulative impacts. These documents included Federal resource management plans, reports provided by the State of Nevada, environmental impact statements and assessments, and records of tribal meetings. Except for some factual changes and clarifications that have been included in the Final EIS, DOE believes that the Draft EIS adequately characterized the cumulative impacts associated with the proposed repository.

10 (1168)
Comment - EIS000119 / 0010
Federal agencies, including the DOE, the BLM [Bureau of Land Management], US Forest Service, the National Park Service, the United States Air Force, the United States Navy, the Bureau of Indian Affairs and US Fish and Wildlife Service have repeatedly failed to fulfill their obligations under NEPA [National Environmental Policy Act] by refusing to acknowledge such impacts [cumulative] in their NEPA reviews and provide the mitigation measures that are appropriate.

Nye County's analyses and evaluations identified a range of direct and indirect cumulative impacts in areas such as transportation, land use, water resources, lost economic opportunity and others.

The county believes that these are adverse and significant impacts and that they must be mitigated through various measures.

With the cessation of nuclear weapons testing in 1992, Nye County has made substantial efforts to plan for its economic future in the US 95 corridor.

The EIS does not recognize these plans and it does not reflect an obligation by DOE to ensure that this proposal will not thwart those plans.

Nye County by virtue of its location, characteristics and its overwhelming federal presence has been disproportionately impacted by past, present and continuing federal actions.

Nye County must receive just equity offsets, mitigation, and compensation from the United States to mitigate the cumulative effects of these past and present actions and the proposed repository should it go forward.

Response
Impacts of the Proposed Action, along with other past, present, and reasonably foreseeable actions that are spatially and temporally related to impacts of the repository, are discussed throughout Chapter 8 of the EIS. These other actions include, among others, activities at the Nevada Test Site, the Beatty waste-disposal site, and Nellis Air Force Range. Based on its method of analysis in Chapter 8, the Department believes that it has accounted for all past, present, and reasonably foreseeable actions in Nye County that could meaningfully contribute to cumulative impacts with the repository.

After publishing the Draft EIS, DOE reviewed activities in the region of influence and updated information in the Final EIS where appropriate. Chapter 8 of the Final EIS includes a more detailed discussion of cumulative impacts related to water use at the repository and water availability and water rights issues in Nye and surrounding counties.

The Department is not considering mitigation of cumulative impacts that are unrelated to the proposed repository.

Comment - EIS000578 / 0001
I'd like to convey my concerns about what I think is a huge void in this whole Environmental Impact Statement, and that is the fact of addressing what's already there. I think it's important to know that. I don't think any of us would be here if it wasn't for the fact that that place had about 1500 or so, give or take a hundred, nuclear bombs blown up down there, and it's my opinion that the place is probably the most irradiated place on the planet now.

My concern is that there have been I think 1200 underground tests down there. We're all concerned about the water tables. I know a person personally who helped drill some of the holes they blew the bombs off in. They were a mile deep. If they didn't get through three or four water tables by then, I think we're dreaming.

So what I would like to know is if any tests or any environmental study has ever been done to figure out what is there now, and is this study being done so we'll know relatively, I mean, how much more could we screw up the place versus what is already there.

Nobody ever talks about it. I very rarely hear anything about this in the news, in the media. I have been to a couple of these meetings. Nobody really ever talks about that.

I think we have got military and that entity of government not transmitting information to you folks who I think need it. And I would like to know because I think that the place is already contaminated. I'm not in favor particularly of having any more come there, but my concern is knowing what's already there.

I think we have got our heads buried in the sand when it comes to knowing anything at all about what's there already. And I don't know how we can even approach this particular study without knowing what already exists there, and I don't think you can make a rational decision about anything until we know, and just as a citizen, I'd like to know.

Response
DOE described past activities at the Nevada Test Site in the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996). Section 8.3.2.1 of the Draft EIS discussed the activities at the Nevada Test Site and acknowledged the potential for large amounts of radioactivity as a potential long-term impact. In the Final EIS the Department has updated the information based on more recent analyses of the potential long-term impacts from these activities.

In 1998, the Department published *Accelerating Cleanup: Paths to Closure* (DIRS 107294-DOE 1998) and has continued to update that report with supplemental information to present the status of cleanup efforts in the DOE complex. The report estimated a total cost of less than $3 billion (DIRS 107294-DOE 1998) for all projects at the Nevada Test Site. In addition to cleanup and remediation activities, this estimate includes subsurface monitoring and surveillance of the sites for up to 100 years (DIRS 107294-DOE 1998).

The Department is continuing environmental restoration at the Nevada Test Site and is studying and monitoring groundwater contamination of the underground test areas. No long-term plans for remediating the underground test areas have been developed.

Comment - EIS000392 / 0002
Cumulative effects: The DEIS fails to examine all of the past and reasonably foreseeable actions discussed for cumulative impacts. Specifically the impacts of low level radioactive waste transportation to the Nevada Test Site (NTS) are ignored. Issues such as land withdrawal, water resources, cultural resources, socioeconomic impacts and environmental justice have received inadequate analysis.

Response
Section 8.4 of the EIS discusses the cumulative impacts of waste transport to a repository at Yucca Mountain along with shipments of low-level radioactive waste to the Nevada Test Site. Sections 8.2 and 8.3 describe other possible cumulative impacts. Since the publication of the Draft EIS, DOE has revised some of these analyses and believes that the Final EIS presents a reasonable estimate of the cumulative impacts that could be expected in the region.

10 (1792)
Comment - EIS000630 / 0009
Military air space impacts. Also absent from the EIS was the adequate analysis of the cumulative impacts and the potential conflicts between the military air space practice areas, the ranges to the south, and the rail route.

Response
Section J.3.3 in the EIS describes the scenarios considered in the evaluation of transportation accidents, which included military airspace operated by the U.S. Air Force.

10 (1808)
Comment - EIS000332 / 0007
DOE fails to include reasonably foreseeable action proposals identified in other federal, state, and local documents (e.g., many DOI [Department of the Interior] actions are not included; Las Vegas Valley Water District water right applications are not included). DOE also relies upon analyses performed by other agencies where such agencies failed to identify impacts to Nye County and its resources, even when Nye provided supporting analyses and documentation through the agencies' administrative process.

Response
Chapter 8 of the EIS evaluates the cumulative impacts of the repository along with the impacts of other Federal, non-Federal, and private actions. If the impacts from the repository would not interact or somehow overlap in time or space with impacts from these other actions, DOE did not include them in the assessment of cumulative impacts. The commenter suggests that actions by the Department of the Interior and the Las Vegas Valley Water District should have been included in the assessment of cumulative impacts. However, the water rights applications filed by the Las Vegas Valley Water District are not within the groundwater basins potentially affected by the repository. Actions by the Department of the Interior that could have cumulative impacts with the Proposed Action are described in Section 8.1.2.2 of the EIS.

The commenter suggests that DOE relied upon analyses by other agencies where such agencies fail to identify impacts to Nye County, even when Nye County provided supporting analyses and documentation through the agencies' administrative processes. DOE cites analyses performed by other agencies when they provide insight to or a context for the Proposed Action. Whether these analyses reflect Nye County's input is not germane to the Department's use of documents. On the other hand, DOE has documented opposing viewpoints and analyses in the EIS. DOE included these views if they were based on scientific, regulatory, or other information supported by credible data and analytical methods. For example, opposing views on the nature of the groundwater system at Yucca Mountain are discussed in Section 3.1.4.2.2. Opposing views on other subjects are discussed elsewhere in this EIS.

10 (1815)
Comment - EIS000332 / 0013
With the cessation of nuclear weapons testing in 1992, Nye County has made substantial efforts to plan for its economic future in the US-95 corridor. The DEIS does not recognize these plans, and does not reflect a DOE obligation to ensure that the YMP [Yucca Mountain Project] will not thwart those plans. Nye County, by virtue of its location, characteristics, and overwhelming federal presence has been disproportionately impacted by past, present, and continuing federal actions. Nye County must receive just equity offsets, mitigation, and compensation from the U.S. to mitigate the cumulative [impacts] of these past and present actions, and the proposed repository, should it go forward.

Through Nye County's analyses and evaluations, a range of direct and indirect cumulative impacts have been identified (land use, water resources, lost economic opportunity, and others). Nye County believes that these impacts, although adverse and significant, can be mitigated through various measures.

Nye County will present its technical basis and evaluations to support the position that impacts stemming from the implementation of the proposed action can be mitigated, and will continue to request mitigation pursuant to NEPA [National Environmental Policy Act].

Response
Consistent with regulations of the Council on Environmental Quality (40 CFR 1508.7), DOE considered past, present, and reasonably foreseeable actions in its assessment of cumulative impacts and has reviewed a number of actions both current and proposed to determine their relevance. The expression "reasonably foreseeable" refers to future actions for which there is reasonable expectation that the action could occur, such as a proposed action under analysis, a project that already started, or a future action that has obligated funding.

DOE structured the cumulative impact assessments in Chapter 8 of the EIS by identifying actions the effects of which could coincide in time and space with the effects from the proposed repository and associated transportation activities.

The identification of the relevant actions was based on reviews of resource, policy, development, and land use plans prepared by agencies at all levels of government and from private organizations, other environmental impact statements, environmental assessments, and tribal meeting records. Consistent with regulations of the Council on Environmental Quality [1502.16(c) and 1506.2], in addition to the assessment of potential environmental impacts, the potential conflicts with plans issued by various entities were considered to the extent they provided relevant information.

The commenter indicated that Nye County would present its technical basis and evaluations to support their position that impacts from the Proposed Action can be mitigated. DOE would consider this information, when it is available, and would develop appropriate mitigation actions consistent with the Council on Environmental Quality regulations (40 CFR Parts 1500-1508) and Section 116(c) of the NWPA. Chapter 9 of the EIS identifies DOE-determined impact reduction features, procedures and safeguards, and mitigation measures under consideration for inclusion in the project plan and design. Chapter 9 also identifies ongoing studies that could eventually influence mitigation measures related to the project plan and design.

Comment - EIS000622 / 0011
There is also no cumulative figures that I could find regarding the fact that this is being built adjacent to the Nevada Nuclear Test Site. The Nevada Nuclear Test Site is already exposing everyone in the area through the air, through soils that blow around in high level winds, through the water, and there's not information about how this would cumulatively affect people in terms of genetics, natural wildlife or human health. I think this is inadequate and needs to be addressed with a lot more concern.

Response
Table 8-1 of the EIS lists the past, present, and reasonably foreseeable actions that DOE analyzed in Sections 8.2, 8.3, and 8.4 for cumulative impacts. Activities at the Nevada Test Site that would affect the cumulative impact analyses included past nuclear weapons testing; treatment, storage, and disposal of low-level radioactive waste,

mixed waste, transuranic waste, high-level radioactive waste, and hazardous waste; construction and operation of an intermodal transfer station near Caliente for the shipment of low-level radioactive waste to the Nevada Test Site; historic shipments of radioactive materials to and from the Nevada Test Site for other DOE facilities; and possible future shipments of radioactive materials to the Nevada Test Site. DOE believes that it has considered all past, present, and reasonably foreseeable actions on the Nevada Test Site in the cumulative impact analyses in Chapter 8.

10 (2330)
Comment - EIS000614 / 0015
The following issue needs to be addressed and thoroughly analyzed concerning direct impacts to Lander County in a detailed manner: military overflights and other federal agency interactions.

Response
DOE did consider the potential impacts of military overflights in its analysis of the proposed Yucca Mountain Repository. Section J.3.3, for example, describes potential transportation accidents associated with military operations from Nellis Air Force Base. As described in Section 8.1.2.2, the Department also considered other Federal activities in the region.

10 (2761)
Comment - EIS000897 / 0002
Will radiation sources in the area, other than the repository, be considered in a total dose calculation? Will the recently reported spent fuel buried somewhere in Area 25 of the Nevada Test Site be included? What about the cumulative impacts to groundwater from nuclear testing?

Response
The EIS discusses possible radiological sources other than the repository in Chapter 8. The cumulative impacts of such actions would not always be directly additive, however, due to spatial differences in the sources, time differences in potential releases, and differing transport mechanisms. For instance, the maximally exposed individual dose from airborne emissions from a particular facility would not be additive to the maximally exposed individual dose from the repository because the calculations are for two different locations. Therefore, DOE has quantified the impacts given such differences among the various potential sources of radiological emissions.

Section 8.3.2.1 describes the activities on the Nevada Test Site that could contribute to cumulative impacts with the proposed repository. Since issuing the Draft EIS, DOE has revised some of the analyses of impacts associated with the Nevada Test Site. Sections 8.2.2.2 and 8.2.7 now include information on radiation exposure from past nuclear weapons testing, and Section 8.3 includes updated estimates of future impacts to groundwater and air resources from activities on the Test Site.

There are no known sites in Area 25 where spent nuclear fuel has been buried. Parts from the old nuclear rocket program, and perhaps some fuel from this program, might be buried somewhere in Area 25, but nothing definite is known about the nature of the material or where it might be buried. This material was not accounted for in the cumulative impacts analysis because its existence, location, amount, and characteristics are not known.

10 (3004)
Comment - EIS000692 / 0005
I would like to say that it is almost laughable to any Nevada citizen that the DOE seriously claims to be taking cumulative impacts into consideration in the final choice between a Yucca Mountain repository and the two no action scenarios.

One look at the cumulative impacts evaluated sheet of your presentation should be enough to disqualify Yucca Mountain from further study.

Response
DOE has prepared this EIS so the Secretary of Energy can consider it, together with other factors required by the NWPA, in making a determination whether to recommend Yucca Mountain for development as a repository, rather than to present a choice between the Proposed Action and the No-Action Alternative.

DOE believes that Chapter 8 of the EIS provides a credible discussion of the cumulative impacts from the repository, along with the impacts of past, present, and reasonably foreseeable activities in the region. These discussions include short- and long-term cumulative impacts of the repository, the cumulative impacts of transportation, and the cumulative impacts of manufacturing disposal containers and shipping casks.

10 (3092)
<u>Comment</u> - EIS000706 / 0005
Despite [the key role of Clark County] there is almost no evaluation of the potential implications of transporting nuclear waste through our urbanized, congested and increasingly developing valley.

The DEIS also fails to evaluate cumulative impacts associated with other Nevada Test Site activities. As an example, there is no examination of the probable use of the Nevada Test Site as the disposal site for the nation's low level radioactive waste. This offers the potential to dramatically increase the total numbers of shipments through Clark County and Southern Nevada.

<u>Response</u>
Section 8.4 of the EIS discusses the cumulative impacts of transportation in the region, and includes the impacts of shipping a wide variety of nuclear materials. DOE examined many documents to determine the likely number of waste shipments in the region and the resultant impacts. For all the actions identified in Section 8.4, the Department described the radiological impacts and the impacts from vehicle accidents.

Section 8.2.12.2 discusses the cumulative impacts from the storage of low-level waste, which includes the reasonably foreseeable action of the Nevada Test Site becoming a regional low-level waste-disposal site.

10 (3990)
<u>Comment</u> - EIS000724 / 0005
Another problem with the DEIS is that there is no way to discover the total risk associated with the Yucca Mountain Project. The DEIS should clearly spell out what the accumulation of all the possible impacts could be, especially for the residents of southern Nevada. For instance, what if I were born near Yucca Mountain and I grew up drinking contaminated water and eating contaminated food? What if I am an involved worker at Yucca Mountain and I become pregnant and nurse my child? How can I determine from reading the DEIS what the total risk is to myself and my child? Or, what if I am a truck driver who transports casks from the east coast to Yucca Mountain, and I live along the transportation route and my partner is a crossing guard at one of the intersections on the transportation route, and we have a child who attends a school on the route. How can I determine our total risk as a family?

<u>Response</u>
DOE is not able to calculate past and future doses to each resident in the region. To do so would require accounting for lifestyle habits such as cross-country airline flights, past residence in locations that might have substantially higher or lower background cosmic radiation, medical diagnostic tests and treatments, etc. However, the Department has calculated the impacts to various receptor groups in Chapters 4 through 8, which provide a reasonable estimate of radiation doses. These groups include involved radiation workers, noninvolved workers, members of the public exposed along the transportation route, and members of the public in the vicinity of the proposed repository. To estimate impacts, individuals could identify the appropriate receptor group or groups to which they belong and add the impacts for individuals in those groups. For example, if an individual was a noninvolved worker and lived near the repository, that person would be in two receptor groups: the general public and the noninvolved worker group. This would provide a first-order approximation of the total radiation dose to that individual.

10 (4206)
<u>Comment</u> - EIS001160 / 0022
The DEIS does not adequately address issues raised and substantiated by White Pine County during the scoping process. For example:

The repository EIS must consider the possibility that U.S. Highways 93 and 6 and State Highway 318 through White Pine County will be used for both high-level and low-level radioactive waste [LLRW] shipments. Alternatives considered within the EIS should consider with and without LLRW shipments along highway access options through White Pine County. The DEIS does not consider the cumulative impacts (radiological, socioeconomic, etc.) of shipments of HLW [high-level radioactive waste] and LLW through White Pine County.

Response
Under regulations issued by the U.S. Department of Transportation (49 CFR 397.101), truck shipments of spent nuclear fuel and high-level radioactive waste could not use a route through White Pine County. Therefore, an analysis of cumulative impacts is not necessary. However, Appendix J of the EIS evaluates the sensitivity of impacts to variations in routing through Nevada. For comparison purposes, Section J.3.1.3 considers a route through White Pine County, but this route would not be used.

10 (4555)
Comment - EIS000225 / 0006
Nye County consultant Thomas Buqo and Steve Frishman, a consulting geologist with the State Nuclear Projects Agency, questioned calculations by Yucca Mountain Project scientists that show the radioactive inventory after 1,000 years of waste storage would be 120 million curies, or units of radioactivity. That amount is less than half the current burden of 300 million curies left from below-ground nuclear tests at the Nevada Test Site. Frishman said the Yucca Mountain inventory would be at least 4 billion curies after 1,000 years of decay, potentially adding more contamination to ground water supplies in Nye County than from what exists now as a result of full-scale U.S. nuclear weapons.

Response
DOE is not aware of the origin of the 120-million-curie estimate provided by the commenter. Table A-10 in the EIS provides the estimated curies of each radionuclide projected for disposal in the repository. If one added the amounts of each radionuclide in the list, the total would be approximately 14 billion curies. This is the estimate of the number of curies of various radionuclides at the time of receipt at the repository. By considering the radioactive decay of the radionuclides for 1,000 years, the radionuclide inventory remaining in the mountain at that time would be approximately 140 million curies.

It appears that the commenter might be referring to the number of kilograms of uranium projected for Modules 1 and 2, which was listed as 120 million in Table 8-36 of the Draft EIS. This figure was used to evaluate the potential for uranium (evaluated here for its chemical toxicity as opposed to its radioactivity) to affect the offsite drinking water, along with any other chemically toxic materials that could dissolve in the groundwater (see Section 8.3.1.1 of the EIS).

DOE recognizes, and the EIS acknowledges, that the radioactivity stored in the repository would be greater than the radioactivity that is currently estimated at the Nevada Test Site. However, the quantity of activity alone is not the sole indicator of risk. As described in the EIS, the repository would be an engineered facility designed to contain the material placed in it over very long periods. This is very different from underground detonation sites at the Nevada Test Site where the radioactivity is not in a facility designed for long-term containment.

10 (4570)
Comment - EIS001521 / 0084
Page 8-35, fifth paragraph--the 15,000 acre-feet per year reference should be to page 3-40, Table 3-11 (not Table 3-10), and the correct withdrawal amount is 14,000 acre-feet (not 15,000 acre-feet as stated).

Response
The comment is correct, and DOE has revised the EIS accordingly.

10 (4610)
Comment - EIS001430 / 0008
Page 8-74, 2. incorrectly states that Figure 8-3 (p. 8-11) shows the locations of underground nuclear tests.

Response
Thank you for your comment. DOE has changed the text to refer to the appropriate figure.

10 (4611)
Comment - EIS001430 / 0009
Page 8-7, bullet 2 has different numbers of waste packages given than in Table 8-34 (p. 8-60).

Response
Thank you for your comment. The Department has changed the reference in bullet two to refer correctly to the actual number of waste packages listed under the reference "DIRS 102030-CRWMS M&O 1999."

10 (4749)
Comment - EIS001450 / 0010
There are several problems where words state that a figure or table shows something that it doesn't, as noted below:

a. Page 8-7 — the text in the second bullet gives different (and lower) ranges for the number of waste packages than the totals for each category in referenced Table 8-34 (page 8-60).

b. Page 8-74, activity 2 — this description incorrectly states that Figure 8-3 (page 8-11) shows the locations of underground nuclear tests; the location of the nuclear and high explosive test zones are, however, shown on Figure 3-2 (page 3-8).

Response
DOE has changed the text in the Final EIS as follows: (a) the reference in bullet 2 was changed to refer correctly to the actual number of waste packages that are listed under the reference "DIRS 102030-CRWMS M&O 1999"; and (b) the reference to Figure 8-3 was changed to the correct figure.

10 (5167)
Comment - EIS001910 / 0006
The Draft EIS does not go far enough to address cumulative impacts which are likely results because of past, present and future impacts from NTS [Nevada Test Site] activities. For instance, the DOE mentions a proposed federal action to return certain lands of the Timbisha Shoshone. An important factor left out regarding this return is that the land was subjected to years of radioactive fallout from the Nevada Test Site. The amount of radiation exposure experienced by the indigenous people residing in the area has not been assessed nor have any baseline health studies been conducted. The people still living in the area may have experienced significantly higher levels of exposure because of the many exposure pathways common to Native American peoples. The added impacts of long-term releases from the transportation of radioactive waste and spent nuclear fuel cannot be accurately calculated. The status of the Indian nation populations should give rise to a higher degree to assurance that they will be protected from increased exposures.

The absence of previous exposure data also is important regarding impacts of long-term releases from the transportation of radioactive waste and spent nuclear fuel. A true picture of potential impacts from transportation exposure cannot be accurately calculated unless information from past Nevada Test Site releases can be added to the project exposure data.

A joint NCI/CDC [National Cancer Institute/Centers for Disease Control] effort to assess human health impacts from bomb testing at the NTS is currently underway. The people whose homelands are near the Nevada Test Site were subjected to multiple detonations of atomic weapons. This project affirms what Native American people in the area have known for years--that radioactive fallout caused significant negative health impacts which includes chromosomal damage, debilitating diseases, and mortality.

Utmost protective considerations must be accorded to the people indigenous to this area. An apparent conclusion or response to the Timbisha land return issue may be that the reservation is being created well after the Yucca Mountain has begun, thereby absolving the DOE of its trust responsibility. Once again, the Timbisha Shoshone have lived there thousands of years prior to any encroachment or intrusion of federal actions.

The fact of primary habitation of indigenous peoples, whom the federal trust responsibility is to protect, is an important point in regard to the divergence of opinion of ground-water protection requirements. The Native American tribes and citizens are entitled to assess the viability of the water protection issues. The DOE acknowledges that further studies of impacts are needed along transportation corridors. The tribes do not have emergency response programs in place and are isolated from federal, or other assistance in an emergency situation. At the pace and funding level proposed by current DOE officials charged with delivery of emergency preparedness program planning for corridor states and tribes, when the shipments commence, even several years from now, it does not appear that tribes will be ready. Tribal governments will continue to have unmet needs and unfunded mandates.

Response
The commenter is correct that the assessment of impacts of past nuclear weapons testing at the Nevada Test Site is part of an ongoing effort by several organizations, including the National Cancer Institute and the Centers for Disease Control. However, the available information does not indicate that these assessments have concluded "that radioactive fallout caused significant negative health impacts which includes chromosomal damage, debilitating diseases, and mortality." Readers interested in further information about the effects of past testing of nuclear weapons should refer to the *National Cancer Institute Study Estimating Thyroid Doses of I-131 Received by Americans From Nevada Atmospheric Nuclear Bomb Tests* (DIRS 152469-Institute of Medicine and National Research Council 1999).

DOE has reviewed the available information and has included a discussion in Chapter 3 of the Final EIS on the health impacts of past above-ground weapons testing at the Nevada Test Site. In addition, Chapter 8 considers these impacts as they contribute to cumulative impacts.

Since DOE issued the Draft EIS, Congress enacted legislation, signed by the President, that created the Timbisha Shoshone Trust Lands. These lands consist of discontinuous parcels in southeastern California and southwestern Nevada. The Bonnie Claire Alternate variation of the Carlin and Caliente Corridors crosses a parcel of the trust lands near Scottys Junction, Nevada. In addition, potential shipments using the Caliente route for heavy-haul trucks would cross the same parcel on U.S. 95. DOE believes that radiation exposure impacts to persons on the Timbisha Shoshone Trust Lands from the repository, spent nuclear fuel and high-level radioactive waste transportation, and other past, present, and reasonably foreseeable activities, including past weapons testing, would be small due to the initial indications that minimal exposures would be associated with the parcels that comprise the reservation, including the parcel near Scottys Junction.

The commenter also correctly states that DOE would conduct further studies of impacts along a rail corridor or route for heavy-haul trucks should one of the implementing alternatives described in the EIS be selected for use in transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain (see Section 6.3.3 of the EIS). The studies would be conducted and reported in accordance with the applicable requirements of the National Environmental Policy Act.

As stated in Appendix M of the EIS, approximately 4 years prior to the first shipment through state or tribal reservation boundaries, DOE plans to implement Section 180(c) of the NWPA through a grants program. It is DOE's objective to provide funding and technical assistance, subject to annual appropriations, to assist states and tribes to obtain access to the increment of training necessary to prepare for NWPA shipments (63 *FR* 23753, April 30, 1998).

10 (5186)
Comment - EIS001443 / 0011
The DEIS treats both geohydrologic and transportation impacts of the proposed repository as "stand alone" issues without recognition of the fact that the repository would operate in an environment already heavily impacted by past and ongoing nuclear waste activities. Territory adjacent to the Yucca Mountain site is heavily contaminated by radioactive materials as a result of decades of Atomic Energy Commission (AEC)/Department of Energy nuclear testing, while many of the roadways and rail corridors expected to be used for transport of spent nuclear fuel and high-level nuclear waste are already in service for the transport of low level and defense wastes to the Nevada Test Site and the Waste Isolation Pilot Plant in New Mexico. Operation of the Yucca Mountain repository would be one in a series of similar, linked actions undertaken by a single agency: the Department of Energy. The additional risks which Yucca Mountain would place on groundwater resources, human populations and national and regional transportation resources must be analyzed and weighted within the context of past, present and foreseeable non-Yucca Mountain-related AEC/DOE actions in order to meet the intent of NEPA [National Environmental Policy

Act] and allow decisionmakers and the public to place the proposed action in the proper context. The NEPA exemptions provided DOE by the Nuclear Waste Policy Act do not include exemption from addressing cumulative impacts.

Response
DOE believes that Chapter 8 of the EIS contains a credible discussion of the impacts from the repository that could be cumulative with the impacts of past, present, and reasonably foreseeable activities in the region. This chapter includes discussions of short- and long-term cumulative impacts of the repository, the cumulative impacts of transportation, and the cumulative impacts of manufacturing disposal containers and shipping casks. Section 8.3 discusses the impacts of past nuclear weapons testing at the Nevada Test Site and the cumulative effects of this action and of the proposed repository. Section 8.4 discusses the cumulative effects of the transportation of radioactive material in the area, including waste transport to the Test Site and the Waste Isolation Pilot Plant.

10 (5187)
Comment - EIS001443 / 0012
The DEIS should be amended to include description of the environmental context within which repository operations and transportation of nuclear waste will take place. Specifically, the DEIS needs to map and quantify the current level of environmental contamination in the region, and current and projected non-Yucca Mountain nuclear and hazardous waste shipment activity. This information needs to be compiled in a manner such that the incremental increase in risk posed by the repository and the total risk to humans and natural resources posed by the sum of DOE activities is clearly discernable.

Response
DOE believes that Chapter 8 of the EIS contains a credible discussion of the impacts from the repository that could be cumulative with the impacts of past, present, and reasonably foreseeable activities in the region. This chapter includes discussions of short- and long-term cumulative impacts of the repository, the cumulative impacts of transportation, and the cumulative impacts of manufacturing disposal containers and shipping casks. Section 8.4 of the EIS contains an analysis of the cumulative transportation impacts that could occur as the result of past, present, and reasonably foreseeable actions. While the total impacts from these separate actions is not necessarily the sum of the impacts of the individual actions, the list of impacts in Table 8-58 provides a sense of the scale of the potential impacts.

10 (5261)
Comment - EIS001887 / 0020
The Draft EIS fails to adequately assess cumulative impacts from past, current, and future activities at the Nevada Test Site (NTS). Estimates of the NTS contribution to off-site radiation exposures and projections of future cumulative exposures are based on woefully inadequate and incomplete data. Known and suspected contaminated sites in the proposed withdrawal area are not acknowledged, and their remediation status is not described.

DOE's own estimates place the combined source term for all tests conducted at the NTS at 300 million curies. The geographic scope of existing groundwater contamination in the region may exceed 300 square miles and extend to depths ranging from 500 to 5,000 feet. Yet the Draft EIS concludes that the maximum potential dose from the underground testing inventory is calculated to be 0.2 millirem per year and that the cumulative annual dose from both NTS and Yucca Mountain sources would [be] 0.42 millirem per year.

In fact, DOE does not have the data required to calculate a base case scenario for determining groundwater travel time in the region, let alone to make an estimate of radionuclide movement in the groundwater. Estimates of hydraulic conductivity contained in the Draft EIS (e.g., movement of contaminants through the groundwater) rely on only one data set obtained from a single well for a period of fifty years. This limited data is then extrapolated over a 10,000 year period to produce the estimated 0.2 millirem per year dose figure (as the contribution to cumulative groundwater impacts caused by nuclear testing). As a result, it is not possible, with any reasonable level of confidence, to estimate the amount of radionuclides released through the groundwater to the biosphere in the region of influence beneath the NTS and offsite locations. Both the State of Nevada and DOE's own independent peer review group (2) have documented these facts as part of ongoing technical and regulatory reviews of DOE's Underground Test Area program for the NTS.

Developing believable and reasonable estimates of the potential cumulative impacts to groundwater from existing contamination beneath the NTS and future contamination from a proposed repository at Yucca Mountain is mandatory for assessing the degree to which the Proposed Action would affect public health and safety. The Draft EIS fails to make this fundamental assessment and is, therefore, deficient. The Draft EIS fails to meet the basic requirement of NEPA [National Environmental Policy Act] as defined by the Council of Environmental Quality implementing regulations, Sec. 1500.1(b).

The Draft EIS also fails to adequately assess impacts from contaminated sites known to be located within the proposed repository withdrawal area. For example, it is known that there are high-level waste residues from the nuclear rocket program buried at an unknown location in Area 25 of NTS. The Draft EIS must contain affirmative information regarding the location of this material and assure that, if it is in the proposed withdrawal area, it will be recovered and managed according to applicable laws, regulations, and orders. In addition, there are reportedly at least 20 other known contaminated sites within the portion of the NTS that is included in the proposed withdrawal area. These areas must be fully rehabilitated under the jurisdiction of NTS so they are not passed on to OCRWM [Office of Civilian Radioactive Waste Management], where they would remain a continuing hazard. The impacts associated with required clean-up activities should have been addressed in the Draft EIS.

(2)"External Peer Review Group Report on Frenchman Flat Data Analysis and Modeling Task, Underground Test Area Project," (ITLV/13052-077A0), prepared for U.S. Department of Energy, Nevada Operations Office under contract No. DE-ACO8-97NV13052 (September 1999).

Response
Section 8.3.2.1.1 of the EIS acknowledges that there is uncertainty in estimating potential impacts to groundwater from past weapons testing on the Nevada Test Site. Some groundwater parameters are not known with certainty, and other information cannot be disseminated to the public due to national security concerns. The Draft EIS analyzed the cumulative impacts to groundwater from the repository, as well as from past underground weapons testing and low-level radioactive waste disposal at the Nevada Test Site. The Final EIS contains additional, more detailed analyses based on more recent data.

DOE believes that the values and assumptions used in the updated analyses in the Final EIS ensures the Department considered the associated range of cumulative impacts. DOE chose these values based on analyses in the Nevada Test Site EIS (DIRS 101811-DOE 1996) and believes it has made a reasonable estimate of the impacts. As stated in the EIS, DOE believes that its assumptions resulted in a conservative estimate of the true impacts. It is true that the Department used data for hydraulic properties based on measurements from a single well, as stated in Section 8.3.2.1.1. This point is one of the sources of uncertainty in the analysis; DOE used the best available data and the professional judgment of its analysts to arrive at an estimate of the impacts.

DOE has not determined future responsibilities for the management of Area 25. There are no known sites in Area 25 where spent nuclear fuel has been buried. Parts from the old nuclear rocket program, and perhaps some fuel from that program, might be buried somewhere in Area 25, but nothing definite is known about the nature of the material or where it might be buried. This material was not accounted for in the cumulative impacts analysis because its existence, location, amount, and characteristics are not known.

Comment - EIS000817 / 0160
P. 8-1. So now you want to dump everything you can in the repository if you open it -- surely not what Nevada was told at the beginning of this speculation! So if the NRC [Nuclear Regulatory Commission] says put it in the repository -- Congress will agree -- and in all these other types of waste go -- further complicating materials interaction analysis -- and the "radioactive soup" at the end of repository life becomes more "spicy" than before. (And Nevada gets the Nevada Test Site waste and Beatty Waste Disposal area, too.) Poor Nevada.

Response
Comments that DOE received from the public during the scoping process for this EIS expressed the concern that more spent nuclear fuel and high-level radioactive waste would be generated than the 70,000 metric tons of heavy metal accounted for in the Proposed Action. In response to those comments, DOE evaluated the emplacement of the total projected inventory of commercial spent nuclear fuel and DOE spent nuclear fuel and high-level radioactive

waste (Inventory Module 1) and of that total inventory plus the inventories of commercial Greater Than-Class-C low-level waste and DOE Special-Performance-Assessment-Required waste (Inventory Module 2). Sections 8.2 and 8.3 of the EIS examine the cumulative short- and long-term impacts of the Proposed Action along with the disposal of Inventory Modules 1 and 2. The analysis of future activities in Chapter 8 is not restricted to activities that would occur with certainty; rather, the analysis gives an estimate of potential cumulative impacts from actions that are reasonably foreseeable.

Disposal of more than 70,000 metric tons of heavy metal at the repository would require legislative action by Congress unless a second licensed repository was in operation. Disposal of Greater-Than-Class-C low-level waste and Special-Performance-Assessment-Required waste at the repository would require either legislative action or a determination by the Nuclear Regulatory Commission that the material should be classified as high-level radioactive waste.

Comment - EIS001887 / 0188
Page 3-79; Section 3.1.8 - Occupational and Public Health and Safety

It is known that there is some high-level waste residue from the nuclear rocket program buried at an unknown location in Area 25 of NTS [Nevada Test Site]. The Draft EIS must contain affirmative information regarding its location and assure that, if it is in the proposed withdrawal area, it will be recovered and managed according to applicable laws, regulations, and orders. Also, there are reportedly some 20 contaminated sites within the portion of Area 25 of the NTS that is included in the proposed withdrawal area. Before issuance of a Final EIS, these areas must be fully rehabilitated under the jurisdiction of NTS so they are not passed on to OCRWM [Office of Civilian Radioactive Waste Management] where they would remain a continuing hazard.

Response
DOE has not determined future responsibilities for the management of Area 25. There are no known sites in Area 25 where spent nuclear fuel has been buried. Parts from the old nuclear rocket program, and perhaps some fuel from this program, might be buried somewhere in Area 25, but nothing definite is known about the nature of the material or where it might be buried. This material was not accounted for in the cumulative impacts analysis because its existence, location, amount, and characteristics are not known.

Comment - EIS001660 / 0045
Mineral County submits Eureka County's analysis as Mineral County's comments (see Attachment E). [Following is text from reference.]

Analysis of shared rail use inadequate. The analysis of the impacts of shared public/private use of DOE branch rail lines is inadequate. (pp. 8-4, -15) The analysis properly belongs in Chapter 6, Transportation Impacts. The statement that predicting increases in rail traffic from shared use would be difficult and, therefore, is not done is unacceptable. The DEIS says there will be impacts, and they must be analyzed, disclosed, and mitigated as necessary. (p. 8-87)

Analysis of impacts on public services inadequate. The DEIS does not adequately address cumulative impacts on emergency response services. The DEIS says that cumulative operations impacts would result because of the extra 14 years of shipping required for Modules 1 or 2 (p. 8-85) but that the DOE expects no cumulative socioeconomic impacts. This conclusion is contradictory and improbable since state, local, and tribal government emergency services would continue to be impacted.

Other comments. The failure of Congress to ratify the Nuclear Test Ban Treaty makes the future resumption of nuclear weapons tests more likely. (pp. 8-3,-11, -12) The statement that interim storage was not analyzed for cumulative impacts because it is uncertain is inappropriate; it is reasonably foreseeable and must be included. (p. 8-5) The inadequacies of the air pollution analysis are similar to those in Chapter 4: the discussion is vague and the conclusions unsupported by the evidence, particularly the statement that there will be no effect on the Las Vegas Valley air basin. (pp. 8-24 to 8-30) The statement that the final EIS will review new information from the Pipeline

Southeast Expansion Project for cumulative impacts is unacceptable, since the public will not have the opportunity to comment (p. 8-85).

Response

DOE structured the cumulative impact assessments presented in Chapter 8 of the EIS by identifying actions the effects of which could coincide in time and space with the effects from the proposed repository and associated transportation activities. Consistent with Council on Environmental Quality regulations (40 CFR 1508.7), DOE considered past, present, and reasonably foreseeable actions in its assessment of cumulative impacts and has reviewed a number of actions, current and proposed, to determine relevance. The expression "reasonably foreseeable" refers to future actions for which there is reasonable expectation that the action could occur, such as a proposed action under analysis, a project that has already started, or a future action that has obligated funding.

The identification of the relevant actions was based on reviews of resource, policy, development, and land use plans prepared by agencies at all levels of government and from private organizations, other environmental impact statements, environmental assessments, and tribal meeting records. Consistent with Council on Environmental Quality regulations [40 CFR 1502.16(c) and 1506.2], in addition to the assessment of potential environmental impacts, the potential conflicts with plans issued by various entities were considered to the extent they provided relevant information. Once DOE selected a transportation mode and specific transportation corridor, more definitive information could be developed on potential conflicts with land uses and various agency plans and policies and, ultimately, the mitigation measure that could be needed to resolve conflicts and impacts on a given area.

In the case of shared rail use, DOE believes that the rail lines discussed in Chapter 8 of the EIS would have benefits for the surrounding communities and industries. However, potential sharing of the rail line is speculative at this point, and including these rail lines in the cumulative impact analyses could result in a misrepresentation of those impacts.

In relation to public services, the continuation of operations for an additional 14 years would not result in an increase or decrease in emergency response services. Because the status quo would be maintained, DOE does not expect socioeconomic impacts.

Since 1992, there has been a moratorium on nuclear testing. Even though the Nevada Test Site must maintain the ability to resume testing, the Department does not believe that a resumption of testing is a reasonably foreseeable action. Therefore, it was not included in the analyses in Chapter 8 of the EIS. Nevertheless, a recent evaluation of impacts from a resumption of underground testing at the Nevada Test Site (DIRS 103273-Walck 1996) concluded that the only impact such testing would pose on the repository would be ground motion from the energy released by the detonations. DOE has determined that such effects would not exceed the seismic design criteria for the repository. In other words, the design-basis earthquake for the repository would generate stronger ground motions than would underground nuclear detonations on the Nevada Test Site. Because DOE has designed the repository to survive the design-basis earthquake with minimal damage, ground motion from the resumption of underground testing would be unlikely to result in substantial damage to the surface or underground facilities at Yucca Mountain.

DOE believes that interim storage at Yucca Mountain is not a reasonably foreseeable action, and that it is inappropriate to analyze potential impacts of that action in the EIS. As stated in Section 2.2 of the EIS, if Yucca Mountain was determined to be unsuitable or not approved by the President or Congress, DOE would prepare a report to Congress. This report, required by the NWPA, would contain DOE recommendations for further action to ensure the safe, permanent disposal of spent nuclear fuel and high-level radioactive waste, including the need for new legislative authority. Other than this action, the future course that Congress, DOE, and the commercial nuclear power utilities would take is uncertain. Several possibilities would be pursued, including centralized interim storage, for example, the Private Fuel Storage Facility proposed in northern Utah (see Section 8.1.2.3 of the EIS), or the study of another location for a deep geologic repository.

Section 8.3.2.1 describes the activities on the Nevada Test Site that could be cumulative with impacts from the proposed repository. Since issuing the Draft EIS, DOE has revised some of the analyses of impacts associated with the Test Site. For example, Sections 8.2.2.2 and 8.2.7 of the EIS now include information on radiation exposure from past nuclear weapons testing, and Section 8.3 includes updated estimates of future impacts to groundwater and air resources from activities on the Nevada Test Site.

10 (5556)
Comment - EIS001887 / 0189
Page 3-83; Section 3.1.8.2 - Radiation Environment in the Yucca Mountain Region

This section references Bechtel 1998, page 7-5, the Annual Site Environmental Report for the Nevada Test Site. All of the off-site radiological doses in this report are given as EDE, effective dose equivalents. EPA's [the Environmental Protection Agency's] Clean Air Package 1988 (CAP-88 PC) program was used to calculate the doses. The dose being calculated is actually the committed effective dose equivalent (CEDE) and should not be given as an EDE.

Response
The commenter is correct in noting that the Clean Air Package 1988 software calculates the committed effective dose equivalent. In addition, Clean Air Package 1988 calculates doses from external exposure. However, the committed effective dose equivalent is merely a designation for effective dose equivalent calculated for internal exposures. The term "committed" refers to the fact that following intake (regardless of the length of intake), the individual is committed to receive a given dose until the radioactive material is effectively removed from the tissues of the body. Therefore, the committed effective dose equivalent that results from intakes during a year (that is, an annual intake) can be compared and added to the effective dose equivalent that results from external radiation exposure. When the International Commission on Radiological Protection introduced the concept of effective dose equivalent (DIRS 101075-ICRP 1977), the concept included both internal and external exposures.

Comment - EIS001887 / 0344
Page 8-12; Section 8.1.2.2 - Federal Actions - DOE Waste Management Activities

The statement in paragraph 2 of this section regarding potential short- and long-term cumulative impacts of waste management activities is not consistent with information in Table 8-1 (page 8-4) that indicates no short-term cumulative impacts from future potential waste management activities.

Response
DOE has revised Table 8-1 to indicate that there are no short-term impacts beyond those evaluated for Nevada Test Site activities.

10 (5741)
Comment - EIS001887 / 0345
Page 8-22; Table 8-5 - Summary of cumulative short-term impacts in the proposed Yucca Mountain Repository region.

Utilities: Table 8-5 states that peak electric power demand would require an upgrade of the transmission and distribution system. In order for this EIS to be complete, it should include an evaluation of impacts of a specific proposed upgrade since it is acknowledged that an upgrade would be required as part of the Proposed Action. Section 8.2.11 does not provide an evaluation of the impacts of the necessary upgrade.

Response
To the extent reasonable, DOE analyzed the impacts of upgrading the electrical transmission system in Section 4.1.11.2 of the EIS. Because this analysis identified no adverse impacts to the environment, the Department did not repeat the discussion in Chapter 8. To avoid confusion on this issue, the Department has added text to Chapter 8 that refers to the discussion in Chapter 4.

10 (5743)
Comment - EIS001887 / 0347
Page 8-31; Section 8.2.2.2.2 - Radiological Air Quality

This section incorrectly states that the 2.5 mrem per year cumulative dose is "about 40 percent" of the 10 mrem annual dose regulatory limit.

<u>Response</u>
The Department has updated Section 8.2.2.2.2 of the EIS to reflect the proper percentage for the cumulative dose in relation to the annual dose limits.

10 (5744)
<u>Comment</u> - EIS001887 / 0348
Page 8-36; Section 8.2.4 - Biological Resources

This section is deficient in two major respects. First, an ecosystem approach was not adopted for the Draft EIS and second, thermal loading impacts are not factored into cumulative effects. Therefore, this section is inadequate.

<u>Response</u>
The commenter's contention that DOE should have used an ecosystem approach in analyzing the Proposed Action is described as an opposing view in Section 3.1.5. That section also contains DOE's reasons for selecting the analytic approach used in the EIS. The Department believes that the approach used in the EIS is adequate.

10 (5745)
<u>Comment</u> - EIS001887 / 0349
Page 8-37; Section 8.2.5 - Cultural Resources

DOE should make provisions for identifying, evaluating, and treating historic properties if Inventory Module 1 or 2 is authorized.

<u>Response</u>
The Department realizes that the implementation of Inventory Modules 1 or 2 would disturb more land than was analyzed for the Proposed Action. As discussed in Section 8.2.5, if either inventory module is implemented, the Department would fulfill its obligations under Section 106 of the National Historic Preservation Act, as amended to ensure that cultural resources (including historic properties) were preserved to the extent possible.

10 (5746)
<u>Comment</u> - EIS001887 / 0350
Page 8-59; Section 8.3 - Cumulative Long-Term Impacts in the Proposed Yucca Mountain Repository Vicinity

The performance assessment results shown in tables for this section are based on a Total System Performance Assessment (TSPA) code and supporting analyses developed prior to those that will be used in the site suitability evaluation for site recommendation. The Draft EIS must include a description of the current TSPA and include its results and analyses rather than relying on an acknowledged incomplete and obsolete TSPA. In order to meet the need for a complete and accurate evaluation of the long-term impacts of the Proposed Action, DOE should issue a new Draft EIS for public review and comment that includes information and analyses consistent with the Site Recommendation Report.

<u>Response</u>
Section 8.3 of the Final EIS contains the results of the most current Total System Performance Assessment for the flexible design.

10 (5747)
<u>Comment</u> - EIS001887 / 0351
Page 8-74; Section 8.3.2.1 - Past, Present, and Reasonably Foreseeable Future Actions at the Nevada Test Site - Item Number 5. Shallow Land Radioactive Waste Disposal

There has been no demonstration of the "absence of a groundwater pathway." Section 8.3.2.1.3 does not provide any basis for this assertion.

<u>Response</u>
The commenter is correct. DOE has changed the EIS accordingly.

10 (5748)
Comment - EIS001887 / 0352
Pages 8-74 to 8-76; Section 8.3.2.1.1 - Underground Nuclear Testing

The discussion in this section of the Draft EIS addresses cumulative impacts associated with groundwater contamination within the Yucca Mountain region. The discussion covers contamination beneath the Nevada Test Site (NTS).

Between 1951 and 1992, DOE conducted more than 1,000 nuclear tests at the NTS. Nearly one third of these tests were conducted in or near the groundwater. State officials contend that as much as 300 square miles of surface and subsurface area on and off the NTS are contaminated with radionuclides. The Draft EIS states that the estimated radionuclides source term for all subsurface tests was 300 million curies.

This section of the Draft EIS concludes by stating that "...the maximum potential dose from the underground testing inventory is calculated to be 0.2 millirem per year...." The document further states that the maximum cumulative impact of the Proposed Action in 10,000 years (i.e., radionuclides released from Yucca Mountain at the proposed point of compliance (20 kilometers from the repository) would be 0.22 millirem per year. Adding this to the NTS release of 0.2 millirem per year produces a cumulative release of 0.42 millirem per year.

The State of Nevada believes it is not yet possible, with any reasonable level of confidence, to estimate the release of radionuclides through the groundwater to the biosphere in the region of influence beneath the NTS and offsite locations. In fact, DOE does not have the data required to calculate a base case scenario for determining groundwater travel time in the region, let alone to make an estimate of hydraulic conductivity (important for determining the rate of movement of contaminants in the groundwater). The State of Nevada has repeatedly documented these facts as part of the State's ongoing regulatory review of DOE's Underground Test Area program for the NTS. The State's detailed comments are available on the World Wide Web at the following addresses:

http://www.state.nv.us./ndep/boff/ndep13.htm
http://www.state.nv.us./ndep/boff/ndep11.htm

It should also be noted that DOE's current program for assessing groundwater contamination beneath the NTS was recently criticized by an independent external peer review group commissioned by DOE. Overall, the reviewers found inadequate data to support groundwater flow modeling at NTS. They noted that available groundwater level and permeability data were inadequate for the assessment of groundwater flow directions, rates, and travel times in the vicinity of the contaminated areas.(35)

Despite assumptions presented in the Draft EIS, any attempt by DOE to present a "bounding-analysis" of potential cumulative groundwater contamination caused by nuclear testing at the NTS is simply not possible. Moreover, estimates of hydraulic conductivity contained in the Draft EIS rely on only one data set obtained from only one well in a period of fifty years. Using this limited information and then extrapolating the data over a 10,000-year period to produce the estimated 0.2 millirem per year dose figure is pure fiction.

Current estimates suggest the geographic scope of existing groundwater contamination in the region may exceed 300 square miles and extend to depths ranging from 500 to 5,000 feet.

Developing believable and reasonable estimates of the potential cumulative impacts to groundwater from existing contamination beneath the NTS and future contamination that would escape from a proposed repository at Yucca Mountain is mandatory for assessing the degree to which the Proposed Action would affect public health and safety. The Draft EIS fails to make this basic, rudimentary assessment and is, therefore, deficient. The Draft EIS fails to meet the basic requirement of NEPA [National Environmental Policy Act] as defined by the Council of Environmental Quality implementing regulations, Sec. 1500.1(b).

Groundwater contamination attributable to underground nuclear weapons testing has been found off the NTS on the Nellis Air Force Range. Also, contamination has been detected within the NTS boundaries as far as 0.8 miles from a nuclear test location known to be the source of the contamination.

(35) “External Peer Review Group Report on Frenchman Flat Data Analysis and Modeling Task, Underground Test Area Project,” (ITLV/13052-077A0), prepared for U.S. Department of Energy, Nevada Operations Office under contract No DE-ACO8-97NV13052 (September, 1999).

Response
Section 8.3.2.1.1 of the EIS acknowledges that there is uncertainty in estimating potential impacts to groundwater from past weapons testing on the Nevada Test Site. For the Final EIS, the Department has refined the Nevada Test Site groundwater impact analysis to consider not only the total inventories of radionuclides, but also the relative source term radionuclide concentrations and dilution factors for the repository and the Nevada Test Site. However, some groundwater parameters are not known with certainty, and other information cannot be disseminated to the public. The Draft EIS analyzed the cumulative impacts to groundwater from the repository, as well as from past underground weapons testing and low-level radioactive waste disposal at the Nevada Test Site. The Final EIS contains additional, more detailed analyses based on more recent data.

DOE believes that the values and assumptions used in the updated analyses in the Final EIS provide a conservative estimate of cumulative impacts. DOE chose these values based on analyses in the Nevada Test Site EIS (DIRS 101811-DOE 1996) and believes it has made a reasonable estimate of the impacts. As stated in the EIS, DOE believes that its assumptions resulted in a conservative estimate of the impacts. It is true that the Department used data for hydraulic properties based on measurements from a single well, as stated in Section 8.3.2.1.1. This point is one of the sources of uncertainty in the analysis; DOE used the best available data and the professional judgment of its analysts to arrive at an estimate of the impacts.

10 (5749)
Comment - EIS001887 / 0353
Page 8-77; Section 8.3.2.1.3 - Future Nevada Test Site Low-Level Waste Disposal

Paragraph 3 under this section of the Draft EIS states that “DOE proposes to locate the Mixed Waste Disposal unit, which will be a landfill, on about 0.18 [square] kilometers (45 acres) of the Area 5 site, immediately north of the developed Radioactive Waste Management Site landfill area. The design has been completed, the unit has been included in the Resource Conservation and Recovery Act [RCRA] permit application, and the environmental assessment is being updated.”

Virtually all of the information stated above is outdated and incorrect. DOE’s permit application related to the Area 5 site is at least five years out of date. DOE’s current RCRA permit re-application was submitted to the State in October 1999. This re-submittal only requests authorization to use an existing mixed waste trench (pit 3) for disposal of defense low-level mixed waste generated on NTS [the Nevada Test Site].

Response
The Department acknowledges that the information in Section 8.3.2.1.3 of the Draft EIS contained errors. At this time, DOE is only seeking a permit for Area 5 interim status, pit 3, mixed-waste disposal unit. DOE resubmitted its permit application on November 2, 1999.

In the future, if the mixed waste volume warrants it, the Department may consider obtaining a new unit and hence a new permitted facility. However, the current projected waste volumes do not indicate that an additional mixed waste disposal unit is necessary.

Section 8.3.2.1.3 of the Final EIS reflects this updated information.

10 (5750)
Comment - EIS001887 / 0354
Page 8-89; Section 8.4.2.4 - Biological Resources and Soils

The section concerning Nevada transportation impacts appears to address only the intermodal transfer stations and not the routes to be followed through the state. For these reasons, the section is inadequate. Guidance such as that provided by Clark and Cantor (1997) should have been followed to supplement CEQ’s 1997, “Considering Cumulative Effects Under the NEPA.”

Response
Cumulative impacts from transporting waste through Nevada are described in Section 8.4.2. As indicated, the Carlin Corridor could have cumulative impacts with gold-mining activities in Crescent Valley that could require mitigation (see Section 8.1.2.3 for more information about these activities). Direct and indirect impacts from constructing and operating a branch rail line, and upgrading highways, are described in Section 6.3.

In general, the analysis of cumulative impacts in Chapter 8 followed the process recommended in the Council on Environmental Quality's handbook *Considering Cumulative Effects Under the National Environmental Policy Act* (DIRS 103162-CEQ 1997). This process included the identification, through research and consultations, of Federal, non-Federal, and private actions with possible effects that would be coincident with those of the Proposed Action on resources, ecosystems, and human communities.

10 (5964)
Comment - EIS001879 / 0054
With respect to cumulative impacts, the Yucca Mountain EIS finds that the potential impacts to groundwater would be small, limited to the immediate vicinity of the land disturbances associated with the repository, and that some minor incremental risk would occur from drinking the groundwater down gradient of the repository at some distant time in the future. These conclusions are inconsistent with statements in the Draft EIS.

Response
DOE recognizes that some radionuclides or potentially toxic chemicals would eventually enter the environment outside the repository. The regional flow model prepared by the U.S. Geological Survey (DIRS 100131-D'Agnese et al. 1997) suggests that some of the water from the Nevada Test Site flows to the south toward the Amargosa Valley in the vicinity of Yucca Mountain. However, the actual transport times and groundwater pathways from radionuclide contaminants on the Nevada Test Site are not clear at this time. Section 8.3.2.1.1 contains a qualitative calculation of the cumulative radiological impact from the Test Site and Yucca Mountain that indicates that the potential cumulative peak dose would be well below the regulatory limits established by the Environmental Protection Agency in 40 CFR Part 197. This combined peak dose would occur only if the peak concentrations from the Test Site and Yucca Mountain occurred at the same time and same location, which would be unlikely.

10 (5968)
Comment - EIS001879 / 0052
Let me briefly summarize the results of Nye County's water resource studies for the record. Our evaluations found that the direct impacts of water withdrawals for the proposed repository will be limited to a localized lowering of water levels that was not deemed to be significant. However, the evaluation did find that the predicted leakage from the repository and the cumulative impacts of the proposed repository will indeed be significant and that mitigating measures must be implemented. The Draft Yucca Mountain EIS is inadequate with regard to its evaluation of impacts on water resources and corresponding mitigation and, must be revised extensively.

The cumulative impacts on water resources will include the direct and indirect impacts of: 1) the total radiological burden that will be imposed on Nye County; 2) the impacts of federal land withdrawals on water resource availability; 3) the impacts of federal policies regarding nuclear weapons testing, waste disposal, and environmental protection; and 4) the water resource use and management practices on both private and federal lands in the County.

Response
DOE is relying on both the inherent natural geologic features of Yucca Mountain and the engineered barriers to isolate the spent nuclear fuel and high-level radioactive waste from the human environment (see Section 2.1 of the EIS). The waste packages to be emplaced in the repository are an important component of the engineered barrier system, as are other features that would be engineered into the repository. Some of these engineered features are proposed solely as mitigation measures to improve the long-term performance of the repository and decrease long-term impacts to the region's water resources. Chapter 9 of the EIS discusses these mitigation measures.

In relation to the cumulative impacts on water resources, Section 8.2.3 describes the cumulative short-term impacts to water resources, and Section 8.3 describes the cumulative long-term impacts to water resources. DOE believes that these sections contain a credible discussion of the cumulative impacts to water resources from the repository and from past, present, and reasonably foreseeable activities in the Death Valley flow system. The Final EIS contains additional information on water use by Federal activities within this region of influence. DOE's position, as stated in the EIS, is that cumulative water withdrawals would affect the region's water resources, but that land withdrawals would not be directly linked. Water users in Nye County who are potentially affected by the Proposed Action are hydraulically downgradient from Air Force and DOE users on the Nevada Test Site and Yucca Mountain. As described in Section 8.2.3.2, DOE recognizes that water use for the repository would decrease, to a limited extent and in the short term, water that would be available to downgradient users. The land that would be withdrawn for the repository would not alter the quantity of water available to downgradient users. That is, the land withdrawal itself would not affect water resources.

In relation to Federal policies, the EIS addresses the impacts that have resulted or could result from these policies in the affected area, but not the impacts of the policies themselves. In addition, the impacts that have resulted from water management practices in the affected area are described in the EIS, but not the impacts of the practices themselves. Water management practices that affect parts of Nye County but that are outside of the proposed repository's region of influence for water resources are not within the scope of the EIS.

10 (5972)
Comment - EIS001879 / 0050
In total, the United States has implemented a policy of permissible pollution upgradient of the communities of Amargosa Valley and Pahrump and absolute preservation of the groundwater quality and quantity in the areas downgradient of these communities. Nye County, in their water resource planning efforts is between the proverbial rock and a hard place. Yucca Mountain will perpetuate the policy of permissible pollution and will further reduce the quantity of water that is available to meet future water demands in the County.

Under 40 CFR 1508.18(b)(3) NEPA [National Environmental Policy Act] mandates that the impacts of federal policies must be evaluated in an EIS. The Yucca Mountain EIS must be revised to address the impacts of these contrasting federal water resource policies. The YMP [Yucca Mountain] DEIS does not evaluate the cumulative impacts of implementing these federal policies and actions, on a regional backdrop of rapid growth.

In short, Nye County has faithfully served as the nation's sandbox for almost half a century. Unfortunately, the Department of Energy and the Air Force have contaminated their portions of the sandbox and the Department of Interior demands that their portions be left pristine. These policies have had far reaching consequences for the County and greatly hamper water-planning efforts.

Response
The Nuclear Waste Policy Act of 1982 makes it the policy of the United States to dispose of the Nation's spent nuclear fuel and high-level radioactive waste permanently in a geologic repository. The performance of a repository at Yucca Mountain, if built, would have to be in compliance with groundwater protection standards established specifically for the repository by the Environmental Protection Agency (40 CFR Part 197). If the repository could not meet these standards, the site would be disqualified.

Section 8.2.3.2.2 of the Final EIS includes a more detailed discussion of water withdrawal issues, including current and projected water use for current and reasonably foreseeable activities in the region of influence.

10 (5974)
Comment - EIS001879 / 0049
The proposed repository is predicted to leak additional radioactive contamination into the aquifers in the southwestern portion of the Nevada Test Site...water that is currently potable will be contaminated if the DOE's Performance Assessment is correct. This will result in a significant adverse impact on the water resources that must be mitigated.

Response
The Environmental Protection Agency (EPA) has developed groundwater protection standards and individual protection standards for the proposed Yucca Mountain Repository (40 CFR Part 197). EPA developed the standards for a 10,000-year compliance period to protect human health and the environment, including groundwater. The impacts reported in this EIS for the first 10,000 years would be at levels well below the EPA standards.

In addition, 40 CFR Part 197 provides that the EIS report peak dose values. Therefore, the EIS reports such values for the period of geologic stability (1 million years). The mean of the peak dose would be above the EPA standard applicable to the first 10,000 years, but still below the average annual background dose to residents of the United States.

Given the EIS results for the 10,000-year period and the period after that, DOE believes it is not necessary to envision any mitigating action beyond that already provided by the design of the repository system. It is unreasonable to identify other potential mitigation needs and actions for the post-10,000-year period because of the inability to foresee what standards might be protective that far in the future, or what technologies might be available and implemented, if necessary, to achieve such standards.

10 (5980)
Comment - EIS001879 / 0010
The DOE, through their selection of a reduced region of influence, limited their analysis to only the direct impacts of their water withdrawals from a single basin while ignoring documented impacts that occur over a much broader region. Further, the Department ignored other federally prepared reports that detailed the direct, indirect, and cumulative impacts of Department of Defense, Energy, and the Interior actions over the same region. This approach is inconsistent with the CEQ [Council on Environmental Quality] guidance for considering cumulative impact assessment under NEPA [National Environmental Policy Act] and with 40 CFR 1508.25. The methods used in the Draft EIS should be revised to be consistent with CEQ guidance.

The Draft EIS states, with regard to cumulative impacts, that the potential impacts to groundwater would be small and limited to the immediate vicinity of the land disturbances associated with the action and that some minor incremental risk would occur from drinking the groundwater down gradient of the repository at some distant time in the future.

The approach used is inconsistent with statements presented in the Draft EIS. Specifically:

“The general path of water that infiltrates through Yucca Mountain is south toward Lathrop Wells, into and through the area around Death Valley Junction in the lower Amargosa Valley. Natural discharge of groundwater from beneath Yucca Mountain probably occurs farther south at Franklin Lake Playa;” Vol. I, p. 5-23.

“The implementation of the proposed action could potentially affect the water supply in Death Valley National Park, which is down gradient from Yucca Mountain;” Vol. II, Appendix C, page C-9.

The region of influence evaluated for cumulative impacts cannot be smaller than the region over which impacts are expected to occur. Thus, the Department’s approach is inconsistent with the letter and intent of NEPA, CEQ guidance, and other federal documents including the Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (DOE, 1996) and the Special Nevada Report. The cumulative impacts on water resources will include the direct and indirect impacts of 1) the total radiological burden that will be imposed on Nye County; 2) the impacts of federal land withdrawals on water resource availability; 3) the impacts of federal policies regarding nuclear weapons testing, waste disposal, and environmental protection; and 4) the water resource use and management practices on both private and federal lands in the County.

If the DOE chooses to continue to ignore the local perspective by not evaluating the impacts identified in the Nye County document and by other federal agencies, then it is imperative that Nye County’s perspective be clearly documented in the EIS as an opposing technical viewpoint, as discussed in Section 2.5.3 of the Draft EIS.

Response
In general, the analysis of cumulative impacts in Chapter 8 followed the process recommended in the Council on Environmental Quality’s handbook *Considering Cumulative Effects Under the National Environmental Policy Act* (DIRS 103162-CEQ 1997). This process included the identification, through research and consultations, of Federal, non-Federal, and private actions with possible effects that would be coincident with those of the Proposed Action on resources, ecosystems, and human communities.

Section 4.1.3 of the EIS states that the region of influence for groundwater includes “aquifers under the areas of construction and operations that DOE could use to obtain water, and downstream aquifers that repository use or long-term releases from the repository could affect.” The affected environment for groundwater therefore includes the pathway that groundwater beneath Yucca Mountain would travel, as well as the downgradient aquifers that could be affected by water withdrawals at Yucca Mountain. As indicated in Section 3.1.4.2.1, the primary discharge point for groundwater flowing beneath Yucca Mountain is believed to be Franklin Lake Playa in Alkali Flat, but DOE recognizes that some groundwater reaching this far might bypass this playa and continue on to Death Valley. In addition, the section notes that a small amount of the groundwater that flows beneath the Amargosa Desert might travel through fractures in the relatively impermeable Precambrian rocks at the southeastern end of the Funeral Mountains toward springs in the Furnace Creek Wash area of Death Valley. For the cumulative impacts analysis in Section 8.3.2 of the EIS, areas of groundwater north of Yucca Mountain on the Nevada Test Site were included because these areas could contribute to the cumulative impacts to groundwater. DOE believes that the region of influence considered for the evaluation of cumulative impacts is appropriate.

The second paragraph of the comment identifies two statements from the Draft EIS. The first is that cumulative impacts to groundwater would be small and limited to the immediate vicinity of the repository, and the second is that there would be impacts to downgradient areas at some time in the future. DOE believes that these two comments refer to discussions of short-term and long-term cumulative impacts to groundwater in Sections 8.2 and 8.3 of the EIS, respectively. Similar to Chapter 4, short-term impacts are those associated with the construction, operation and monitoring, and closure of the repository. As in Chapter 5, long-term impacts are those associated with the performance of the repository over thousands of years after closure. The statement that describes short-term impacts as being limited to the immediate area can be found almost verbatim in Section 8.2.3.2.2; however, the sentence immediately following the statement reads, “The exception to this would be the potential impact from water demands on groundwater resources.” DOE acknowledges that impacts to water resources must be considered over a larger area and that they extend to the region of influence described in the preceding paragraph. The evaluation of long-term cumulative groundwater impacts (Section 8.3) is consistent with the methodology described in Chapter 5. That is, impacts associated with groundwater use and consumption are calculated for several different locations at increasing distances along the primary water pathway, as described in the commenter’s quote from Chapter 5. DOE believes that the approaches used to evaluate cumulative impacts are consistent with those used in Chapters 4 and 5.

The comment’s second quote [from Draft EIS Section C.2.13 (Section C.2.1.5 in the Final EIS)] deals with the potential for the Proposed Action to affect the water supply in Death Valley National Park. As described above, the Park is part of the region of influence for groundwater because it is located over “downstream aquifers that repository use or long-term releases from the repository could affect.” Neither Chapter 5 nor the cumulative impacts addressed in Chapter 8 specifically address risks at the Park as a result of groundwater use and consumption. However, it can be clearly seen in the evaluations presented in both chapters that risks would decrease with increased distance from Yucca Mountain. Accordingly, impacts to the Park, because it is far away on the groundwater flow path, would be less than those for the farthest distance specifically discussed in the text.

DOE does not agree with the comment that the region of influence for groundwater, as described here and in the EIS, is smaller than the region over which impacts are expected to occur. DOE believes that the approach used for defining this region of influence is appropriate. The region of influence is consistent with that used for the cumulative impact analysis presented in the Nevada Test Site EIS, which is referenced in the comment. The Nevada Test Site EIS states, “The extent of the region of influence can vary widely from one resource to another. For example, the region of influence for land use generally includes all impacts on land use in a broad region surrounding the area affected by the program alternatives. The region of influence for groundwater would generally be much smaller, encompassing only those groundwater-flow systems that are affected by the program alternatives, and by all past, present, and future action that have or could affect these groundwater-flow systems” (DIRS 101811-DOE 1996).

The Yucca Mountain EIS sets the Death Valley flow system as the groundwater region of influence because all groundwater in this flow system potentially contributes to the aquifers downgradient from Yucca Mountain. The EIS evaluates all past, present, and reasonably foreseeable future actions that might contribute to impacts to this flow system. It does not, however, attempt to address as cumulative actions any Federal or non-Federal actions in the State of Nevada or even Nye County that are not within the Death Valley flow system. A broader scope of analysis might have been appropriate for an effort such as the *Special Nevada Report* (DIRS 153277-SAIC 1991; described in Section 8.2 of the Final EIS), but it is not appropriate for the Yucca Mountain EIS.

Section 8.2.3.2.2 of the EIS describes Nye County's perspective on cumulative impacts with respect to groundwater impacts. This paragraph references *Nye County Perspective: Potential Impacts Associated with the Long-Term Presence of a Nuclear Repository at Yucca Mountain, Nye County Nevada* (DIRS 103099-Buqo 1999). The paragraph states that the county's position is that cumulative impacts should include additive contamination as radionuclides ultimately reached the groundwater, constraints on development of groundwater due to land withdrawal, and reduction of water available for Nye County development because of use by Federal agencies. DOE does not believe that the local perspective has been ignored, but does believe that the scope of the cumulative impacts must be defined as, or limited to, those other past, present, and future actions that could actually be cumulative to those of the Proposed Action. In the case of groundwater, this would mean those other actions that could actually affect the same flow system that would be affected by the Proposed Action.

10 (6000)
<u>Comment</u> - EIS001879 / 0027
p. C-9, Section C.2.13

The Draft EIS states "the implementation of the proposed action could potentially affect the water supply in Death Valley National Park, which is down gradient from Yucca Mountain". As such, the region of influence for the water resources impacts of Yucca Mountain clearly extends to the regional discharge point of the groundwater flow system in which it is located. The EIS section on cumulative impacts should be revised to incorporate the larger area of influence.

<u>Response</u>
Section 4.1.3 of the EIS states that the region of influence for groundwater includes "aquifers under the areas of construction and operations that DOE could use to obtain water, and downstream aquifers that repository use or long-term releases from the repository could affect." The affected environment for groundwater therefore includes the pathway that groundwater beneath Yucca Mountain would travel, as well as the downgradient aquifers that might be affected by water withdrawals at Yucca Mountain. As indicated in Section 3.1.4.2.1, the primary discharge point for groundwater flowing beneath Yucca Mountain is believed to be Alkali Flat (Franklin Lake Playa), but DOE recognizes that some groundwater reaching this far might bypass this playa and continue on to Death Valley. In addition, the section notes that a small amount of the groundwater that flows beneath the Amargosa Desert might travel through fractures in the relatively impermeable Precambrian rocks in the southeastern end of the Funeral Mountains toward springs in the Furnace Creek Wash area of Death Valley. In Chapter 5 and Section 8.3.1, potential impacts are evaluated at several distances from Yucca Mountain. The most distant is the primary discharge point at Alkali Flat. Locations farther away, such as Death Valley, would have decreased impacts. In Chapter 8, groundwater impacts from the Nevada Test Site north of Yucca Mountain are considered because these impacts could be cumulative with impacts from a repository at Yucca Mountain.

10 (6044)
<u>Comment</u> - EIS001898 / 0005
The assessment of cumulative impacts in the DEIS does not fully address the impacts associated with past, present, and reasonably foreseeable future actions relating to groundwater use, land use, and cultural and biological resources.
Basis:

A "cumulative impact" is an impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency or person undertakes such other actions (40 CFR 1508.7). A complete cumulative impacts assessment would provide an understanding of whether the Proposed Action might push a resource, ecosystem, or human community beyond a critical threshold and preclude sustainability (CEQ, 1997, page 7). Therefore, the FEIS should assess the additional, incremental impacts from the action at hand when added to impacts from past, present, and reasonably foreseeable future actions (40 CFR 1508.7).

Section 4.1.3 (Environmental Consequences of Repository Construction, Operation and Monitoring, and Closure - Impact to Hydrology) acknowledges that repository construction and operation will impose water demands on the available supplies at Yucca Mountain and the surrounding area. Similarly, Section 6.3.2.1 (Impacts Common to Nevada Branch Rail Line Implementing Alternatives) acknowledges that water withdrawal will be required to support construction of a branch rail line. These demands could create impacts on water resources, particularly in light of other possible future uses. Creation of a Timbisha Shoshone Tribal Homeland with agricultural water rights is a reasonably foreseeable action that could contribute to exceeding the sustainable yield in the Death Valley National Park region (Buqo, 1999, p. 25). Further, it is foreseeable that the continued growth of Clark, Nye, and Lincoln Counties and Las Vegas, Pahrump, and Beatty will impact available groundwater resources. An increased cumulative demand for water, particularly when coupled with reduced water supplies resulting from land withdrawal and Federal land acquisition, could lead to aquifer overdrafting, increased pumping costs, and associated socioeconomic impacts. The cumulative impacts on groundwater resources stemming from the Proposed Action and these other actions are not adequately considered in the DEIS.

The cumulative impacts assessment also needs to further evaluate combined impacts to other specific resources (e.g., the desert tortoise, land use, cultural resources). The cumulative impacts of a Proposed Action, coupled with other Federal actions in the area [e.g., activities at NTS (the Nevada Test Site), Nellis Air Force Range (AFR)] and impacts from extensive growth in Nye, Lincoln, and Clark Counties, on the ranges and habitats of local fauna, such as the desert tortoise, should be documented. In addition, land withdrawal by DOE in conjunction with Department of Interior limitations on land use in Ash Meadows may result in cumulative impacts related to land use that have not yet been fully assessed. Similarly, the impact that private projects such as the Cortez Gold Mine Pipeline projects and the Apex Bulk Commodities Intermodal Transfer Station have on resources (e.g., biological and cultural resources) may not have been fully considered.

Recommendation:

DOE should complete its analysis of cumulative impacts for resources, ecosystems, and human communities by augmenting analyses already performed for individual components for the proposal. The analysis should consider all past, present, and reasonably foreseeable future actions, both Federal and non-Federal, within appropriate spatial and temporal boundaries.

Response

Since the issuance of the Draft EIS, the Department has continued to evaluate actions in the region of influence that could pose a potential cumulative impact. As a result of these reviews, the Department identified several new actions for which information was not available for the Draft EIS. These actions come from several agencies and private companies. For instance, Section 8.1.2.2 of the Final EIS contains an expanded discussion of the Timbisha Shoshone Homeland Act, along with possible implications to groundwater rights. Chapter 8 also contains discussions of other actions by the Bureau of Land Management (e.g., the Ivanpah Cargo Airport, the Moapa Paiute Energy Center); these actions were considered when evaluating the cumulative impacts for the technical discipline areas.

As part of the updated analyses, the Department has expanded the land-use discussion in Chapter 8 to address specifically the known actions that have been identified since the publication of the Draft EIS. Where possible, the Department has identified changes in land use along with estimates of area to be disturbed and possible impacts with other actions in the area. In addition, all discipline areas (for example, biological resources and cultural resources) were reviewed to ensure that the appropriate level of discussion was included to address the potential cumulative impacts of all the actions. However, not all actions could be evaluated to the same level of detail because information was not always available to allow an in-depth evaluation.

Comment - EIS001654 / 0030
Page S-59. Cumulative Impacts

We support the inclusion of additional analyses relating to cumulative impacts of the Nevada Test Site and other activities affecting the same region as the repository. That is how it must seem to many long-time community residents who have been "living with" the impacts of those other activities. Conducting such analyses and providing them to the community would show an appropriate effort to see things from their perspective rather than "having the blinders on" by looking only at the repository impacts.

We are less certain that it is appropriate to consider emplacement of additional waste beyond the NWPA [Nuclear Waste Policy Act] established maximum quantity of 70,000 tons (Inventory Modules 1 and 2.) We realize that the quantity of material to be disposed may grow to those levels, but there are many uncertainties associated with how and where that will be disposed. While it is a potential additional quantity to be brought to Yucca Mountain it may not be a real-world possibility. It seems speculative to conduct such an analysis for this document.

Response
Since the issuance of the Draft EIS, the Department has continued to evaluate actions in the region of influence that could pose a potential cumulative impact. As a result of these reviews, the Department identified several new actions for which information was not available for the Draft EIS. These actions come from several agencies and private companies.

The consideration in Section 8.2 of additional volumes of nuclear waste beyond that authorized in the Nuclear Waste Policy Act (Inventory Modules 1 and 2) does not presume that disposal of this additional waste in the repository would be approved by Congress. Comments that DOE received from the public during the scoping process for this EIS expressed the concern that more spent nuclear fuel and high-level radioactive waste would be generated than the 70,000 metric tons of heavy metal accounted for in the Proposed Action. DOE acknowledges that the emplacement of Inventory Module 1 or 2 at Yucca Mountain would require legislative action by Congress unless a second repository was in operation.

10 (6575)
Comment - EIS001632 / 0060
Page 8-27, Section 8.2.2.1.2: This section refers to 40 CFR Part 61 which contains EPA's [Environmental Protection Agency's] Clean Air Act regulations for radiological effluents from a variety of facilities; however, this rule is not applicable to Yucca Mountain. More appropriate references are 40 CFR Part 191, Subpart A (Environmental Standards for Management and Storage, 50 *FR* 38066, September 19, 1985) or proposed 40 CFR Part 197, Subpart A (Environmental Standards for Storage), both of which address airborne radiological releases and external exposures from Yucca Mountain during the operational period.

Response
DOE referenced 40 CFR Part 61 primarily because it provided a direct comparison to an air quality emission standard. Since publication of the Draft EIS, the Environmental Protection Agency promulgated *Public Health and Environmental Radiation Protection Standards for Yucca Mountain, Nevada,* at 40 CFR Part 197, which included an annual dose limit to a member of the public of 15 millirem (40 CFR 197.4). In accordance with requirements of the Energy Policy Act, the Nuclear Regulatory Commission subsequently promulgated Yucca Mountain licensing criteria, which includes a Preclosure Public Health and Environmental Standard at 10 CFR 63.204 of 15 millirem per year to a member of the public. The appropriate sections of the EIS (including those mentioned in Chapter 8) have been updated to reflect a comparison to the recently promulgated standard of 15 millirem.

10 (6578)
Comment - EIS001632 / 0061
Page 8-47, Table 8-22: This table and several other tables in section 8 list "MEI [maximally exposed individual] dose (millirem)", but do not indicate whether this dose occurs in one year or over the total closure period. Some of the doses are rather large compared to established radioactive waste standards, such as the 58 millirem listed for the MEI dose for Inventory Module 1 or 2. To properly judge the impact, the exposure period must be specified.

Response
The maximally exposed individual dose values in Table 8-22 of the Draft EIS are the integrated doses over the period of closure; six years each for the high and intermediate thermal-load scenarios and 15 years for the low thermal-load scenario. In Table 8-28 of the Final EIS (the table that corresponds to Table 8-22 of the Draft EIS), the closure period for the Inventory Modules ranges from 12 to 23 years for the higher-temperature and lower-temperature repository operating modes.

10 (6580)
Comment - EIS001632 / 0062
Page 8-66, Table 8-46: For Inventory Module 1, the gross alpha concentration is missing.

Response
The Department has revised the table to include the information on gross alpha concentration in Table 8-49 of the Final EIS.

10 (6581)
Comment - EIS001632 / 0063
Page 8-74, Item 7 and the final paragraph: This item, Greater Confinement Disposal (GCD), does not indicate that there is transuranic radioactive (TRU) waste at the Nevada Test Site, in addition to low-level radioactive waste (LLW). The final EIS should so note since the TRU waste has a greater potential for adding to the impact from Yucca Mountain than does the LLW.

Response
As indicated in Section 8.3.2.1, information on Greater Confinement Disposal on the Nevada Test Site is from the *Final Environmental Statement on the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996). DOE included the description as it appears in the Nevada Test Site Final EIS, but DOE did not base its analysis on this description. Rather, the Department relied on the analyses in the Nevada Test Site EIS for input to Chapter 8. The Department acknowledges, however, that transuranic radionuclides are a part of the category of Greater Confinement Disposal, with americium isotopes as one example. The discussion in Section 8.3.2.1 of the Final EIS includes the presence of transuranic radionuclides in this category.

10 (6583)
Comment - EIS001632 / 0064
Page 8-75, Table 8-55: Out of the 9.3 million curies in GCD [Greater Confinement Disposal], tritium and americium are the only ones identified as "major or known isotopes." DOE needs to state the basis for determining a "major isotope."

Response
As indicated in Section 8.3.2.1, information on Greater Confinement Disposal on the Nevada Test Site is from the *Final Environmental Impact Statement on the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996). The designation of "major known isotopes or wastes" is intended only to give the reader a broad sense of what would be included in the appropriate waste category and does not affect the analysis in this EIS. The Department relied on the analyses in the Nevada Test Site EIS for input to Chapter 8. As a consequence, DOE did not repeat the detailed composition of the radioactivity at the Nevada Test Site in this chapter.

A footnote to Table 8-53 in the Final EIS clarifies that the table is intended for information purposes only.

10 (6585)
Comment - EIS001632 / 0065
Page 8-77, Section 8.3.2.1.2: This section assumes that the risk of radiological impacts is directly scalable to the radiological content of the waste disposed in the GCD [Greater Confinement Disposal] facility. However, the GCD wastes are disposed in a different manner than that contemplated for the Yucca Mountain repository (namely, closer to ground surface) and the source term likely contains a different mixture of radionuclides than anticipated for disposal at Yucca Mountain; therefore, relating the risk of GCD disposal to its inventory is overly simplistic and should be re-examined.

Response
In response to this comment, DOE has reexamined the discussion of waste subject to Greater Confinement Disposal and has modified Section 8.3.2.1.2 of the EIS to indicate that there is no credible mechanism for the long-term release of materials from the Greater Confinement Disposal to the accessible environment.

The material subject to Greater Confinement Disposal is placed in boreholes that are approximately 37 meters (120 feet) deep; the waste itself is no closer than approximately 21 meters (70 feet) to the surface. DOE has reviewed previous analyses at the Nevada Test Site and has concluded that there is no credible pathway for long-term release of materials by resuspension of nonvolatile radionuclides because the material is sufficiently far below the surface. In addition, evapotranspiration exceeds precipitation in this region and this, coupled with the fact that the boreholes are sufficiently above the water table, indicates that there is no credible scenario for the Greater Confinement Disposal material to enter the groundwater.

10 (6727)
Comment - EIS001878 / 0078
Analysis of shared rail use inadequate. The analysis of the impacts of shared public/private use of DOE branch rail lines is inadequate. (pp. 8-4, -15) The analysis properly belongs in Chapter 6, Transportation Impacts. The statement that predicting increases in rail traffic from shared use would be difficult and, therefore, is not done is unacceptable. The DEIS says there will be impacts, and they must be analyzed, disclosed, and mitigated as necessary. (p. 8-87)

Analysis of impacts on public services inadequate. The DEIS does not adequately address cumulative impacts on emergency response services. The DEIS says that cumulative operations impacts would result because of the extra 14 years of shipping required for Modules 1 or 2 (p. 8-85), but that the DOE expects no cumulative socioeconomic impacts. This conclusion is contradictory and improbable since state, local, and tribal government emergency services would continue to be impacted.

Reasonably foreseeable related actions not disclosed. The DEIS fails to disclose a proposal under consideration by the Nuclear Regulatory Commission to construct an independent spent fuel storage installation at the Skull Valley Indian Reservation in Tooele County, Utah, as described in the *Federal Register* on February 9, 2000. The DOE knew, or should have known, that this project, if approved, would add to the cumulative environmental impacts of the proposed action. Eureka County is especially concerned about this proposal due to its immediate proximity to Nevada and the potential for increased transportation-related impacts on Eureka County and neighboring counties from shipments of SNF [spent nuclear fuel] and HLW [high-level radioactive waste] to and from Tooele County.

The DEIS also fails to disclose the cumulative impacts on Nevada from the proposed action and the Fallon Range Training Complex Requirements, NAS [Naval Air Station] Fallon, as described in the FEIS prepared for that project by the Navy and the BLM [Bureau of Land Management] (January 2000). For example, the DEIS does not disclose that the proposed Carlin corridor would pass through an area at the north end of Big Smoky Valley, southeast of Austin, NV, where the Navy plans to install up to five fixed or mobile electronic warfare sites and a tracking instrumentation subsystem site. Nor does the DEIS disclose that staging areas for training aircraft and enemy aircraft, and air-to-air/electronic warfare training areas associated with NAS Fallon are presently located over portions of the proposed Carlin corridor. (See Exhibit K.) The DOE knew, or should have known, that activities associated with NAS Fallon would add to the cumulative environmental impacts of the proposed action.

Other comments. The failure of Congress to ratify the Nuclear Test Ban Treaty makes the future resumption of nuclear weapons tests more likely. (pp. 8-3, -11, -12) The statement that interim storage was not analyzed for cumulative impacts because it is uncertain is inappropriate; it is reasonably foreseeable and must be included. (p. 8-5) The inadequacies of the air pollution analysis are similar to those in Chapter 4: the discussion is vague and the conclusions unsupported by the evidence, particularly the statement that there will be no effect on the Las Vegas Valley air basin. (pp. 8-24 to 8-30) The statement that the final EIS will review new information from the Pipeline Southeast Expansion Project for cumulative impacts is unacceptable, since the public will not have the opportunity to comment (p. 8-85).

Response
In the case of shared use of a branch rail line in Nevada, the Department believes that the rail line would have benefits for nearby industries and communities in Nevada, as discussed in Section 8.1.2.3 of the EIS. Sharing of the

rail line is, however, speculative at this point, and including these rail lines in the cumulative impact analyses could result in a misrepresentation of those impacts.

With regard to public services, the continuation of operations for an additional 14 years is not expected to result in an increase or decrease in emergency response services. Because the status quo would be expected to be maintained, the Department does not expect socioeconomic impacts to occur. Since issuing the Draft EIS, the Department has reviewed several activities that have become better defined. For example, a discussion of the Private Fuel Storage facility at the Skull Valley Reservation has been added to Chapter 8 of the Final EIS. Other projects/facilities were reviewed but were not included if cumulative impacts were unlikely.

Since 1992, there has been a moratorium on nuclear testing. Even though the Nevada Test Site must maintain the ability to resume testing, the Department does not believe that a resumption of testing is a reasonably foreseeable action. Therefore, it was not included in the analyses in Chapter 8 of the EIS. Nevertheless, a recent evaluation of impacts from a resumption of underground testing at the Nevada Test Site (DIRS 103273-Walck 1996) concluded that the only impact such testing would pose on the repository would be ground motion from the energy released by the detonations. DOE has determined that such effects would not exceed the seismic design criteria for the repository. In other words, the design-basis earthquake for the repository would generate stronger ground motions than would underground nuclear detonations on the Nevada Test Site. Because DOE has designed the repository to survive the design-basis earthquake with minimal damage, ground motion from the resumption of underground testing would be unlikely to result in substantial damage to the surface or underground facilities at Yucca Mountain.

The analysis of air impacts used the best available data. Standard analytical techniques were used to obtain a reasonable estimate of air concentrations and consequent impacts. With no further detail from the commenter, addressing specific concerns about the analysis is not possible.

10 (7115)
Comment - EIS001106 / 0010
Section 8.2.4, page 8-36, on Biological Resources is deficient in two major respects. First, an ecosystem approach was not adopted for the DEIS, and second, thermal loading impacts are not factored into the cumulative effects. Section 8.4.2.4, page 8-89, on Biological Resources and Soils concerning transportation impacts in Nevada appears to address only the intermodal transfer stations and not the routes to be followed through the state. For these various reasons, the section is inadequate. Guidance such as that provided by Clark and Cantor (1977) should have been followed for this section to supplement CEQ’s 1997, “Considering Cumulative Effects Under the NEPA.”

Response
DOE did not adopt an ecosystem approach for biological analysis in this EIS. An “ecosystem” approach is one method for analyzing potential impacts on biological resources. DOE discusses its evaluation of the ecosystem approach and its reasons for choosing other analytical tools in Section 3.1.5 of the EIS.

The EIS analysis describes the affected environment and potential impacts to the regional ecosystems surrounding Yucca Mountain in Sections 3.1.5.1 and 4.1.4 of the EIS, respectively. The assessment of cumulative biological impacts in Sections 8.2.4 and 8.4.2.4 considered resource management plans and other planning documents for the region, not just the immediate ecosystem surrounding Yucca Mountain. This assessment included the regional ecosystems affected by the other major actions described in Section 8.1. The transportation analysis relied on earlier analyses in National Environmental Policy Act documents and on new analyses specific to this EIS. Appendix J discusses the analysis methods.

10 (7123)
Comment - EIS001106 / 0015
There has been no effort on the DOE’s part to integrate environmental documentation for the YMP [Yucca Mountain Project] with other anticipated or ongoing federal activities. In this context, the DOE should address relationships between short-term uses of environmental resources and long-term productivity into the future.

Response
Chapter 8 of the EIS analyzes a range of past, present, and reasonably foreseeable future actions that, along with the repository, could contribute to cumulative impacts. In preparing this chapter, DOE reviewed many documents to

determine where there was potential for cumulative impacts. These documents included resource plans, EISs, environmental assessments, tribal meeting records, and other documents prepared by Federal, local, and private organizations. Section 10.2 addresses the relationship between short-term uses of the environment and long-term environmental productivity.

10 (7152)

Comment - EIS001337 / 0049

In comments to the scope of the EIS, Lincoln County and the City of Caliente urged DOE to consider the cumulative effects which may result from the incremental impact of the proposed action and alternatives thereto when added to other past, present, and reasonably foreseeable future actions. Of particular concern to the County and City was the cumulative effects of exposure to various source terms for radiation within the region. As a component to their comments, the County and City referenced research they had sponsored which determined that consideration of cumulative exposures to radiation is a scientifically defensible undertaking.(14) The County and City recommended that the repository EIS consider the cumulative exposure risk associated with previous DOE weapons testing activities, on-going DOE weapons activities, on-going DOE low-level radioactive waste (LLRW) management activities, potential future LLRW management activities at NTS [Nevada Test Site], potential LLRW transportation activities through Lincoln County, proposed high-level waste transport and disposal in Nevada, and natural and other human-induced sources of background radiation. While the DEIS provides a generic assessment of cumulative risks, the analysis is not transportation corridor, county, or community specific. As a consequence, the assessment of cumulative risk is not useful in discriminating between routing alternatives. Nor does the analysis prove useful in determining where and in what manner risks might best be mitigated.

Consistent with requirements of NEPA [National Environmental Policy Act], the County and City recommended that the repository EIS consider how construction and operation of repository system components within Lincoln County will conflict with existing federal, state and local land use plans, policies, or controls. In particular, the County and City felt that conflicts with the Lincoln County Masterplan and the City of Caliente Masterplan should be evaluated. The DEIS does not consider conflicts with plans developed by Lincoln County or the City of Caliente.

(14) Goble, Robert, Perspectives on Risks from the Nevada Test Site: Feasibility and Methods for Assessing Cumulative Radiological Exposure Risks Associated with Department of Energy Activities at the Nevada Test Site, Center for Technology, Environment and Development of the George Perkins Marsh Institute on the Human Dimensions of Global Environmental Change, Clark University, Worcester, MA. June 1994.

Response

Consistent with Council on Environmental Quality regulations (40 CFR 1508.7), DOE considered past, present, and reasonably foreseeable actions in its assessment of cumulative impacts and has reviewed a number of current and proposed actions to determine relevance. The expression “reasonably foreseeable” refers to future actions for which there is reasonable expectation that the action could occur, such as a proposed action under analysis, a project that has already started, or a future action that has obligated funding.

DOE structured the cumulative impact assessments presented in Chapter 8 of the EIS by identifying actions the effects of which could coincide in time and space with the effects from the proposed repository and associated transportation activities. The actions evaluated in Chapter 8 include some of those recommended by the commenter such as previous underground testing at the Nevada Test Site, low-level radioactive waste disposal at the Nevada Test Site and Beatty, and high-level radioactive waste shipments in Nevada.

The identification of the relevant actions was based on reviews of resource, policy, development, and land-use plans prepared by agencies at all levels of government and from private organizations, other environmental impact statements, environmental assessments, and Native American tribal meeting records. Pursuant to Council on Environmental Quality regulations at 40 CFR 1502.16(c) and 1506.2, in addition to the assessment of potential environmental impacts, the potential conflicts with plans issued by various governmental entities were considered to the extent they provided relevant information. Of particular interest to the commenter, DOE reviewed and considered a number of documents submitted by or prepared for Lincoln County and communities within Lincoln County. Two of the documents reviewed were the City of Caliente Master Plan (prepared by Intertech Consultants and Sweetwater Consulting Services in 1990) and the Alamo Land Use Plan (prepared by Sweetwater Consulting Services and R.O. Anderson Engineering in 1992). While the Alamo plan deals primarily with zoning issues for the town, the Caliente plan discusses actions for dealing with potential population growth generated by the construction and operation of a repository at Yucca Mountain. The document generally expresses a need to annex lands that are contiguous to and south of the city within Meadow Valley Wash. The Caliente intermodal transfer station would be in Meadow Valley Wash (see Figure 6-17 of the EIS). The commenter is also referred to Sections 6.3.2 and 6.3.3 of the EIS, which provide estimates of changes in population and other economic measures for each relevant implementing alternative. The transportation analysis in the Final EIS includes a sensitivity analysis that assigns all potential impacts to Caliente. The analysis conservatively estimates the potential transportation actions on a community level. However, definitive information is not available on specific tracts of land that could be required for a specific transportation mode or route. Once DOE selected a transportation mode and specific transportation corridor, more definitive information would be developed on potential conflicts with land uses and various agency plans and policies and ultimately the mitigation measures that could resolve conflicts and impacts on a given area.

DOE agrees with the commenter that the cumulative impacts of radiological exposures can be scientifically based. Section 3.1.8.2 of the EIS estimates the annual radiation dose to a hypothetical individual in Springdale, Nevada, from airborne radioactive materials from past nuclear weapons testing at the Nevada Test Site, and indicates that DOE had made quantitative estimates of the offsite doses from releases from past weapons testing at the Nevada Test Site (DIRS 146592-Black and Townsend 1998). Section 6.3 of the EIS describes the potential impacts of each transportation alternative in Nevada, including estimates of impacts to health and safety in Nevada from incident-free waste transport to Yucca Mountain and from transportation accidents, as well as regional socioeconomic impacts to potentially affected counties (see Figures 6-5 through 6-8).

Section 8.4 of the EIS analyzes potential cumulative impacts in Nevada from the Proposed Action and other past, present, and reasonably foreseeable future actions by Federal agencies and private groups. The analyses include transportation impacts from the Expanded Use Alternative (Alternative 3) for the Nevada Test Site. This alternative includes the shipment of low-level radioactive waste to the Nevada Test Site from offsite locations [based on the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996)]. Section 8.2.12.2 of the Yucca Mountain EIS discusses the cumulative impacts from storage of low-level waste and includes as a reasonably foreseeable action of the potential that the Nevada Test Site would be selected as a regional DOE low-level waste disposal site. Table 8-58 of the EIS summarizes cumulative transportation-related radiological impacts from the Proposed Action, Inventory Modules 1 and 2, and other Federal, non-Federal, and private actions nationwide from 1943 to 2047. The table lists potential impacts from past, current, and projected Federal waste transport activities, including shipments of low-level waste to the Nevada Test Site, shipments of transuranic waste to the Waste Isolation Pilot Plant in New Mexico, and shipments of spent nuclear fuel and high-level radioactive waste to various storage and disposal sites throughout the Nation. In response to public comments, Appendix J of the EIS now contains maps showing routes used in analyzing impacts and provides estimates of radiological and nonradiological impacts for each state. This is in addition to the route maps that were included in the Draft EIS (see Section 2.1.3.2 of the EIS for national routes and Section 2.1.3.3 for Nevada maps). Based on this information, DOE has concluded that the cumulative impacts of future transportation activities, past nuclear-weapons testing, and other Federal and private programs involving transportation of radioactive materials in the State of Nevada would be small.

Comment - EIS001106 / 0029
The Yucca Mountain DEIS is deficient in terms of best professional practice for EIA [environmental impact assessment] because natural ecosystem and landscape boundaries were not adopted. Programs as important as the YMP [Yucca Mountain Project] is in terms of long-lived contaminants and future human generations require regional planning and execution in the context of ecosystems and regional landscape boundaries. Otherwise, long-term and cumulative impacts cannot be addressed adequately. In terms of holistic environmental quality and EIA, the YMP DEIS is deficient as a NEPA [National Environmental Policy Act] document.

Response
The EIS considered the regional ecosystems surrounding Yucca Mountain based on resource management plans and other planning documents for the region (see Sections 3.1.5.1 and 4.1.4). The assessment of cumulative impacts in Chapter 8 considered not only the immediate ecosystem surrounding the proposed repository, but also the regional ecosystems affected by the other major actions described in Section 8.1.

10 (7369)

Comment - EIS001106 / 0032

In programs such as the YMP [Yucca Mountain Project] it is necessary that potential conflicts between future projects be addressed in a reasonably foreseeable manner. The Yucca Mountain region in particular is susceptible to such long-term impacts that have to be addressed in a context of ecosystem management. Such is among the intents of the existing Five-Party Cooperative Agreement for the region that the DOE has refused to adopt for the YMP.

Response

The five-party Cooperative Agreement coordinates and enhances management of natural resources in the Great Basin and Mojave Desert ecosystems on the Nellis Air Force Range, Desert National Wildlife Range, and the Nevada Test Site. The five agencies are DOE's Nevada Operations Office (operator of the Nevada Test Site), the U.S. Air Force (operator of the Nellis Air Force Base), the Bureau of Land Management's Las Vegas Field Office, the U.S. Fish and Wildlife Service, and the State of Nevada.

DOE agrees that it is important to interact with other agencies to minimize conflicting programs or actions. Appendix C of the EIS describes DOE's agency interactions. One of the purposes of these interactions is to discuss issues of concern with organizations that have an interest in or authority over land that repository-related actions could affect or with some other interest the Yucca Mountain Project could affect. In addition, DOE has solicited and documented input from stakeholder groups through the EIS scoping process, comments on the Draft EIS, and other means. These interactions are described in the *Summary of Public Scoping Comments Related to the Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nevada* (DIRS 104630-YMP 1997) and in this Comment-Response Document.

Chapter 8 of the EIS estimates the potential cumulative impacts associated with various agency actions in the defined region of influence. The actions identified were based on documents issued by, and discussions with, DOE's Nevada Test Site, the U.S. Air Force, the Bureau of Land Management, the U.S. Fish and Wildlife Service, and the State of Nevada. The documents include resource management plans, EISs, environmental assessments, strategic plans, consultation documents, and tribal meeting records.

If the repository was recommended and approved for development, DOE would consider including the Yucca Mountain Project in the Cooperative Agreement, and would reevaluate the need for a site-specific land-use plan to ensure compliance with all applicable requirements. That plan, based on the principles of ecosystem management and sustainable development, would formally synthesize the Yucca Mountain Project policies and procedures already in place; draw on the successes of the Resource Management Plan for the Nevada Test Site; and solicit input from Federal and State agencies, stakeholders, and the general public.

Comment - EIS001106 / 0035

The intent of NEPA [National Environmental Policy Act] is that contributions to global environmental problems be avoided. Global environmental "commons" such as the atmosphere applies to the YMP [Yucca Mountain Project] in the context of radioactivity and must be addressed by competent EIA [environmental impact assessment] in the DEIS. This in particular is an issue regarding future cumulative impacts and future generations.

Response

The repository EIS does not report global adverse impacts because such impacts would be negligible. As stated by the National Academy of Sciences "..the most likely pathway for global distribution are gaseous releases of carbon dioxide containing the radioactive isotope of carbon-14, that eventually will escape from the waste containers, or by widespread distribution of foodstuffs grown with contaminated water." However, the Academy stated, "In general, the risks of radiation produced by such wide dispersion are likely to be several orders of magnitude below those to a critical group." For example, the Academy estimated that the average dose to members of the global population, based on the release of 91,000 curies of carbon-14, is 0.0003 millirem per year, and equated that to an annual risk of fatal cancer of 1.5 in 10 billion (DIRS 100018-National Research Council 1995). For comparison, the individual dose standard set by the Environmental Protection Agency in 40 CFR Part 197 of 15 millirem per year for the maximally exposed individual is 50,000 times that dose.

Because of large uncertainties, DOE considers estimates of global health effects to be highly speculative and, therefore, did not estimate global collective doses or health effects in the EIS. However, DOE agrees with the Environmental Protection Agency (64 *FR* 46976, August 27, 1999) and the National Council on Radiation Protection and Measurements (DIRS 101858-NCRP 1995) that optimizing the protectiveness of design alternatives merits the estimation of population doses. The Department believes it can obtain information important to design optimization by estimating collective dose to the regional populations within 80 kilometers (50 miles) of the repository, thereby precluding the need to perform the more speculative global health risk calculations. For these reasons, the EIS evaluated in detail potential radiological exposures to the maximally exposed individual and regional populations (80 kilometers) from both groundwater and atmospheric pathways. Sections 5.4 and 5.5 of the EIS describe the results of these evaluations for waterborne and atmospheric releases, respectively.

10 (7413)
Comment - EIS001912 / 0008
The DEIS does not consider the impact of underground weapons testing on regional groundwater resources. Additionally, the impact assessment does not consider the collective impact of all actions added together. Instead the analysis only looks at the proposed action added to a single cumulative action. The approach taken in the DEIS is inconsistent with the Council on Environmental Quality regulations.

Response
Section 3.1.8 of the Final EIS discusses estimates of radiation doses to individuals from past weapons testing on the Nevada Test Site. DOE has included this information in Sections 8.2.2.2.2 and 8.2.4.7 as contributing to short-term cumulative radiological impacts. Sections 8.2.2.2.2 and 8.2.4.7 now include information on radiation exposure from past nuclear weapons testing, and Section 8.3 includes updated estimates of future impacts to groundwater and air resources from activities on the Nevada Test Site. Section 8.2.4.7 incorporates the human health impacts from transportation discussed in Section 8.4. In addition, DOE has revised Chapter 8 to present the information more clearly and to clarify that it did consider the cumulative effects of all actions taken together.

In addition to the foregoing, the assessment of impacts of past nuclear weapons testing is part of an ongoing effort by several organizations, including the National Cancer Institute and the Centers for Disease Control. Readers interested in further information about the effects of past testing of nuclear weapons should refer to the *National Cancer Institute Study Estimating Thyroid Doses of I-131 Received by Americans From Nevada Atmospheric Nuclear Bomb Tests* (DIRS 152469-Institute of Medicine and National Research Council 1999).

10 (7443)
Comment - EIS001969 / 0004
Cumulative environmental effects from the future operation of the Yucca Mountain repository and past activities at the NTS [Nevada Test Site] are also of concern. Possible impacts to groundwater and spring discharges resulting from activities at NTS, approximately 25 miles north of Ash Meadows NWR [National Wildlife Refuge], are being evaluated by DOE, the Service and the U.S. Geological Survey (USGS). Activities at the NTS which may have resulted in contamination of the region include both atmospheric and subterranean tests of nuclear devices and other tests involving radioactive materials, controlled atmospheric releases of numerous gaseous materials, and disposal and destruction of various types of solid and liquid wastes. The extent to which these activities have placed wildlife resources at risk is still under investigation. DOE’s Environmental Management Program is focused on identifying the nature and extent of contamination from the nuclear weapons programs at DOE facilities. This process is underway at the NTS with ongoing environmental restoration and waste management activities.

Response
This comment accurately summarizes some of the issues involving the potential cumulative impacts associated with the Proposed Action and some of the ongoing evaluations being conducted by the Department and other agencies, including the U.S. Fish and Wildlife Service. In preparing Chapter 8 of the EIS, the Department reviewed many past, present, and reasonably foreseeable future actions to determine where there was potential for cumulative impacts. Chapter 8 of the EIS describes both the short-term and long-term impacts of the proposed repository, along with transportation and manufacturing cumulative impacts.

10 (7582)
Comment - EIS001909 / 0004
Section 8.1.2.1

"Inventory Modules 1 and 2 represent the reasonably foreseeable future actions of disposing of all projected commercial and DOE spent nuclear fuel and all high-level radioactive waste as well as Greater-Than-Class-C waste and Special-Performance-Assessment-Required waste in the proposed repository (see Figure 8-1)."

The DEIS fails to account for the cumulative impacts of HLW [high-level radioactive waste] and DOE SNF [spent nuclear fuel] depicted in Inventory Module 1 and Inventory Module 2 (Figure 8-1) which are not disposed of in the proposed Yucca Mountain repository. These cumulative impacts should be addressed in the DEIS.

Response
The EIS analyzes a Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain. The cumulative impacts are limited to those that would overlap in space and time with impacts from the repository. Therefore, the impacts of materials not disposed of at Yucca Mountain would not contribute to the cumulative impacts of the repository. For the No-Action Alternative, DOE evaluated the impacts of retaining spent nuclear fuel and high-level radioactive waste at existing sites or at sites where Records of Decision would move these materials. For example, in the Record of Decision for the *Final Supplemental Environmental Impact Statement, Defense Waste Processing Facility* (60 *FR* 18589, April 12, 1995), DOE decided to complete construction and operate the Defense Waste Processing Facility at the Savannah River Site to pretreat, immobilize, and store high-level radioactive waste. Similarly, the preferred alternative of the *Hanford Site Final Environmental Impact Statement for the Tank Waste Remediation System* (DIRS 103214-DOE 1996) was to vitrify high-level radioactive waste and store it onsite until final disposition in a geologic repository. In the Record of Decision (60 *FR* 28680, June 1, 1995) for the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement*, DOE decided to keep production reactor fuel at the Hanford Site, consolidate aluminum-clad fuel at the Savannah River Site, and transfer non-aluminum-clad fuels (including spent nuclear fuel from the Fort St. Vrain reactor and naval spent nuclear fuel) to the Idaho National Engineering and Environmental Laboratory.

DOE will continue to make decisions on the types and quantities of materials it will move, as well as the timing of these activities, in programmatic documents. The EISs on these actions contain evaluations of impacts related to these decisions.

10 (7594)
Comment - EIS001912 / 0072
The cumulative impact analysis considers a repository with much higher volumes of waste. This scenario should be included in Chapter 5 and not the cumulative impact section. Congress did limit the amount of waste which could be stored in the repository. However, by including a high waste volume scenario in the cumulative impact section assumes that laws will be changed to accommodate a greater amount of waste. If such an assumption is made for the cumulative impact analysis why couldn't it be made for the proposed action? Furthermore, an EIS can consider other alternatives not specifically authorized by Congress.

Response
The Proposed Action described in this EIS considers a volume of spent nuclear fuel and high-level radioactive waste (70,000 MTHM) that could be disposed of in accordance with the NWPA.

The analysis of cumulative impacts must include past, present, and reasonably foreseeable future actions. Future actions include reasonably foreseeable actions, even though these actions are not certain to occur. After considering public scoping comments, the Department determined that the disposal of additional, compatible wastes in the repository to be reasonably foreseeable and has considered the impacts of this action in Chapter 8.

The consideration in Section 8.2 of additional volumes of nuclear waste beyond that authorized in the Nuclear Waste Policy Act (Inventory Modules 1 and 2) does not presume that disposal of this additional waste in the repository would be approved by Congress. Comments that DOE received from the public during the scoping process for this EIS expressed the concern that more spent nuclear fuel and high-level radioactive waste would be generated than the 70,000 metric tons of heavy metal accounted for in the Proposed Action. DOE acknowledges that the emplacement of Inventory Module 1 or 2 at Yucca Mountain would require legislative action by Congress unless a second repository was in operation.

10 (7629)
Comment - EIS001912 / 0104
The cumulative analysis must assume loss of institutional control to be parallel with the analysis in the no-action alternative.

Response
The institutional control assumptions in the cumulative impact evaluation are essentially the same as those for the impact evaluations of the Proposed Action and the No-Action Alternative. Scenario 1 of the No-Action Alternative includes an analysis of impacts under effective institutional control for at least 10,000 years and is consistent with the portion of the analysis of the Proposed Action that includes an analysis of effective institutional control for the first 100 years after closure. The Scenario 2 analysis of the No-Action Alternative does not consider effective institutional control after approximately 100 years and is parallel to the portion of the Proposed Action analysis in which long-term performance after 100 years also does not include institutional control. The cumulative impact analyses for Modules 1 and 2 used these same assumptions (see Chapter 8 of the EIS).

In the evaluation of cumulative impacts from other Federal, non-Federal, and private actions, such as underground testing at the Nevada Test Site and low-level radioactive waste disposal at the Nevada Test Site and Beatty, assumptions related to the loss of institutional control were based on the best available information. For these actions, in general, credit was not taken for future institutional controls past the point in time when remediation activities would be complete. In all cases identified, planned remediation actions would be complete within 100 years.

10 (7803)
Comment - EIS001227 / 0002
In reference to the Nellis range renewal Legislative EIS a statement appears at the top of page 8-10. This statement includes “[t]he Air Force is proposing no substantial new activities in the future…” I suggest that the change of hands for approximately 144,640 acres, that the Air Force has proposed in the LEIS, is potentially substantial and this issue should be fully covered in the Yucca Mountain Final EIS.

Adjacent Nuclear Testing Effects Poorly Understood and Poorly Reported

In the last paragraph of Section 8.3.2.1 (Page 8-74) was the suggestion that the cumulative effects from surface radioactive contamination at the Nevada Test Site was unimportant due to a less-than-40-curie source term. This needs some closer examination, especially in the light that much of the contamination debris resulting from nuclear explosives testing is still shrouded in secrecy, ostensibly to prevent the proliferation of nuclear weapons.

First, [it’s] helpful to understand that each nuclear explosive is essentially a miniature nuclear reactor that is designed to “burn” a portion of its nuclear fuel in less than one microsecond, rather than in the two to three year time period common to nuclear power reactors. As with nuclear power reactors, the “burn” or fission process results in the production of spent fuel debris containing fission products such as cesium-137 and strontium-90 along with substantial quantities of unfissioned fuel debris. One significant difference in the composition of most nuclear explosion debris is that it almost always contains between one to three kilograms of plutonium-239. The spent nuclear fuel that may end up at Yucca Mountain would contain plutonium-239 concentrations of only around 1/2%. The spent fuel that may be brought to Yucca Mountain is subject to strict engineered containment standards. The spent nuclear fuel that was generated by approximately 1,021 nuclear detonations at the Nevada Test Site was not subject to anything like the power reactor and Yucca Mountain containment standards. It was blasted into the environment, be that the atmosphere or the underground environment. Effectively, the Nevada Test Site was the location of over one-thousand nuclear reactor explosions. At the Nevada Test Site 100 nuclear test explosions were conducted in the atmosphere.

Underground, 921 detonations were conducted.

One estimate is that approximately 260 of those detonations were conducted below the local water table or within 100 meters above it.

Since the vast majority of these explosions had high-energy-yields, much of the radioactive debris generated and released by the above groundwater explosions, ended up below or just above the existing water table. Unlike the Yucca Mountain site, no research has gone into looking at the possible rise of groundwater in the underground nuclear testing areas of the Nevada Test Site. The blown-up nuclear reactors in these areas will not be analyzed to see how many thousands of years it will take before their containers have corroded through. The radioactive debris has already been scattered. Most of it is contained in a highly heterogeneous glassy matrix, a material is quite different from the laboratory grade borosilicate glass that high-level nuclear waste is required to be encased in.

The nuclear explosives that were detonated in the atmosphere were not significantly different from those detonated underground and one result is that the radioactive debris released by each of those explosions was similar. Notice on page 8-75 that the radionuclide release estimate for the 921 detonations conducted underground is 300 million curies. The estimated source term amount left on the surface by 100 atmospheric tests, a couple of dozen shallow underground tests, plutonium dispersal tests ("safety tests"), and rocket and jet tests, was less-than-40-curies. It is worth asking the question, if approximately 15% of the tests were conducted in the atmosphere, then why isn't the surface source term closer to 45 million curies rather than 40 curies? What happened to approximately 45 million curies of radioactive debris? I believe a part of the answer lies in inaccurate surface radiation surveys and a failure to look for, or detect, plutonium that now lies slightly below the surface. Still, a goodly portion of the nuclear explosion debris drifted down-wind to fall out all over our nation.

This section of the Yucca Mountain Draft EIS mentions the lack of contamination data associated with the underground nuclear test areas. I believe that part of the dearth of information is due to the fact that much information on the vast majority of the underground nuclear tests still remains classified. In addition, the DOE has limited access to the sources of contamination so little external analysis of this subject can be performed. NEPA [National Environmental Policy Act] analysis of the Yucca Mountain potential repository situation should not be hindered by information restrictions associated with adjacent past and on-going DOE nuclear weapons programs. Each and every time an analysis is hindered by such programs the public and the public's elected representatives should be duly informed via open media presentations. The public has a right to know when governmental agencies are withholding information from them. The recently reported incidents at the uranium enrichment plant at Paducah, Kentucky are not unusual. The AEC [Atomic Energy Commission] and DOE have a lengthy record of putting production missions ahead of local health and safety. Deceiving workers and local residents with vague and deceptive terms has become second-nature to generation after generation of DOE functionaries. The draft EIS failed to mention that the DOE continues to explosively disperse small quantities of plutonium-239 in underground rooms at the Nevada Test Site as part of its subcritical test program. Nor did it mention that the DOE has no firm plan in place to remediate that contamination upon the conclusion of the test series.

The Cumulative Impacts section should have also mentioned that the nuclear debris produced and dispersed by underground nuclear explosions is not covered by the U.S. Environmental Protection Agency's regulations that are associated with Spent Nuclear Fuel, High-Level and Transuranic Radioactive Waste.

The Code of Federal Regulations, Title 40, Section 191.3, involving containment requirements, does not apply to this form of spent nuclear fuel. In addition, the Section 191.14 containment assurance requirements do not apply. This includes the strict requirements to mark the debris sites and prevent human intrusion.

Draft EIS, Section 8, on the cumulative impacts, largely treated the nuclear explosion tests impacts as something that happened in the past. It failed to mention that since the remaining debris contains large quantities of plutonium-239 the hazard from the dispersed debris will continue for a longer period than for the power reactor spent fuel material that is proposed for burial at Yucca Mountain. This section barely mentioned the fact that the Nevada Test Site is being kept ready so that the underground nuclear explosive testing program can be resumed in the event that such a need is deemed necessary. This is an issue which was given only very minor coverage in the 1996 Nevada Test Site EIS. It is an issue that certainly should have been covered in some detail in the Yucca Mountain Draft EIS. Surely, this issue deserves substantial coverage in the Final EIS for the proposed Yucca Mountain repository.

In 1987, the President's Council on Environmental Quality (CEQ) issued a guidance handbook that described how to analyze cumulative impacts and prepare the necessary NEPA reports on this issue.

This guidance should have been used in the preparation of the Yucca Mountain Draft EIS. NEPA cumulative impact review guidance was recently issued by the U.S. Environmental Protection Agency (EPA).

Both these documents should have been utilized in reviewing the adequacy of the Cumulative Impacts section of the Yucca Mountain Draft EIS.

Response

This comment expresses four general concerns: (1) the effect of a land transfer discussed in the *Renewal of the Nellis Air Force Range Land Withdrawal: Legislative Environmental Impact Statement* (DIRS 103472-USAF 1999), (2) the adequacy of the inventories used to assess the contribution of nuclear testing to cumulative impacts, (3) the applicability of regulations and standards to the contents of the repository, (4) compliance of the cumulative impact analysis with the requirements of the National Environmental Policy Act.

DOE has made several changes to Chapter 8 of the EIS. These changes deal in particular with concerns 2 and 4 listed in the preceding paragraph. The following paragraphs discuss the four concerns.

1. Transfer of Land Discussed in the Nellis Air Force Base Legislative EIS

The comment apparently refers to two parcels of land with a total size of approximately 580 square kilometers (225 square miles). The first parcel, known as Pahute Mesa, is part of Public Land Order 99606, which was withdrawn for the use of Nellis Air Force Base but has been used historically by the Nevada Test Site for underground testing under a Memorandum of Understanding. This parcel is in the upper northwest corner of the Nevada Test Site. The second parcel, known as the Groom Range, is part of Public Land Order 01662, which provided land for nuclear testing activities by the Atomic Energy Commission (a DOE predecessor agency). This parcel has been used historically by Nellis Air Force Base for flight operations under an understanding with the Nevada Test Site. The land transfer referred to in the Air Force's Legislative EIS (accomplished by recent legislation) was merely a transfer of jurisdiction to match actual use with ownership. That is, Pahute Mesa was transferred to the Nevada Test Site and the Groom Range was transferred to the Air Force. Because this entails no change in activities from those evaluated in this EIS, there would be no effect on cumulative impacts.

2. Inventories from Testing

Section 8.3.2.1 of the EIS describes the activities on the Nevada Test Site that could contribute to cumulative impacts with the proposed repository. Since issuing the Draft EIS, DOE has revised some of the analyses of impacts associated with the Nevada Test Site. Sections 8.2.2.2 and 8.2.7 now include additional information on radiation exposure from past nuclear weapons testing. These revisions include consideration of the subcritical tests mentioned in the comment. In relation to atmospheric testing inventories, most of the material probably dispersed as fallout over the entire world. This was a major reason for the use of underground testing. In relation to the form of contamination, the analysis assumed that the radioactive material had no containment and was readily available for transport. The revised groundwater transport calculations took credit for immobilization. The analysis also assumed that the dissolution rate of the glass matrix in underground detonation points on the Nevada Test Site is not remarkably different than that of commercial spent nuclear fuel analyzed in the *Viability Assessment of a Repository at Yucca Mountain* (DIRS 101779-DOE 1998).

The National Environmental Policy Act requires that an agency use the best available data and methods to prepare an EIS. DOE used the best available data for the Draft EIS and for the revised analysis in the Final EIS. Where these data were incomplete or highly uncertain, the Department used conservative assumptions.

3. Applicability of Regulations and Standards

The commenter says that the EIS should acknowledge that radioactive materials on the Nevada Test Site, unlike repository materials, are not subject to the provisions of 40 CFR Part 191. In fact, neither site is subject to this standard. In 1985, the Environmental Protection Agency issued 40 CFR Part 191 as the performance standard for high-level radioactive waste repositories. The Federal courts subsequently remanded the regulation to the Environmental Protection Agency for reconsideration. Further, the Energy Policy Act of 1992 required the Environmental Protection Agency to develop radiation protection standards specific to Yucca Mountain. In response to these events, the Environmental Protection Agency promulgated regulations at 40 CFR Part 197 (*Environmental Radiation Protection Standards for Yucca Mountain, Nevada*). The protection standards in 40 CFR Part 197 provide the same level of protection as those in 40 CFR Part 191. However, in other ways, the new rule is quite different from 40 CFR Part 191. A key difference is that the new rule does not contain a release standard based on cumulative curie amounts of specific radionuclides, relying instead on the individual protection and groundwater protection standards.

In dealing with cumulative impacts, the analysis in the Draft EIS did not consider the standards for other past, present, and future activities. Rather, it assessed the actual impacts and combined them with the projected impacts of the Proposed Action. For the sake of perspective, the EIS discusses standards (such as 40 CFR Part 197) to enable informed judgment of the magnitude of potential impacts. If the Yucca Mountain site was recommended and approved, the repository License Application and its supporting compliance analysis would make direct comparisons to the standard. The analysis combined the effects of nuclear testing with projected releases from the repository, analyzed those effects for the same performance measures, and assumed the effects would arrive at the same time (for maximally conservative results) and would migrate to the biosphere in the same manner. Thus, comparisons of the cumulative impacts probably would be made to the same standard. The EIS compares nuclear test debris to the same standard used for the repository. However, demonstration of compliance with the standard would consider only material released from the repository. Section 8.3 of the Final EIS now discusses this issue.

4. Analysis of Cumulative Impacts under the National Environmental Policy Requirements

In general, the analysis of cumulative impacts in Chapter 8 followed the process recommended in the Council on Environmental Quality's handbook *Considering Cumulative Effects Under the National Environmental Policy Act* (DIRS 103162-CEQ 1997). This process included the identification, through research and consultations, of Federal, non-Federal, and private actions with possible effects that would be coincident with those of the Proposed Action on resources, ecosystems, and human communities. DOE believes the analysis of cumulative impacts meets all National Environmental Policy Act provisions and implementing regulations (40 CFR Part 1500 *et seq.* and 10 CFR Part 1021). The documents mentioned in the comment contain guidance rather than regulations. However, DOE has revised Chapter 8 of the Final EIS to provide a clearer presentation of cumulative impacts consistent with established regulations. The presentation contains a more detailed analysis of activities at the Nevada Test Site, as discussed above.

10 (7805)
Comment - EIS001653 / 0007
The DEIS does not consider the impact of underground weapons testing on regional groundwater resources. Additionally, the impact assessment does not consider the collective impact of all actions added together. Instead the analysis only looks at the proposed action added to a single cumulative action. The approach taken in the DEIS is inconsistent with Council on Environmental Quality (CEQ) regulations.

Response
Section 8.3.2 discusses the impacts of underground weapons testing on regional groundwater resources. In Chapter 8 of the Final EIS, DOE clarified the discussion in the Draft EIS on the additive effects of past, present, and future actions.

10 (7853)
Comment - EIS001227 / 0004
Include Conceptual Plans

Conceptual plans for the remediation of the underground test areas should have been included in the Cumulative Impacts section.

For example, one remedial cost estimate was put at $7.29 trillion dollars and would involve the largest open-pit mining operation in the world. Certainly this would represent more than a insignificant cumulative impact. The plan included a conceptual proposal to pipe massive quantities of groundwater through the proposed Yucca Mountain repository area. That certainly should have been in the Draft EIS and should be explained, in detail, in the Final Yucca Mountain EIS.

Response
DOE has not proposed to proceed with the kind of major remediation project such as that described by the commenter. Should DOE propose to pursue a specific goal for remediation of the underground test area at the Nevada Test Site, the Department would undertake appropriate environmental review for such a proposal including analysis of alternative means for accomplishing that remediation. At this time, however, an evaluation of the environmental impacts (including cumulative impacts) of undefined, potential management approaches at the underground test area would be largely speculative. This EIS does analyze cumulative impacts from potential future releases from the Nevada Test Site, assuming no remediation (see Section 8.3.2.1). Remediation of the Nevada Test Site would further reduce these small cumulative impacts.

10 (8113)
Comment - EIS001653 / 0071
The cumulative impact analysis considers a repository with much higher volumes of waste. This scenario should be included in Chapter 5 and not the cumulative impact section. Congress did limit the amount of waste that could be stored in the repository. However, by including a high waste volume scenario in the cumulative impact section assumes that laws will be changed to accommodate a greater amount of waste. If such an assumption is made for the cumulative impact analysis why couldn't it be made for the proposed action?

Response
The consideration in Section 8.2 of additional volumes of nuclear waste beyond that authorized in the Nuclear Waste Policy Act (Inventory Modules 1 and 2) does not presume that disposal of this additional waste in the repository would be approved by Congress. However, DOE considers the possibility to be reasonably foreseeable. Therefore, it is appropriate to examine the impacts of this additional waste under cumulative impacts, rather than under the Proposed Action.

10 (8176)
Comment - EIS001653 / 0102
The cumulative impact analysis does not consider the collective impact of all actions taken together. Instead it looks at only the proposed action with one other action at a time. This approach does not comply with CEQ [Council on Environmental Quality] regulations. Please explain.

Response
While DOE analyzed the collective impact of all actions together, it acknowledges that the presentation in Chapter 8 of the Draft EIS should have been clearer. Therefore, DOE has revised Chapter 8 to include summary sections that clearly indicate the contribution (or lack of contribution) from each activity to the cumulative impacts.

10 (8189)
Comment - EIS001873 / 0012
The proposal to ship low-level nuclear waste via an intermodal station at Caliente is directly linked to the similar proposal for high-level waste in that establishment of the former facility, primarily as an alternative to avoid shipment through Las Vegas, could weigh heavily in the eventual choice of a Caliente high-level waste corridor. For this reason the cumulative impacts of both projects need more than the slight attention they receive in the DEIS. Caliente will likely receive either all or none of the combined impacts, and more information is needed on transportation risks, especially under socioeconomic impacts. All of the above issues are examples of the factors that DOE must set forth for the decisionmakers. Lincoln County and Caliente are representative of communities, not just in Nevada but in 43 states, whose concerns must be addressed. It is no surprise that DOE has deferred considering the transportation issue. A decision to designate Yucca Mountain will impact millions of people. Failure to face the transportation issue will not make it go away.

Response
The potential impacts of each transportation alternative in Nevada are described in Section 6.3 of the EIS. Included are estimates of impacts to health and safety in Nevada, as well as regional socioeconomic impacts to potentially

affected counties, including Lincoln County. Section 8.4.2 analyzes potential cumulative impacts in Lincoln County and elsewhere in Nevada from the Proposed Action and other past, present, and reasonably foreseeable future actions by Federal agencies and private groups. Table 8-58 summarizes cumulative transportation-related radiological impacts from the Proposed Action, Inventory Modules 1 and 2, and other Federal, non-Federal, and private actions nationwide. The table considers potential impacts from current Federal waste-transport activities. These include shipments of low-level waste to the Nevada Test Site, shipments of transuranic waste to the Waste Isolation Pilot Project in New Mexico, and shipments of spent nuclear fuel and high-level radioactive waste to various storage and disposal sites throughout the nation from 1943 to 2047. The Final EIS includes maps of each state showing the routes DOE used in its analysis of impacts in the Draft EIS.

10 (8446)
Comment - EIS001397 / 0014
Over 1,000 nuclear bombs have been detonated at the Nevada Test Site [NTS], above, below and directly within existing water sources. The cumulative effect of NTS radiation contamination in conjunction with Yucca Mountain contamination on the regional aquifers is not addressed in the DEIS at all. Use of potentially contaminated waters to form concrete barriers is not addressed at all. Excessive pumping of aquifers and how this might affect water flow [or] contaminate waters to surrounding communities and ranches and farms is not addressed. This must be rectified completely within the final document.

Response
Chapter 8 of the EIS discusses the impacts to groundwater from past activities on the Nevada Test Site. Sections 8.2 and 8.3 describe short- and long-term cumulative impacts from the repository and other past, present, and reasonably foreseeable actions. Section 8.2.3.2 addresses cumulative short-term impacts to groundwater, including impacts from other Federal and non-Federal actions. These impacts relate primarily to the cumulative consumption of groundwater. Section 8.3 describes the cumulative long-term impacts from contaminant migration from the proposed repository, the Test Site, and the Beatty low-level waste site.

DOE recognizes that some radionuclides or potentially toxic chemicals would eventually enter the environment outside the repository. The regional flow model prepared by the U.S. Geological Survey (DIRS 100131-D'Agnese et al. 1997) suggests that some of the water from the Nevada Test Site flows to the south toward the Amargosa Desert in the vicinity of Yucca Mountain, but the actual transport times and the groundwater pathways from radionuclide contaminants on the Test Site are not clear at this time. Section 8.3.2.1.1 contains a qualitative calculation of the cumulative radiological impact from the Test Site and Yucca Mountain. As indicated, the potential cumulative peak dose for 10,000 years would be well below the regulatory limits established by the Environmental Protection Agency in 40 CFR Part 197. This combined peak dose would occur only if the peak concentrations from the Nevada Test Site and Yucca Mountain occurred at the same time and same location, which would be unlikely.

With regard to the current quality of the groundwater at Yucca Mountain, there is no evidence to suggest that this water has been contaminated by past activities on the Nevada Test Site. See Section 3.1.4.2.2 of the EIS for more information.

Section 4.1.3 discusses water for the repository and the resulting impacts to water availability. In brief, water consumption for the repository could lower the local water table. Additional water consumption in upgradient groundwater areas on the Nevada Test Site could, to some extent, decrease the availability of water in the Amargosa Desert. The amount of water needed for the repository, however, would be small compared to current water consumption in the Amargosa Desert. Therefore, the Proposed Action would have little impact on the availability of water in the region.

Section 5.4 describes the long-term migration of contaminants from the repository.

10 (8499)
Comment - EIS000817 / 0162
P. 8-10. Two spaceports? VentureStar? Kistler Aerospace Satellite Launch? And recovery? So how does all this activity relate to airplane crash analysis into dry cask storage? What could possibly crash into a full cask array on several pads of casks at Yucca Mountain? What all flies over that area from the test site or Nellis Air Force Range?

Is a lot of it secret? Does the right hand know what the left hand is doing here??? Great! A possible vehicle launch or recovery accident from the VentureStar/Kistler project. All we need! This is a risk that should not be taken. There are unknowns here. This just gets worse and worse.

Response
Transportation casks arriving at the repository would be moved into the Waste Handling Building and the contents unloaded and stored in 50-foot-deep water pools inside the building. The Waste Handling Building would be made of concrete and this material would protect the waste stored in pools inside the building from external phenomena such as aircraft crashes. In the unlikely event that a space vehicle launched from the Nevada Test Site crashed into the Waste Handling Building, the impact from the crash would probably not exceed the impacts from the maximum seismic event considered in Appendix H of the EIS. This seismic event is assumed to cause a total collapse of the Waste Handling Building and damage all of the 294 fuel assemblies stored inside (DIRS 152579-Montague 2000). Therefore, DOE believes the impacts from highly unlikely events, such as the crash of a space vehicle, have been adequately considered (see Section H.2.1.5). As noted in Chapter 8 of the Final EIS, the Kistler activity described by the commenter is currently on hold.

10 (8500)
Comment - EIS000817 / 0163
P. 8-13. This Timbisha Shoshone Reservation creation possibility is of great interest. Why? Seems to me we probably owe it to them, right? For some broken treaty of the past? In any case, I'm all for it, but not if they get contaminated land. We are always "dumping" on Native Americans.

Response
The Department of the Interior has issued the *Final Legislative Environmental Impact Statement: Timbisha Shoshone Homeland* (DIRS 154121-DOI 2000). Chapter 8 of the repository EIS discusses the potential cumulative impacts of the proposed repository and the Timbisha Shoshone Homeland.

10 (8501)
Comment - EIS000817 / 0164
P. 8-14. Wow! And here you have gold and copper mining transport further complicating things. -- More traffic congestion and possible pollution.

Response
Section 8.4.2 of the EIS discusses the cumulative impacts from waste transport to the repository and other transportation activities in Nevada, including impacts from the Cortez Gold Mine. As discussed in that section, operation of the mine could have impacts on rail traffic and land use.

10 (8553)
Comment - EIS000817 / 0168
P. 8-78. Is American Ecology the one with all the controversy?

Response
As discussed in Section 8.3.2 of the EIS, American Ecology, through its subsidiary, U.S. Ecology, currently operates a hazardous waste treatment, storage, and disposal facility near Beatty, Nevada. The adjacent low-level radioactive waste disposal facility was closed in 1993 and is now under custody and control of the State of Nevada.

10 (8683)
Comment - EIS001816 / 0003
The existing radionuclide contamination from NTS [Nevada Test Site] testing is the closest, real world analogous, field laboratory for study by Yucca Mountain. YM [the Yucca Mountain Project] has done an exhaustive search in the literature and in the field to understand the geochemistry of radionuclides in groundwater like that of the NTS region. If the NTS UGTA [Underground Testing Area] program were to characterize the near-field area (plume) of groundwater contamination around a number of limited sites at Pahute Mesa, YM must evaluate the benefit to the DEIS analysis that a direct exchange of this type of information would provide, and how it would reduce major uncertainties in the cumulative hydrologic analysis section.

Response
Interactions with the Nevada Test Site Underground Test Area program have been an integral part of the ongoing multiyear effort to produce the combined Yucca Mountain/Nevada Test Site regional groundwater flow model of the Death Valley hydrologic system. Examples of data from the Underground Test Area program, which incorporates data gathered from the Pahute Mesa region and other areas, include results from tracer transport tests, water table elevations, water temperature measurements, hydrologic parameters, geologic data (structural and stratigraphic), hydrochemistry and isotopic data, evapotranspiration parameters, and colloid chemistry. The series of Underground Test Area boreholes in the Oasis Valley sub-basin are providing many types of basic hydrogeologic data on this important part of the Death Valley hydrologic system.

The incorporation of these various types of data refines the existing flow models and so reduces uncertainty in regional and site-scale groundwater flow processes and directions. The long-term performance analysis in Chapter 5 of the EIS benefits from the Underground Test Area data through the use of improved regional and site-scale flow models.

10 (8690)
Comment - EIS001816 / 0005
Section 8.3 Cumulative Long Term Impacts (page 8-76): the statement regarding the maximum potential dose from the underground testing inventory is calculated to be 0.2 millirem per year at 20 kilometers. Using the entire estimated source term, and a number of other assumptions about flow path processes for NTS [Nevada Test Site] water to migrate to a downgradient receptor for a dose of 0.2 millirem is a possible scenario. The YM [Yucca Mountain] DEIS must define how they intend to incorporate new information from the UGTA [Underground Testing Area] program about radionuclide migration in groundwater to adjust the cumulative dose at a downgradient receptor.

Response
The Department used the best available information to prepare the Draft EIS. Since issuing the Draft, DOE has revised some of the analyses of impacts associated with the Nevada Test Site. Section 8.3 now includes updated estimates of the potential dose from the underground testing.

The Yucca Mountain Project has a working relationship with the Nevada Test Site's Underground Test Area program to produce a regional groundwater flow model of the Death Valley hydrologic system. DOE will continue to foster this relationship to plan for future groundwater studies and groundwater monitoring. DOE continues to evaluate the extent of contamination from past underground testing and to refine the groundwater monitoring network based on the results of ongoing evaluations. As new information becomes available, DOE will use it to update impact estimates as appropriate.

10 (8695)
Comment - EIS001816 / 0007
Section 8.3 Cumulative Long Term Impacts (page 8-73): This section must include an analysis of the cumulative federal impact of siting a CERCLA [Comprehensive Environmental Response, Compensation, and Liability Act of 1980] type (Superfund) site like YM [Yucca Mountain] down gradient of an existing Superfund-qualifying site like the NTS [Nevada Test Site] and particularly Pahute Mesa. The NTS Federal Facility Agreement and Consent Order (FFACO, 1996) was negotiated and signed to be a CERCLA-like cleanup agreement for the NTS. Although the NTS does more than qualify to be ranked as a CERCLA site, it was deliberately not put on the national priority list (NPL) CERCLA program. The YM DEIS should do an analysis of this federal action as it pertains to the cumulative impact of the repository program because it too someday will be a CERCLA site. After all, YM is basically a very sophisticated and highly engineered form of underground injection of waste. It too will qualify for the NPL in the years 3,000 or 12,000 or when who knows. Based on DOE modeling YM will contaminate at least one square mile of the subsurface.

Response
Chapter 8 of the EIS describes the cumulative impacts from the repository, along with past, present, and reasonably foreseeable future actions at the Nevada Test Site, Nellis Air Force Base, the Beatty low-level radioactive waste disposal site, and other non-Federal actions in the affected area (see Table 8-1). The cumulative impact assessment considered all past, present, and reasonably foreseeable activities on the Nevada Test Site rather than the Test Site's

regulatory classification. The fact that the Test Site has not been designated as a Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) site was not a barrier to this cumulative impact assessment. Whether or not CERCLA standards would apply thousands of years in the future, and whether the Test Site would eventually be designated as a CERCLA site, would not affect the Department's assessment of potential cumulative impacts in the repository area.

10 (8699)
Comment - EIS001816 / 0009
Section 8.3 Cumulative Long Term Impacts (page 8-76): The utilization of computer modeling to predict groundwater velocities and radioactive transport is an approximation that cannot be validated. In fact, many parameters incorporated into the modeling of all systems eventually contributing to the groundwater source term and subsequent estimation of dose are sophisticated estimates. If the NTS UGTA [Nevada Test Site Underground Testing Area] program were to characterize contaminant plumes (near field) from underground testing within the aquifer, the DEIS must describe how valuable this information would be toward reducing many of the great uncertainties in the repository modeling program.

Response
DOE will continue to evaluate data gathered from the Underground Test Area program at the Nevada Test Site. As advances are made in characterizing contaminant plumes on the Test Site, the Yucca Mountain Project will use the results of these analyses to reduce the uncertainties of computer modeling associated with the long-term performance of the repository and cumulative impacts. Section 5.2.4 of the EIS discusses these uncertainties. It also discusses the possible effects that these uncertainties could have on the impacts estimated for the repository. The summary in Section 5.2.4 describes the assessment of repository performance as a "snapshot in time" that will be refined with additional work. DOE believes the performance assessment results reported in the EIS are conservative, and that additional work will increase confidence in these estimates.

10 (8724)
Comment - EIS002119 / 0009
There is also inadequate analysis of cumulative effects because of planned or present shipments of low-level waste, through waste to and from the NTS and present movement of hazardous material. There may be severe economic impacts within that context. The only cumulative effects we see, although there was some -- there's some lip service provided, is cumulative effects based upon this campaign only. However, we are operating in a context of a number of shipments and of a number of different materials.

Response
Section 8.4 of the EIS describes the cumulative impacts of past, present, and reasonably foreseeable shipments of radioactive materials throughout the Nation and through Nevada. Table 8-58 lists the collective worker-dose and general population dose (in person-rem), and traffic fatalities, from these actions from 1943 to 2047.

10 (8741)
Comment - EIS001816 / 0011
Section 8.3 Cumulative Long Term Impacts: Although the DOE estimates of groundwater basin perennial yield in the vicinity of YM [Yucca Mountain] far exceed the anticipated consumption from operation of the repository and usage in the Amargosa Valley, the DEIS must do further analysis to assess the cumulative impacts of possible increases in groundwater consumption in the next 50 years from: the Nevada Science, Technology, and Museum Corridor; NTS [Nevada Test Site] Development Corporation activities in Area 25; Interim Storage in Area 25; and water importation from Area 25; to augment the Las Vegas Valley Colorado River supply.

Response
Consistent with Council on Environmental Quality regulations (40 CFR 1508.7), DOE considered past, present, and reasonably foreseeable actions in its assessment of cumulative impacts and has reviewed a number of actions both current and proposed to determine relevance. The expression "reasonably foreseeable" refers to future actions for which there is reasonable expectation that the action could occur, such as a proposed action under analysis, a project that has already started, or a future action that has obligated funding. DOE believes that the analyses described in Chapter 8 adequately account for reasonably foreseeable future actions that could have a cumulative impact with the repository.

10 (8747)
Comment - EIS001816 / 0013
Section 3.1.13 (page 3-94) and Section 8.2.13 and 8.3.2.1.3 (page 8-77): Although E.O. [Executive Order] 12898 defines Environmental Justice with respect to minority populations of color and income only, the DEIS must go further and analyze the environmental justice or equity of operating and siting the YM [Yucca Mountain] repository in Southern Nevada where there is already substantial, existing radioactive contamination prior to what Yucca Mountain may bring to the region. The NTS [Nevada Test Site] is predicted to possibly dispose of 7.7 million cubic feet of low-level waste through 2070. In a cumulative impact analysis of these two major federal programs, YM appears to unfairly burden and stigmatize the southern Nevada region with additional radioactive source term material compared to other waste disposal sites. For the year 2050 it is recommended that the DEIS analyze the estimated, cumulative number of curies and nuclear waste volumes in Southern Nevada combined from all federal programs and discuss a broader concept of environmental justice.

Response
As discussed in Sections 8.2.13 and 8.4.12 of the EIS, environmental justice concerns would exist (1) if an activity would have significant environmental impacts and (2) if such impacts would have disproportionately high and adverse human health or environmental effects on minority or low-income populations. Analyses for the EIS indicated that there would be no significant impacts with regard to environmental justice.

An analysis of the cumulative number of curies and waste volumes, as suggested by the commenter, would not address the impact of the activity. DOE used the number of curies and waste volumes as input to the calculations, but not as a sole indicator of an effect. To estimate the impacts, the analysis accounted for the amount of radioactivity at the Nevada Test Site and the repository thousands of years into the future.

10 (8814)
Comment - EIS000869 / 0004
I am aware of the continuing possibility of nuclear contamination of air, land, table and surface water in and around the Nevada Test Site. There are also continuing questions as to land and earth fracture stability secondary to nuclear testing near existing fault lines.

Response
Section 8.3.2.1 of the EIS describes the activities on the Nevada Test Site that could contribute to cumulative impacts with the proposed repository. Since issuing the Draft EIS, DOE has revised some of the analyses of impacts associated with the Test Site. Sections 8.2.2.2 and 8.2.7 now include information on radiation exposure from past nuclear weapons testing, and Section 8.3 includes updated estimates of future impacts to groundwater and air resources from activities on the Test Site. There is no evidence that past testing of nuclear weapons at the Nevada Test Site has fractured the rock at Yucca Mountain or otherwise affected the stability of Yucca Mountain.

10 (8860)
Comment - EIS000869 / 0028
S.6, Cumulative Impacts of the Proposed Action, states that the "DOE could not reasonably predict future actions for the indefinite future. For that reason DOE did not attempt to estimate cumulative impacts beyond about 100 years...." I am not familiar with any person or agency that would have the ability to predict any future 10,000 years away. It is this extraordinary time period that is a major issue with all the alternatives presented in the Draft Environmental Impact Statement.

Response
The complete statement from Section S.6 of the EIS is, "DOE could not reasonably predict future actions for the indefinite future. For that reason DOE did not attempt to estimate cumulative impacts beyond about 100 years with the exception of impacts of radioactive materials reaching the groundwater or atmosphere and resulting in potential impacts to the public." DOE estimated cumulative impacts to groundwater for longer periods, including 1 million years in some cases (for example, see Table 8-48).

The projections included in the EIS are for the undisturbed case in which there is some ability to produce statistical projections of future ranges of climate patterns, geologic features and changes, behavior of engineered components, and other features, events, and processes. DOE made similar evaluations of long-term atmospheric impacts. The most difficult problem with impact forecasts is predicting the future behavior of people and institutions, which is speculative. This is why the EIS analysis did not project many cumulative impacts beyond 100 years.

DOE acknowledges that 10,000 years (and even more so, 1 million years) is an extraordinary period over which to predict the behavior of the system. However, it is possible in many cases to describe this behavior in a way to determine with reasonable assurance that the repository would meet applicable regulatory standards set by Federal agencies (that is, the Nuclear Regulatory Commission and the Environmental Protection Agency). DOE and the Nuclear Regulatory Commission would apply these regulatory standards to judge the adequacy of the predicted behavior of the system. Environmental Protection Agency standards (40 CFR Part 197) require the analysis for the 10,000-year period and, in some cases (for example, the requirement to Caliente Peak dose and assess during the refining period of geologic stability), for considerably longer (1 million years).

10 (8862)
<u>Comment</u> - EIS000869 / 0029
S.6.1., Occupational and Public Health and Safety. Radiological Impacts to Workers compares fatalities under Module 1 or 2 to fatalities under the Proposed Action. There is not a timeframe mentioned in this paragraph. Considering that the previous paragraph has half the deaths mentioned in paragraph two, occurring in the first 100 years of repository operations, I am led to assume that the second paragraph is addressing the first 200 years. The Long-Term Radiological Impacts to public health occur from radionuclides ultimately from Yucca Mountain, past weapons testing on the Nevada Test Site, and past, present, and future disposal of radioactive waste on the Nevada Test Site and near Beatty, Nevada. The cumulative impacts from radionuclides released to groundwater are estimated at less than about 0.003 latent cancer fatality over 10,000 years. Again, I must assume that this is an ideal scenario without earthquakes, flooding, heavy rains, or other natural disasters which have been known to occur in this area. It also does not address nonfatal radiological effects. Radionuclides released to the air, land, dust, or other exposures are not addressed as long-term radiological impacts. Perhaps this was an oversight or perhaps it was intentionally omitted. It is an aspect that required due diligence as the down-winders in Southern Utah can attest.

<u>Response</u>
The EIS analyses assumed that the timeframe is 100 years, the expected period the repository would remain open. The “previous paragraph” referred to in the comment refers to impacts to workers from industrial (that is, non-nuclear) hazards and is unrelated to the paragraph on radiological impacts to workers.

10 (8864)
<u>Comment</u> - EIS000869 / 0030
S.6.3, Transportation, estimates implementation of the Proposed Action, and transportation of radioactive nuclear materials to result in 310-354 latent cancer fatalities. This emplacement period is an approximate 25-year time span. So this is estimating over 12 latent cancer fatalities, to worker and the public populations, per year just from transportation of radioactive nuclear materials. This is an unbelievably high number just from transportation and it is unrealistic to assume that the storage would result in less injuries, deaths, and latent cancer fatalities.

<u>Response</u>
The 310 to 354 latent cancer fatalities cited in the comment is a highly conservative estimate of the cumulative impact of all past, present, and reasonably foreseeable nationwide transport of all types of radioactive materials over a period of 90 years. This category includes shipments of radiopharmaceuticals for nuclear medicine and shipments of low-level radioactive waste to commercial disposal facilities. As shown in Table 8-58 of the EIS, the Proposed Action represents less than 5 percent of the total estimated cumulative impact. Section 8.2.7 of the EIS shows that the cumulative impacts from the operation and monitoring phase would be no greater than those from transportation, and the long-term impacts shown in Section 8.3.2.1.1 for the repository would be lower still.

10 (8881)
<u>Comment</u> - EIS001834 / 0022
A major flaw of the DEIS is that readers cannot determine their total risk in regard to the Yucca Mountain Project. The DEIS’s lack of clarity and disjointedness make it difficult if not impossible to see how more than one risk factor could combine in order to get a picture of the total risk. The DEIS should provide some way for readers to determine “personal cumulative risk.”

<u>Response</u>
As part of its analysis of Proposed Action impacts, the Department attempted to quantify, where possible, the total radiation dose that local residents could have received. The Department calculated the total risk to the population based on the assumption that radiation risks from different exposures are additive. However, the Department cannot in this analysis account for each individual resident's past radiation exposure. To do so would require accounting for lifestyle habits such as the frequency of airline flights, past residence in locations that receive substantially higher or lower cosmic radiation, the type and frequency of medical diagnostic tests and treatments, and a myriad of other factors. Therefore, the Department provided an estimate of the exposure of affected individuals in Chapter 4. Then the Department identified those actions that are imminent or reasonably foreseeable to add to the estimates from Chapter 4 to determine the overall cumulative impact estimates.

10 (8889)
<u>Comment</u> - EIS001834 / 0030
The DEIS does not adequately address the cumulative impacts associated with a nuclear waste repository at Yucca Mountain combined with the past, present, and future activities in the region, such as the Nevada Test Site [NTS], Nellis Air Force Range, and Beatty Low Level Waste Dump.

For example, the groundwater is already contaminated at the Nevada Test Site, and the aquifer that flows beneath the NTS is the same aquifer that is beneath Yucca Mountain. Therefore, contamination from Yucca Mountain would add to an already existing problem and make matters worse for the environment and the people who are dependent upon that aquifer for drinking, farming, and washing. Further, if current trends continue, a significantly higher number of people will be dependent upon that aquifer for water in the future. This increased population coupled with the cumulative effects of radioactive contamination would lead to higher doses and more cancer for the people in the Yucca Mountain and Amargosa Valley area.

Also, the above named sites also have effects on the desert environment, and these impacts must be considered in conjunction with the impacts that a nuclear dump at Yucca Mountain would add.

Finally, as the Nuclear Regulatory Commission has noted, the cumulative effects of water usage, land use, and biological resources. We request that the DOE calculate these cumulative effects and factor them into the DEIS. In order to ensure that all of these considerations are included, the DOE should rewrite the Cumulative Impacts section to more clearly and accurately characterize the total impacts from all of the environmental disaster areas in the Yucca Mountain regional area.

<u>Response</u>
Chapter 8 of the EIS analyzes a range of past, present, and reasonably foreseeable future actions that could contribute to cumulative impacts. In preparing this chapter, DOE reviewed many documents to determine where there was potential for cumulative impacts. These documents included resource plans, EISs, environmental assessments, tribal meeting records, and other documents prepared by Federal, state, local, and private organizations.

Since publication of the Draft EIS, new information on cumulative impacts has become available. DOE has made every effort to include this new information in the Final EIS. For example, Sections 8.3.2.1 and 8.3.2.2 of the Final EIS contain a more complete assessment of the potential dose from past underground weapons testing and low-level radioactive waste disposal inventories on the Test Site. These new assessments used updated data from the Test Site and revised population projections. This information was then used to reexamine cumulative impacts to future populations who could reside in the Amargosa Desert.

Based on its method of analysis, the Department believes that it has accounted for those actions that would cumulatively affect Nye County and surrounding areas and has addressed those areas of impacts cited by the commenter. However, in response to this and other comments, the Department has revised the discussion in Chapter 8 to better present its methodology in estimating potential cumulative impacts.

Chapter 8 discusses cumulative impacts to land use, water resources, cultural resources, biological resources, socioeconomics, and environmental justice. The Department has revised some of the analyses since publication of the Draft EIS and believes that the Final EIS presents a reasonable estimate of the cumulative impacts to the region.

Finally, the Department acknowledges that Chapter 8 of the Draft EIS could have been clearer. Therefore, the Department has revised Chapter 8 to include summary sections that clearly indicate the contribution (or lack thereof) of each activity to cumulative impacts.

10 (8906)

Comment - EIS000869 / 0033

Groundwater contamination has already occurred at the Nevada Test Site and is reaching the borders of the Test Site. It is possible that it may have already contaminated groundwater in Beatty, Western Shoshone land, and in smaller communities surrounding the Nevada Test Site. It needs to be kept from progressing and the contaminated areas from becoming larger.

Response

The quality of the groundwater in the saturated zone at Yucca Mountain is described at the end of Section 3.1.4.2.2 of the EIS. Water samples from wells in the area exceeded the secondary standard for fluoride, as well as a proposed standard for radon. Fluoride and radon occur naturally in the rock through which the groundwater flows. Overall, groundwater quality at Yucca Mountain is good. There is no evidence that activities on the Nevada Test Site have contaminated the groundwater beneath Yucca Mountain. The last paragraph of Section 3.1.4.2.2 describes the results of groundwater monitoring at the Nevada Test Site and the nature and extent of contaminant migration.

Section 8.2.3.2 addresses cumulative short-term impacts on groundwater including those that could be additive to the Proposed Action from other Federal and non-Federal actions. These impacts relate primarily to water consumption and the resultant impacts on the availability of water resources in the area. Section 8.3 discusses cumulative long-term impacts including contaminant migration, and Sections 8.3.2.1 and 8.3.2.2 address cumulative impacts from activities on the Nevada Test Site and the Beatty low-level radioactive waste site, respectively.

DOE recognizes that some radionuclides or potentially toxic chemicals would eventually enter the environment outside the repository. The regional flow model prepared by the U.S. Geological Survey (DIRS 100131-D'Agnese et al. 1997) suggests that some of the water from the Nevada Test Site flows to the south toward the Amargosa Valley in the vicinity of Yucca Mountain, but the actual transport times and groundwater pathways from radionuclide contaminants on the Test Site are not clear at this time. Section 8.3.2.1.1 contains a qualitative calculation of the cumulative radiological impact from the Test Site and Yucca Mountain. As indicated, the potential cumulative peak dose for 10,000 years would be well below the regulatory limits established by the Environmental Protection Agency in 40 CFR Part 197. This combined peak dose would occur only in the unlikely event that the peak concentrations from the Nevada Test Site and Yucca Mountain occurred at the same time and at the same location.

Comment - EIS001888 / 0066

Cumulative [impacts] throughout the DEIS are not readily identified given that the procedures used to define impacts are not sufficiently sensitive to isolate impacts among subgroups. With the methodologies available today to analyze data, and given the unprecedented nature of DOE's proposal to ship large volumes of nuclear waste across the nation, it is reasonable to expect DOE to analyze potential impacts at a variety of scales. Without such detail, neither Clark County nor communities along the transportation routes will be able to effectively assess impacts and design appropriate mitigation strategies. NEPA [National Environmental Policy Act] Regulation: Sec. 1502.14 Alternatives including the proposed action; Sec. 1502.16 Environmental consequences: Sec. 1502.22 Incomplete or unavailable information. Forty Most Asked Questions Concerning CEQs [the Council on Environmental Quality] NEPA Regulations. l9a. Mitigation Measures.

Response

The Department acknowledges at the beginning of Chapter 6 of the EIS that it is uncertain at this time when DOE would make any transportation-related decisions. The Department continues by saying it believes that the EIS provides the information necessary to make decisions regarding the basic approaches to waste transport (that is, mostly rail or mostly truck shipments), as well as the choice among alternative transportation corridors. DOE identified mostly rail in the Final EIS as its preferred mode of transportation both nationally and in the State of Nevada. DOE has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was recommended and approved, DOE would issue, at some future date, a Record of Decision to select a mode of transportation. Thereafter, for example, if mostly rail was selected (both nationally and in Nevada), DOE would then identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in the State of Nevada.

Comment - EIS001888 / 0067
In Chapter 8, the DEIS has understated the scale and complexity of the cumulative impacts of DOE programs for the simultaneous disposal of low-level and high-level radioactive waste. According to DOE's Draft Waste Management Programmatic EIS* and later documents, the Nevada Test Site (NTS) is a preferred regional disposal site for low-level radioactive waste. This program will occur over a number of years, and would greatly increase the total number of truck shipments of radioactive waste through southern Nevada. Under present regulation, these shipments may be routed on the same highway system through Clark County as the shipments to a Yucca Mountain repository.

Despite assurances in the programmatic EIS, the Yucca Mountain DEIS did not contain an authoritative examination of the cumulative impacts of both DOE disposal programs on Nevada and Clark County. According to some estimates, the shipment of low-level radioactive waste from DOE defense sites across the nation to the NTS will last for approximately 70 years. The waste will be shipped by truck, conceivably through the most densely populated and sensitive parts of Clark County. The low-level radioactive waste (LLW) shipping campaign could result in the transport of up to 12 truckloads per day for more than 70 years.

*U.S. Department of Energy. *Draft Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage and Disposal of Radioactive and Hazardous Waste*, DOE/EIS-0200-D, 1995.

Response
Section 8.4 of the EIS discusses the cumulative impacts of transportation in the region. This discussion includes the impacts of transporting low-level radioactive waste to the Nevada Test Site from offsite locations [the "Expanded Use Alternative" for the Nevada Test Site (DIRS 101811-DOE 1996)]. Table 8-58 shows that the radiological impacts of waste transport for the Proposed Action along with other past, present, and reasonably foreseeable shipments of radioactive material would be minor. To arrive at a conservative estimate of the collective radiation dose, the Department assumed that the same population of people (public and workers) would be exposed to each action that involved the transport of radioactive material.

The duration of shipments of low-level waste to the Nevada Test Site was assumed to be 10 years, based on Section E.7.2 of the Final Programmatic Waste Management EIS (DIRS 101816-DOE 1997). Routing details have not been determined. However, routing decisions would be in accordance with regulations of the U.S. Department of Transportation.

10 (9355)
Comment - EIS001888 / 0068
The DOE has already established a poor record for managing and transporting LLW [low-level radioactive waste] in Clark County. For example, after an incident with a LLW highway shipment from Ohio to the NTS that was found to be leaking non-radioactive water, the shipping campaign was suspended for over eighteen months as an internal investigation* was conducted. The two major findings were that DOE had not enforced its own requirements regarding the fabrication and deployment of the containers, and that institutional processes between and among DOE facilities, the State of Nevada, local governments and others had failed to provide effective control of this and similar situations.

Another example is regarding DOE's statements and subsequent efforts to minimize risk and impacts of LLW shipments on Clark County. In this case, representatives of DOE Nevada acknowledged that there are administrative means that may be used by DOE to assure that LLW shipments avoid high-risk areas. However, later inaction by DOE resulted in the continuation of shipments through the areas of concern in the Las Vegas Valley, except for truckers that voluntarily used other routes.

*U.S. Department of Energy Fernald Environmental Management Project. *Type B Accident Investigation Board Report of the December 15, 1997, Leakage of Waste Containers Near Kingman, Arizona*, February 1998.

Response
The incident to which the commenter refers occurred in December 1997 and involved the shipment of low-level waste from the Fernald Site in Ohio to the Nevada Test Site. The driver of the truck noticed that liquid was leaking from the container and followed the proper steps to notify local authorities and DOE. Subsequent investigation revealed that the liquid was not contaminated. Steps have been taken to prevent such an incident from occurring again. There was no harm to workers or the environment from the incident in question. With regard to Yucca Mountain, all waste (spent nuclear fuel and high-level radioactive waste) would be in solid form (that is, no liquid or other material that could leak).

With regard to shipping routes for specific shipments, the Department acknowledged in the Programmatic Waste Management EIS (DIRS 101802-DOE 1995) that "DOE proactively works with states, regional entities, and carriers during large shipping campaigns to ensure that safe routing alternatives and safe havens are utilized." However, the selection of any route will pose a risk to some portion of the public; the avoidance of one area would affect other areas through which the shipment was routed. Regulations by the U.S. Department of Transportation govern the routing of radioactive materials, and carriers are responsible to the U.S. Department of Transportation for routes that are used.

10 (9356)
Comment - EIS001888 / 0069
The DEIS analysis of cumulative impacts shows no consideration of the context in which spent nuclear fuel (SNF) will be transported to Yucca Mountain. There is also no information about other hazardous commodities on the roads and railways. There is no discussion of the substantial impacts of the DOE's LLW [low-level radioactive waste] disposal program on Clark County and the likely relationship between the LLW and SNF disposal programs.

The DEIS also does not present a description of the impacts of these programs on the infrastructure (e.g., highways, roadside facilities) of Clark County, nor does it provide sufficient information about the necessary emergency management requirements to respond to the DOE's programs. To rectify the substantial omissions in the DEIS, the DOE must prepare a supplemental evaluation of cumulative impacts that describes the current context in which SNF will be transported. This additional analysis must address the current hazardous materials shipments in urban Clark County and rural Nevada for both rail and truck modes, it must describe the process used to identify and measure cumulative impacts and it must measure those impacts.

Response
Section 8.4 of the EIS discusses the cumulative impacts from the transport of radioactive materials in the region. It includes the impacts of transporting waste to the Nevada Test Site under the Expanded Use Alternative (Alternative 3) described in the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996). This alternative includes shipments of low-level radioactive waste to the Test Site from offsite locations. Section 8.2.12.2 discusses the cumulative impacts of storing low-level waste, including the reasonably foreseeable action that the Nevada Test Site is selected as a regional DOE low-level waste disposal site. Impacts to people and the environment from shipments of nonradioactive hazardous materials on the Nation's roads and railways are not examined because such shipments are unrelated to the Proposed Action, which is to transport and dispose of radioactive materials at Yucca Mountain.

Section 8.4.1.2 and Table 8-58 of the EIS summarize cumulative transportation-related radiological impacts from the Proposed Action, Inventory Modules 1 and 2, and other Federal, non-Federal, and private actions nationwide. The table summarizes potential impacts from current Federal waste transport activities. These include shipments of low-level waste to the Nevada Test Site, shipments of transuranic waste to the Waste Isolation Pilot Plant in New Mexico, and shipments of spent nuclear fuel and high-level radioactive waste to various storage and disposal sites throughout the Nation. DOE believes that these impacts would be minor.

10 (9357)
Comment - EIS001888 / 0070
In the paragraph below, citations are provided from the DEIS regarding its analysis of cumulative impacts on cultural resources and socioeconomic conditions. These are included to demonstrate that, in non-compliance with NEPA [National Environmental Policy Act] Regulation, Section 1502.22, DOE has not provided sufficient detail to analyze potential cumulative impacts resulting from the proposed repository at Yucca Mountain. Because of this deficiency, the DEIS inadequately addressed potential mitigation needs.

DEIS Statement, p. 8-37: Cumulative Impacts on Cultural Resources. "...the emplacement of either module would require small additional disturbances to land in areas already surveyed during site characterization activities. Because repository construction, operation and monitoring, and closure would be Federal actions, DOE would identify and evaluate cultural resources, as required by Section 106 of the National Historic Preservation Act, and would take appropriate measures to avoid or mitigate adverse impacts to such resources. As a consequence, archaeological information gathered from artifact retrieval during land disturbance would contribute additional cultural resources information to the regional database for understanding past human occupation and use of the land. However, there would be a potential for illicit or incidental vandalism of archaeological or historic sites and artifacts as a result of increased activities in the repository area, which would be extended for Module 1 or 2, and this could contribute to an overall loss of regional cultural resources information.

"The Native American view of resource management and preservation is holistic in the definition of cultural resources, incorporating all elements of the natural and physical environment in an interrelated context (AIWS 1998, all). The Native American perspective on cultural resources is further discussed in Chapter 3, Section 3.1.6. Potential impacts resulting from the Proposed Action described in Chapter 4, Section 4.1.5, would also apply to Inventory Module 1 or 2."

DEIS Statement, p. 8-39: Cumulative Impacts on Socioeconomic Conditions. "The Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada (DOE 1996f, all) presents various scenarios for Nevada Test Site actions. The Record of Decision for that EIS states that DOE would implement a combination of three alternatives: Expanded Use, No Action (continue operations at current levels) regarding mixed and low-level radioactive waste management, and Alternate Use of Withdrawn Lands regarding public education (61 *FR* 65551, December 13, 1996). Under this combination of alternatives, the Nevada Test Site could generate an increase of approximately 4,550 direct jobs, and most of these workers would be likely to live in Clark County (Department of Energy 1996f, page 5-17)."

Response
DOE believes that the analytical approach used in Chapter 8 of the EIS to examine cumulative impacts is consistent with all applicable requirements including regulations implementing the National Environmental Policy Act promulgated by the Council on Environmental Quality, including 40 CFR 1502.22. Chapter 8 provides the appropriate amount of information for understanding cumulative impacts that could be associated with a repository at Yucca Mountain, including cumulative impacts to cultural resources and socioeconomic conditions. In addition, the Department believes that the mitigation measures described in Chapter 9 are responsive to the potential impacts from the repository identified by the analysis (see Section 9.2.4).

In general, the analysis of cumulative impacts in Chapter 8 followed the process recommended in the Council on Environmental Quality's handbook *Considering Cumulative Effects Under the National Environmental Policy Act* (DIRS 103162-CEQ 1997). This process included the identification, through research and consultations, of Federal, non-Federal, and private actions with possible effects that would be coincident with those of the Proposed Action on resources, ecosystems, and human communities.

10 (9467)
Comment - EIS001888 / 0138
Further, if DOE is planning to piggyback rail shipments, then the cumulative impacts from this activity should be identified in the DEIS.

Response
In the Final EIS, DOE identifies mostly rail as its preferred mode of transportation both nationally and in the State of Nevada. Possible sharing of a branch rail line is speculative at this time. Therefore, analyzing the cumulative impacts of shared use at a rail line could result in a misrepresentation of those impacts.

10 (9485)
Comment - EIS001888 / 0150
[Summary of comments noted by Clark County Nuclear Waste Divisions staff at various citizens' meetings.]

Concern that DOE is not taking into account that Nevada is already impacted by the Low-Level Waste shipments that are going to NTS [Nevada Test Site] and the continuing effects of the nuclear tests that were performed there.

Concern that DOE is not considering all the impacts Southern Nevada has already received from operations at the NTS.

Response
Table 8-58 of the EIS summarizes cumulative transportation-related radiological impacts from the Proposed Action, Inventory Modules 1 and 2, and other Federal, non-Federal, and private actions nationwide. The table considers potential impacts from current Federal waste-transport activities. These include shipments of low-level waste to the Nevada Test Site, shipments of transuranic waste to the Waste Isolation Pilot Project in New Mexico, and shipments of spent nuclear fuel and high-level radioactive waste to various storage and disposal sites throughout the nation from 1943 to 2047.

Impacts from operation of the Nevada Test Site are described in Section 8.2.7 of the EIS. Future impacts to groundwater from past weapons testing are described in Section 8.3.2.1.1. Section 3.1.8 of the Final EIS discusses estimates of radiation doses to individuals from past weapons testing on the Nevada Test Site. This information has been included in Sections 8.2.2.2.2 and 8.2.7 as contributing to short-term cumulative radiological impacts. Readers interested in further information about the effects of past testing of nuclear weapons should refer to the *National Cancer Institute Study Estimating Thyroid Doses of I-131 Received by Americans From Nevada Atmospheric Nuclear Bomb Tests* (DIRS 152469-Institute of Medicine and National Research Council 1999).

10 (9660)
Comment - EIS001888 / 0319
The cumulative effects portion of the DEIS understates the scale and complexity of the cumulative impacts of the DOE's waste disposal program. Despite assurances in the Waste Management Programmatic Environmental Impact Statement, the DEIS does not contain an authoritative examination of the cumulative impacts of both DOE disposal programs on Nevada and Clark County. According to some estimates, the shipment of Low Level Radioactive Waste [LLW] from DOE defense [sites] across the nation to the Nevada test Site will last for approximately 70 years. The waste will be shipped by truck, and may be shipped through the most densely populated and sensitive parts of Clark County. The LLW shipping campaign will require up 12 trucks per day for the entire 70 years of the program. The chart in Figure 11 depicts the recent LLW shipments through Clark County to the Nevada Test Site.

Response
Section 8.4 of the EIS describes the cumulative impacts of past, present, and reasonably foreseeable shipments of radioactive materials throughout the nation and in Nevada. Table 8-58 lists the collective worker dose and general population dose (in person-rem), and traffic fatalities, from these actions between 1943 and 2047.

10 (9663)
Comment - EIS001888 / 0321
The DEIS provides no information about the context in which SNF [spent nuclear fuel] will be transported. There is no information about other hazardous commodities on the roads and railways. There is no discussion of the substantial impacts of the DOE's LLW [low-level radioactive waste] disposal program on Clark County and the likely relationship between the LLW and SNF disposal programs.

To rectify the substantial omissions in the DEIS, the DOE prepare a supplemental statement of cumulative impacts that describes the current context in which SNF will be transported. This additional statement must address: the current hazardous materials shipments in urban Clark County and rural Nevada for both rail and truck modes, it must describe the process used to identify and measure cumulative impacts and it must measure those impacts.

Response
Section 8.4 of the EIS discusses the cumulative impacts from the transport of radioactive materials in the region (see Appendix M). It includes the impacts of transporting waste to the Nevada Test Site under the Expanded Use Alternative (Alternative 3) described in the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996). This alternative includes shipments of low-level radioactive waste to the Test Site from offsite locations. Section 8.2.12.2 discusses the cumulative impacts of storing low-level waste, including the reasonably foreseeable action that the Nevada Test Site is selected as a regional DOE low-level waste disposal site. Impacts to people and the environment from shipments of nonradioactive hazardous materials on the nation's roads and railways are not examined because such shipments are unrelated to the Proposed Action, which is to transport and dispose of radioactive materials at Yucca Mountain.

Section 8.4.1.2 and Table 8-58 of the EIS summarize cumulative transportation-related radiological impacts from the Proposed Action, Inventory Modules 1 and 2, and other Federal, non-Federal, and private actions nationwide. The table summarizes potential impacts from current Federal waste transport activities. These include shipments of low-level waste to the Nevada Test Site, shipments of transuranic waste to the Waste Isolation Pilot Project in New Mexico, and shipments of spent nuclear fuel and high-level radioactive waste to various storage and disposal sites throughout the nation. DOE believes that the impacts from these shipments has been and will continue to be minor.

10 (9716)
Comment - EIS002151 / 0006
The most serious environmental disaster in the project is the soil and groundwater from nuclear testing. That deadly soil and water is moving off the Nevada Test Site. It doesn't stay contained on the test site. That's something that the workers have even talked about, the scientists have talked about, Corbin Harney has talked about, the Western Shoshone National Council has talked about, so it's important that we listen to that. The U.S. Government has already proven they will contaminate the land over a thousand times. We believe that test site has had over a thousand bombs. It's not even under a thousand.

Response
DOE describes the effects of weapons testing at the Nevada Test Site in Section 8.3.2 of the EIS.

10 (9740)
Comment - EIS001888 / 0324
[Clark County summary of comments it has received from the public.]

Requests for a review of the effects of past DOE (and predecessor) activities in Southern Nevada have not been addressed in the DEIS.

Response
Section 8.3.2.1 of the EIS describes the activities on the Nevada Test Site that could contribute to cumulative impacts with the proposed repository. Since issuing the Draft EIS, DOE has revised some of the analyses of impacts associated with the Nevada Test Site. Sections 8.2.2.2 and 8.2.7 now include information on radiation exposure from past nuclear weapons testing, and Section 8.3 now includes updated estimates of future impacts to groundwater and air resources from activities on the Nevada Test Site. Section 8.4 discusses the cumulative impacts of transportation in the region, including impacts from the Expanded Use Alternative (Alternative 3) described in the Nevada Test Site EIS (DIRS 101811-DOE 1996). This alternative includes the shipment of low-level radioactive waste to the Nevada Test Site from offsite locations. Section 8.2.12.2 of this EIS discusses the cumulative impacts from storing low-level waste, including the reasonably foreseeable action of the Test Site as a regional DOE low-level waste disposal site.

10 (9749)
Comment - EIS001888 / 0333
[Clark County summary of comments it has received from the public.]

Commenters expected the EIS to analyze the cumulative environmental and radiological risks and hazards from all past, current and proposed radioactive waste and special nuclear materials activities at Yucca Mountain, the NTS [Nevada Test Site], and surrounding environs. Commenters identified commercial and DOE-owned SNF [spent nuclear fuel], foreign research reactor SNF, HLW [high-level radioactive waste], Greater than Class C waste, special case waste, LLW [low-level radioactive waste], TRU [transuranic] waste, and special nuclear materials that should be included in these analyses. These analyses are also expected to consider transportation (all communities and Indian Nations, all routes, all modes, all rail spurs storage and/or disposal, and treatment. More specifically, commenters requested that the EIS address: (1) both the 70,000 MTHM [metric tons of heavy metal] limit and the total estimated 85,000 MTHM of SNF, (2) all DOE-owned SNF, (3) all foreign research reactor SNF (~19.2 MTHM), (4) ~28,372 canisters of HLW (to be modified to reflect decisions from Hanford's tank waste EIS), (5) ~70,000 cubic feet of Greater than Class C, and (6) ~2.6 million cubic feet of special case waste. Commenters requested that the cumulative impact analyses assess the significance of direct and indirect long-term effects on the human and natural environment, such as impacts to human health (to "downwinders," local communities, and workers), ecosystems (with reliance on the NTS resource management plan), air quality, soils, socioeconomics, and local and regional groundwater resources. Impacts should be developed in consideration of: (1) contaminant levels from past weapons testing and associated research and development activities at NTS, (2) waste disposed of or planned for disposal at the NTS, (3) waste disposed of at the Beatty low-level waste site, (4) ongoing waste management, environmental restoration, and decontamination and decommissioning activities at NTS, (5) military operations, and (6) discharge of toxic metals from abandoned mines. Cumulative impacts must be assessed in time frames that range from 1,000 to 1,000,000 years. Commenters requested that the cumulative impact analyses be supported by credible scientific data, including the development of baseline health data, which have undergone peer review. In addition, the way in which equity and fairness issues are involved should be considered.

Response
The Department believes that the Draft EIS adequately analyzed the cumulative environmental and radiological impacts of the repository. As shown in Figure 8-1 and Appendix A, the EIS analyzed several categories of nuclear materials to be placed in the repository, as follows: up to 105,000 metric tons of heavy metal of commercial and DOE spent nuclear fuel, including foreign research reactor fuel in the 15 categories of fuel analyzed (see Table A-16); over 22,000 canisters of high-level radioactive waste using the calculation method described in Appendix A; about 2,000 cubic meters (70,000 cubic feet) of Greater-than-Class-C waste; and about 4,000 cubic meters (140,000 cubic feet) of Special-Performance-Assessment-Required waste. These materials represent the currently proposed and reasonably foreseeable inventories that could be placed in the repository.

In relation to the impact assessment, Chapter 8 of the Final EIS discusses the short- and long-term cumulative effects on human health (Sections 8.2.7, 8.3.1.2, 8.3.2, 8.2.8, and 8.4.2.7); ecosystems (Sections 8.2.4 and 8.4.2.4); air quality (Sections 8.2.2, 8.3.1.2.3, 8.3.1.3.3, and 8.4.2.2); soils (Sections 8.2.4 and 8.4.4); socioeconomics (Sections 8.2.6 and 8.4.2.6); and local and regional groundwater (Sections 8.2.3, 8.3.1.2.1, and 8.4.2.3).

In the analyses described in the sections cited above, the Department considered past weapons testing and waste management activities at the Nevada Test Site (Sections 8.3.2.1.1 and 8.3.2.1.3), as well as activities at the Beatty low-level radioactive waste disposal facility (Section 8.3.2.2). The analysis did not include environmental restoration and decontamination and decommissioning activities at the Nevada Test Site. However, DOE updated Table 8-58 of the EIS to include analysis of the Expanded Use Alternative from the Nevada Test Site EIS (DIRS 101811-DOE 1996).

The Department did not include an analysis of the discharge of metals from abandoned mines for several reasons. First, older abandoned mines have been present in the area for decades, and the Department believes the impacts are captured in the baseline information discussed in Chapter 3. Second, any discharges would not result in a short-term cumulative impact with the Proposed Action because the repository would have no waterborne releases for at least 10,000 years. Third, long-term impacts of the mines are speculative because of continuing efforts to clean up the abandoned mines. This issue is being addressed not only by the State of Nevada but also by the U.S. Congress. In March 2000, Congressman Jim Gibbons (Nevada) introduced House Resolution 2753, Abandoned Mine Restoration

Act of 1999. This legislation, and other similar legislation, could provide the means to restore the environment of mines, removing any toxic metals that could cause further harm to the environment in the future. The number of mines that would be included in this effort is still unknown, as are the cleanup criteria that might be applied.

10 (9752)
Comment - EIS001888 / 0335
[Clark County summary of comments it has received from the public.]

Several commenters requested that the EIS reveal and otherwise evaluate the effect of past DOE activities in southern Nevada. More specifically, commenters requested (1) a history of decisions by DOE (and DOE-predecessors the Energy Research and Development Administration and the Atomic Energy Commission) that have affected the health and safety of organisms within a 700-mile radius of Yucca Mountain, (2) a summary of Research conducted on the effects on health and safety from radiation exposure, (3) a list and summary of past and pending litigation on radiation exposure, (4) that the EIS examine the global risks from nuclear-related activities, and environmental restoration and waste management at the NTS [Nevada Test Site], including the transportation of wastes, and (5) that the repository EIS be coordinated with the EIS on the NTS.

Response
In response to item 1 of the comment, Chapter 8 of the EIS describes the cumulative impacts from the repository, along with past, present, and reasonably foreseeable future actions at the Nevada Test Site, Nellis Air Force Base, the Beatty low-level radioactive waste disposal site, and other non-Federal actions in the affected area (see Table 8-1). With the exception of some factual changes and clarifications in the Final EIS, DOE believes that the Draft EIS adequately characterized the cumulative impacts associated with the proposed repository, which includes activities at the Nevada Test Site.

In relation to item 2, the effects of radiation on health and safety have been studied extensively over the past century and are better known than those of most toxins. Our current knowledge about the health effects of radiation is based in large part on exposures of individuals to large doses of radiation that exceed any U.S. public or worker dose limit. Appendix F of the EIS contains more information about the current state of knowledge about the health effects of radiation.

In response to item 3 of the comment, DOE did not include a summary of past and pending litigation on radiation exposure because this information would not aid decisionmakers to evaluate the potential impacts of the repository. Worker protection and the long-term performance of the repository are governed by established radiation protection standards. It is against these standards that the radiological impacts of the repository will be judged.

In relation to item 4, the EIS did not report potential global impacts to environmental "commons," such as surface waters, because there would be no release of radioactive material to major rivers, and thus no releases to the oceans. As stated by the National Academy of Sciences (DIRS 100018-National Research Council 1995), "…the most likely pathway for global distribution are gaseous releases of carbon dioxide containing the radioactive isotope of carbon-14, that eventually will escape from the waste containers, or by widespread distribution of foodstuffs grown with contaminated water." However, the National Academy of Sciences also stated, "In general, the risks of radiation produced by such wide dispersion are likely to be several orders of magnitude below those to a critical group." For example, the Academy estimated that the average dose to members of the global population, based on the release of 91,000 curies of carbon-14, to be 0.003 microsievert per year (0.0003 millirem per year). The Academy equated that to an annual risk of fatal cancer of 1.5 in 10 billion (1.5×10^{-10}). For comparison, the standard set by the Environmental Protection Agency in 40 CFR Part 197 of 15 millirem per year for the reasonably maximally exposed individual is a factor of 50,000 times higher.

Because of large uncertainties, the Department considers estimates of global health effects highly speculative and, therefore, did not estimate global collective doses or health effects in the EIS. However, the Department agrees with the Environmental Protection Agency (64 *FR* 46976, August 27, 1999) and the National Council on Radiation Protection and Measurements (DIRS 101858-NCRP 1995) that, for purposes of optimizing protectiveness of design alternatives, estimation of population doses is merited. However, the Department believes that information important to design optimization can be obtained by estimating collective dose to the regional populations within 80 kilometers [50 miles] of the repository, thereby precluding the need to perform the more speculative, global health risk calculations. For these reasons, the EIS evaluated in detail potential radiological exposures to the reasonably maximally exposed individual and regional populations (80 kilometers) from both groundwater and atmospheric pathways. Sections 5.4 and 5.5 present the results of these evaluations for waterborne and atmospheric releases, respectively.

In relation to item 5 of the comment, the repository EIS is consistent with information and analyses in the Nevada Test Site EIS (DIRS 101811-DOE 1996). As indicated in Section 8.3.2.1.1 of the repository EIS, the Nevada Test Site EIS was used as a source of information for cumulative long-term impacts. Furthermore, the Nevada Test Site EIS was a source document for the transportation impacts described in Section 8.4.1.2 of the repository EIS. In addition, representatives of the Yucca Mountain Project and the Nevada Test Site continue to maintain an open dialogue to ensure that decisions made at either facility support the common goals of both facilities and protect the environment and the health and safety of workers and the public.

10 (9887)
Comment - EIS001888 / 0435
In general, the EIS should estimate the "long-term cumulative impacts to the environment and therefore to humans."

Response
Chapter 8 describes the cumulative long-term impacts of the repository, along with the impacts of past, present, and reasonably foreseeable activities in the affected region. Geologic and hydrologic studies and computer modeling conducted by DOE, the U.S. Geological Survey, and other organizations indicate that the repository would perform in compliance with 40 CFR Part 197.

10 (10006)
Comment - EIS001888 / 0502
[Clark County summary of comments it has received from the public.]

Cumulative impacts are not being adequately measured.

Response
Chapter 8 of the EIS describes the cumulative impacts from a repository at Yucca Mountain, along with past, present, and reasonably foreseeable future actions at the Nevada Test Site, Nellis Air Force Base, the Beatty low-level radioactive waste disposal site, and other non-Federal actions in the affected area (see Table 8-1). In preparing Chapter 8, DOE reviewed many documents to determine the potential for cumulative impacts. These documents included resource management plans, EISs, environmental assessments, and records of tribal meetings prepared by Federal, state, local, and private organizations. DOE believes that the EIS adequately characterizes the cumulative impacts associated with the proposed repository.

Comment - EIS002216 / 0001
Well, I'd like to pose the question about the existing contamination, the ongoing low-level waste disposal and the existing contamination that's at the Nevada Test Site [NTS] right now, especially those of you folks that are in Amargosa.

We don't have a monitoring network out there for you folks yet. We don't know where the source term is going. It's not protected by engineered barrier.

So this is more directed toward people who are working on the Yucca Mountain Project because with the advisory board and the existing citizen interest, we don't address the existing contamination very well at all, and that program is moving forward without much public scrutiny, with a lack of oversight.

The governor's requested 40 million more dollars to throw at the program, and like Yucca Mountain, you just don't just solve a problem by throwing more money at it.

You've got to have some oversight, some technical strategy. You've got to have a plan.

The NTS is on the stage of becoming the nation's premier low-level waste disposal facility, and there's not much the State of Nevada can do to stop that.

And the existing contamination has been in the groundwater for years and we don't know the extent or the duration and the magnitude of that contamination.

Response
As a result of monitoring concerns expressed by many commenters, DOE has supported Nye County in its program (called the *Early Warning Drilling Program*) to characterize further the saturated zone along possible groundwater pathways from Yucca Mountain as well as the relationships among the volcanic, alluvial, and carbonate aquifers. Information from the ongoing site characterization program (and possible Testing and Performance Confirmation Program, which is described below) would be used in conjunction with that of the Early Warning Drilling Program to refine the Department's understanding of the flow and transport mechanics of the saturated alluvium and valley-fill material south of the proposed repository site, and to update conceptual and numerical models used to estimate waste isolation performance of the repository. When DOE published the Draft EIS, only limited information from the Early Warning Drilling Program was available. Since then, however, this program has gathered additional information, which DOE has incorporated in the EIS.

In addition, DOE has installed a series of test wells along the groundwater flow path between the Yucca Mountain site and the Town of Amargosa Valley as part of an alluvial testing complex. The objective of this program is to better characterize the alluvial deposits beneath Fortymile Wash along the east side of Yucca Mountain. Single- and multiwell tracer tests have begun and the results thus far have strengthened the basis of the site-scale saturated flow and transport model. Information from this program has been incorporated in the EIS.

If the site was approved, DOE would institute a Testing and Performance Confirmation program, elements of which would address the hydrologic system. The purpose of this program would be to further evaluate the accuracy and adequacy of the information used to determine whether the repository would meet long-term performance objectives. The Testing and Performance Confirmation program, which would continue through closure of the repository (possibly as long as 300 years), would offer a means to further understanding of the hydrologic system and reduce uncertainties.

10 (10691)
Comment - EIS002141 / 0002
It is almost absurd that an Environmental Impact Statement is being done for the Nevada Test Site when you consider that there are almost 1,000 repositories already there. I understand that you have to prepare [an] Environmental Impact Statement, but the truth is the nuclear weapons program has already created all of those repositories.

The Environmental Impact Statement should consider the environmental impact of Yucca Mountain in the context of the fact that these repositories are already there. The additional impact of a well designed, highly controlled repository will be zero and the Environmental Impact Statement should reflect that.

Response
The Draft EIS contained results of a cumulative groundwater impact analysis which included potential impacts from past weapons testing and low-level radioactive waste disposal at the Nevada Test Site. However, for the Final EIS, DOE completed additional, more detailed analyses based on the most recent data available. Section 8.3.2.1.1 contains the results.

10 (10878)
Comment - EIS000053 / 0001
The Military Lands Withdrawal Act of 1986 required the preparation of the Special Nevada Report. This report, finalized in September 1991, contains a description of current and proposed defense-related activities in the State of Nevada, an analysis of their impacts, and possible actions that could be taken to mitigate those impacts. The report was prepared jointly by the Departments of the Air Force, Navy, and Interior with the Department of Army and Department of Energy listed as cooperating agencies. Per Section 6(b)(1)(D) of The Act, the Special Nevada Report

was mandated to include the lands withdrawn or being considered for withdrawal for use by the Department of Energy.

With respect to water resources, a number of impacts were found to result from the cumulative land withdrawals including the lack of access to potentially developable water resources, water quality impairment resource

consumption by federal agencies, and resource competition with non-federal water users. Page 8-97 of the Special Nevada Report states that:

"The withdrawal of land from public access and/or the purchase of water rights by DOD and DOE has the greatest potential for effects on Nevada....The water resources associated with these lands could, if they exist and were available, play an important role in the continued growth of southern Nevada."

The Special Nevada Report is not referenced in the Draft EIS for Yucca Mountain nor are the direct, indirect, or cumulative impacts of federal land withdrawals and water use considered and evaluated. These impacts are significant. The failure of the Draft EIS for Yucca Mountain to incorporate the findings of the Special Nevada Report is a serious inadequacy in the document. The Draft EIS must be revised to include these findings of the Special Nevada Report and must include an evaluation of the cumulative consequences of the land withdrawal for the proposed repository at Yucca Mountain.

Response
DOE has revised Section 8.2 of the EIS to include a discussion of the *Special Nevada Report* (DIRS 153277-SAIC 1991). It should be noted, however, that the *Special Nevada Report* is more than 10 years old and many changes have occurred since the report was prepared. In its analysis of cumulative impacts in the Draft EIS, the Department was obligated to consider past, present, and reasonably foreseeable future actions based on the current understanding of these actions. For that reason, the *Special Nevada Report* was not referenced in the Draft EIS. Instead, the Department reviewed current resource plans prepared by Federal agencies, EISs and environmental assessments, tribal meeting records, and other documents representing Federal, State, local, and private organizations to determine past, present, and reasonably foreseeable actions that, combined with the proposed repository, could contribute to cumulative impacts. For example, recent National Environmental Policy Act documents for the Nevada Test Site and the Nevada Test and Training Range (formerly known as the Nellis Air Force Range) describe past, present, and future activities for those areas. DOE considered those activities in the cumulative impacts analyses in Chapter 8 of the EIS.

10 (11101)
Comment - EIS002135 / 0007
But in my written statement which I will present, I will attempt to show why the DEIS fails to adequately address the cumulative impacts of the entire nuclear chain for mining nuclear weapons and nuclear waste production, which I believe that this DEIS should show; not just Yucca Mountain, but it should show the cumulative impacts of the entire nuclear chain.

Response
Chapter 8 of the EIS discusses the impacts of the repository along with past, present, and reasonably foreseeable future actions that could be spatially and temporally related to impacts of the repository. Activities and impacts that are outside the affected area, including the mining of uranium, are not within the scope of the EIS.

For information about the impacts of mining uranium, see the Nuclear Regulatory Commission's analyses in the *Generic Environmental Impact Statement for License Renewal of Nuclear Plants* (DIRS 101899-NRC 1996).

10 (11178)
Comment - EIS000466 / 0010
The draft EIS does not consider cumulative impact.

Response
Chapter 8 of the EIS is devoted entirely to cumulative impacts.

10 (11407)
Comment - EIS002251 / 0005
The EIS is national in scope, but I think we have a world-wide problem here. We all know that radiation is spread throughout the world from numerous events from the Nevada Test Site. And I think that the DOE needs to consider the whole world in its comments on this, because the whole world and all animal life and plant life are being affected now as we see higher and higher rates of cancer and the declining species in this world.

Response
The repository EIS does not report global adverse impacts because such impacts would be negligible. As stated by the National Academy of Sciences "..the most likely pathway for global distribution are gaseous releases of carbon dioxide containing the radioactive isotope of carbon-14, that eventually will escape from the waste containers, or by widespread distribution of foodstuffs grown with contaminated water." However, the Academy stated, "In general, the risks of radiation produced by such wide dispersion are likely to be several orders of magnitude below those to a critical group." For example, the Academy estimated that the average dose to members of the global population, based on the release of 91,000 curies of carbon-14, is 0.0003 millirem per year, and equated that to an annual risk of fatal cancer of 1.5 in 10 billion (DIRS 100018-National Research Council 1995). For comparison, the individual dose standard set by the Environmental Protection Agency in 40 CFR Part 197 of 15 millirem per year for the maximally exposed individual is 50,000 times that dose.

Because of large uncertainties, DOE considers estimates of global health effects to be highly speculative and, therefore, did not estimate global collective doses or health effects in the EIS. However, DOE agrees with the Environmental Protection Agency (64 *FR* 46976, August 27, 1999) and the National Council on Radiation Protection and Measurements (DIRS 101858-NCRP 1995, Report 121) that optimizing the protectiveness of design alternatives merits the estimation of population doses. The Department believes it can obtain information important to design optimization by estimating collective dose to the regional populations within 80 kilometers (50 miles) of the repository, thereby precluding the need to perform the more speculative global health risk calculations. For these reasons, the EIS evaluated in detail potential radiological exposures to the maximally exposed individual and regional populations (80 kilometers) from both groundwater and atmospheric pathways. Sections 5.4 and 5.5 of the EIS describe the results of these evaluations for waterborne and atmospheric releases, respectively.

10 (11490)
Comment - EIS002254 / 0003
What will it take to stop ongoing contamination?

Response
Assuming the commenter's reference to "ongoing contamination" means the Nevada Test Site, DOE is conducting widespread monitoring and remediation of selected sites that were contaminated by past activities on the Nevada Test Site. With regard to the repository, the NWPA requires DOE to study Yucca Mountain to determine its suitability for use as a repository, and to prepare an EIS that describes the impacts of such a repository. Modeling of the long-term performance of the repository shows that the combination of natural and engineered barriers at the site would keep releases below the limits established for the repository by the Environmental Protection Agency in 40 CFR Part 197.

10 (11505)
Comment - EIS002137 / 0006
Alternate routes. I'll give you an alternate route: To Carlin, the railroad system. Out of the -- out of the county called Clark right through the geographical center of the State of Nevada. Once the waste is hauled, what do we have? We have a railroad system for the economic development and issues of geographical center for the State of Nevada.

Response
In the Final EIS DOE identifies mostly rail as its preferred mode of transportation both nationally and in the State of Nevada. DOE has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was recommended and approved, DOE would issue, at some future date, a Record of Decision to select a mode of transportation. Thereafter, for example, if mostly rail was selected (both nationally and in Nevada), DOE would then identify a preference for one of the rail corridors in consultation with affected stakeholders,

particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in the State of Nevada. If rail was selected in Nevada, DOE has committed to preparing additional National Environmental Policy Act studies and documentation for the specific alignment of a rail route within the selected rail corridor.

10 (11522)
Comment - EIS002252 / 0008
The Draft Environmental Impact Statement fails to adequately address cumulative impacts for the entire nuclear chain for mining, nuclear weapons, and waste production.

Response
The cumulative impact assessment in Chapter 8 of the EIS includes past, present, and reasonably foreseeable actions in the affected area. Many studies have addressed, in quantifiable terms, the radiation levels in the environment from the nuclear fuel cycle. DOE believes that the baseline descriptions of the affected environment in Chapter 3 capture background levels of radiation that persist in the environment from nuclear facilities such as uranium mines, mills, fuel-processing plants, nuclear powerplants, and waste transport. According to the *Final EIS for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Components* (DIRS 103218-DOE 1996), the estimated dose to individuals from the nuclear fuel cycle is less than 1 millirem per year. That is, radioactive fallout from atmospheric weapons tests, emissions of radioactive material from DOE facilities, emissions from mineral extraction facilities, and transportation of radioactive materials combined contribute less than 1 millirem per year to the average dose to an individual.

10 (12092)
Comment - EIS002307 / 0006
Section 6 of the DEIS is incorrect about the transportation risks involved because the DEIS uses highway conditions that do not reflect actual highway conditions that would be present in transporting the spent nuclear fuel.

Response
The transportation analysis in Chapter 6 of the EIS used the best available information concerning the condition of highways being considered for waste transport. In addition, highway conditions, including accident and fatality rates, would be unlikely to change much between now and the time when waste shipments could begin.

10 (12123)
Comment - EIS001887 / 0422
Integration of policies within and among government agencies is necessary to prevent wasteful duplication. The NEPA [National Environmental Policy Act] process is meant to minimize conflicting goals by integrating related activities, legislation, and policies to avoid internal and interagency conflicts. Often, threats to the environment can be traced to unintended effects of conflicting federal efforts. Avoidance of this by integrating government activities is a direct purpose of NEPA for encouraging productive harmony between humans and their environment. Thus, the EIA [environmental impact assessment] process should reveal the need for integrated federal public works planning to minimize conflicting programs. However, much federal activity and related legislation is in response to particular considerations with little effort given to inadvertent consequences, environmental effects, socioeconomic impacts, or other consequences. In a pluralistic democratic society, each stakeholder group pushes its agenda with indifference to the values of other groups, and often federal agencies make no effort to avoid the shortcoming. Once again, in programs such as the YMP [Yucca Mountain Project], it is necessary that potential conflicts between future projects be addressed in a reasonably foreseeable manner. The Yucca Mountain region in particular is susceptible to such long-term impacts that have to be addressed in a context of ecosystem management. Such is among the intents of the existing Five-Party Cooperative Agreement for the region that DOE has refused to adopt for the YMP.

Response
The five-party Cooperative Agreement coordinates and enhances management of natural resources in the Great Basin and Mojave Desert ecosystems on the Nellis Air Force Range, Desert National Wildlife Range, and the Nevada Test Site. The five agencies are DOE's Nevada Operations Office (operator of the Nevada Test Site), the U.S. Air Force (operator of the Nellis Air Force Base), the Bureau of Land Management's Las Vegas Field Office,

the U.S. Fish and Wildlife Service, and the State of Nevada. If the repository was recommended and approved for development, DOE would consider including the Yucca Mountain Project in the Cooperative Agreement, and would reevaluate the need for a site-specific land-use plan to ensure compliance with all applicable requirements. That plan, based on the principles of ecosystem management and sustainable development, would formally synthesize the Yucca Mountain Project policies and procedures already in place; draw on the successes of the Resource Management Plan for the Nevada Test Site; and solicit input from Federal and State agencies, stakeholders, and the general public.

DOE agrees it is important to interact with other agencies to minimize conflicting programs or actions. Appendix C of the EIS describes agency interactions. One of the purposes of these interactions is to discuss issues of concern with organizations that have an interest in or authority over land that repository-related actions could affect or with some other interest the Yucca Mountain Project could affect. In addition, DOE has solicited and documented input from stakeholder groups through the EIS scoping process, comments on the Draft EIS, and other means. These interactions are described in the *Summary of Public Scoping Comments Related to the Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and High-Level Radioactive Waste at Yucca Mountain, Nevada* (DIRS 104630-YMP 1997) and in this Comment-Response Document.

Chapter 8 of the EIS estimates the potential cumulative impacts associated with various agency actions in the defined region of influence. The actions identified were based on documents issued by, and discussions with, DOE's Nevada Test Site, the U.S. Air Force, the Bureau of Land Management, the U.S. Fish and Wildlife Service, and the State of Nevada. The documents include resource management plans, EISs, environmental assessments, strategic plans, consultation documents, and tribal meeting records prepared by Federal, state, local, and private organizations.

10 (12247)
Comment - EIS001816 / 0027
Cumulative Impacts: In the year 2010 it is possible that on the roads in Lincoln and especially Nye County, there could be nuclear waste transportation by truck from three sources: 1) Yucca Mountain HLW/SNF [high-level radioactive waste/spent nuclear fuel]; 2) DOE NTS [Nevada Test Site] LLW [low-level radioactive waste] disposal; and 3) DOE NTS Plutonium soil cleanup. The DEIS must analyze for the estimated number of trucks that would move on Nevada roads each day under this possible scenario. The DEIS must analyze for how much emergency response training and other mitigation effort would be required to adequately manage this much potential nuclear waste transportation in Southern Nevada.

Response
DOE has expanded Section 8.4.2 of the Final EIS to include an assessment of the cumulative impacts in Nevada of transporting transuranic radioactive materials from high- and low-level radioactive sites to the Nevada Test Site. Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions the Department would transport spent nuclear fuel and high-level radioactive waste. The training shall cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified approximately 5 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) policy and procedures.

The Price-Anderson Act establishes a system of financial protection (compensation for personal injury and property damage, including loss of use of property) for the public in a nuclear accident, regardless of who causes the damage. See Section M.8 of the EIS for a discussion of the Price-Anderson Act.

10 (12248)
Comment - EIS001816 / 0010
Section 8.3 Cumulative Long Term Impacts (page 8-73): It has reported that Area 25 will eventually come under the administrative control and responsibility of the DOE-YM [Yucca Mountain] program. It has also been reported that the radioactive contamination in parts of Area 25 particularly to support the nuclear rocket program will come under the stewardship of the entity responsible for managing Area 25. If the NTS EM [Environmental Restoration

and Waste Management] program eventually completes its mission in the next decade and DOE-YM is the designated steward for Area 25, the DEIS must analyze the DOE-YM requirement to negotiate a FFACO [Federal Facility Agreement and Consent Order]-like agreement with the State of Nevada to become the legal steward and subsequent environmental manager for all Area 25 sites.

Response
DOE has not determined future responsibilities for the management of Area 25. There are no known sites in Area 25 where spent nuclear fuel has been buried. Parts from the old nuclear rocket program, and perhaps some fuel from this program, might be buried somewhere in Area 25, but nothing definite is known about the nature of the material or where it might be buried. This material was not accounted for in the cumulative impacts analysis because its existence, location, amount, and characteristics are not known.

10 (12271)
Comment - EIS001879 / 0023
p. 8-59 through 8-73, Section 8.3.1

The EIS should state that chromium groundwater concentrations would exceed the Maximum Contaminant Level at the 95th percentile for the Inventory Module 1 high thermal load scenario at 5 and 20 kilometers.

Response
DOE has revised Section 8.3.1 to include appropriate comparisons of chromium groundwater concentrations with Maximum Contaminant Level Goals. The estimated peak concentration of chromium in well water during the 10,000-year postclosure period from the Proposed Action or from Inventory Module 2 would be far below the Maximum Contaminant Level Goals listed in Table 8-52 of the Final EIS.

10 (12319)
Comment - EIS010242 / 0030
Page 3-22: Section 3.3 - Cumulative Impacts

Cumulative impacts should be re-evaluated based on responses to the comments provided above, [additional truck shipments, hazardous metals, etc.] as some will result in potentially significant changes in the assessment.

Response
Since the issuance of the Supplement to the Draft EIS, the Department has continued to evaluate actions in the region of influence that could pose a potential cumulative impact. As a result of these reviews, the Department identified several new actions for which information was not available for the Draft EIS. These actions come from several agencies and private companies. For instance, Chapter 8 of the Final EIS contains an expanded discussion of the Timbisha Shoshone Homeland Act, along with possible implications to groundwater rights. Chapter 8 also contains discussions of other actions by the Bureau of Land Management (such as the Ivanpah Cargo Airport and the Moapa Paiute Energy Center), and these actions were considered when evaluating the cumulative impacts for the technical discipline areas.

As part of the updated analyses, the Department has expanded the land-use discussion of Section 8.2.1 to specifically address the known actions that have been identified since the publication of the Draft EIS. Where possible, the Department has identified changes in land use along with estimates of acres to be disturbed and possible impacts with other actions in the area. In addition, all discipline areas (for example, biological resources and cultural resources) were reviewed to ensure that the appropriate level of discussion was included to address the potential cumulative impacts of all the actions. Not all actions could be evaluated to the same level of detail because information was not always available to allow an in-depth evaluation.

10 (12338)
Comment - EIS001879 / 0009
The Military Lands Withdrawal Act of 1986 required the preparation of the Special Nevada Report. This report, finalized in September 1991, contains a description of current and proposed defense-related activities in the State of Nevada, an analysis of their impacts, and possible actions that could be taken to mitigate those impacts. The report was prepared jointly by the Departments of the Air Force, Navy, and Interior with the Department of Army and

DOE listed as cooperating agencies. Per Section 6(b)(1)(D) of the Act, the Special Nevada Report was mandated to include the lands withdrawn or being considered for withdrawal for use by the DOE.

With respect to water resources, a number of impacts were found to result from the cumulative land withdrawals including the lack of access to potentially developable water resources, water quality impairment, resource consumption by federal agencies, and resource competition with non-federal water users. Page 8-97 of the Special Nevada Report states that:

“The withdrawal of land from public access and/or the purchase of water rights by DOD [the Department of Defense] and DOE has the greatest potential for effects on Nevada... The water resources associated with these lands could, if they exist and were available, play an important role in the continued growth of southern Nevada.”

The Special Nevada Report is not referenced in the Draft EIS for Yucca Mountain. Neither are the direct, indirect, or cumulative impacts of federal land withdrawals and water use considered and evaluated. These impacts are significant. The failure of the Draft EIS to incorporate the findings of the Special Nevada Report is a serious inadequacy in the document. These impacts continue to occur, have never been mitigated, and will be exacerbated by the additional land withdrawal and subsequent constraints on water availability. The EIS must be revised to include the findings of the Special Nevada Report and must include an evaluation of the cumulative consequences of the land withdrawal for the proposed repository at Yucca Mountain.

It is not acceptable for the DOE to assert that the Special Nevada Report has been superseded by recent NEPA [National Environmental Policy Act] documents prepared by the Departments of Energy, Defense, or the Interior as the Special Nevada Report is not a NEPA document but rather an independent evaluation of impacts. That recent NEPA documents prepared by these Departments did not take into account the findings of the Special Nevada Report represents the continued failure of federal agencies to perform adequate impact evaluations in the preparation of those documents, and is not a valid basis for the DOE to also ignore the findings of this important Congressionally mandated report.

Response
Chapter 8 of the Final EIS has been revised to include a discussion of the *Special Nevada Report* (DIRS 153277-SAIC 1991). It should be noted, however, that the *Special Nevada Report* is more than 10 years old, and many changes have occurred since the report was prepared. For instance, in December 1998 the Navy decided to reduce sharply its request to withdraw airspace over central Nevada, even though the impacts of a larger withdrawal were discussed in the *Special Nevada Report* (for information about the Navy’s current airspace requirements in Nevada. The Department is obligated to provide technical analyses based on the current state of knowledge. For that reason, the Department did not reference the *Special Nevada Report* in the Draft EIS. Instead, the Department reviewed current resource plans, EISs, environmental assessments, tribal meeting records, and other documents prepared by Federal, state, local, and private organizations as a means to determine past, present, and reasonably foreseeable actions that, combined with the repository, could contribute to cumulative impacts.

10 (12381)
Comment - EIS001888 / 0389
[Clark County summary of comments it has received from the public.]

Commenters suggested that the analyses address cumulative impacts considering both (1) critical habitats for threatened, endangered, and sensitive species, including impacts from radiation exposure during accident-free operations and from accidents, and (2) impacts to wildlife habitat and migration (wild horses, bald eagles), and big game populations along transport corridors/corridor improvements/borrow areas (Big Smoky Valley, Lincoln County, Clark County, Elko region) and the loss of hunter-generated revenue.

Response
Section 8.2.4 of the EIS describes short-term cumulative impacts to biological resources from the construction and operation of the proposed repository. DOE expects such impacts to be negligible during incident-free operations and from accidents. Section 5.9 addresses impacts to biological resources after repository closure. Because radiological impacts to humans would be small (within the regulatory limits established by 40 CFR Part 197), DOE did not quantify impacts to biological resources from exposure to contaminated groundwater.

Section 6.1.2.4 of the EIS summarizes impacts to biological resources from waste transport through Nevada, and Sections 6.3.1.1, 6.3.2, and 6.3.3 describe these impacts in more detail for legal-weight truck, rail, and heavy-haul truck and associated intermodal transfer stations, respectively. Loss of wildlife habitat from construction of a branch rail line would be the greatest potential impact to biological resources, potentially affecting the desert tortoise, a threatened species. Loss of desert tortoise habitat would amount to approximately 2.4 square kilometers (590 acres) for the Caliente-Chalk Mountain Corridor, 3 square kilometers (740 acres) for the Caliente and Carlin Corridors, 5 square kilometers (1,200 acres) for the Valley Modified Corridor, and more than 11 square kilometers (2,700 acres) for the Jean Corridor. All the corridors have a low abundance of desert tortoises with the exception of limited areas along the Jean Corridor where abundance is higher.

The potential for impacts from upgrading Nevada highways for heavy-haul truck use would be small because road modifications would occur in previously disturbed rights-of-way. The construction of an intermodal transfer station could disturb about 0.2 square kilometer (50 acres) of desert tortoise habitat. Other special-status species could be affected, depending on the route. Impacts from Nevada transportation operations, with the exception of infrequent wildlife kills by vehicles, would be unlikely. As with heavy-haul trucks, legal-weight truck shipments would have negligible impacts on biological resources because they would use existing highways.

Economic impacts from the loss of hunting revenues would be negligible from the construction and operation of a branch rail line or an intermodal transfer station. DOE bases this conclusion on the analyses in Chapter 6 of the EIS that show impacts to wildlife from any of the transportation implementing alternatives would be small.

In the Final EIS, DOE identifies mostly rail as its preferred mode of transportation both nationally and in the State of Nevada. DOE has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was recommended and approved, DOE would issue, at some future date, a Record of Decision to select a mode of transportation. Thereafter, for example, if mostly rail was selected (both nationally and in Nevada), DOE would then identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in the State of Nevada. If rail was selected in Nevada, DOE has committed to preparing additional National Environmental Policy Act studies and documentation for the specific alignment of a rail route within the selected rail corridor.

10 (12589)
Comment - EIS001816 / 0008
Section 8.3 Cumulative Long Term Impacts (page 8-76): The Federal Facility Agreement and Consent Order (FFACO) requires the DOE-NV [the DOE Nevada Operations Office] to determine the contaminant boundary for underground testing radioactive water at the NTS [Nevada Test Site] for a 1,000 year period. The contaminant boundary will be based on the 4 millirem/year standard for groundwater. Yucca Mountain must explain why it prefers the groundwater standard of the EPA [Environmental Protection Agency] over the NRC [Nuclear Regulatory Commission] to set this performance standard for the repository. If the NTS UGTA [Underground Test Area] program has to define groundwater contaminant boundaries at 4 millirem/year, and the State of Nevada has to define compliance boundaries at 4 millirem/year, Yucca Mountain should adhere to the same standard just in case existing plumes migrate closer to and beneath the repository footprint. Existing NTS radioactive contamination occurs in the same hydrologic units as those predicted to be contaminated by leakage from the repository over time, therefore, the DEIS must analyze for the 4 millirem/year standard and the reasons for regul [sentence cut off].

Response
The Nuclear Waste Policy Act, as amended, directed the Environmental Protection Agency and the Nuclear Regulatory Commission to develop standards for the performance of the proposed repository at Yucca Mountain and these agencies have done so. The Environmental Protection Agency's standards are at 40 CFR Part 197 and the Nuclear Regulatory Commission's standards are at 10 CFR Part 63.

The 10,000-year peak dose reported in the EIS at the 95th percentile for the Proposed Action would be 0.58 millirem per year at 18 kilometers (11 miles). The dose would decrease to 0.28 millirem per year at 30 kilometers (19 miles), which is the distance to most of the population that could be affected by groundwater transport (see Table 5-4).

Even with the addition of radiological contaminants from past weapons testing on the Nevada Test Site, and the possibility of additional wastes at the repository (Inventory Modules 1 and 2), the cumulative dose at 18 kilometers would be about 2.6 millirem per year. Even though not legally bound by the Federal Facility Agreement and Settlement Order standard, the performance of the repository would be compatible with that Order.

10 (12599)
Comment - EIS010279 / 0019
The description of *Cumulative Impacts (p. 3-22)* is completely inadequate. Stating that cumulative impact changes between the DEIS designs and the proposed designs in the SDEIS would be "proportional" or a "20-percent increase" does not explain anything. Cumulative impacts of the present designs of the proposed project need to be evaluated in plain language.

Response
DOE regrets the confusion. As described at the end of Section 3.3 of the Supplement to the Draft EIS, DOE expected the cumulative impacts associated with the flexible design to be essentially the same as the cumulative impacts described in Chapter 8 of the Draft EIS. DOE has continued to evaluate actions since the Supplement was issued and has updated Chapter 8 accordingly.

Comment - EIS001816 / 0006
Section 8.3 Cumulative Long Term Impacts (page 8-76): the statement regarding no radioactive contamination attributable to underground tests has been detected in monitoring wells off the Nevada Test Site [NTS]. There is a saying that goes, "Absence of evidence is not evidence of absence." There is no state of the art monitoring system on or off of the NTS, because the federal government hasn't constructed one based on where [contaminants] are know to migrate. It is highly likely that underground test contamination is past the NTS boundary because the phenomenon of prompt injection has probably blown the radionuclides past the NTS boundary the same way it probably blew Europium 0.8 miles at the Benham test site with some assistance from colloids. Yucca Mountain must analyze how to establish a joint effort with the UGTA [Underground Testing Area] program to establish a state of the art monitoring network in Nye County to monitor both existing and future radionuclide contamination in the groundwater system.

Response
The Yucca Mountain Project has a working relationship with the Nevada Test Site's Underground Test Area Program to produce a regional groundwater flow model of the Death Valley hydrologic system. DOE will continue to foster this relationship to plan for future groundwater studies and groundwater monitoring.

As a result of monitoring concerns expressed by many commenters, DOE has supported Nye County in its program (called the *Early Warning Drilling Program*) to characterize further the saturated zone along possible groundwater pathways from Yucca Mountain as well as the relationships among the volcanic, alluvial, and carbonate aquifers. Information from the ongoing site characterization program (and possible performance confirmation program, which is described below) would be used in conjunction with that of the Early Warning Drilling Program to refine the Department's understanding of the flow and transport mechanics of the saturated alluvium and valley-fill material south of the proposed repository site, and to update conceptual and numerical models used to estimate waste isolation performance of the repository. When DOE published the Draft EIS, only limited information from the Early Warning Drilling Program was available. Since then, however, this program has gathered additional information, which DOE has incorporated in the EIS.

In addition, DOE has installed a series of test wells along the groundwater flow path between the Yucca Mountain site and the Town of Amargosa Valley as part of an alluvial testing complex. The objective of this program is to better characterize the alluvial deposits beneath Fortymile Wash along the east side of Yucca Mountain. Single- and multiwell tracer tests have begun and the results thus far have strengthened the basis of the site-scale saturated flow and transport model. Information from this program has been incorporated in the EIS.

If the site was approved, DOE would institute a Testing and Performance Confirmation Program, elements of which would address the hydrologic system. The purpose of this program would be to evaluate the accuracy and adequacy of the information used to determine whether the repository would meet long-term performance objectives. The

Testing and Performance Confirmation Program, which would continue through closure of the repository (possibly as long as 300 years), would offer a means to further understanding of the hydrologic system and reduce uncertainties.

Comment - EIS010317 / 0006

Section 3.3 of the DEIS-S is titled "Cumulative Impacts." This section consist of just two short paragraphs. The FEIS should devote far more space to this section. For example, the new proposals for installing titanium shields over the waste package will require the mining of large quantities of titanium ore, frequently in other parts of the world. It would be appropriate to examine the cumulative environmental impact of extracting, processing and transporting such large amounts of titanium. Also, an evaluation should be made to assess the possible impact on other users of titanium such as the U.S. aerospace industry and the U.S. submarine construction industry. Since the proposals include the use of large quantities of other expensive metals, such as nickel and molybdenum and chromium, and environmental examination of the environmental impacts of their extraction, production and transport would be in order.

Response

The Supplement to the Draft EIS addressed the requirements for, and the availability of, titanium, and compared these requirements to U.S. production (see Section 3.1.15 of the Supplement). Section 4.1.15.5.4 of the Final EIS also addresses titanium requirements. The Department recognizes that a substantial amount of titanium would be required for the drip shields. The impacts of acquiring titanium were not examined in the Supplement or in the Final EIS because this material would not be required for almost 100 years.

The Draft EIS addressed the requirements for, and the availability of, nickel, molybdenum, and chromium, and compared these requirements to U.S. production. Section 4.1.15.5.4 of the Final EIS also addresses these requirements. As stated, the annual demand for nickel by the Yucca Mountain Project would be less than 1 percent of U.S. consumption and about 0.1 percent of world production. Because the Project's demand for these materials would not be expected to affect U.S. or world markets, the impacts of acquiring these materials were not examined in the EIS.

Comment - EIS010317 / 0007

Another cumulative impact that was not mentioned in the DEIS-S, and only hinted at in the DEIS, involves the nearly one thousand underground nuclear detonations conducted at the adjacent Nevada Test Site. These, explosively blasted spent-fuel like debris into the underground formations that lay "up-stream" from the Yucca Mountain Study site. The testers were exempt from the waste containment regulations that a Yucca Mountain repository must meet. In fact, about a third of the tests were conducted below, or just above, the water table, often leaving nuclear debris in regions with flowing water. In 1997 the DOE's Nevada Operations Office released a report, largely generated by its contractors, that estimated that a partial cleanup of the NTS underground test areas could cost as much as $7.3 trillion ("Focused Evaluation of Selected Remedial Alternatives for the Underground Test Area (DOE/NV--465, April 1997). The Cumulative Impacts section of the FEIS should mention that $7.3 trillion figure as a point of reference.

Response

Section 8.3.2.1 of the Draft EIS discussed the activities at the Nevada Test Site and acknowledged the potential for large amounts of radioactivity as a potential long-term impact. In the Final EIS the department has updated the information based on more recent analyses of the potential long-term impacts from these activities.

With regard to remediation estimates for the underground test areas, the 1997 report cited by the commenter does list a cost that could be as high as $7.3 trillion. However, it is important to realize that this report was prepared for the purpose of evaluating technologies that could be used to aid in remediation, not as a planning document for cleanup of the Nevada Test Site.

In 1998, the Department published *Accelerating Cleanup: Paths to Closure* (DIRS 107294-DOE 1998) and has continued to update that report with supplemental information to present the status of cleanup efforts in the DOE complex. The report estimated a total cost of less than $3 billion for all projects at the Nevada Test Site. In addition to cleanup and remediation activities, this estimate includes subsurface monitoring and surveillance of the sites for up to 100 years (DIRS 107294-DOE 1998).

The Department is continuing environmental restoration at the Nevada Test Site and is studying and monitoring groundwater contamination of the underground test areas. No long-term plans for remediating the underground test areas have been developed, and the wide range of costs, technical issues, and health and safety considerations in the report cited by the commenter make it premature to project an impact on the region from these activities.

10 (13452)
Comment - EIS010296 / 0038
On page 3-7, it is noted that the range of water demand for lower-temperature operations, combined with ongoing NTS [Nevada Test Site] water demand would be slightly below the lowest estimate of sustained yield for the hydrographic area (western two thirds of the Jackass Flats Groundwater basin, see p. 4-29 of the Draft EIS), but the addition of an aging facility could lead to water use of 100 percent of the lowest estimated perennial yield. It would be as low as 16 percent of the maximum estimated perennial yield. Buqo (1999) notes on p. 14 that "Localized water-level declines and changes in flow directions in the vicinity of DOE water supply wells has occurred and will continue to occur in proportion to the level of water needed to support the Test Site Operations. Overdraft has historically occurred on the NTS in the Yucca Flat hydrographic basin because of its perennial yield (700 acre feet per year). Future DOE water withdrawals on the NTS are not expected to exceed the perennial yields of any of the source basins." The estimates of perennial yield are exactly that - estimates. The estimated use might greatly exceed actual perennial yield.

Response
The Department used estimates of perennial yield that were prepared by the Nevada State Engineer. The Department recognizes that these are estimates, but they represent the best estimates available.

10 (13527)
Comment - EIS010392 / 0010
In light, of the effects on transportation, the cumulative impacts analysis should be re-evaluated. As it is now, the cumulative impacts analysis is not sufficient.

Response
The design evaluated in the Supplement to the Draft EIS (the flexible design) does not substantially affect the results of the cumulative-impacts evaluation described in Chapter 8 of the Draft EIS. The basic elements of the Proposed Action described in the Draft EIS are identical to the Proposed Action described in the Supplement; that is, to construct, operate and monitor, and eventually close, a geologic repository at Yucca Mountain. Because the design enhancements described in the Supplement had little effect on other elements of the repository program, the scope of the Supplement was limited to a discussion of the new design and its associated impacts. The transport of spent nuclear fuel and high-level radioactive waste to the repository would not be affected by the repository design described in the Supplement or how this design might evolve further. The amount of waste that could be transported to the repository is fixed. Therefore, the impacts of waste transport to the repository, including cumulative impacts, were not evaluated in the Supplement. In Chapter 6 of the Final EIS, DOE has modified and updated several analyses related to the transport of spent nuclear fuel and high-level radioactive waste to Yucca Mountain in response to public comments. Many of these changes are based on updated population data, and projections of future populations, near possible transport routes.

Impact Mitigation and Compensation

11. IMPACTS MITIGATION AND COMPENSATION

11.1 Impacts Mitigation

11.1 (6)
Comment - 11 comments summarized
Constructing, operating and monitoring, and closing the proposed repository would require the use of water. DOE proposes to take this water from an aquifer that underlies both the repository site and the Amargosa Valley, which underlies a portion of Nye County, Nevada, and might also provide water in eastern portions of Inyo County, California. The placement of waste in the repository would position a large radionuclide burden upgradient from the Amargosa Valley, although the repository design would contain radionuclides for thousands of years, with substantial isotopic decay during containment.

Commenters stated that DOE should provide Nye County users a safe and adequate water supply to replace water the repository would take for activities during construction, operations and monitoring, and closure. Commenters also stated that DOE should guarantee Nye County users a safe and adequate supply to replace water that radionuclides from the repository could contaminate. Commenters stated further that DOE should provide long-term monitoring after repository closure to detect any radionuclides reaching the Amargosa Valley aquifer to provide warning to Nye County and Inyo County users. Some commenters compared the requested provision of water to the provision of water to residents living near failed hazardous waste sites.

Response
The EIS evaluates the potential for repository activities to affect both water availability and water quality. The updated analysis in this Final EIS projected that the Proposed Action would result in extremely small releases of radioactive contamination to the environment in the first 10,000 years after repository closure (more than 10,000 times less than the individual protection standard set by 40 CFR Part 197.)

In addition to the 10,000-year compliance period, DOE evaluated potential impacts for the period of geologic stability at the repository (that is, 1 million years). DOE performed this evaluation, in accordance with 40 CFR Part 197, to gain insight into the very-long-term performance of the repository and thus provide information for making both design and licensing decisions. These results show a mean peak dose rate that would be much lower than background levels. As a consequence, DOE does not anticipate impacts to water supplies that would require mitigation.

However, Section 116(c) of the Nuclear Waste Policy Act, as amended (the EIS calls the amended act the NWPA), establishes a procedure outside the EIS process by which affected units of local government, such as Nye County, could request assistance to mitigate impacts on affected units of local government if the repository was developed. Section 116(c) commits DOE to participate in this process and to provide assistance consistent with direction from Congress.

11.1 (45)
Comment - 6 comments summarized
Commenters stated that DOE should propose to continue state and local government oversight functions through the performance confirmation period as a mitigation measure.

Response
The Testing and Performance Confirmation Program is designed to meet specific Nuclear Regulatory Commission requirements (defined at 10 CFR 63.102(M) and 10 CFR Part 63 Subpart F). The program allows for continued oversight through tests, experiments, and analyses to evaluate the accuracy and adequacy used to determine with reasonable expectation that the repository would meet postclosure performance requirements. This could be a lengthy program of monitoring and testing that could last as long as 300 years after the end of waste emplacement. It would provide data to future decisionmakers who would make the choices on closing the repository or retrieving the wastes. DOE is not able to determine what its commitment to oversight funding would be at this time because of dependence on Congressional funding and other factors.

11.1 (48)

<u>Comment</u> - 4 comments summarized

Commenters stated that the Draft EIS does not include any real mitigation measures and that repository design features should not be part of mitigation. Commenters asked for long-term groundwater monitoring plans and contingency plans as mitigation measures. Commenters asked DOE to propose mitigation measures for transportation-related impacts.

<u>Response</u>

Under the Council on Environmental Quality regulations implementing the National Environmental Policy Act (40 CFR 1508.20) mitigation includes those activities that:

- Avoid the impact altogether by not taking a certain action or parts of an action
- Minimize impacts by limiting the degree or magnitude of the action and its implementation
- Repair, rehabilitate, or restore the affected environment
- Reduce or eliminate the impact over time by preservation or maintenance operations during the life of the action
- Compensate for the impact by replacing or providing substitute resources or environments

In its Forty Most Asked Questions, the Council on Environmental Quality states that mitigation "measures must include such things as design alternatives that would decrease pollution emissions, construction impacts . . ." (46 *FR* 18026, March 21, 1981). Alternative design measures to reduce impacts are properly included as mitigation measures. Chapter 9 of the EIS describes management actions that DOE could use to reduce or mitigate adverse impacts to the environment that could occur if the Department implemented the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste.

As described in this Final EIS, DOE has established a cooperative agreement with Nye County to install a series of groundwater monitoring wells in the Amargosa Desert and the southern portion of the Nevada Test Site. The purpose of this program, called the Early Warning Drilling Program, is to characterize and monitor the saturated zone along potential transport pathways from Yucca Mountain. In addition to the flow and transport characterization data DOE will gain, the program will provide Nye County with its own independent monitoring and testing capability. In addition, DOE would design and implement a postclosure monitoring program in compliance with Nuclear Regulatory Commission regulations (10 CFR Part 63). Before closure, DOE would submit a license amendment application to the Commission, which would describe DOE's proposal for continued oversight to prevent any activity that would pose an unreasonable risk of breaching the repository's engineered barriers. DOE has modified the EIS to include the types of monitoring and other institutional controls it would contemplate.

Section 9.3 of the EIS discusses some mitigation measures DOE has identified that could reduce potential impacts from the national transportation of spent nuclear fuel and high-level radioactive waste. These measures address the possible impacts from the construction of a branch rail line or an intermodal transfer station in Nevada; construction of other transportation routes; upgrading of existing Nevada highways to accommodate heavy-haul vehicles; transportation of spent nuclear fuel and high-level radioactive waste from existing storage sites to the proposed repository; and fabrication of casks and canisters.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states and affected units of local government through which it plans to transport spent nuclear fuel or high-level radioactive waste.

Section 116(c) of the NWPA provides that an affected unit of local government or the State of Nevada can request financial and technical assistance from DOE and that such assistance can be designed to mitigate the impacts on affected units of local government from the development of the proposed repository and the characterization of the Yucca Mountain site. DOE would base any decision to provide assistance under Section 116 on an evaluation of a report submitted by an affected unit of local government or the State of Nevada to document likely economic, social, public health or safety, and environmental impacts.

11.1 (76)
Comment - 5 comments summarized
Commenters said that the United States needs to mitigate, through equity offsets and compensation, the cumulative impacts from the repository and from other Federal activities that have adversely affected Nye County's ability to plan and grow. Among the agencies mentioned were the Department of Defense (Air Force and Navy), Department of the Interior (Bureau of Land Management, National Park Service, and Fish and Wildlife Service), the Department of Agriculture (Forest Service), as well as continuing activities at the Nevada Test Site by DOE. Commenters contend that Nye County has been disproportionately affected by these activities.

Response
Impacts of past, present, and reasonably foreseeable future actions and their relationship to the Proposed Action and Inventory Modules are discussed throughout Chapter 8 of the EIS. While preparing this chapter, analysts reviewed numerous documents to determine where there was potential for cumulative impacts. Only those activities with a potential for cumulative impacts on environmental resources (including such things as land use and water) potentially affected by the repository were included in the discussion [for example, the Nevada Test Site, waste disposal sites, Nellis Air Force Range (now called the Nevada Test and Training Range), DOE waste management activities]. DOE reviewed resource plans, environmental impact statements, environmental assessments, strategic plans, consultation documents, Native American tribal meeting records, and other documents representing Federal, local, and private agencies and plans for public development and documented the potential for activities described in those documents or plans to present cumulative impacts.

DOE has examined the potential for the proposal to cause socioeconomic impacts in Nye County, including the potential for cumulative impacts. Based on its method of analysis, the Department believes that it has accounted for those reasonably foreseeable actions that could affect Nye County.

After DOE issued the Draft EIS, it again reviewed impacts from the proposed project and potential cumulative activities in the region of influence and has updated information where appropriate. This Final EIS includes a more detailed discussion of cumulative impacts including projected water use for the proposed Yucca Mountain Repository and water availability and water rights issues in Nye and surrounding counties.

Section 116(c) of the NWPA establishes a procedure outside the EIS process by which affected units of local government, such as Nye County, can report effects from the proposed repository to DOE and receive impact assistance upon agreement with DOE on matters raised in the report. Section 116(c) commits DOE to participate in this process and to provide assistance consistent with direction from Congress.

11.1 (97)
Comment - 3 comments summarized
Commenters stated that DOE should document all mitigation commitments in a Record of Decision and should not issue a separate or standalone Mitigation Action Plan. They quoted the Council on Environmental Quality National Environmental Policy Act implementing regulations (40 CFR 1505.2) as saying the Record of Decision must include the following: a statement explaining the decision; an explanation of alternatives DOE considered and those that were environmentally preferable; factors DOE considered in making its decision; an explanation of mitigation measures, if any, that DOE adopted or, if there were no mitigation measures, an explanation; and a monitoring and enforcement program for any adopted mitigation measures. Commenters further stated that a Mitigation Action Plan would not fulfill the requirements of and would be outside the legal framework of the National Environmental Policy Act governing minimization of the effects of major Federal actions. Commenters placed great significance on the institutional and legal stature of the Record of Decision and contended that commitments to mitigation not contained in a Record of Decision would not be commitments at all.

Response
Section 114(a)(1) of the NWPA authorizes the Secretary of Energy to decide whether to recommend approval of the Yucca Mountain site to the President for development as a repository for the disposal of spent nuclear fuel and high-level radioactive waste. A comprehensive statement of the basis for the recommendation, including a Final EIS, must accompany such a recommendation. However, the decision to approve the site rests not with the Secretary, but with the President. Because the President would make this decision, DOE does not anticipate issuing a Record of Decision if the Secretary recommends the site to the President.

DOE regulations (10 CFR 1021.331) require preparation of a Mitigation Action Plan when mitigation measures are identified in a Record of Decision. At this time DOE has not decided whether or not it would prepare a Mitigation Action Plan. However, the Yucca Mountain site, if approved in accordance with the NWPA, would be subject to licensing by the Nuclear Regulatory Commission. DOE, in submitting an application to construct and operate a repository would identify relevant mitigation measures to the Commission for its consideration, and could reasonably expect a comprehensive set of mitigation measures or conditions of approval to be part of the licensing process.

DOE anticipates that the repository design would continue to evolve, creating additional opportunities for mitigation and potentially eliminating the need for some mitigation measures currently under consideration. Chapter 9 of the EIS, which provides DOE's initial list of possible mitigation measures available at this time, identifies DOE-determined impact reduction features, procedures, and safeguards; and mitigation measures under consideration for inclusion in the project plan and design. Section 9.1.3 identifies ongoing studies that could eventually influence mitigation measures related to the repository.

11.1 (102)
Comment - 12 comments summarized
Commenters said that the Final EIS should identify which mitigation measures DOE is committed to and which it is considering. Specifically, commenters asked for guarantees on what mitigation DOE would perform, asserting that the Federal Government has a history of claiming sovereign immunity and of not compensating victims of radiation "damage" from Federal activities. One commenter said the Draft EIS did not establish a basis for mitigation negotiations because it did not assign specific roles and responsibilities for actions that cause impacts or ameliorate impacts. Several commenters stated that the EIS must, but the Draft EIS did not, identify and evaluate all feasible alternatives and specific measures for mitigating all potential impacts of the repository system and potential accidents that are identified in the EIS, whether or not they would be "significant." Similarly, a commenter stated that DOE needs to identify the specific measures required to minimize the impacts associated with the flexible design. A commenter said that mitigation measures should not be eliminated from consideration in the EIS because they are outside the jurisdiction of DOE or because they are not likely to be accepted or enforced. One commenter said a Record of Decision and a Mitigation Action Plan should include a comprehensive identification and evaluation of measures to mitigate each repository system impact. Some commenters stated that monitoring, avoidance, minimization, rectification, and reduction or elimination must be considered, as well as consultation with other appropriate agencies, as opposed to promises to consult, conduct further studies, only monitor, and request outside reviews. Further, commenters said the EIS must demonstrate that the mitigation measures would be sufficient to offset or otherwise minimize negative effects on the States of California and Nevada, local communities, and other states and communities along transportation routes. One commenter said that the EIS should present the full costs of remediation for a transportation accident and that DOE should establish an escrow fund to pay for such remediation and for compensation of affected parties.

Response
Chapter 9 of the EIS discusses mitigation measures DOE could implement or has identified for consideration. However, DOE has not yet made commitments to any specific mitigation measures. Section 116(c) of the NWPA provides for financial and technical assistance to mitigate likely economic, social, public health and safety, and environmental impacts. Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance to the environmental impacts considered in this EIS. Any decision to provide assistance under Section 116 would be based on an evaluation of any reports submitted by an affected unit of local government or the State of Nevada that documented the potential impacts for which mitigation assistance might be required.

DOE regulations (10 CFR 1021.331) require preparation of a Mitigation Action Plan when mitigation commitments are defined in a Record of Decision. At this time DOE has not decided whether or not to prepare a Mitigation Action Plan. However, the Yucca Mountain site, if approved in accordance with provisions of the NWPA, would be subject to licensing by the Nuclear Regulatory Commission. DOE, in submitting an application to construct and operate a repository would identify relevant mitigation measures to the Commission for its consideration, and could reasonably expect a comprehensive set of mitigation measures or conditions of approval to be part of the licensing process.

In its Forty Most Asked Questions, the Council on Environmental Quality states that mitigation measures must include such things as design alternatives that would decrease pollution emission and construction impacts (46 *FR* 18026, March 21, 1981). The evolved repository design described in the Supplement to the Draft EIS and this Final EIS would reduce impacts of, and the uncertainties involved with, long-term repository performance.

Regarding compensation and remediation in the event of an accident, the Price-Anderson Act establishes a system of financial protection (compensation for damages, loss, or injury suffered) for the public in a nuclear accident. The Act provides liability coverage for commercial activities operating under a license from the Nuclear Regulatory Commission and DOE activities by establishing a system of private insurance and Federal indemnification that generally ensures that up to $9.43 billion is available to compensate for damages suffered. Payment would be from Federal funds, or, if public liability arose out of nuclear waste activities funded by the Nuclear Waste Fund, from that Fund. As of November 2001, Congress was working on legislation associated with Price-Anderson Act Reauthorization.

Responsibility for cleanup of released materials would be shared between DOE, the owners of the materials, and carriers under regulation of the Motor Carrier Act of 1980. Section J.1.4.2.5 of the EIS provides information on the cost of cleanup and ecological restoration following a transportation accident.

Comment - EIS000049 / 0004
In the past the government has done business with Nye County and when dollars were paid to the county and the community closest to the project is Amargosa and our community will be increased with population and the schools and housing and other services should be taken into account as to what we could do and how we could fund these problems without increasing our taxes. We have the second largest county in the nation and the population isn't very many. We are the second largest township in the country and the lowest population so you can bet we have high taxes now and when this project takes place the only logical thing would be to give a real look at the help you could give to make the transition as easy as possible.

Response
DOE has expanded its socioeconomic discussions in Chapter 3 to clarify the magnitude of potential impacts described in Chapters 4 and 6. This discussion includes a projection of baseline parameters through 2035 based on the most recently available information and assumptions. In the Final EIS, DOE provides a quantified estimate of school enrollment and changes in law enforcement and public service personnel requirements.

As indicated in Chapter 9 of the EIS, Section 116(c)(2)(A)(i) and (ii) of the NWPA state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

Under the NWPA, the Section 116 impact assistance review process and this EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would not necessarily be limited either by the impacts identified in this EIS or by its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by affected units of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts. DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

11.1 (514)
Comment - EIS000154 / 0002
No mitigation. No mention of the fact that the town water system for Goldfield is pumped thirteen miles out in the flats right alongside the highway into town.

Response
Transportation analyses in Chapter 6 of the EIS indicate that shipments of spent nuclear fuel and high-level radioactive waste would not pose any harm to facilities such as Goldfield's water system.

Section 116(c) of the NWPA establishes a procedure, unrelated to the EIS process, by which affected units of local government, such as Nye County, can report effects from the proposed repository to DOE and receive impact assistance upon agreement with DOE on matters raised in the report. Section 116(c) commits DOE to participate in this procedure and to provide assistance consistent with direction from Congress.

11.1 (653)
Comment - EIS000157 / 0001
I would like to recommend that as part of the impact mitigation discussion in the final EIS, the DOE cooperate with the Nevada Division of Health, the Nevada Nuclear Waste Project Office, the Nevada Department of Environmental Protection, and Nye County as host to the proposed repository and other potentially affected counties and communities to facilitate a baseline radiological health assessment to be used in the future to accurately analyze potential health impacts of the proposed Yucca Mountain project.

Response
DOE has extensively evaluated the potential for public exposure to radionuclides in the Yucca Mountain region. Studies are continuing. Sections 3.1.8 and 8.2.7 of the EIS describe the DOE's work in this area. The affected environment and the potential cumulative health impacts associated with the repository (Section 9.2) discusses potential health-related mitigation measures.

The EIS analysis of public health does not show a potential for significant impacts to the population in the region of the proposed site. On this basis, DOE has concluded that a new baseline radiological health assessment is not warranted as an addition to the EIS evaluation of the Yucca Mountain proposal or for later comparative analyses.

11.1 (655)
Comment - EIS000192 / 0002
The Draft EIS identifies a number of impacts resulting from transportation of the nuclear material. However, there is no mention of mitigation measures that will be taken to minimize these impacts. The mitigation measures have to be addressed per NEPA requirements.

Response
Section 9.3.6 of the EIS mentions five mitigation measures under consideration to reduce health and safety impacts from transportation of radioactive materials, including measures to reduce exposure to radionuclides and measures to reduce accidents. Other parts of Section 9.3 describe measures to mitigate transportation impacts that DOE has adopted or is considering.

11.1 (764)
Comment - EIS000140 / 0004
In the EIS, there is nearly a complete lack of attention given to identification and evaluation of measures designed to mitigate impacts of spent fuel management within Nevada.

Response
Chapter 9 of the EIS describes many actions that are under consideration to mitigate potential impacts associated with a repository at Yucca Mountain.

11.1 (1188)
Comment - EIS000114 / 0009
What about the lack of payments equal to taxes for our county? You have an Environmental Impact Statement. What about the socioeconomic impacts and what are you going to do for us here in Pahrump and for Nye County? You've done crap.

Response

Payments-Equal-To-Taxes (PETT) are made pursuant to Section 116(c)(3)(A) of the NWPA which requires the Secretary of Energy to "…grant to the State of Nevada and any affected unit of government, an amount each fiscal year equal to the amount such State or affected unit of government, respectively, would receive if authorized to tax site characterization activities…." These payments, historically and for the future, are determined by estimating the amount of Yucca Mountain Project property, purchases (in and out of the State of Nevada), and business activities (employees) within the jurisdiction of an affected unit of local government. Nye County and the State of Nevada have been eligible to receive PETT since commencement of site characterization activities in May 1986. The other affected units of government include Clark, Lincoln, Esmeralda, Eureka, White Pine, Churchill, Lander, and Mineral Counties in Nevada, and Inyo County, California. Potentially, they have been eligible to receive PETT since the passage of the Nuclear Waste Policy Amendments Act of 1987.

For PETT relating to property taxes in Nye County, DOE and the County entered into a settlement agreement in July1994 (amended in May 1999) whereby DOE would make specified payments on a fixed disbursement schedule. The current agreement runs through 2003.

As noted above, DOE acquires data from the Yucca Mountain Project organizations that purchase or acquire property for use in Nevada, have employees in Nevada, or use property in Nevada. These organizations include Federal agencies, national laboratories, and private firms. Not all of these organizations have Federal exemption status, so they pay the appropriate taxes. The purchases (sales and use tax), employees (business tax), and property (property or possessory use tax) of the Yucca Mountain Project organizations that exercise a Federal exemption are subject to the PETT (DIRS 103412-NLCB 1996).

The actual sales and use taxes, property taxes, and Nevada business taxes paid by Yucca Mountain Project organizations from May 1986 through September 2000 have been calculated. These organizations paid sales and use taxes of $2.5 million for purchases made in Clark County, paid property or possessory taxes of about $90,000 in Clark County, and paid the State of Nevada about $810,000 in business taxes (DIRS 156763-YMP 2001). The PETT for sales or use taxes from May 1986 through June 2000 was about $4.4 million for purchases in Clark County. For property taxes, it was about $940,000 in Clark County. About $130,000 was paid to the State of Nevada in business taxes.

DOE has not estimated and does not intend to make long-term PETT estimates. While the NWPA requires PETT payments, such payments are not discriminating factors in the EIS decisionmaking process.

In the Final EIS, DOE has expanded the socioeconomic discussions in Chapter 3 to clarify the magnitude of the potential impacts described in Chapters 4 and 6. This discussion includes a projection of baseline parameters through 2035 based on the most recently available information and assumptions. The Final EIS provides a quantified estimate, to the extent possible, of school enrollment and changes in law enforcement and public service personnel requirements. Other socioeconomic impact discussions are included in Sections 6.1.2.7 (related to transportation of spent nuclear fuel and high-level radioactive waste), and 8.2.6 (related to cumulative impacts).

The Final EIS incorporates Nevada population data developed by and received from county and State officials. In response to comments, DOE has updated its population estimates in the regions of influence to reflect the most recent state and local information, as well as Bureau of the Census 2000 population summary data for Nevada. For the repository- and transportation-related regions of influence, DOE performed REMI computer model simulations to establish an updated population baseline by accounting for population estimates and projections provided by county governments. In the absence of county information, population estimates and projections from the Nevada State Demographer's Office were used. The updated population baselines were then used to estimate populations for Clark, Nye, and Lincoln Counties and the Rest of Nevada through 2035. These population projections were then compared and adjusted to the 2000 Census population summary data. In this way, model population projections were calibrated to reflect the best available information.

The Final EIS baseline used REMI model projections of population totals for each Nevada county in the region of influence and the Rest of Nevada through 2035. The Clark County projections correspond to those used by the University of Nevada, Las Vegas (DIRS 136698-Riddel and Schwer 1999), which also used the REMI EDFS 53-sector model. DOE based inputs to Nye County projections for the Final EIS on data identified in Nye County documents (DIRS 150996-Williams 2000; DIRS 148140-PIC 1998). The Nye County projections provided during the comment period are based in part on a REMI 14-sector model. DOE used (1) Lincoln County and Rest of Nevada projections through 2018 by the Nevada State Demographer's Office (DIRS 155350-State of Nevada 1999) as inputs to population projections for these areas; (2) county projections and Nye County source documents to project population distributions within the 80-kilometer (50-mile) radiological monitoring grid; and (3) California Department of Finance projections (DIRS 150294-California State Department of Finance 1998) for Inyo County as the basis for projecting population distributions for Inyo County sections of the grid (see Section 3.4 of the EIS).

11.1 (1201)
Comment - EIS000379 / 0001
As far as the nuclear accident involving trucking transport, it's been stated that there are potentially an estimated 40,000 trucking accidents a year in the US. If that's true, it means that the potential of an accident is quite high, and that brings me back to this thought about mitigation and how do you mitigate this sort of an accident with these kinds of materials? Because we know that ionizing radiation has effects. Some of the things that it causes are leukemia, birth defects, mental retardation, and physical deformations, cancers. So, essentially, there's really no mitigation.

It was stated here tonight that there is a cleanup fund, and there's legislation that ensures that if there's an accident, there's plenty of money to clean it up. But the problem that I see with this is that it's not really a matter of money. How do you mitigate cancer or how do you mitigate deformed babies? These sorts of things are just not easily remedied.

Response
In Chapter 6 of the EIS, DOE has analyzed potential impacts from transportation accidents. Given the number of shipments to the proposed repository, traffic accidents would be probable. However, DOE believes that such accidents would be unlikely to release radioactive material, primarily because of the structural integrity of the transportation casks. In the more than 2,700 shipments of spent nuclear fuel in the U.S. over the past three decades, there have been seven accidents, with no releases of radioactive materials to the environment. The risk assessment results discussed in the EIS demonstrate that radiological risks to persons on and near transportation corridors would be very small. The small risks, and the fact that these shipments would be a small fraction of all cargo shipped, means that moving spent nuclear fuel and high-level radioactive waste should not be the cause of major disruptions of the use of transportation corridors.

The Price-Anderson Act establishes a system of financial protection (compensation for damages, loss, or injury suffered) for the public in a nuclear accident, regardless of who causes the damage. Section M.8 of the EIS discusses this Act. Under the Motor Carrier Act of 1980 DOE, the owners of the materials, and carriers would share responsibility for cleanup of released materials. Under provisions of the DOE Draft Policy for implementing Section 180(c) of the NWPA, the Department would provide training for emergency response personnel. Section M.6 discusses these provisions.

11.1 (1473)
Comment - EIS010340 / 0002
I also recommend that all cultural resources on the Yucca Mountain Project be left in place. If any are removed, that this group be notified as soon as possible.

Response
DOE would include avoidance of significant archaeological sites as a mitigative option. Due to cultural value and cost, preservation of archaeological sites in place is the preferred option. If avoidance was not possible, a data recovery effort would be necessary to preserve the archaeological data. DOE is committed to using Native American monitors on field crews when significant data recovery (collection of resources) at a site is necessary. Archaeological contractors are on-call to monitor known sites for potential impacts from project activities. In addition, Native Americans can come to the site to monitor locations during Native American Interaction Program field trips, or during special trips, as necessary. Section 9.2.5 of the EIS contains additional information regarding proposed mitigative measures.

11.1 (1809)
<u>Comment</u> - EIS000332 / 0008
Nye County has repeatedly attempted to utilize the administrative process to inform DOE and other federal agencies of the impacts that have occurred, continue to occur, and will likely be exacerbated by the implementation of yet another federal action in Nye County. Federal agencies have repeatedly failed to fulfill their obligations through the NEPA [National Environment Policy Act] administrative process, and have failed to provide mitigations that are required. Nye County will continue to identify environmental issues, the potential impacts, and appropriate mitigation measures, and will ensure that the County's position is made part of the DOE's Administrative Record for the NEPA process.

<u>Response</u>
DOE acknowledges Nye County's active role in monitoring Yucca Mountain Repository-related activities. The Department has received and reviewed studies issued by the County and utilized this information in the Final EIS to the fullest extent possible. For example, the Final EIS socioeconomic baseline projections for the County incorporate projections provided by Nye County in its quarterly population updates. DOE has included the Nye County input in its project record and is cognizant of the issues Nye County has identified. DOE will work with Nye County and other potentially affected units of government to determine reasonable management actions required to mitigate potential adverse environmental impacts pursuant to 10 CFR 1508.20 and Section 116(c) of the NWPA.

11.1 (1819)
<u>Comment</u> - EIS000771 / 0003
What guarantees will be in place by the DOE?

1. Transportation
2. Security -- Transportation and Containers
3. Evacuation Plans
4. Medical Plans -- Residents
5. Payments to Nevada for storage
6. Warning system -- Disaster
7. Insurance -- Residents

<u>Response</u>
DOE intends to implement the requirements of Sections 180(c) and 116(c) of the NWPA. Section 180(c) requires the Secretary of Energy to provide technical assistance and funds to states for training public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions spent nuclear fuel and high-level radioactive waste would pass. The training is required to cover procedures for safe routine transportation and for dealing with emergency response situations.

In addition, Section 116(c)(2) of the NWPA requires the Secretary of Energy to provide financial assistance to the State of Nevada and any affected unit of local government requesting such assistance to mitigate the impacts of the development of a repository and site characterization. The State and any affected unit of local government can request such assistance by submitting a report on probable economic, social, public health and safety, and environmental impacts.

With regard to the topics of concern listed in the comment, transportation and transportation security would be in full compliance with applicable U.S. Department of Transportation and Nuclear Regulatory Commission regulations. DOE would develop emergency response plans, including evacuation plans and warning systems, as part of the activities required by Section 180(c) of the NWPA. The State, affected units of local government, and Native American tribes can request financial and technical assistance to implement these plans under Section 180(c).

The Price-Anderson Act provides liability coverage for commercial activities operating under a license from the Nuclear Regulatory Commission and for DOE activities. The Price-Anderson Act establishes a system of private insurance and Federal indemnification that generally ensures that as much as $9.43 billion is available to compensate for damages suffered by the public from a "nuclear incident," regardless of who causes the damage. Payment would be from Federal funds or, if public liability arose from activities funded by the Nuclear Waste Fund (for example, activities at a geologic repository), from that Fund. The liability of all responsible parties is limited to the amount of coverage provided by the Price-Anderson Act system. State and local governments cannot be required to provide additional compensation. DOE has revised the EIS to include more details about indemnification under the Price-Anderson Act (see Section M.8.1).

Price-Anderson indemnification would apply to transporters of nuclear waste from commercial nuclear utilities and from DOE sites to the repository. In addition to Price-Anderson indemnification, the Motor Carrier Act of 1980 and implementing regulations (49 CFR Part 387) require all motor vehicles carrying spent nuclear fuel or high level radioactive waste to maintain financial responsibility of at least $5 million, which would be available to cover public liability from a non-nuclear incident and for environmental restoration. Federal law does not require rail, barge, or air carriers of radioactive materials to maintain liability coverage, although these carriers often carry such insurance voluntarily. Regardless of whether they had insurance, a radioactive materials incident involving these carriers would be subject to state law applicable to any other type of accident.

Congress would have to approve additional payments to Nevada and affected units of local government, other than Payments-Equal-To-Taxes that they would have received if the activity was a non-Federal activity.

11.1 (1822)
Comment - EIS000198 / 0003
We're being asked to place our children's futures in the hands of some what at first will be highly paid hourly personnel, and as time goes by, these positions will be held by untrained people.

Response
If the proposed repository became operational, the personnel involved in repository operations would be well trained, and training would be maintained in accordance with the Nuclear Regulatory Commission's license requirements. The Commission's final rules for Disposal of High-Level Radioactive Wastes in a Geologic Repository at Yucca Mountain include training and certification requirements for personnel operating systems and components that are identified as important to safety in the Safety Analysis Report.

11.1 (1877)
Comment - EIS000443 / 0009
The DEIS does not consider property values. In the consequences of its court cases in New Mexico have shown property along waste transportation routes decreases in value. This needs to be examined for Nevada as well.

Finally, EIS should obtain estimates of loss of property values along the likely shipping routes which gets to the points of identifying national routes.

Response
DOE did not address potential change in property values near waste-transport routes because of the dynamic nature of real estate values and other factors that can influence property values. Assessing the perceived impact to property values or the impact of stigma is problematic because it does not depend on the actual physical effects or risks of the Proposed Action, but on the negative perception of those effects or risks by the public. Section 2.5.4 and Appendix N of the EIS provide additional information and addresses the issue of stigma from the Yucca Mountain Project.

Definitive information is not available on specific tracts of land that could be required for a specific transportation mode or route. For land that would be required or materially affected, the Department would fairly compensate landowners pursuant to Federal procedures. Should DOE be required to exercise its right of eminent domain, it would do so pursuant to applicable laws and regulations.

11.1 (2410)
Comment - EIS001160 / 0129
The effect of transport corridors be designated as "heavy-haul nuclear free" as a mitigating measure in order to alleviate concerns of motorists who wanted to avoid worst case scenario nuclear accidents should be considered within the FEIS. The extent to which such a measure might also reduce the possibility of exposure if there was a highway accident causing a loss of containment should be addressed within the FEIS.

Response
If the proposed repository was approved for the Yucca Mountain site and if DOE selected heavy-haul truck as a transportation mode in Nevada, heavy-haul trucks would operate in accordance with permits issued by the State of Nevada. As a consequence, the State would be responsible for providing information for motorists identifying the routes that would be used. Impacts presented in Chapter 6 of the EIS include exposure to passing motorists and a motorist stuck in traffic during incident-free transportation. These exposures, which would be very low for motorists on Nevada highways, would be about equal to exposures for persons who lived along transportation routes. The EIS also presents and discusses estimates of the dose to a maximally exposed individual in the event of an improbable maximum reasonably foreseeable accident in which radioactive materials were released from a cask (see Section 6.3.3). Mitigation measures that could be adopted to further reduce the possibility of accidents are addressed in Section 9.3.6 of the EIS.

11.1 (3167)
Comment - EIS001195 / 0005
A large mine haulage road would be intersected by the [Carlin] corridor. A crossing designed to safely accommodate loaded mine haulage trucks with a gross vehicle weight of 1,000,000 pounds must be incorporated. Additionally, other multiple crossings will be needed to provide access for ancillary mining facilities/activities and ranching needs. Safety measures tailored to both light vehicles and the large mining equipment must also be provided for at all crossings.

Additionally, we [Cortez Gold Mines] would require the installation of large culverts at strategic locations to allow for the future installation of dewatering pipelines that feed our infiltration galleries.

Response
DOE is aware of the Cortez Gold Mines operation in Crescent Valley (see Sections 8.1.2.3 and 8.4.2 of the EIS). At this time, however, definitive information is not available on specific tracts of land that could be required for a given transportation alternative. For any land that would be required, the Department would compensate landowners under Federal acquisition procedures. In other cases, as indicated in Section 9.3.1 of the EIS, mitigation measures would be developed where construction and operation of transportation facilities would result in (1) impacts to publicly used lands (2) direct and indirect land loss, and (3) displacement of capital improvements. Specific mitigation measures could include the items mentioned by the commenter.

11.1 (4571)
Comment - EIS001521 / 0085
Page 9-5, second bullet--(Surface-Water Measures Under Consideration) Using “hay bales” as more-or-less mitigative devices to trap sediment will be a short-term solution at best (by the way, straw is much cheaper). Using fabric fences and longer lasting “weir-notched” dams to create an impoundment for trapping sediment would be more reliable in accomplishing this task.

Response
DOE has changed Section 9.2.3.1 of the EIS to reflect that it would use sediment- trapping devices such as hay or straw bales, fabric fences, and weir-notched dams. DOE would choose the most appropriate methods for specific situations.

11.1 (4869)
Comment - EIS000337 / 0007
Pg. 2-37, Section 2.1.2.3, Repository Closure, 2nd par: There is no discussed plan on how the sealed repository will be monitored. If there is a monitoring plan, what is the plan if the monitoring reports a significant failure due to unforeseen problems. There must be a contingency plan in place before the DEIS is approved.

Response
The Testing and Performance Confirmation Program is designed to meet specific Nuclear Regulatory Commission requirements (see 10 CFR 60.137, 10 CFR 63.102(m), and 10 CFR Part 63 Subpart F). As defined, the program consists of tests, experiments, and analyses to evaluate the accuracy and adequacy of the information used to determine, with reasonable expectation, that performance objectives would be met. The *Performance Confirmation Plan* (DIRS 146976-CRWMS M&O 2000) formally documents and describes the Testing and Performance

Confirmation Program. DOE understands that ensuring public safety requires continued stewardship and has developed components for site stewardship programs including long-term monitoring of the site. The Proposed Action includes a lengthy program of monitoring and testing. This program would give future decisionmakers the option to take corrective actions, if required, and make societal choices on closing the repository or retrieving the wastes. After closure, a postclosure monitoring program required by 10 CFR Part 63 (see, for example, 10 CFR 63.51) would be further defined during the processing of the license amendment for permanent closure. The program would allow for continued oversight to prevent any activity at the site that poses an unreasonable risk of breaching the repository's engineered barriers, or increasing the exposure for individual members of the public to radiation beyond allowable limits. The license amendment for permanent closure must specifically provide an update of the assessment for the repository's performance for the period after permanent closure, as well as a description of the program for post-permanent-closure monitoring. Deferring a description of this program until the closure period would enable the identification of appropriate technology, including technology that could become available in the future.

11.1 (5204)
Comment - EIS001443 / 0028
All of the design alternatives considered in the EIS lead, ultimately, to a repository that is expected to leak (albeit at different rates depending on the particular choice of tunnel configuration, waste packaging, assumptions regarding geology, climate, and the response of the waste packages to the repository environment). Given the scale and complexities of the aquifers subject to potential contamination by the project, mitigation of impacts to these resources will range somewhere between extremely expensive to completely impossible. The DEIS should explain DOE's stance on providing mitigation, and either consider the adoption of feasible mitigation measures or state that such impacts cannot or will not be mitigated by the Federal government.

Response
The Environmental Protection Agency and the Nuclear Regulatory Commission have issued standards for the long-term performance of the proposed Yucca Mountain Repository (40 CFR Part 197 and 10 CFR Part 63, respectively). The standards set performance levels to protect the public health and safety. These levels do not presume absolute containment of the radioactive material forever. Rather, they specify safe levels of exposure for 10,000 years.

The long-term performance analysis described in Chapter 5 of the EIS demonstrates that the full range of predicted behaviors of the repository system would result in levels of contaminants in the groundwater well below the Environmental Protection Agency and Nuclear Regulatory Commission standards. The repository is expected to meet these standards, even if there were no institutional controls to avoid or mitigate impacts. Therefore, using the best available techniques and data, DOE concluded that the repository would maintain safety and environmental protection in accordance with the standards and that further mitigation would not be necessary.

DOE is considering a range of possible mitigation measures aimed at reducing effects of the proposed repository project. These measures would complement the physical features, procedures, and safeguards already incorporated in the project plan and design to reduce environmental consequences. Chapter 9 of the EIS, which provides DOE's initial list of commitments available at this time, identifies DOE-determined impact reduction features, procedures, and safeguards and mitigation measures under consideration for inclusion in the project plan and design. Chapter 9 also identifies ongoing studies that could eventually influence mitigation measures related to the project plan and design. For example, Section 9.2 discusses mitigation measures DOE would implement or consider to reduce potential impacts from the construction, operation and monitoring, and eventual closure of the proposed repository. Similarly, Section 9.3 discusses mitigation measures to reduce potential impacts from the national transportation of spent nuclear fuel and high-level radioactive waste.

11.1 (5554)
Comment - EIS001660 / 0046
Mineral County's comments have identified many areas where the impact assessment is incomplete and inadequate including: agriculture, air quality, archeological and ethnographic resources, environmental justice, flood plains and wetlands, land use and community development, local government, mining, public health and safety, public services, recreation, soils, transportation, vegetation, water, wild horses and burros, endangered species, and wildlife. Since impacts in these areas have not been fully disclosed, the discussion of mitigation is also inadequate.

Pending a complete and thorough analysis of the transportation impacts of the proposed action, a required mitigation list is difficult to prepare. However, based on Mineral County's comments to date, that mitigation must be included at least for:

- Reductions in the size, number, and productivity of federal grazing allotments;
- Emissions of fugitive dust, diesel particulate, and smoke from fires caused by the construction and operations on the improvements of alternative routes;
- The spread of noxious weeds, which may adversely affect agriculture, other vegetation, wild horses and burros, bison, and wildlife;
- Direct and indirect damage to archeological and ethnographic resources;
- Economic impacts on the mining, construction, services, and agricultural sectors of the economy;
- Environmental justice impacts on residents of rural areas;
- Damage to wetlands and changes in the boundaries of the flood plains from large storms;
- Radiological risks to the public along transportation routes;
- Damage or displacement of public infrastructure during rail corridor construction and related alternative transportation improvements;
- The taking of private property; reduced private property values due to perceived risk and stigmatization; reduced private property value due to restrictions on access; and fiscal, agricultural, and groundwater impacts caused by accelerated parcelization of private property,
- Direct and indirect fiscal impacts on Mineral County and other local governments;
- Restrictions on legal or physical access to mining claim and mineral deposits;
- Direct and indirect impacts on the provision of education and other essential public services;
- Recreational impacts from construction on the improvements of railway lines and alternative routes, as well as impacts caused by improved access to the back country and wildlife habitat;
- Adverse impacts on the existing surface transportation systems, including the Union Pacific railroad, I-80, US 6, US 50, NV278, NV 306, NV 376, and minor roads that provide access to private property, public lands, and mining claims;
- Direct and indirect impacts on rare and sensitive plants and their habitats;
- Direct and indirect impacts on wild horses, burros, and bison, including their forage, water, movement, and safety; and
- Direct and indirect impacts on designated riparian habitats and wildlife generally, including impacts from fragmentation, noxious weeds, interference with migration, disturbance or dewatering of water sources, and increased risk of wildlife.

Response

The possibility of impacts in Mineral County and the appropriateness of mitigation measures would depend on the mode and actual route of transportation of spent nuclear fuel and high-level radioactive waste to the proposed repository. However, candidate rail corridors do not directly pass through Mineral County. This Final EIS identifies mostly rail as the preferred mode of transportation both nationally and within Nevada. If the site was approved, the choice of a final route alignment after the selection of a transportation corridor would be the subject of additional National Environmental Policy Act documentation, including analysis of and decisions regarding, potential mitigation measures. However, the EIS analysis did not show a potential for significant impacts to Mineral County in the areas the commenter identifies, and thus did not indicate a need for proposing specific mitigation measures.

Section 116(c) of the NWPA establishes a procedure by which affected units of local government such as Mineral County can report effects from the proposed repository to DOE and receive impact assistance upon agreement with DOE on matters raised in the report. Section 116(c) commits DOE to participate in this procedure and to provide assistance consistent with direction from Congress. DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

11.1 (5999)
Comment - EIS001879 / 0024
p. 9-5 to 9-6 Section 9.2.2.2, [Mitigating Measures for] Groundwater

The Draft EIS states that "The selection of a potential site with favorable characteristics is a fundamental impact reduction measure" is misleading and should be deleted. Site selection is not a mitigating measure.

Response
DOE agrees that this statement is misleading. An appropriate correction has been made to the EIS.

11.1 (6048)
Comment - EIS001898 / 0007
The DEIS does not include a thorough discussion of mitigative measures or of long-term environmental monitoring to measure the impacts on the environment.

Basis:

The DEIS does not identify what options will be combined for a Proposed Action. Public comments on the DEIS can be used by DOE to help in the selection of those options that will form the Proposed Action, refine its analysis of environmental impacts, and evaluate the need for particular mitigative measures. In this connection, it is important to ensure that all environmental impacts have been identified or bounded in order to provide a basis for decisions for mitigative measures. Mitigative strategies currently address dust suppression, the desert tortoise, and occupational health and safety. In addition, the FEIS needs to evaluate the need for mitigative strategies for water use, economic, social, cultural, biological, or public health and safety impacts.

For example, the discussion in Chapter 9 (Management Actions to Mitigate the Potential for Environmental Impacts) of the DEIS does not fully address mitigative measures for Native American interests, including several measures presented by the AIRD [American Indian Resource Document; American Indian Perspectives on the Yucca Mountain Site Characterization Project and the Repository Environmental Impact Statement] (American Indian Writers Subgroup, 1998), such as ways to alleviate the severity of the effects on Native American cultural, religious, subsistence, recreational, ceremonial and associated uses of Yucca Mountain. The suggested mitigation actions in the AIRD include providing emergency preparedness training, establishing emergency medical facilities, and providing controlled access to sacred or ceremonial areas or resources.

Further, it is not apparent that a complete monitoring program for mitigative strategies has been clearly defined. The FEIS should include monitoring as a way of evaluating the effectiveness of any mitigative measures, such as measures to reduce impacts from transportation or waste handling at intermodal or site surface-based facilities (40 CFR 1505.2(c)).

Recommendation:

The FEIS should provide reasonable mitigative strategies to address potentially significant adverse impacts from the Proposed Action. Mitigative measures which comprise these strategies should be implementable and effective in reducing environmental impacts. Moreover, the FEIS should discuss monitoring to assess the environmental impacts and the effectiveness of planned mitigative measures. As appropriate, this monitoring could be integrated with DOE's long-term performance confirmation monitoring.

References:

American Indian Writers Subgroup. *American Indian Perspectives on the Yucca Mountain Site Characterization Project and the Repository Environmental Impact Statement.* American Indian Resource Document MOL 19980420.0041. Las Vegas, NV: American Indian Writers Subgroup, Consolidated Group of Tribes and Organizations. 1998.

Response

At present, DOE does not have definitive information on specific tracts of land or community elements that the Proposed Action could affect, so it is premature to identify specific mitigation measures categorically. If the repository was approved, however, DOE would have discussions with potentially affected units of local government and consider appropriate support and mitigation measures. DOE would also continue its ongoing interactions with Native American tribes. In addition, specific mitigation measures could be part of a Mitigation Action Plan or similar plan, such as terms and conditions to Biological Opinions from the U.S. Fish and Wildlife Service and Nuclear Regulatory Commission licensing conditions. DOE, in submitting an application to construct and operate a repository, would identify relevant mitigation measures to the Commission for its consideration, and could reasonably expect a comprehensive set of mitigation measures or conditions of approval to be part of any licensing process. At this time, DOE has not decided whether to prepare a Mitigation Action Plan. As described in Chapter 9 of the EIS, DOE intends to commit to reasonable management actions required to mitigate potential adverse environmental impacts. The Department would develop mitigation actions in cooperation with potentially affected units of local government.

Section 116(c)(2)(A)(i) and (ii) of the NWPA state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS. This section also allows payments to the State of Nevada and to any affected unit of local government equal to taxes they would have received if the activity was performed by a non-Federal entity.

Under the NWPA, the Section 116 impact assistance review process and the Yucca Mountain Repository EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would not be limited either by the impacts identified in this EIS or by its findings on such impacts. A decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts. Similarly, Section 180(c) of the NWPA requires the Secretary of Energy to provide technical assistance and funds for training public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions DOE would transport spent nuclear fuel and high-level radioactive waste.

Mitigation measures discussed in the EIS include those for water use (Sections 9.2.3 and 9.3.3), cultural resources (Sections 9.2.5 and 9.3.5), biological resources (Sections 9.2.4 and 9.3.4); and public health and safety (Sections 9.2.6 and 9.3.6). Chapter 9 discusses impacts in addition to the areas mentioned in this comment. Conversely, DOE has generally not proposed mitigation measures in areas where analyses did not identify consequential impacts. In some instances, an analysis might reveal impacts for which there would be no practical mitigation measures. Decisionmakers would consider the unmitigated consequences in weighing the need for the project against the potential for adverse consequences.

With regard to this comment's example of mitigative measures for Native American interests, DOE supported the preparation of the American Indian Writers Subgroup document (DIRS 102043-AIWS 1998) and used it as a primary reference to the EIS (see Sections 3.1.6.2.2 and 4.1.13.4). DOE would include avoidance of significant archaeological sites as a mitigative action where feasible. If avoidance was not feasible, a data recovery effort would preserve the archaeological data. In addition, DOE would implement Section 180(c) of the NWPA, which requires the Secretary of Energy to provide technical assistance and funds for training public safety officials of appropriate units of government and Native American tribes through whose jurisdictions transportation of spent nuclear fuel and high-level radioactive waste would occur. The training would cover procedures for safe routine transportation and for dealing with emergency response situations.

Since issuing the Draft EIS, DOE has continued to evaluate design features and operating modes that would reduce uncertainties in or improve long-term repository performance, and would improve operational safety and efficiency. The result of the design evolution process was the development of the flexible design (which the Supplement to the Draft EIS called the Science and Engineering Report Flexible Design). Although this design focuses on controlling the temperature of the rock between the waste emplacement drifts (as opposed to areal mass loading) the basic elements of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain remain unchanged.

DOE would monitor impacts during the construction and operation of the repository. A postclosure monitoring program, required by 10 CFR Part 63, would include monitoring activities around the repository after closure. The regulation requires submittal of a license amendment for permanent closure of the repository [10 CFR 63.51(a)(1) and (2)]. This amendment must provide an update of the assessment for repository performance for the period after permanent closure, as well as a description of the program for postclosure monitoring. This program would include continued oversight to prevent any activity at the site that posed an unreasonable risk of breaching the repository's engineered barriers or increasing the exposure of individual members of the public to radiation beyond allowable limits. The details of this program would be defined during the processing of the license amendment for permanent closure. Deferring final development of this program until the closure period would enable a more complete understanding of the circumstances of the repository at closure and incorporation and use of new technologies that could become available by closure.

11.1 (6744)
<u>**Comment**</u> - EIS001878 / 0080
Pending a complete, thorough analysis of the transportation impacts of the proposed action, a list of required mitigation is difficult to prepare. Nevertheless, based on Eureka County's comments to date, mitigation must be included at least for:

- Conversion of agricultural land and water rights to other uses, fragmentation of range and grazing allotments, loss of forage, restrictions on livestock movement, loss of water supplies or restricted access to such supplies, loss of livestock in accidents, changes in value of agricultural land, changes in costs of agricultural production, and increased harassment of livestock;

- Emissions of fugitive dust, diesel particulates, and smoke from fires as well as reduced visual range caused by rail corridor construction and operations;

- Direct and indirect damage to, and loss of, archeological and ethnographic resources;

- Economic impacts on the mining, services, construction, and agricultural sectors of the economy;

- Environmental justice impacts on residents of rural areas;

- Damage to springs, wetlands, and surface waters (including the Humboldt River), and changes in the boundaries of flood plains;

- Radiological risks to the Humboldt River;

- Damage or displacement of public infrastructure (including the Crescent Valley airport) during rail corridor construction, as well as increased demand on public infrastructure due to construction employment;

- The direct and indirect housing impacts of a 500-person (or larger) construction crew;
- The taking of private property; reduced private property values due to perceived risk, stigmatization, restricted access, and other factors; and fiscal, agricultural, and groundwater impacts caused by accelerated parcelization of private property;
- Direct and indirect fiscal impacts on Eureka County and other local governments;
- Restrictions on legal or physical access to mining claims and mineral deposits; division of mining claims; and takings of private property rights related to mining;
- Direct and indirect impacts on the provision of education and other public, social, and medical services;
- Adverse impacts on the quality of life in Eureka County and neighboring areas, including diminished environmental quality, impacts on fish and wildlife, impacts from noise, impacts on scenery and views, diminished safety and security, loss of traditional livelihoods, and other effects;
- Recreational impacts from construction of a railroad bed, access roads, borrow pits, and fences, as well as impacts caused by improved access to the back country and wildlife habitat;
- Impacts on scenic resources, including both expansive views and features of interest;
- Impacts on soils from construction and operation of a railroad bed and access roads, including cuts, fills, and soil compaction;
- Impacts on solid waste disposal infrastructure;
- Adverse impacts on the existing surface transportation systems, including the Union Pacific railroad, I-80, US 6, US 50, NV 278, NV 306, NV 376, R.S. 2477 roads, and other roads that provide access to private property, public lands, and mining claims;
- Direct and indirect impacts from the spread of noxious weeds, and impacts on rare and sensitive plants and their habitats;
- Damage to groundwater resources from a radiological accident or the discharge of hazardous materials; adverse impacts on existing water rights; takings of private property rights in water; and adverse effects of well development and closure;
- Direct and indirect impacts on wild horses and burros, including impacts on their ranges, herd management areas, forage, movement, water supplies, safety, and management costs; and
- Direct and indirect impacts on the Bates Mountain antelope release area, designated riparian habitats, the Simpson Park habitat management area, and wildlife habitat generally, including impacts from conversion of habitat, fragmentation of habitat, loss of forage, restrictions on movement, diminished safety, loss of monetary and nonmonetary value, and increased management costs.

Specifically regarding mitigation of environmental impacts caused by fencing of railroad tracks and access roads, the DOE must commit to consultation not only with the BLM but also with local agricultural producers, public safety officials, and local governments to determine whether or not fences are needed at any location.

Response

Under the Council on Environmental Quality Regulations implementing the National Environmental Policy Act (40 CFR 1508.20) mitigation includes those activities that:

- Avoid or eliminate the impact over time by preservation or maintenance operations during the life of the action.
- Avoid the impacts by limiting the degree or magnitude of the action and its implementation.

- Repair, rehabilitate, or restore the affected environment.
- Compensate for the impact by replacing or providing substitute resources or environments.

Chapter 9 of the EIS discusses the mitigation measures DOE has identified that could reduce potential impacts from the operation of the repository and the transportation of spent nuclear fuel and high-level radioactive waste and covers many of the subject noted by the comment related to Eureka County. The mitigation measures specifically identified in Section 9.3 of the EIS are based upon the impacts discussed in Section 6.3 of the EIS and includes land use; air quality; biological resources and soils; hydrology, including surface water and groundwater; cultural resources, occupational and public health and safety; aesthetics; waste management; socioeconomics; noise; utilities, energy, and materials; and environmental justice.

Before selecting the mode or route in Nevada, the Department would have consultations with agencies at the Federal, State, and county levels. The selected mode and route would require a more detailed environmental and engineering analysis.

Mitigation measures that could be implemented to minimize potential impacts from the construction and operation of a transportation corridor would depend on several factors, including the corridor selected and the final alignment of the route within the corridor. Avoidance of impacts would be among the factors considered in corridor selection and route alignment. Once DOE selected a corridor and aligned a route, it could determine the need for and nature of any mitigation measures.

11.1 (6771)
<u>Comment</u> - EIS001878 / 0081
Mitigation related to emergency response and management. Mitigation measures for impacts to local governments for emergency response and management activities made necessary by the proposed action (including the transportation alternatives) are incomplete or absent. This is a significant oversight. Local emergency response resources will typically be the first on the scene of any accident involving the transportation of SNF [spent nuclear fuel] and HLW [high-level radioactive waste]. The DOE's National Transportation Program publication, Transporting Radioactive Materials, Answers to Your Questions (June 1999) says (p. 24), "As with any traffic accident, the local, Tribal, and State police, fire departments, and rescue squads are the first to respond to transportation accidents involving radioactive materials."

The introduction to Chapter 9 (p. 9-1) tries to head off any discussion of specific mitigation actions for emergency response services and emergency management actions. The discussion is based on an over-simplified reference to Section 116(c) of the Nuclear Waste Policy Act. While Section 116(c) may help mitigate impacts to public health and safety, it does not eliminate the need for identification of specific mitigation actions in the DEIS. Furthermore, it does not constitute the universe of mitigation measures for public health and safety.

Through the DEIS, DOE must examine all relevant mitigation measures, including mitigation of ongoing impacts over the life of the proposed waste shipments.

The discussion of occupational health and safety (p. 9-23) includes no mitigation to reduce the impacts from waste shipment transportation accidents. For example, it does not mitigate impacts from the lack of local emergency response capabilities. Such mitigation could include dedicated emergency response teams (not local government teams) that would be immediately available within a short response time to the scene of an accident. The teams could travel in conjunction with, but away from, SNF and HLW shipments, or they could be stationed strategically and equipped for quick initial response. Such teams would be a particularly effective mitigation where there are few or no local emergency resources.

Further, mitigation actions should address all phases of emergency management, including preparedness, response, and recovery. Thus, they should address programs, funding, and training.

Some mitigation actions described in Chapter 9 are so general that it is not possible to determine what they would consist of or how effective they would be. For example, the DEIS suggests a measure to "improve design of affected roadways to reduce accidents." (p. 9-23) The mitigation measures must be specifically designed to reduce or eliminate foreseeable hazards from the operation of rail lines in Nevada. They must address hazards at rail crossings, during switching, when shipments are parked on sidings, and from train derailments.

Response
As the commenter notes, mitigation measures that could be adopted to further reduce potential impacts associated with the transportation of spent nuclear fuel and high-level radioactive waste to a repository at Yucca Mountain, including measures to reduce the possibility of accidents, are addressed in Section 9.3.6 of the EIS. The development of mitigation actions related to emergency management, including preparedness, response, and recovery is premature because such mitigation actions, if needed, could differ from community to community, from mode to mode, and from route to route. As stated in Chapter 6 of the EIS, DOE cannot confidently identify the mode of transportation and routes that would be used beginning almost 10 years in the future and continuing for an additional 24 years. Nevertheless, DOE could fund mitigation measures that a qualifying local government sought to implement. Section 116(c)(2)(A)(i) and (ii) of the NWPA state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada to document likely economic, social, public health or safety, and environmental impacts. If the proposed repository was to become operational, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

If there was a decision to construct and operate the proposed repository, and after the identification of transportation modes and routes, local jurisdictions would be better able to identify the likely economic, social, public health and safety, or environmental impacts that would be the basis for a request for economic assistance, which could include assistance in providing additional medical and emergency response capabilities, under Section 116(c) of the NWPA.

With respect to training, including emergency response training, as required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to States for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdiction DOE would transport spent nuclear fuel and high-level radioactive waste. DOE anticipates that training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations.

11.1 (7182)
Comment - EIS001337 / 0073
Page 2-44 Nevada Transportation - Transportation is the major source of interest/concern to the people living in Lincoln County. This is due to the extreme likelihood that shipments to Yucca Mountain will pass through our county. Based upon objections expressed by Nevada leaders and actions taken related to DOE low-level waste transportation routing it is unlikely that any of the final routes, rail or highway, will go through Clark County. Likely routes whether legal weight truck, heavy-haul truck or rail will be through the rural areas of the State. The Draft EIS identifies a number of impacts resulting from transportation of nuclear material. However, there is no mention of mitigation measures that will be taken to minimize these impacts. It is essential that the EIS address mitigation plans in detail.

Response
Section 9.3 of the EIS discusses mitigation measures that DOE could adopt to reduce potential impacts associated with the transportation of spent nuclear fuel and high-level radioactive waste to a repository at Yucca Mountain, including measures to reduce the possibility of accidents. The Department would identify and implement more specific mitigation measures if the repository was approved and a particular transportation mode and route were selected.

In addition, DOE could fund mitigation measures that a local government sought to implement. Section 116(c)(2)(A)(i) and (ii) of the NWPA state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." DOE would base a decision to provide assistance under Section 116 on an evaluation of a report submitted by affected units of local government or the State of Nevada to document likely economic, social, public health and safety, or environmental impacts. If the proposed repository became operational, DOE would hold discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

11.1 (7229)
Comment - EIS001337 / 0122
Page 9-21 Section 9.3.4.2. This section does not include any measures to replace vegetation or animal unit months (AUM's) of forage lost to rail spur construction.

Response
As indicated in Section 9.3.1 of the EIS, DOE would evaluate appropriate mitigation measures that would minimize impacts to grazing lands. These actions could include providing access to lands on both sides of a rail line via underpasses, revegetation, and assisting in providing water should there be a need.

11.1 (7302)
Comment - EIS010485 / 0006
The Mitigation process, and Native review of any proposed mitigation is also not discussed [in the Supplement to the Draft EIS].

Response
DOE did not discuss any of the specifics concerning the mitigation process and Native American reviews in the Supplement to the Draft EIS, although it did acknowledge it would consult with Native American tribes and organizations to ensure the implementation of the most appropriate mitigation measures to reduce any adverse effects (see Section 3.1.6 of the Supplement to the Draft EIS). However, the interaction program with Native American groups designed to ensure the identification and evaluation of issues important to Native American, as well as a discussion of potential mitigation measures for the repository and transportation corridors, can be found in Sections 3.1.6.2, 9.2.5, and 9.3.5, respectively, of the EIS.

11.1 (7415)
Comment - EIS001912 / 0010
We are extremely concerned that DOE proposed no mitigation measures for waste transportation, particularly in light of the latent cancer fatalities associated with the program.

Response
Mitigation measures that could be adopted to reduce potential impacts associated with the transportation of spent nuclear fuel and high-level radioactive waste to a repository at Yucca Mountain, including measures to reduce the possibility of accidents, are addressed in Chapter 9 of the EIS. Although radiation exposures would be small, Section 9.3.6 lists measures under consideration that could minimize radiation exposure for workers. More specific mitigation measures, including measures to reduce dose to the public during incident-free transportation, could be identified and implemented if the repository was approved and a particular transportation mode and route were selected.

11.1 (8182)
Comment - EIS001653 / 0106
Much of the mitigation in Chapter 9 should be included in the proposed action.

Response
Chapter 9 of the EIS describes a combination of mitigation measures that include measures that would be part of the Proposed Action; measures that are under consideration; and possible measures that DOE is still studying.

If the Nuclear Regulatory Commission granted a license for the repository project, DOE would define these mitigation measures in more detail and would establish its commitments.

11.1 (8187)
Comment - EIS001653 / 0108
None of the discussion in the long-term performance section [9.2.8] has much to do with mitigation. It has more to do with site selection, design, and defense in depth. Without these measures it is doubtful that DOE would even have a proposed action, which could meet regulatory standards.

Response
Section 9.2.6 of the EIS lists mitigation measures that DOE is considering that could reduce the long-term potential for possible radionuclide releases from the proposed repository.

11.1 (8188)
Comment - EIS001653 / 0109
Transportation mitigation needs to include the following:

- Efforts to monitor impacts to land values and development.
- Specific contingency plans for spill situation that describe roles, responsibilities and financial assistance.
- Mitigation assistance to local communities for emergency response capabilities, management and training.
- Measures to monitor and compensate for loss of visitors or other related economic development associated with transportation and repository development.
- Specific transportation mitigation measures such as escorts, dedicated mains, time of day restrictions, etc.
- Specific measures to accommodate heavy haul trucks, highway improvements, roadway maintenance and financial assistance committed by DOE.

Response
Chapter 9 of the EIS discusses mitigation measures DOE has determined it could use to reduce potential impacts from the construction, operation and monitoring, and eventual closure of the proposed repository. DOE believes that it is speculative to estimate impacts to land values and development, loss of visitors, or other perceived economic issues, and has not addressed them in the EIS. Estimating such impacts could result in a misrepresentation of the direct impacts of an action.

The Price-Anderson Act establishes a system of financial protection (compensation for damages, loss, or injury suffered) for the public in a nuclear accident, regardless of who causes the damage. Section M.8.1of the EIS discusses the Price-Anderson Act. Under the Motor Carrier Act of 1980, DOE, the owners of the materials, and the carriers would share responsibility for cleanup of released materials. Under provisions of the DOE Draft Policy for Implementing Section 180(c) of the NWPA, the Department would provide technical assistance and funding for emergency response personnel. Appendix M also discusses these provisions.

Sections 2.1.3.3, 6.3, 9.3, and J.3 of the EIS discuss Nevada transportation. Specifically:

- Section 2.1.3.3.3.2 discusses road upgrades for candidate routes, along with the specific routes potentially used for heavy-haul truck transportation. Similarly, Section 2.1.3.3.2.1 discusses branch rail line construction and mitigation measures for the five rail implementing alternatives.
- Section 6.3 discusses impacts that could occur in Nevada from the construction and operation of a branch rail line or from upgrades to highways and the construction and operation of an intermodal transfer station.
- Section 9.3 discusses mitigation measures DOE would have to implement, has decided to implement, or has identified for consideration to reduce potential impacts from the transportation of spent nuclear fuel and high-level radioactive waste.
- Section J.2.3 discusses the use of dedicated rail lines.

11.1 (8190)
Comment - EIS001653 / 0110
DOE needs to establish a committee of potentially affected areas to review and monitor transportation shipments and potential impacts similar to the Transportation Protocol Working Group established by DOE-NVO [Nevada Operations Office]. The group could also address issues related to emergency response and management, risk perceived impacts, and whether they actually materialize and other issues.

Response
DOE could establish a committee analogous to the Transportation Protocol Working Group if the Yucca Mountain site was designated for a repository. DOE has noted the potential consideration of such a committee in Chapter 9 of the Final EIS, which identifies potential impact reduction features, procedures, and safeguards; and mitigation measures under consideration for inclusion in the project plan and design.

11.1 (8416)
Comment - EIS001873 / 0078
P.9-21. Surveys of biological resources at some future date do not constitute mitigation. These resources must be identified prior to the route decisions.

Response
Section 6.3.2 of the EIS discusses biological impacts that could occur as a result of implementing each Nevada transportation alternative. If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

11.1 (8664)
Comment - EIS001837 / 0024
Mitigation measures are lacking. The DOE does not propose to move the people living in harms way. The DEIS should have addressed the issue of buying the homes along the railroad and helping the people to move if the DOE is going to implement this kind of disruptive, potentially dangerous nuclear waste shipment plan.

Response
Regarding requirements for land associated with branch rail line development, definitive information is not available at this time on specific tracts that DOE could need for a given transportation alternative. For land that would be required or otherwise affected, the Department would fairly compensate landowners under Federal acquisition procedures. If DOE was required to exercise its right of eminent domain, it would do so in compliance with applicable laws and regulations.

11.1 (8702)
Comment - EIS010004 / 0002
I would just offer one suggestion and that has to do with building a camp for YMP [Yucca Mountain Project] workers.

Within 3 or 4 miles of the tunnel entrance, DOE should build a man-camp along the lines of the camp that was used for over 10 years at Area 12. The rooms should be set up for one person, and each room should have its own bathroom. The camp could start off as a 200 man (and women) camp with room for expansion.

The cost should be $1 per day, and $1 per meal. This is just so you could keep track of how many workers are staying and eating in camp. This is very much along the lines as “Systems.” (Over the hill.) If the DOE did this they would attract a high quality of worker, particularly "travelers" who are staying in Las Vegas motels until they can catch a call out of the union hall.

The lack of a man-camp at YM has always been the number one drawback to working there. (Please don't tell me about the man-camp in Mercury. DOE and Bechtel have turned that once fine camp into an overpriced, under performing, cost prohibitive, joke.)

Response
DOE appreciates the suggestion and the commenter's participation in the National Environmental Policy Act process.

11.1 (9087)
Comment - EIS001873 / 0079
P.9-23. This document must include a commitment to these safety measures.

Response
Chapter 9 of the EIS, which provides DOE's list of possible mitigation measures identified at this time, including impact reduction features, procedures and safeguards; and mitigation measures under consideration for inclusion in the project plan and design. Chapter 9 also identifies ongoing studies that could eventually influence mitigation measures related to the project plan and design. The Department notes that current contracts for operations of DOE sites do contain requirements and incentives for minimizing worker exposure to ionizing radiation, and that such provisions could be expected in contracts for operating the proposed repository and transportation of materials to the repository. The Department currently contracts for bus transportation of workers to the Nevada Test Site, and that bus transportation would be expected to continue. Other measures could be implemented as appropriate. DOE anticipates that the project plan and design would continue to evolve, creating additional opportunities for mitigation and potentially eliminating the need for some mitigation measures currently under consideration.

11.1 (9309)
Comment - EIS001888 / 0036
DOE needs to reflect on how local elected officials consider a major federal project such as the one being proposed in the DEIS. In making decisions, local officials must use any information, no matter how uncertain or well defined, to consider the implications to their constituents. This basic criterion may be stated as follows, "Is an event or impact from that event more likely than not to happen and, if so, what must we do to mitigate any harmful effects?"

In other words, the standard of proof for technical or statistical decision-making may have the appearance of being more stringent but it is generally much less related to the real world than that which needs to be considered by local elected officials and the public when evaluating the effects of major projects.

It should also be noted that technical or statistical data, even when applied with accepted "industry" standards, often provide an artificial appearance of reality. Often there isn't sufficient experience, information or data to substantiate the numbers.

It is this need on the part of local governments that must be met in order for an environmental impact statement to reflect reality. Thus, DOE does a great disservice to local communities when the DEIS is not written to take into account the potential effects of the Yucca Mountain Program on the economy of Clark County and in other potential impact areas. For example, effects on program costs and the liability of local governments, on the necessity for transportation infrastructure improvements, on the potential loss of value of property, and the potential stigmatization of local area services and products have all been documented as impacts elsewhere. But, they have not been addressed in the Yucca Mountain DEIS. To reiterate, while there may be questions regarding the present or future occurrence of such impacts and their potential magnitude, it is important that there at least be acknowledgement of the issues in the DEIS.

If these impacts of greatest concern to the residents and elected officials of Clark County are not addressed, there can be no reasonable expectation that meaningful mitigation planning can take place. Since a major goal of an EIS is to provide a broad enough scope and enough detail to allow for such action, this DEIS must be considered incomplete and insufficient.

Response
The commenter accurately notes that the EIS makes use of statistical techniques in some disciplines to estimate potential environmental impacts. The commenter states that this provides an artificial appearance of reality and that often there isn't sufficient experience, information, or data to substantiate the numbers. This argument is precisely why DOE does not include the impacts of perceived risks, such as lost property value due to stigmatization, in its environmental impact documents, or attempt to presume what agencies need to do to serve their citizens. DOE has focused its evaluations on the parameters most likely to provide the decisionmaker discriminating information between alternatives.

Regarding mitigation, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures. In addition, as required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions DOE would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. In addition, Sections 116(c)(2)(A) of the NWPA provides for financial and technical assistance and 117(c) of the Act sets forth assistance guidelines covering a number of issues including emergency preparedness and response, state liability arising from accidents, and necessary road upgrading.

11.1 (9315)
Comment - EIS001888 / 0045
The DEIS also does not contain sufficient detail in order to evaluate mitigation needs. While this may be addressed in future documents, the current DEIS language provides no guarantees. Thus, a whole range of issues and responsibilities are left ambiguous. This could result in a significant harm to the residents of Clark County.

Response
If the repository was approved, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures. As described in Chapter 9 of the EIS, DOE intends to commit to reasonable management actions required to mitigate potential adverse environmental impacts. DOE would develop mitigation actions in cooperation with potentially affected units of local government. At present, DOE does not have definitive information on specific tracts of land or community elements that could be adversely affected, so it is premature to identify specific mitigation measures categorically.

Section 116(c)(2)(A)(i) and (ii) of the NWPA state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

Under the NWPA, the Section 116 impact assistance review process and the Yucca Mountain Repository EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would be independent of the impacts identified in this EIS or its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 that documented likely economic, social, public health and safety, and environmental impacts.

11.1 (10507)
Comment - EIS002105 / 0007
As a 54-year resident of the state, having two children I have raised in the state, my wife and I, I certainly do not want to [see] the State of Nevada become a wasteland in any way, shape or form, and I don't think that the acceptance of this material will cause that. Do I feel the waste will come to our state? Yes, I do. Should we be properly compensated? Yes, we certainly should be. Should every reasonable precaution be taken to protect our future generations? Of course. Every precaution should be taken. But I do feel that we're going to have the

material and I think that we need to protect ourselves economically, scientifically, every way we possibly can, but in the long run, the material has to go somewhere.

Response
The NWPA establishes a comprehensive process for determining the suitability of Yucca Mountain as a repository and for determining whether a repository should be constructed and operated at the site. After completion of site characterization and the issuance of the Final EIS, the Secretary of Energy must determine whether to recommend the site to the President. If the Secretary recommends the site to the President, the President must then decide whether to recommend the site to Congress. If the President recommends the site to Congress, then the State of Nevada has 60 days in which to submit a notice of disapproval regarding the site designation. Congress could then, if it chooses, override Nevada's disapproval by passing a resolution of repository siting approval within 90 calendar days of continuous session of Congress following receipt of the notice of disapproval from the State. If Congress overrode the State of Nevada's disapproval, DOE would submit an application for authorization to construct a repository to the Nuclear Regulatory Commission, which could approve or deny the application. If Congress does not pass an override resolution, then the site would be disapproved. Nevada citizens, through their democratically elected representatives in Congress and in the State Legislature and Governor's Office, have had and will continue to have opportunities to make their views known.

The NWPA also provides for funding to the State of Nevada and to the affected units of local government for the purpose of participating in the NWPA process of characterizing and selecting a site for a geologic repository. In addition, Section 116(c) of the NWPA requires DOE to provide financial and technical assistance to the State of Nevada and to the affected units of local government to mitigate the impacts of the development of a repository and the characterization of the site. Section 116(c)(3)(A) also authorizes the State of Nevada and any affected unit of local government to collect an amount equal to the amount that the state or local government would receive if authorized to tax site characterization, repository development and activities (known as Payments-Equal-To-Taxes, or PETT). If the repository was constructed and operated at Yucca Mountain, the State and local governments would also be able to collect an amount equal to the taxes imposed on other non-Federal real property and industrial activities. Financial assistance comes from the Nuclear Waste Fund, which is funded by contributions from nuclear utility ratepayers.

11.1 (10802)
Comment - EIS002043 / 0003
A significant concern to the people of Esmeralda County and particularly those residing in Goldfield, is the transportation of nuclear material. Esmeralda County believes that it is highly likely that political considerations will result in the county serving as a major corridor for nuclear waste transportation to the Yucca Mountain Site. Spent nuclear fuel and high-level radioactive waste will likely be transported through Esmeralda County by either legal weight truck, heavy-haul truck, rail or a combination of modes. The Draft EIS identifies a number of impacts resulting from transportation of the nuclear material without mention of any mitigation measures that will be taken to minimize these impacts. DOE needs to address mitigation measures in detail.

Is the Department not addressing impact mitigation because it assumes that impact mitigation will be achieved through implementation of Section 116c(2) of the Nuclear Waste Policy Act?

If yes, does the Department intend to work directly with each Affected Unit of Local Government to address impact mitigation needs?

In accordance with NEPA the Department should develop specific measures to mitigate impact. These measures should be described in detail in the EIS.

Response
Chapter 9 of the Yucca Mountain EIS discusses mitigation measures that DOE could use to reduce potential impacts from the construction, operation and monitoring, and eventual closure of the proposed repository.

Training for emergency response personnel would be provided under provisions of the DOE Draft Policy for implementing Section 180(c) of the NWPA. These provisions are described in Appendix M.6 of the EIS.

Sections 2.1.3.3, 6.3 and J.3 of the EIS discuss Nevada transportation. Specifically, the following items noted in this comment are discussed:

Section 2.1.3.3.3.2 discusses time-of-day restrictions for heavy-haul trucks and road upgrades for candidate routes and specific routes to be used for heavy-haul transportation. Similarly, Section 2.1.3.3.2.1 discusses rail-line construction and mitigation measures for the five rail implementing alternatives.

Section 9.3 discusses mitigation measures DOE is required to implement, has determined to implement, or has identified for consideration, to reduce potential impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

Section 6.3 discusses the impacts that could occur in Nevada for the construction and operation of a branch rail line or from upgrades to highways and the construction and operation of an intermodal transfer station.

Section J.2.3 discusses the use of dedicated rail.

DOE intends to fully implement the provisions of Section 116(c)(2). The Department regards the process established by that section to be separate from the EIS process. Section 116(c)(2)(A)(i) and (ii) of the NWPA states that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

Under the NWPA, the Section 116 impact assistance review process and the Yucca Mountain Repository EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, provision of assistance under Section 116 would be independent of the impacts identified in this EIS or its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 that documented likely economic, social, public health and safety, and environmental impacts.

Need for any additional mitigation measures from construction and operation of transportation routes would depend on the transportation corridor selected and the final alignment of the route within the corridor. Once a specific corridor and route alignment was selected, mitigations appropriate to that corridor and route could be determined.

11.1 (11329)
Comment - EIS002267 / 0003
[DOE] has provided insufficient scope and detail to allow for planning and negotiation of mitigation and management plans. This is because they have narrowly defined the scope and nature of the impact, thus insuring that few impacts of significance would be identified.

Response
The Department has defined the scope of the analysis and defined impacts in accordance with Council on Environmental Quality and DOE guidance and regulations implementing the National Environmental Policy Act. Mitigation measures that DOE could undertake to reduce potential environmental impacts below the level described in the EIS are discussed in Chapter 9.

Section 180(c) of the NWPA requires the Department to provide funds and technical assistance for training for public safety officials of appropriate units of local government through whose jurisdictions the Department would to transport spent nuclear fuel or high-level radioactive waste. Further, Section 116(c) of the Act requires the Secretary to provide financial and technical assistance to the State and affected units of local government requesting such assistance to mitigate the impacts of the development of the repository.

11.1 (11451)
Comment - EIS010096 / 0009
Table S-2 – The SDEIS predicts a 30 to 60 percent increase in material transport related traffic fatalities under the low temperature alternative yet offers no suggestions for mitigating increased transportation risk nor considers whether any mitigation measures proposed in the DEIS remain valid. The implications of increased material transport through Lincoln County and the City of Caliente should be addressed in the FEIS.

Response
Section 9.3 of the Draft EIS discussed potential mitigation measures for transportation; these measures are still valid. Section 9.3 of this Final EIS contains additional information on mitigation of impacts.

DOE could also consider additional mitigation measures if the repository was approved and if decisions were made on the mode of transportation and the specific corridors that would be used. Any additional mitigation measures would be evaluated with appropriate Federal, state, tribal, and local agencies. Subsequent plans could include such things as infrastructure upgrades, operational guidelines aimed at alleviating specific problems, and emergency response training and assistance under Sections 116 and 180 of the NWPA.

11.1 (11914)
Comment - EIS000308 / 0001
The last statement under Section S.8 [of the Draft EIS] is unacceptable. The DOE MUST be committed to research and development of additional measures to improve the long-term performance of the repository. Anything less is unacceptable. At least TRY to find better ways to mitigate the adverse effects of this thing for future generations.

Response
The Supplement to the Draft Environmental Impact Statement addresses the latest repository design and the corresponding environmental impact analyses. The information provided in the Supplement to the Draft EIS and this Final EIS demonstrates DOE's commitment to the improvement of repository long-term performance.

Since issuing the Draft EIS, DOE has continued to evaluate design features and operating modes that could reduce uncertainties or improve long-term repository performance, including the design of the waste package and improvements in repository operational safety and efficiency. The result of the design evolution process was the development of the flexible design. This design focuses on controlling the temperature of the rock between waste emplacement drifts (as opposed to areal mass loading described in the Draft EIS), but the basic elements of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain remain unchanged. DOE acknowledges in the EIS that the flexible design could be further modified or refined during the License Application process, if the site was approved for development of a repository.

11.1 (12058)
Comment - EIS000226 / 0022
Page 28 of the County/City EIS Scoping Report points out the need for the DEIS to consider unavoidable impacts which can not be mitigated (i.e., additional transportation risk) and that compensation for such impacts must be considered.

Response
The EIS does consider additional transportation risk associated with the repository program. Further, DOE would implement the requirements of Section 180(c) of the NWPA, which requires the Secretary of Energy to provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions transportation of spent nuclear fuel or high-level radioactive waste would travel. The training would cover procedures for safe routine transportation and for dealing with emergency response situations.

11.1 (12433)
Comment - EIS001106 / 0003
2.2.1 Decommissioning and Reclamation: This section provides no details about reclamation procedures, their application, and their chances for success.

Response
Section 7.1 of the EIS addresses potential short-term environmental impacts in the Yucca Mountain vicinity associated with the No-Action Alternative and includes substantial discussion of proposed decommissioning and reclamation activities.

In addition, Section 9.2.4 of the EIS addresses potential mitigation measures for potential impacts to biological resources and soils. Chapter 9 addresses mitigation measures associated with repository construction, operation and monitoring, and closure, and reclamation associated with the No-Action Alternative described in Section 2.2 would be similar in nature.

11.1 (13010)
Comment - EIS010334 / 0007
Under the Supplemental Draft EIS under the cultural resources section it primarily appears to devote itself to archaeological findings. We believe while this is indeed part of the cultural resources, it talks about mitigating issues and a lot of other -- lot of other proposals to try to protect areas in and the like and we believe that it's imperative that the Indian concerns and involvement be included into that section in the final EIS.

Response
This Final EIS incorporates the information provided in the Supplement to the Draft EIS. DOE acknowledges the importance of protecting cultural resources and minimizing potential impacts to them.

11.1 (13012)
Comment - EIS010334 / 0009
On page 3-16 it talks about under section 3.1.13 and this is under the Environmental Justice section, it alludes to and specifically states actually that the DOE will continue its protection of Native American cultural resources and protect the traditional cultural properties. It will implement appropriate mitigation measures.

To date there's been no studies specific to traditional cultural properties as identified under both Bulletins 30 nor as cultural landscapes under -- I'm sorry -- under traditional cultural properties under Bulletin 38 and traditional landscape areas under Bulletin 30. And as such there should be provisions to include those kinds of studies to make those determinations if indeed there's going to be protective measures implemented.

Response
Research to date has identified no traditional cultural properties of interest to groups other than Native American tribes at the Yucca Mountain Repository site itself. Once DOE determines the final mode, transportation corridor, and alignment, it would conduct corridor-specific studies for the alignment in accordance with the requirements of the National Historic Preservation Act and 36 CFR Part 800 to identify traditional cultural properties that might exist in or adjacent to the corridor. During these evaluations the Department would consult, as appropriate, with parties who have an interest in traditional cultural properties along the route.

DOE is committed to ensuring that its analyses include all historic properties that have traditional value to interested parties. The Department agrees that traditional cultural properties are not restricted to those of Native American concern (see DIRS 155897-Parker and King n.d.). Simply, DOE would consider the guidelines pursuant to McClelland et al. (DIRS 155896- n.d.), which addresses protecting rural and other cultural landscapes.

11.1 (13211)
Comment - EIS010244 / 0010
The SDEIS predicts a 30 to 60 percent increase in material transport related to traffic fatalities under the low-temperature alternative yet it does not offer suggestions for mitigating increased transportation risk nor considers whether any mitigation measures proposed in the DEIS remain valid.

Response
Section 9.3 of the Draft EIS discussed potential mitigation measures for transportation; these measures are still valid. Section 9.3 of the Final EIS contains additional information on the mitigation of impacts.

DOE could also consider additional mitigation measures if the repository was recommended and approved and if decisions on the mode of transportation and specific corridors were made. Any additional information would be coordinated with responsible Federal, state, tribal, and local agencies. Subsequent plans could include infrastructure upgrades and operational guidelines aimed at alleviating specific problems. Section 116 of the NWPA provides for participation in the identification of mitigation actions and Section 180 provides for funding and technical assistance for training.

11.1 (13222)
Comment - EIS010244 / 0021
The SDEIS indicates that DOE will continue performance confirmation activities following site approval and designation. DOE should propose to continue state and local government oversight functions to mitigate a longer site characterization like process.

Response
The Testing and Performance Confirmation Program is designed to meet specific requirements of the Nuclear Regulatory Commission (10 CFR Part 63.102(m) and 10 CFR Part 63, Subpart F). The program allows continued oversight. If the site is recommended for further development, the performance confirmation period would begin at the time of the site recommendation and would extend until the beginning of repository closure activities. It would provide data to future decisionmakers on the performance of the repository and support choices on closing the repository or retrieving the wastes. DOE is not able to determine its commitment for oversight funding at this time because of dependence on Congressional funding and other factors. If a repository was constructed at Yucca Mountain, DOE expects that it would be able to fund activities required for regulatory compliance and to implement the oversight provisions of the NWPA.

11.1 (13375)
Comment - EIS010182 / 0017
The SDEIS predicts 30 to 60 percent increase in material transport related traffic fatalities under the low-temperature alternative; however, it offers no suggestions for mitigating increased transportation risk nor considers whether any mitigation measures proposed in the DEIS remain valid. In addition, it predicts up to 50 percent increase in worker transport fatalities. This increase does not correlate with the estimated "small increase" in workers. Furthermore, due to the "blending design," hotter fuel would be shipped/transported sooner. The SDEIS should consider mitigating increased transportation risk and what mitigation measures proposed in the DEIS still remain valid.

Response
Section 9.3 of the Draft EIS discussed potential mitigation measures for transportation, which are still valid. This Final EIS integrates the information provided in the Supplement to the Draft EIS and further elaborates on information obtained since DOE issued the Draft EIS.

DOE could consider additional mitigation measures if the repository was recommended and approved and if decisions on the mode of transportation and specific corridors were made. Any additional mitigation measures would be evaluated with responsible Federal, state, tribal, and local agencies. Subsequent plans could include such things as infrastructure upgrades and operational guidelines aimed at alleviating specific problems. Section 116 of the NWPA provides for participation in the identification of mitigation actions and Section 180 provides for funding and technical assistance for training.

11.1 (13456)
Comment - EIS010296 / 0042
Can radon release be reduced? According to the document, radon will account for 99 percent of the public exposure to radionuclides. Can anything be done to mitigate emissions and reduce those levels? Potential mitigation of the emissions should be addressed in the FEIS.

Response
Radon would emanate from the rock of the subsurface repository, enter the repository drifts, and be exhausted in ventilation air. For purposes of public exposure, the source of the radon would be the ventilation shafts and exhaust ducts that would service the subsurface repository, since the radon would be released in the subsurface ventilation

air. Nevertheless, DOE recognizes natural ventilation could be used to reduce long-term repository temperatures and radon emissions. As a consequence, natural ventilation has been proposed in several lower-temperature operating scenarios for the repository by extending the time during which loaded emplacement drifts were ventilated, so the repository would be operated at lower temperatures. The design of the repository is still evolving and the concept of natural ventilation is a design element that could be further developed for License Application. No members of the public would be routinely exposed within the proposed land withdrawal boundary, because this area would be unavailable to public access. If members of the public entered this area, it would be for limited periods, and not for the continuous yearly exposure considered for people living outside the land withdrawal area. If members of the public did visit the Yucca Mountain operations areas, they would be subject to DOE's radiation protection limits and guidance. Any potential radiation exposure from radon or other sources would be of limited duration and any potential radiation dose would be expected to be very low.

11.2 Impacts Compensation

11.2 (56)
Comment - 3 comments summarized
Commenters contend that the EIS has not identified adequate impact mitigation and state that EIS mitigation measures for the Proposed Action must include a special trust or escrow account for prompt and complete compensation to persons affected by radiation along transportation routes, as well as a baseline health assessment to enable the identification of such effects. Commenters stated that the mitigation program must include compensation for takings of private property rights, as required by the Constitution of the United States.

Response
Although DOE has characterized the environment along the candidate transportation routes in Nevada, it has not performed a baseline health assessment. DOE believes it has estimated the potential environmental impacts, including the health impacts, in sufficient detail to allow decisionmakers to determine the relative merits of each transportation scenario. However, DOE would assess the environmental and engineering conditions along the selected corridor in a subsequent National Environmental Policy Act document.

The Price-Anderson Act establishes a system of financial protection (compensation for damages, loss, or injury suffered) for the public in a nuclear accident, regardless of who causes the damage. See Section M.8 for a discussion of the Price-Anderson Act. Responsibility for cleanup of released materials would be shared between DOE, the owners of the materials, and carriers under regulation of the Motor Carrier Act of 1980. Funding and technical assistance for training of emergency response personnel would be provided under Section 180(c) of the NWPA. These provisions are described in Appendix M.8 of the EIS.

At present, definitive information is not available on specific tracts of land that could be required for a given transportation alternative. Where practicable, DOE would align corridors and design facilities to minimize the potential for impairment of private property rights. However, for any taking of property that could be required, DOE would compensate landowners under Federal acquisition procedures. If DOE needed to exercise its right of eminent domain, it would do so pursuant to applicable laws and regulations. DOE believes these actions, as well as those described in Chapter 9 of the EIS, would be appropriate and effective means of mitigating project impacts.

11.2 (108)
Comment - 13 comments summarized
Commenters stated that, because the project serves a national purpose, it is important that Nevada, which has not been the direct beneficiary of nuclear power, not bear the undue burden attributed to this project. Commenters further stated that it is important and entirely appropriate that state and local impacts of the project be offset through mitigating measures, financial and otherwise. Commenters said that a large compensatory package should be developed for residents of the repository area, who, commenters believe, are being disproportionately affected by a problem for which the whole country is responsible. Commenters believe that they should be entitled to discretionary use of funds received, and not be told how to spend them. Commenters stated that a great opportunity exists to derive maximum benefits not only during the repository study period but also during the waste isolation operation period as well.

Response
Under the Council on Environmental Quality regulations (40 CFR 1508.20) for implementing the National Environmental Policy Act, mitigation includes activities that (1) avoid the impact altogether by not taking a certain action or parts of an action; (2) minimize impacts by limiting the degree or magnitude of the action and its implementation; (3) repair, rehabilitate, or restore the affected environment; (4) reduce or eliminate impacts over time by preservation or maintenance operations during the life of the action; or (5) compensate for the impact by replacing or substituting resources or environments.

Section 116(c)(2)(A)(i) and (ii) of the NWPA states that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS. Any decision to provide assistance under Section 116 would be based on an evaluation of any reports submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts. Neither Section 116(c) nor any other section of the NWPA gives DOE discretion to provide general financial assistance to individuals.

DOE is considering a range of mitigation measures aimed at reducing adverse effects of the proposed repository project. The mitigation analyses in Chapter 9 of the EIS discuss impact reduction measures for the repository and for waste transport, as well as other mitigation measures DOE continues to evaluate in the event the Nuclear Regulatory Commission granted a license for the repository project.

Section 9.2 of the EIS discusses mitigation measures DOE has determined it would implement, or has identified for consideration, to reduce potential impacts from the construction, operation and monitoring, and eventual closure of the proposed repository.

Section 9.3 discusses mitigation measures DOE is required to implement, has determined to implement, or has identified for consideration, to reduce potential impacts from the transportation of spent nuclear fuel and high-level radioactive waste. These measures address impacts from the possible construction of a branch rail line or an intermodal transfer station in Nevada; construction of other transportation routes; upgrading of existing Nevada highways to accommodate heavy-haul vehicles; transportation of spent nuclear fuel and high-level radioactive waste from existing storage sites to the proposed repository; and fabrication of casks and canisters.

11.2 (202)
Comment - 4 comments summarized
Several commenters asked how they would be compensated for decreases in land values due to their proximity to candidate rail corridors. Some of these commenters also raised health-based concerns related to their possible proximity to routes.

Response
At present, definitive information is not available on specific tracts of land that could be required for a given transportation alternative. For any taking of property that could be required, the Department would compensate landowners under Federal acquisition procedures. Should DOE be required to exercise its right of eminent domain, it would do so pursuant to applicable laws and regulations. Where practicable, DOE would also align corridors and design facilities to minimize the potential for impairment of private property rights.

With regard to decreases in land values in proximity to rail corridors, DOE's examination of relevant studies and literature concluded that while under some scenarios the perception of risk could result in adverse impacts on portions of a local economy (including property values), there are no reliable methods whereby such impacts could be predicted with any degree of certainty. While possible impacts can be envisioned, they are not inevitable. Any such adverse conditions would likely be an aftereffect of unpredictable future events, such as a serious accident.

The EIS analysis concluded that the potential for risk to public health and safety along any of the alternative transportation routes would be small. Based on the results of the impact analyses in Chapter 6 and Appendix J of the EIS, as well as the results published in numerous other studies and environmental impact analyses cited in the EIS, DOE is confident that spent nuclear fuel and high-level radioactive waste could be and would be safely transported to Yucca Mountain. DOE also believes, as the EIS reports, that the potential impacts of transportation would be so low for individuals who live and work along the routes that impacts to individuals would not be discernible. The EIS analytical results are supported by numerous technical and scientific studies (see Appendix J of the EIS) that have been compiled through decades of research and development by DOE and other Federal agencies of the United States, including the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as the International Atomic Energy Agency.

11.2 (454)
Comment - EIS000091 / 0002
We will have more of an influx of people that will come here to live. I'm quite sure of that, and I hope that they do take care of the problems that Amargosa Valley itself, not Nye County and not the State of Nevada, but Amargosa will take care of X amount of influx of people for schooling their children, housing and medical and transportation.

Response
DOE has expanded its socioeconomic discussions in Chapter 3 of the EIS to clarify the magnitude of potential impacts described in Chapters 4 and 6. This discussion includes a projection of baseline parameters through 2035 based on the most recently available information and assumptions. In the Final EIS, DOE provides a quantified estimate, to the extent possible, of school enrollment and changes in law enforcement and public service personnel requirements.

Under the NWPA, the Section 116 impact assistance review process and the EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would not necessarily be limited either by the impacts identified in this EIS or by its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by affected units of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts.

DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures. In addition, as required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training of public safety officials from appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. In addition, Sections 116(a) and 117(c)(5) of the NWPA set forth assistance guidelines covering a number of issues including emergency preparedness and response, state liability arising from accidents, and necessary road upgrading.

11.2 (809)
Comment - EIS000103 / 0007
We cannot allow Lake Barrett to use the term "applied uncertainty" in this project, and all I can say in conclusion [is] that you cannot put classified waste in our mountain, and if you're going to kill us, I want to be paid for it.

Response
While the exact concerns being expressed by the commenter are not entirely clear, the question of compensation for impacts, possibly focused on public health and safety, is apparent. In that regard, Chapter 9 of this EIS addresses the requirements for impact mitigation and compensation. Section 116(c)(2)(A)(i) and (ii) of the NWPA states that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts. If the proposed repository was to become operational, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

11.2 (982)

Comment - EIS000242 / 0003

Finally, there is the question of equity. The risks posed by the spent fuel and the high-level wastes here in Idaho aren't going away. They're going to Nye County. Nye County will bear the burden of risk reduction in each of the counties where the spent fuel and DOE facilities are located, just as they must bear the legacy of more than 300 million curies of radioactivity left from the nuclear weapons testing area.

Once again, Nye County is called upon to host a facility that carries with it an inherent risk and stigma that will last, for all practical purposes, in perpetuity.

How much will one county be told to do in the national interests? Nye County has faithfully served the nation's need for secure facilities for the testing and development of nuclear and conventional weapons, and has received only negligible benefits from these actions.

The soils and water resources have been contaminated. The water resources over large regions have been effectively taken by land withdrawals. The proposed repository at Yucca Mountain will result in further contamination of the county's groundwater resources in additional land withdrawals.

The adverse cumulative impacts associated with the proposed repository must be adequately mitigated. A comprehensive package of compensation and equity offsets must be put forth as part of the proposed action so that the county has the wherewithal to ensure that the long-term health and safety of its residents is protected. Anything less would be quite unfair.

Response

DOE has examined the potential for socioeconomic impacts in Nye County. In addition, the Department has examined potential cumulative impacts from the repository and other past, present, and reasonably foreseeable future actions in the affected region (see Chapter 8 of the EIS). Based on its analysis, DOE believes that it has accounted for actions that could affect Nye County. After publishing the Draft EIS, DOE reviewed cumulative impacts and updated the information in the Final EIS where appropriate. The review included activities at locations with a potential for cumulative impacts on environmental resources (Nevada Test Site, waste disposal sites, Nellis Air Force Range, DOE waste management activities, etc.). DOE reviewed resource plans, environmental impact statements, environmental assessments, strategic plans, consultation documents, tribal meeting records, and other documents of Federal, local, and private agencies and documented potential direct or indirect impacts.

Potential impact mitigation measures, as explained in Chapter 9 of the EIS, are not limited to impacts identified as part of the EIS process. Section 116 (c) of the NWPA establishes a procedure by which affected units of local government, such as Nye County, can prepare and submit a report to DOE documenting likely economic, social, public health and safety, and environmental impacts and can negotiate impact assistance based on matters raised in that report. Section 116(c) commits DOE to participate in that process and to provide assistance consistent with direction from Congress.

Although DOE can measure the public's perception regarding the geologic repository and transportation of spent nuclear fuel and high-level radioactive waste, there is no known method to translate these perceptions into quantifiable impacts. Researchers in the social sciences have not found a way to reliably forecast linkages between perceptions or attitudes stated in surveys and actual human behavior. While stigmatization of Southern Nevada can be envisioned in some scenarios, it is not inevitable. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this EIS. This issue is discussed in Section 2.5.4 and Appendix N of this Final EIS.

11.2 (996)
Comment - EIS000235 / 0002
Assuming that the nation will move the waste to the Yucca Mountain site, such an action will shift risks to Nevada. Many areas of the nation will become risk free. The Draft EIS does not address the disequitable distribution of risk which will attend the Yucca Mountain project. The Final EIS should identify methods for mitigating/compensating Nevadans for bearing the risks that the rest of the nation does not want.

Response
Section 116(c)(2)(A)(i) and (ii) of the NWPA states that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." DOE could give such assistance to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada to document likely economic, social, public health and safety, and environmental impacts. DOE would enter discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

While the EIS estimates environmental impacts, it does not, nor would it be appropriate to, address the equity of shifting risk from one location to another, although it does discuss overall impacts (or risks). Risk to the public for both preclosure operations and monitoring and postclosure performance would be small, as reported in Chapters 4 and 5, respectively.

11.2 (2415)
Comment - EIS000659 / 0001
I recognize that whether we like it or not, nuclear waste may be transported to our community. We need to be provided information and needed protection for our health and safety and get some compensation for our community. I agree with others that have spoken in the previous meeting that I wish that we could have the matter taken care of sooner so that we don't waste so much of our tax money on this issue over so many years.

Response
Section 116(c)(2)(A)(i) and (ii) of the NWPA states that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the Nuclear Waste Policy Act limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

In terms of impact mitigation, under the Nuclear Waste Policy Act, the Section 116 impact assistance review process and this EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would not necessarily be limited either by the impacts identified in this EIS or by its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 that documented likely economic, social, public health and safety, and environmental impacts. If the proposed repository was to become operational, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

11.2 (2720)
Comment - EIS000637 / 0003
We will be crossing the tracks about six or eight times a day. This is going to greatly impact our lives because we will have to schedule our lives around the train schedule. If it's even available to us. Will it be?

We don't want to be stopped at the crossing waiting for the train to go by because our radiation exposure will go up. We will lose spontaneity in our lives and the freedom to make our decisions for our movement in the valley we live in.

We use our hot springs to improve our health, and it is hardly compatible with train cars full of deadly waste sitting in Beowawe and going by in full view from our hot water therapy bath.

This will definitely devaluate our property and ruin us financially. Even if DOE did compensate us, would it be enough to relocate at another hot springs? Hot springs are not replaceable. We would be lucky to ever find another one to buy.

Response
While DOE has identified rail as the preferred mode of transportation both nationally and in Nevada, it has not identified a preferred corridor for a branch rail line or the schedule of waste shipments. The Department is considering five candidate rail corridors, but has not selected one as preferred. Minimizing impacts to current land uses, such as the potential impacts identified by the commenter for a branch rail line in the Carlin Corridor, would be a primary consideration in the selection of a corridor and a specific route alignment in that corridor.

DOE would have several options for locating a rail alignment within the Carlin Corridor should that corridor be selected. Specific information on the tracks of land that would be needed to construct a branch rail line and other specific impacts to property owners would not be available until DOE conducted surveys and environmental reviews. Therefore, DOE would not consider route-specific mitigation actions until it selected a corridor and a specific track alignment in the corridor. Assuming that another EIS would be prepared in support of alignment selection, mitigation actions would be evaluated in that document. DOE would mitigate or compensate landholders in compliance with applicable Federal laws and regulations.

Assuming one cask per shipment, there would be about 9 shipments per week (based on 10,725 total rail shipments under the national mostly rail scenario as noted in Section J.1.2.1 of the EIS).

11.2 (2968)
Comment - EIS000727 / 0013
There is no mention of actions to prevent, to compensate or to mitigate local governments for increased wear and tear and for damage to the highway infrastructure caused by the 220 foot long transport vehicle.

Response
DOE would consult with potentially affected units of local government and consider appropriate support and mitigation measures. Sections 116(c)(2)(A) and 117(c)(5) of the NWPA establish assistance guidelines on a number of issues, including emergency preparedness and response, state liability arising from accidents, and necessary road upgrading.

11.2 (3123)
Comment - EIS000726 / 0015
Health insurance does not cover nuclear exposure. There is no mention of how people are to be provided health care when they become sick.

Response
Illnesses caused by acute direct exposure to radioactive materials from accidents would be the responsibility of the transporter, and the transporter's insurance would cover such incidents. Cancer caused by low-level radiation exposure resulting from accidents probably would not become evident for many years, and would not be distinguishable from other causes of cancer, including naturally occurring radiation. Health insurance probably would not exclude coverage of such health impacts for reasons of nuclear exposure because of the difficulty of attributing a cause to an illness.

11.2 (3125)
Comment - EIS000726 / 0017
There is no mention of compensation or mitigation because of an increase in government services required because of the activity here. There will be an increased need for government inspectors in several different organizations, increased law enforcement, etc. etc.

Response
Based on the analysis in the EIS, DOE does not believe that there would be a substantial increase in need for government services as a result of the proposed repository. Nevertheless, Section 116(c)(2)(A)(i) and (ii) of the NWPA states that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS. A decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts.

As another form of assistance used to address the need for additional services to support the repository program, Payments-Equal-To-Taxes (PETT) are made pursuant to Section 116(c)(3)(A) of the Nuclear Waste Policy Act, which requires the Secretary of Energy to "…grant to the State of Nevada and any affected unit of government, an amount each fiscal year equal to the amount such State or affected unit of government, respectively, would receive if authorized to tax site characterization activities…." These payments, historically and for the future, are determined by estimating the amount of Yucca Mountain Project property, purchases (in and out of the State of Nevada], and business activities (employees) within the jurisdiction of an affected unit of government. Nye County and the State of Nevada have been eligible to receive PETT since commencement of site characterization activities in May 1986. The other affected units of local government include Clark, Lincoln, Esmeralda, Eureka, White Pine, Churchill, Lander, and Mineral Counties in Nevada, and Inyo County, California. Potentially, they have been eligible to receive PETT since the Nuclear Waste Policy Amendments Act was passed in December 1987.

As noted above, DOE acquires data from the Yucca Mountain Project organizations that purchase or acquire property for use in Nevada, have employees in Nevada, or use property in Nevada. These organizations include Federal agencies, national laboratories, and private firms. Not all of these organizations have Federal exemption status, so they pay the appropriate taxes. The purchases (sales and use tax), employees (business tax), and property (property or possessory use tax) of the Yucca Mountain Project organizations that exercise a Federal exemption are subject to the PETT (DIRS 103412-NLCB 1996).

The actual sales and use taxes, property taxes, and Nevada business taxes paid by Yucca Mountain Project organizations from May 1986 through September 2000 have been calculated. These organizations paid sales and use taxes of $2.5 million for purchases made in Clark County, paid property or possessory taxes of about $90,000 in Clark County, and paid the State of Nevada about $810,000 in business taxes (DIRS 156763-YMP 2001). The PETT for sales or use taxes from May 1986 through June 2000 was about $4.4 million for purchases in Clark County. For property taxes, it was about $940,000 in Clark County. About $130,000 was paid to the State in business taxes.

DOE has not and does not intend to make long-term PETT estimates. While the NWPA requires PETT payments, they are not discriminating factors in the EIS decisionmaking process.

If the proposed repository was to become operational, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures. In addition, as required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions DOE would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. Sections 116(c)(2) and 117(c)(5) of the NWPA set forth assistance guidelines covering a number of issues, including emergency preparedness and response, state liability arising from accidents, and necessary road upgrading.

11.2 (5169)
Comment - EIS001910 / 0008
The DEIS does not include information regarding Indian nations and their current and future economic development initiatives. Tribes along potential corridor routes are investing in tribal and joint economic ventures and which facilities will be along highway transportation routes contained in the DEIS. As part of the trust responsibility to ensure protection of economic well-being of Indian nations, the document needs to include a section of what can be done in the event of a radioactive waste transportation accident which impacts an Indian tribe as the mitigation and liability circumstances can be quite different than state and local government considerations.

Response
As required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions DOE would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would institute this training before beginning shipments to the repository. In the event of an incident involving spent nuclear fuel or high-level radioactive waste, the transportation vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities, if requested, to respond to such an incident. However, state and tribal governments have a primary responsibility to respond to and protect the public health and safety in their jurisdictions in accidents involving radioactive materials.

In addition, Sections 116 and 117(c) of the NWPA set forth assistance guidelines covering a number of issues, including possible public health and safety, environmental, social, and economic impacts; ongoing emergency preparedness and response; liability arising from accidents; and necessary road upgrading. Section 118 of the Act authorizes the Secretary of Energy to provide grants to affected Native American tribes to participate in repository-related activities and to enable such tribes to determine potential economic, social, public health and safety, and environmental impacts of a repository on Native American reservations and its residents. Any affected tribe can request such assistance by preparing and submitting a report on the probable economic, social, public health and safety, and environmental impacts. Section 118(b)(3) requires the Secretary to provide financial and technical assistance to any affected Native American tribe that requests it to mitigate the impacts of the development of a repository where there is a site which the Nuclear Regulatory Commission has authorized construction of a repository. If a repository at Yucca Mountain was recommended and approved for development, DOE would enter into discussions with potentially affected Native American tribes and consider appropriate support and mitigation measures.

The Price-Anderson Act provides liability coverage for commercial activities operating under a license from the Nuclear Regulatory Commission and DOE activities by establishing a system of private insurance and Federal indemnification that generally ensures that up to $9.43 billion is available to compensate for damages suffered by the public, from a "nuclear incident," regardless of who causes the damage. Payment would be from government funds or, if public liability arose out of nuclear waste activities funded by the Nuclear Waste Fund (for example, activities at a geologic repository), from that Fund. The liability of all responsible parties is limited to the amount of coverage provided by the Price-Anderson Act system. State and local governments cannot be required to provide any additional compensation. Price-Anderson Act indemnification would apply to the operators of a nuclear waste repository at Yucca Mountain and to transporters of nuclear waste from commercial nuclear utilities and from DOE sites to the repository. The EIS has been revised to include more details about indemnification under the Price-Anderson Act (see discussion in Section M.8.1 of the EIS). The EIS (Section 3.1.6.2) recognizes that tribes are separate entities from state and local governments. In Section 3.1.13 of the EIS, DOE identifies the minority or low-income populations in the State of Nevada in relation to Yucca Mountain and the alternative rail and heavy-haul truck corridors. Section 3.2.2.1.5 acknowledges the presence of Native American communities in at least two of the candidate rail corridors that are under consideration. DOE has also included maps of the routes used in the transportation analysis that show tribal boundaries in relation to the site and the transportation corridors (see Figures in Appendix J.4). Section 6.3.4 addresses environmental justice impacts that could occur in Nevada as a result of the shipment of spent nuclear fuel and high-level radioactive waste to the proposed repository.

Chapter 9 of the EIS, which provides DOE's initial list of mitigation commitments available at this time, describes management actions that DOE would consider to reduce or mitigate adverse impacts to the environment that could occur if it implemented the Proposed Action. If DOE made a decision on a specific mode and route of transportation through Nevada to the repository site, it would perform additional engineering and environmental studies to support detailed designs and additional National Environmental Policy Act reviews that included potential impacts to minority and low-income populations. Along with these studies, the Department would initiate consultations with responsible Federal, State, tribal, and local agencies to gather information and address potential mitigation of impacts.

11.2 (5721)
<u>Comment</u> - EIS010073 / 0010
Page 2-3 - The SDEIS should consider locating titanium drip shields, emplacement pallets and other required off-site manufactured goods in counties near to Yucca Mountain, in part, to mitigate otherwise unmitigable impacts.

<u>Response</u>
DOE has made no decisions with regard to the procurement or manufacture of waste shipping casks, emplacement pallets, or drip shields. Final determinations would be subject to Federal procurement regulations, total need, timing, manufacturing capabilities, and availability of raw materials. DOE assumed for purposes of analysis that existing vendors in Massachusetts, North Carolina, Ohio, Pennsylvania, and Tennessee would supply waste shipping casks and emplacements pallets. However, DOE would not categorically exclude any location as a possible site for repository support functions.

11.2 (5844)
<u>Comment</u> - EIS001845 / 0006
Provide the funding to counties and states to repair roads, bridges and overpasses to compensate for wear and deterioration caused by heavy loads.

<u>Response</u>
Because existing rail and highway systems would be adequate for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain, infrastructure upgrades would not be necessary and therefore are not included in the analysis. Analyses presented in Section 6.3.3 of the EIS describe the DOE assumptions regarding upgrade and maintenance of highways that would be used by heavy-haul trucks if this mode was selected for transportation in Nevada.

At this time, DOE has not identified a preference for a specific rail corridor within Nevada. A preference for a corridor(s) would be identified in consultation with affected stakeholders, if the Yucca Mountain site was approved pursuant to the NWPA.

Sections 116(c) and 117(c)(5) of the NWPA set forth assistance guidelines covering a number of issues, including necessary road upgrading. In addition, Section 116(c)(2)(A)(i) and (ii) states that "the Secretary shall provide financial and technical assistance to [an affected unit of local government or the State of Nevada]… to mitigate the impact on such [an affected unit of local government or the State of Nevada] of the development of [a] repository and the characterization of [the Yucca Mountain] site. Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Any decision to provide assistance under Section 116 would be based in part on the evaluation of a report submitted by an affected unit of local government or the State of Nevada to document likely economic, social, public health and safety, or environmental impacts. If the proposed repository was to become operational, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

11.2 (6142)
<u>Comment</u> - EIS001888 / 0167
[Summary of comments noted by Clark County Nuclear Waste Division staff at various citizens' meetings.]

Others felt that now is the time to go after DOE for mitigation funds.

Response
As indicated in Chapter 9 of the EIS, Section 116(c)(2)(A)(i) and (ii) of the NWPA state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

Under the NWPA, the Section 116 impact assistance review process and this EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would not necessarily be limited either by the impacts identified in this EIS or by its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of a report by an affected unit of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts. DOE would enter into discussions with the State of Nevada and affected units of local government and consider appropriate support and mitigation measures.

Further, as required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions DOE would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. In addition, Sections 116(a) and 117(c)(5) of the NWPA set forth assistance guidelines covering a number of issues including emergency preparedness and response, state liability arising from accidents, and necessary road upgrading.

11.2 (6143)
Comment - EIS001654 / 0031
Page S-62. Management Mitigation Actions

We may have missed it but there does not appear to be any reference in this section or Chapter 9 that considers socioeconomic impact mitigation measures for the proposed action. That may be because the socioeconomic impact analysis was conducted for an extraordinarily large region of influence that included metropolitan Las Vegas and concluded all impacts were negligible. (See NARUC ES-11 for our critique of that approach.)

DOE should consult with appropriate officials within Nevada and Nye County over alternative means of obtaining community support closer to the site than Las Vegas for a period of peak support need during construction and pre-closure phases of the repository use. However, all such infrastructure would be developed just for that period of need and should be removed at the stage when all the waste has been emplaced and support needs are greatly reduced.

A support "base" could be developed under federal government ground rules and some financial support that could serve many of the housing and community support services closer to the site than Las Vegas, yet would not lead to further permanent development near the repository if there is the risk of radiation, however small, over the long-term performance period of the repository.

There are costs and benefits of such a government-managed approach, but they are worth examining together with State and local stakeholders. The dual objective should be:

- Provide some support functions closer to the repository than Las Vegas, yet,

- Not encourage further development in an area which was chosen for being lightly populated

We realize there is already some resentment among some portion of the Nye County area population over "the government" being an intrusion in their lives. We simply suggest that some cooperative government mitigation measures be considered that enable the repository to be built and reduce the burden on present residents. The suggestion is to consider how to best accommodate an influx of increased demands on community services by having them cooperatively managed with federal government assistance. It may not be the complete answer but it is worth considering through cooperative public-private planning.

Response
Throughout the EIS process, DOE has maintained interactions with a number of government agencies and other organizations (see Appendix C of the EIS). The Department has been sensitive to the concerns of the potentially affected units of local government as defined in the NWPA. DOE has offered local governments the opportunity to submit documents providing their perspectives on issues associated with the EIS. In addition, DOE holds formal meetings twice a year with the affected units of local government. These meetings have included descriptions and briefings on a range of issues of interest to local governments. DOE has also held numerous informal meetings with representatives.

DOE has expanded its socioeconomic discussions in Chapter 3 to clarify the magnitude of potential impacts described in Chapters 4 and 6. This discussion includes a projection of baseline parameters through 2035 incorporating the most recently available information and assumptions.

Section 116(c)(2)(A)(i) and (ii) of the NWPA state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the Nuclear Waste Policy Act limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

Under the NWPA, the Section 116 impact assistance review process and the EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would not necessarily be limited either by the impacts identified in this EIS or by its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts. If the proposed repository became operational, DOE would enter into discussions with the State of Nevada and affected units of local government and consider appropriate support and mitigation measures.

11.2 (6144)
Comment - EIS001888 / 0503
[Clark County summary of comments it has received from the public.]

The State of Nevada and Clark County should negotiate a contract to accept the waste at the border in exchange for funding for a technology center at UNLV [University of Nevada, Las Vegas] and UNR [University of Nevada, Reno] and money for elementary to HS [high school] education.

Response
DOE is authorized to consider some forms of compensation as discussed in Chapter 9 of the EIS. The NWPA allows the Secretary of Energy to provide financial assistance to the State of Nevada and any affected unit of local government requesting such assistance to mitigate the impact of the development of a repository and characterization of the site. The State and any affected unit of local government may request such assistance by preparing and submitting a report on the likely economic, social, public health and safety, and environmental impacts.

In addition to this financial assistance, the Secretary is also authorized to grant to the State and any affected unit of local government an amount each fiscal year equal to that amount they would receive if authorized to tax the site characterization, development, and operation of a repository as they would tax non-Federal real property and industrial activities. Payments-Equal-To-Taxes (PETT) are made pursuant to Section 116(c)(3)(A) of the Act, which requires the Secretary of Energy to grant to the State of Nevada and any affected unit of government, an amount each fiscal year equal to the amount such State or affected unit of government, respectively, would receive if authorized to tax site characterization, and repository development and operation activities. These payments, historically and for the future, are determined by estimating the amount of Yucca Mountain Project property, purchases (in and out of the State of Nevada], and business activities (employees) within the jurisdiction of an affected unit of government.

As noted above, DOE acquires data from the Yucca Mountain Project organizations that purchase or acquire property for use in Nevada, have employees in Nevada, or use property in Nevada. These organizations include Federal agencies, national laboratories, and private firms. Not all of these organizations have Federal exemption status, so they pay the appropriate taxes. The purchases (sales and use tax), employees (business tax), and property (property or possessory use tax) of the Yucca Mountain Project organizations that exercise a Federal exemption are subject to the PETT (DIRS 103412-NLCB 1996).

The actual sales and use taxes, property taxes, and Nevada business taxes paid by Yucca Mountain Project organizations from May 1986 through September 2000 have been calculated. These organizations paid sales and use taxes of $2.5 million for purchases made in Clark County, paid property or possessory taxes of about $90,000 in Clark County, and paid the State of Nevada about $810,000 in business taxes (DIRS 156763-YMP 2001). The PETT for sales or use taxes from May 1986 through June 2000 was about $4.4 million for purchases in Clark County. For property taxes, it was about $940,000 in Clark County. About $130,000 was paid to the State of Nevada in business taxes.

Section 171 of the Act authorizes payments to the State of Nevada of $10 million per year prior to the first shipment of waste, $20 million upon the first spent nuclear fuel receipt, and thereafter $20 million per year until closure. However, receipt of this payment waives the right of the State to disapprove the siting of the repository under Title 1 of the Act, and the State of Nevada has not agreed to do this. Nevertheless, assuming the State's notice of disapproval of the site, and if Congress overrode that disapproval, there would be no impediment to the State accepting these funds.

Other forms of compensation, such as funding of a nuclear research facility at University of Nevada, Las Vegas, could be considered, but would require Congressional approval before they could be implemented if they are not otherwise authorized by the NWPA.

11.2 (7191)
<u>Comment</u> - EIS001337 / 0082
Page 2-69 Table 2-6. Comparison of Tables 2-5 and 2-6 suggests that the No-Action Alternative may be more costly to implement than the Preferred Alternative. The information in Table 2-7 suggests that the No Action Alternative is more risky than the Preferred Alternative. Collectively, these tables suggest that the Nation saves money by transferring risks from the 77 sites with waste inventories to Nevada. The savings to the Nation appears to be on the order of $23 to $28 billion. Given this magnitude of potential savings coupled with the transfer of risk to Nevada, the DEIS must discuss the issue of equity between locales where risk will be reduced and where risk will be concentrated. The concept of compensation of those areas to which risk will be concentrated by those areas in which risk will be reduced or eliminated must be discussed within the DEIS. Conceptually, up to 100 percent of the savings between the No Action and Preferred alternatives should be considered as compensation to those areas in which risk will be concentrated.

<u>Response</u>
The EIS does not address the issue of equity as it pertains to risk or compensation for the Proposed Action through transfer of cost savings. It does, however, address the relative impacts of the Proposed Action and No-Action Alternative (see Section 2.4).

While these issues are not directly addressed in the Final EIS, DOE would address mitigation of impacts by entering into discussions with potentially affected units of local government to consider appropriate support and mitigation measures. Section 116(c)(2)(A)(i) and (ii) of the NWPA state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Furthermore, under the NWPA, the Section 116 impact assistance review process and the EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would not necessarily be limited either by the impacts identified in this EIS or by its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 that documented likely economic, social, public health and safety, and environmental impacts.

11.2 (7233)
Comment - EIS001337 / 0120
Page 9-1 Section 9. In general, the treatment of mitigation in the DEIS is entirely insufficient. Many impacts identified within the DEIS have no mitigation measures identified for them at all (i.e., additional school enrollment in Lincoln County due to transportation activities). In preparing the FEIS, DOE needs to identify all impacts described within the DEIS and the FEIS must identify options for mitigation of all impacts.

Contrary to NEPA [National Environment Policy Act], the DEIS contains several proposed mitigation measures which are simply studies or simply describe studies which will lead to identification of mitigation measures. For most impacts identified within the DEIS, but characterized by DOE as non-significant (i.e., population growth in Lincoln County and [the] City of Caliente and related growth in government expenditures), the DEIS simply does not provide any suggested mitigation measures. In completing the FEIS, DOE should evaluate all listed mitigation measures against the types listed above to discern those which are of an unacceptable form under NEPA.

Response
DOE believes it has identified a reasonable range of mitigation measures it would consider for those impacts that could be minimized or avoided through mitigation actions. Because some decisions have yet to be made, such a transportation mode and specific transportation corridor, additional studies would be required and more definitions information on impacts or possible mitigation actions are not available.

Section 114(a)(1) of the NWPA authorizes the Secretary of Energy to determine whether to recommend approval of the Yucca Mountain site to the President for development as a repository for the disposal of spent nuclear fuel and high-level radioactive waste. A comprehensive statement of the basis for the recommendation, including a Final EIS, must accompany such a recommendation. However, because the decision to approve the site rests not with the Secretary, but with the President. DOE does not anticipate issuing a Record of Decision if the Secretary recommends the site to the President. Consequently, DOE does not anticipate issuing a Record of Decision.

DOE regulations (10 CFR 1021.331) require preparation of a Mitigation Action Plan when mitigation measures are identified in a Record of Decision. At this time, DOE has not decided whether it would prepare a Mitigation Action Plan. However, the Yucca Mountain site, if approved in accordance with provisions of the NWPA would be subject to licensing by the Nuclear Regulatory Commission. DOE, in submitting its application to construct and operate the repository, would identify relevant commitments, including those identified in the Final EIS, to the Commission for its consideration, and could reasonably expect a comprehensive set of mitigation measures or conditions of approval to be part of the licensing process.

DOE will enter discussions with potentially affected units of local government and consider appropriate support and mitigation measures. Chapter 9 of the EIS, which provides DOE’s initial list of commitments available at this time, describes management actions that DOE would consider to reduce or mitigate adverse impacts to the environment that could occur if it implemented the Proposed Action. Chapter 9 states that Section 116 of the NWPA requires the Secretary to provide financial and technical assistance to mitigate impacts of the development of a repository and the characterization of the site. The Section 116 mitigation assistance review process and the EIS process are distinct from one another and the implementation of one does not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would not necessarily be limited either by the impacts identified in the EIS or by its findings on such impacts. Beyond the Payments-Equal-to-Taxes program that DOE has implemented under the requirements of Section 116(c)(3), a decision to provide financial and technical assistance under Section 116(c)(2) would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada that documented probable economic, social, public health and safety, and environmental impacts.

11.2 (8259)
Comment - EIS001777 / 0002
You said this afternoon that there was money for states to help them educate people. Hopefully there is money to help people improve their health after having been affected by this nuclear waste. I did not see in my Belleville News Democrat paper – maybe it was – I don't think it was there. I didn't see anything in the paper, so that is another concern I do have. It has affected our health.

Response
As indicated in Chapters 4, 5, 6, and 8 of the EIS, the transport and disposal of spent nuclear fuel and high-level radioactive waste would cause relatively minor impacts to human health.

As required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states and Native American tribes for training public safety officials through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures for safe routine transportation of these materials and for dealing with emergency response situations. DOE would implement this training before beginning shipments to the repository. In the event of an incident involving spent nuclear fuel or high-level radioactive waste, the transportation vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities, if requested, to respond to such an incident. However, state and tribal governments have a primary responsibility to respond to and protect the public health and safety in their jurisdictions in accidents involving radioactive materials. The EIS does not include detailed training and community education plans. State, local, and tribal agencies and governments would develop such plans.

In addition, Section 116(c)(2) of the NWPA requires the Secretary of Energy to provide financial assistance to the State of Nevada and any affected unit of local government requesting such assistance to mitigate the impacts of the development of a repository and characterization of the site. The State and affected units of local government can request such assistance by submitting a report on probable economic, social, public health and safety, and environmental impacts. This could include, for example, needs for public education programs on the probable impacts of a repository that are identified by the State or any affected unit of local government.

The Price-Anderson Act establishes a system of private insurance and Federal indemnification that generally ensures that as much as $9.43 billion is available to compensate for damages suffered by the public from a nuclear incident, regardless of who causes the damage. Price-Anderson Act indemnification would apply to the operators of a nuclear waste repository at Yucca Mountain and to transporters of nuclear waste from commercial and DOE sites to the repository. Payment would be from Federal funds or, if the liability was from activities funded by the Nuclear Waste Fund (for example, activities at a geologic repository), from that Fund. The liability of responsible parties is limited to the amount of coverage provided by the Act. State and local governments cannot be required to provide additional compensation. DOE has revised the EIS to include more details about indemnification under the Price-Anderson Act (see Section M.8).

11.2 (9112)
Comment - EIS001937 / 0004
In light of the controversy in Nevada regarding compensation for individuals who worked at the Nuclear Test Site, Nye County, Nevada, and who may have been exposed to radiation and/or toxic materials during the course of their work at the location, it is entirely appropriate for the public to have their concerns acknowledged. Assurances that every aspect of engineering, and environmental and biomedical safety has been addressed are not reassuring without also acknowledging that possible risks may not currently be known and that a process for addressing possible future damages is being included in the current planning.

With the contemporary examples of hearings addressing claims for compensation for surviving families and individuals affected by nuclear activities sites such as Hanford, Washington and Oak Ridge, Tennessee, among others, it is clear that the process for handling dangerous materials is not adequate at this point in time. Nor is the process for admitting responsibility, identifying potentially responsible parties, and providing health care and/or compensation for those affected by unsafe practices adequate at this point in time.

It may not be appropriate to address these sorts of issues within the draft EIS, but without acknowledging them and identifying where and when these aspects of the project will be addressed, I cannot, in good conscience, affirm any but the No-Action Alternative.

Response
When Congress passed the Nuclear Waste Policy Amendments Act in 1987, it directed DOE to determine if Yucca Mountain would be a suitable site for a repository. Analyses to date indicate that the Yucca Mountain site would be suitable for a repository and that the risk to populations and the environment would likely be small.

While DOE has made every effort to analyze all potential impacts and assess all risks in the near and long terms, it is not able to assess impacts resulting from currently unknown risks. It is equally hard to put in place a process to address such risks. DOE acknowledges that there are uncertainties associated with the Proposed Action. (Section 5.2.4 of the EIS discusses how DOE has addressed this issue.)

DOE is aware of public criticism of its operations, both ongoing and historic. DOE is working to rectify and eliminate adverse environmental impacts from past programs, and working to ensure that current activities are conducted without environmental insult. DOE continues to incorporate lessons learned from past waste management practices, and the knowledge gained from research and development, into new management programs.

DOE is committed to protecting the safety and health of its workers, the public, and the environment. Policy and proper conduct of operations emphasize safety and environmental considerations above other program goals. Furthermore, DOE intends to design, construct, and operate all new facilities in a safe manner, relying on lessons learned from the last 40 years of managing spent nuclear fuel. DOE also is evolving toward greater openness, as demonstrated by the recent releases of information regarding past programs and practices.

11.2 (9306)
Comment - EIS001888 / 0033
Congress, the NRC [Nuclear Regulatory Commission and others will also employ the DEIS as a major source of information on potential program impacts. Therefore, it is important to Clark County, other affected units of government (AULG), and the State of Nevada that the DEIS adheres to NEPA guidelines and accurately and completely describes potential impacts to our communities from Yucca Mountain Program activities.

To the extent that local impacts are not addressed or inadequately addressed in the DEIS, the chances increase that Congress may not consider, or even be aware of, potentially substantive impacts to AULG. Clark County is concerned that impacts not noted in a document required by the NWPA could result in the disallowance of mitigation request even when supported by other documentation. This is a major factor requiring Clark County, Nevada, to strongly object to the DEIS in its present form. To meet the demands of the National Environmental Policy Act (NEPA) the DEIS must characterize and describe potential Yucca Mountain program-related impacts that may affect our communities. To this DOE has failed in this document.

Response
DOE intends to implement the requirements of Sections 180(c) and 116(c) of the NWPA [42 U.S.C. 10175(c) and 10136(c), respectively]. Section 180(c) requires the Secretary of Energy to provide technical assistance and funds to States for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions, transportation of spent nuclear fuel or high-level radioactive waste would occur. The training is required to cover procedures for safe routine transportation and for dealing with emergency response situations.

In addition, and as discussed in Chapter 9 of the EIS, Section 116(c) requires the Secretary to provide financial assistance to the State of Nevada and any affected unit of local government requesting such assistance to mitigate the impacts of the development of a repository and characterization of the site. The State and any affected unit of local government can request such assistance by preparing and submitting a report on the probable economic, social, public health and safety, and environmental impacts. Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the scope of impacts that might be properly considered under Section 116 to the environmental impacts considered in this EIS.

Besides the Payments-Equal-to-Taxes program already implemented pursuant to the requirements of Section 116(c)(3) of the NWPA, any decision to provide financial and technical assistance under Section 116(c) would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116(c)(2) to document likely economic, social, public health and safety, and environmental impacts.

11.2 (9938)
Comment - EIS001888 / 0466
[Clark County summary of comments it has received from the public.]

Local government funding may fall short of what is needed to provide services to the impacted populations.

Response
DOE does not anticipate impacts that would result in shortfalls to local government funding and the provision of community services. However, there are mechanisms in place to assist affected units of local government.

Section 116(c)(2)(A)(i) and (ii) of the NWPA states that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

Under the NWPA, the Section 116 impact assistance review process and this EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would not necessarily be limited either by the impacts identified in this EIS or by its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of requests for assistance from affected units of local government or the State of Nevada pursuant to Section 116 that documented likely economic, social, public health and safety, and environmental impacts. If the proposed repository became operational, DOE would enter into discussions with the State of Nevada and affected units of local government and consider appropriate support and mitigation measures.

After a decision was made regarding the proposed repository and transportation modes and routes, local jurisdictions would be better able to identify the likely economic, social, public health and safety, and environmental impacts that would be the basis for a request for economic assistance. This could include assistance in providing additional medical and emergency response facilities, under Section 116(c) of the NWPA.

11.2 (9989)
Comment - EIS001888 / 0493
[Clark County summary of comments it has received from the public.]

Several commenters believed that the EIS should discuss possible mitigations to offset or compensate negative socioeconomic impacts and provide analysis of how the measures would offset impacts. Suggested methods to mitigate impacts included use of Department policies that would encourage project employees to reside in specific counties, use of union versus non-union labor, or procurements being awarded to local companies. Some commenters requested this discussion should provide all sources of compensation for the diminution of property values caused by property being located in proximity to transportation routes and sources of compensation for takings of business opportunities and property interests which may be caused by perception-based impacts. One commenter stated the EIS should address how the program will achieve acceptable equity and fairness standards for the key affected communities, states, and participants. This analysis should consider acceptance in terms of a burden placed upon state and local governments and citizens.

Response
DOE appreciates the specific suggestions provided in the context regarding the possible mitigation of socioeconomic impacts. With regard to contracts and employment, DOE would continue to award contracts

pursuant to federal regulations but cannot address the issue of union vs. non-union labor. DOE would not involve itself in where employees live, but could, as it has done in the past, provide some support related to where employees live such as the transportation services to the work site.

The Yucca Mountain Site, if approved in accordance with provisions of the NWPA, would be subject to licensing by the Nuclear Regulatory Commission. DOE, in submitting its application to construct and operate the repository to the Commission, would identify relevant commitments, including those identified in the EIS, to the Commission for its consideration, and could reasonably expect a comprehensive set of mitigation measures or conditions of approval to be part of the licensing process. DOE anticipates that the project plan and design would continue to evolve, potentially eliminating the need for some mitigation measures currently under consideration. Chapter 9 of the EIS, which provides DOE's initial list of possible mitigation measures, also identifies DOE-determined impact reduction features, procedures and safeguards; and mitigation measures under consideration for inclusion in the project plan and design. Chapter 9 also identifies ongoing studies that could eventually influence mitigation measures related to the project plan and design. Additionally, there are mechanisms in place for providing financial and technical assistance to potentially affected units of local government and the state of Nevada.

Chapter 9 of the EIS also discusses Section 116(c)(2)(A)(i) and (ii) of the NWPA, which state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the scope of impacts that could be properly considered under Section 116 to the environmental impacts considered in this EIS. A decision to provide assistance under Section 116 would be based on the evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts.

Another issue of interest is the DOE Payments-Equal-To-Taxes Program. Section 116(c)(3)(A) of the NWPA requires the Secretary of Energy to "…grant to the State of Nevada and any affected unit of local government an amount each fiscal year equal to the amount such State or affected unit of local government, respectively, would receive if authorized to tax site characterization activities at such site, and the development and operation of such repository…." The Yucca Mountain Site Characterization Office is responsible for implementing and administering this program for the Yucca Mountain Project. DOE acquires data from the various project-related organizations that purchase or acquire property for use in Nevada, have employees in Nevada, or use property in Nevada. These organizations include Federal agencies, national laboratories, and private firms. The purchases (sales and use tax), employees (business tax), and property (property or possessory use taxes) of the Yucca Mountain Project organizations that exercise a Federal exemption are subject to the Payments-Equal-To-Taxes Program (DIRS 103412-NLCB 1996).

Concerning perception based impacts or stigma, while DOE can measure the publics perception regarding the geologic repository and transportation of spent nuclear fuel and high-level radioactive waste, there is no known method to translate these perceptions into quantifiable impacts. Research in the social sciences have not found a way to reliably forecast linkages between perceptions or attitudes stated in surveys and actual human behavior. While stigmatization of southern Nevada can be envisioned in some scenarios, it is not inevitable. Consequently, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in the EIS. This issue is discussed in Section 2.5.4 and Appendix N of this Final EIS.

With regard to property values and takings, DOE does not have definitive information on specific tracts of land that could be required. However, the Department would be required to use fair market value in the acquisition of real property. The Department must comply with the policies contained in the Uniform Relocation Assistance and Real Property Acquisition Policies Act, Title III, which includes the provision that the Agency (DOE) offer just compensation.

11.2 (9990)
Comment - EIS001888 / 0495
[Clark County summary of comments it has received from the public.]

Many commenters indicated that the EIS and resulting Record of Decision should commit DOE to providing compensation for those communities and individuals negatively impacted (people nearby an accident, those contracting cancer). Commenters specifically indicated that compensation should be provided for: project oversight by Native Americans (all tribes, not just the National Congress of American Indians), State of Nevada and affected counties; peoples suffering radiological exposure above guidelines preparation of transportation (Section 180(c) of the NWPA), including accidents, education, emergency response, medical training and monitoring to communities along transportation routes; potential disruptions (routine, accidents, sabotage) and environmental damage from the construction and operation of rail spurs (Eureka County); health effects, floodplain damage, loss of game habitat/protected species, wetlands, disruption of crop production/marketing/transportation access, disruption of grazing patterns/marketing potential/mining and transportation access, and disruptions to historical rural and agricultural lifestyles; public safety training in local communities, especially affected governments and along highway or [rail] routes; Clark and Nye counties; infrastructure improvements and maintenance; communities and states that are burdened with HLW [high-level radioactive waste] facilities; police and fire protection, the cost of health/accident/disease prevention programs, and participation in worker safety programs.

Response
DOE has identified for consideration mitigation measures that could reduce the potential impacts from the construction, operation and monitoring, and eventual closure of the proposed repository (Section 9.2 of the EIS). Section 9.3 discusses mitigation measures for transportation. Most of the topics raised by the commenter are discussed in Chapter 9. DOE regulations (10 CFR 1021.331) require preparation of a Mitigation Action Plan when mitigation measures are identified in a Record of Decision. At this time DOE has not decided whether or not it would prepare a Mitigation Action Plan. However, the Yucca Mountain site, if approved in accordance with the NWPA, would be subject to licensing by the Nuclear Regulatory Commission. DOE, in submitting an application to construct and operate a repository would identify relevant mitigation measures to the Commission for its consideration, and could reasonably expect a comprehensive set of mitigation measures or conditions of approval to be part of the licensing process.

In addition, Section 116(c)(2)(A)(i) and (ii) of the NWPA states that “the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site.” Such assistance can be given to mitigate likely “economic, social, public health or safety, and environmental impacts.” Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada that documented likely economic, social, public health and safety, or environmental impacts. If the proposed repository was approved, DOE would enter into discussions with the State of Nevada and affected units of governments and consider appropriate support and mitigation measures.

11.2 (10278)
Comment - EIS002203 / 0003
If it’s scientifically based, let’s go with it, but if it’s not, let’s get what we can get out of this whole thing. I mean, we can get a north/south railroad in this state. We can have four-lane highways between Vegas and Reno. We can have a lot of things, rather than trying to ignore the problem and hope it will go away, because it will not go away.

It is here, and for us not to accept money or not to accept land and trade off for what we’re dealing with the government, it’s ludicrous, because we’re going to get it, guys.

Response
If Yucca Mountain was approved as the site for a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste, DOE would initiate discussions with potentially affected units of local government and consider appropriate support and mitigation measures. Further, under the NWPA, the impact assistance review process and the Yucca Mountain Repository EIS process are distinct from each other, and the implementation of one would not depend on the implementation of the other. Thus, the impacts identified in this EIS or its findings on such

impacts would not necessarily limit the provision of assistance under Section 116 of the NWPA. A decision to provide assistance would be based on evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 that documented likely economic, social, public health and safety, and environmental impacts.

11.2 (10478)

<u>Comment</u> - EIS002103 / 0004

Equity concerns. And believe me, there are equity concerns. We haven't pursued the equity concerns. I've got a wish list. There are equity concerns to be considered. The benefits that could be realized at Yucca Mountain if the timing was right, if the folks were right, if the folks were listening. I've got funding to AULG, affected units of local government.

From the nuclear waste fund for local impact of environmental studies to include credible oversight issue funding. Equity entitlement benefits: A world class environmental and energy research center at the University of Nevada; federal funding for a state of the art emergency response program; water right issues for Southern Nevada growth; transition and release of Nevada's federal lands to the state were eighty-six percent federal; funding for Southern Nevada's infrastructure and transportation systems; a railroad line between the north and Southern Nevada; Nevada university research and educational funding; and last but not least, a stewardship trust fund for grants to the state and county [entities] for site and use of YMP [Yucca Mountain Project] as studies conclude, as a repository during emplacement operations and as a monitored study area and as a closure equity.

<u>Response</u>

The Department is authorized to consider some forms of compensation. Section 116(c)(2) of the NWPA requires the Secretary of Energy to provide financial assistance to the State of Nevada and any affected unit of local government requesting such assistance to mitigate the impact of the development of a repository and characterization of the site. The State and any affected unit of local government may request such assistance by preparing and submitting a report on the likely economic, social, public health and safety, and environmental impacts.

In addition to this financial assistance, the Secretary is authorized to grant to the State and any affected unit of local government an amount each fiscal year equal to that amount they would receive if authorized to tax the site characterization, development, and operation of a repository as they would tax non-Federal real property and industrial activities. Payments-Equal-To-Taxes (PETT) are made pursuant to Section 116(c)(3)(A) of the NWPA, which requires the Secretary of Energy to grant to the State of Nevada and any affected unit of government, an amount each fiscal year equal to the amount such State or affected unit of government, respectively, would receive if authorized to tax site characterization activities at such site, and the development and operation of such repository…" These payments, historically and for the future, are determined by estimating the amount of Yucca Mountain Project property, purchases (in and out of the State of Nevada], and business activities (employees) within the jurisdiction of an affected unit of government.

As noted above, DOE acquires data from the Yucca Mountain Project organizations that purchase or acquire property for use in Nevada, have employees in Nevada, or use property in Nevada. These organizations include Federal agencies, national laboratories, and private firms. Not all of these organizations have Federal exemption status, so they pay the appropriate taxes. The purchases (sales and use tax), employees (business tax), and property (property or possessory use tax) of the Yucca Mountain Project organizations that exercise a Federal exemption are subject to the PETT (DIRS 103412-NLCB 1996).

The actual sales and use taxes, property taxes, and Nevada business taxes paid by Yucca Mountain Project organizations from May 1986 through September 2000 have been calculated. These organizations paid sales and use taxes of $2.5 million for purchases made in Clark County, paid property or possessory taxes of about $90,000 in Clark County, and paid the State of Nevada about $810,000 in business taxes (DIRS 156763-YMP 2001). The PETT for sales or use taxes from May 1986 through June 2000 was about $4.4 million for purchases in Clark County. For property taxes, it was about $940,000 in Clark County. About $130,000 was paid to the State of State in business taxes.

While the NWPA requires PETT payments, they are not discriminating factors in the EIS decisionmaking process. Section 171 of the Act also authorizes payments to the State of Nevada of $10 million per year prior to the first shipment of waste, $20 million upon first spent fuel receipt, and thereafter $20 million per year until closure. However, receipt of this payment waives the right of the State to disapprove the siting of the repository under Title 1 of the Act, and the State of Nevada has not agreed to accept these payments. Nonetheless, assuming the State's notice of disapproval of the site, and if the Congress overrode that disapproval, there would be no impediment to the State accepting these funds.

Other forms of compensation, such as funding of a nuclear research facility at the University of Nevada, Las Vegas, could be considered, but would require Congressional approval before they could be implemented if they are not otherwise authorized by the NWPA.

11.2 (10493)
Comment - EIS002105 / 0006
If you accept the fact that in spite of your perhaps personal likes or dislikes of nuclear waste, it will come to Nevada, then what should Nevada receive as compensation for accepting nuclear waste? I would suggest the following minimum consideration: An annual payment to the State treasury to have State of Nevada, that number to be negotiated, needless to say, by our leaders. Nevada to receive all rights to recycling and also the income that would come from the recycling process. Creation of the world's best nuclear research facility at UNLV [University of Nevada, Las Vegas] as a result of having that facility in this area. The Federal Government to assume all liability and cost of management of the test site.

Response
The Department is authorized to consider some forms of compensation. Section 116(c)(2) of the NWPA, requires the Secretary of Energy to provide financial assistance to the State of Nevada and any affected unit of local government requesting such assistance to mitigate the impact of the development of a repository and characterization of the site. The State and any affected unit of local government may request such assistance by preparing and submitting a report on the likely economic, social, public health and safety, and environmental impacts.

Section 171 of the Act also authorizes payments to the State of Nevada of $10 million per year prior to the first shipment of waste, $20 million upon first spent fuel receipt, and thereafter $20 million per year until closure. However, receipt of this payment waives the right of the State to disapprove the siting of the repository under Title 1 of the Act, and the State of Nevada has not agreed to accept these payments. Nonetheless, assuming the State's notice of disapproval of the site, and if Congress overrode that disapproval, there would be no impediment to the State accepting these funds.

Other forms of compensation, such as funding of a nuclear research facility at University of Nevada, Las Vegas, could be considered, but would require Congressional authorization before they could be implemented if they are not otherwise authorized by the Nuclear Waste Policy Act, as amended.

11.2 (10755)
Comment - EIS002145 / 0002
As a state commander of the Veterans of Foreign Wars, I sat in Senator Reid's office and I asked him about the ten million dollars a year that we've been offered, and he said, "Roy, that money is a carrot that you hold in front of a donkey. If we take that money, we give up all our rights to say no." That was a lie. We went from his office to Senator Bryan's office. I ask him the same question. He said, "Roy, there's no money. There never has been." Which one was telling me the truth? As I said, there are liars on both sides. Gentlemen, this is a national problem -- and ladies, I'm sorry. This is a national problem. It's not just our problem.

Response
Section 171 of the NWPA, requires the Secretary of Energy to offer to enter into a benefits agreement with the State of Nevada. Section 171 specifies the benefits schedule – annual payments for a repository before the first receipt of waste of $10 million per year, $20 million on the first spent nuclear fuel receipt, and $20 million per year thereafter until closure of the facility. Section 171 also specifies that a state accepting these benefits waives its rights under Title I to disapprove the recommendation of a site for a repository.

The State of Nevada has chosen to not enter into such an agreement.

11.2 (10805)
Comment - EIS002043 / 0007
In the discussion of the socioeconomic impacts associated with construction of the Caliente (Pg. 6-57) and Carlin (Pg. 6-63) rail route, the DEIS identifies that the annual average number of construction workers would be 500 to 560 and that there would be 5 construction camps. One of the camps would most likely be in the vicinity of Goldfield and would have a significant impact on this community. The EIS needs to address this impact and how it will be mitigated. These mitigation measures could include financial assistance and temporary structures to accommodate the additional workers and their families.

Response
Section 6.3.2.2 of the EIS presents impacts for the rail corridor implementing alternatives including Carlin and Caliente. Mitigation measures that could be adopted to reduce potential impacts associated with the transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain are addressed in Chapter 9 of the EIS. More specific or additional mitigation measures would be identified and implemented if the repository was approved and a particular transportation mode and route were selected.

In addition, Section 116(c)(2)(A)(i) and (ii) of the NWPA state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health or safety, and environmental impacts." Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada that documented likely economic, social, public health and safety, or environmental impacts. If the proposed repository was approved, DOE would enter into discussions with the State of Nevada and affected units of local government and consider appropriate support and mitigation measures.

After a decision was made regarding the proposed repository and transportation modes and routes, local jurisdictions would be better able to identify the likely economic, social, public health and safety, and environmental impacts that would be the basis for a request for economic assistance, which could include assistance in providing temporary housing facilities or other services, under Section 116(c) of the NWPA.

11.2 (11716)
Comment - EIS000601 / 0003
If the repository is placed in Nevada, we need to charge a million dollars a pound.

Response
While this commenter's particular concept of compensation is not directly addressed in the Draft EIS or within the scope of the EIS as established by the NWPA, Chapter 9 of the EIS does address the requirements for impact mitigation and compensation, indicating that Section 116(c)(2)(A)(i) and (ii) of the NWPA state that "the Secretary shall provide financial and technical assistance to the State of Nevada and any affected unit of local government…to mitigate the impact on such State [Nevada] or affected unit of local government of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Within that broad framework, neither Section 116 nor any other provision of the NWPA limits the impacts that are subject to assistance under Section 116 to the environmental impacts considered in this EIS.

Under the NWPA, the Section 116 impact assistance review process and the EIS process are distinct from one another, and the implementation of one would not depend on the implementation of the other. Thus, the provision of assistance under Section 116 would not necessarily be limited either by the impacts identified in this EIS or by its findings on such impacts. Any decision to provide assistance under Section 116 would be based on an evaluation of a report submitted by an affected unit of local government or the State of Nevada pursuant to Section 116 to document likely economic, social, public health and safety, and environmental impacts. DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

11.2 (12501)
Comment - EIS001878 / 0089
The DEIS must also disclose whether the loss or diminution of a water right would be a taking of private property rights requiring compensation under the Constitution of the United States.

Response
The general purpose of this EIS is to analyze the potential for environmental impacts from the Proposed Action to construct, operate and monitor, and eventually close a repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain. The EIS is not the appropriate forum to make determinations on constitutional matters. The EIS discusses the availability of groundwater resources in Section 3.1.4.2. Section 4.1.3.3 addresses the potential for adverse impacts to groundwater, including the potential for impacts to water availability, anticipated from repository construction and operation. Chapter 5 contains a full discussion of the potential for adverse long-term groundwater impacts and analyzes the potential for groundwater contamination thousands of years after the emplacement of spent nuclear fuel and high-level radioactive waste in the proposed repository. The EIS does not address the issue of whether the loss or diminution of any water right would be a taking of private property rights requiring compensation under the Constitution of the United States. Whether such an effect on a water right, if it occurred, would require compensation is a separate legal question that is beyond the purview of the EIS, and would more properly be a matter for consideration by the courts.

DOE Credibility

12. DOE CREDIBILITY

12 (14)
Comment - 11 comments summarized
Commenters stated that DOE is biased toward the nuclear industry and needs an industry success. Thus, the Draft EIS reads as though lobbyists wrote it. Politicians have restricted DOE personnel's freedom to analyze, and DOE should tell Congress that they have made a mistake. Commenters see a conflict of interest in that approval of the repository would allow DOE to dispose of wastes from its own sites, and question the independence of personnel involved in the evaluation process.

Response
The following provisions of the process for evaluating the proposed site at Yucca Mountain provide a strong guarantee of the integrity of the process and the independence and sufficiency of the EIS.

Congress determined through the passage of the Nuclear Waste Policy Act of 1982 that the Federal Government has responsibility to dispose of spent nuclear fuel and high-level radioactive waste, and that primary responsibility for implementing permanent disposal should rest with the Department of Energy. DOE and its predecessor agencies have had general responsibility for governmental programs involving nuclear materials. DOE actions are taken pursuant to the Nuclear Waste Policy Act of 1982 and, thus, are not done to favor any particular industry or group.

As discussed in EIS Section 1.3, the Nuclear Waste Policy Act, as amended (this EIS refers to the amended act as the NWPA) established a process that locates decisionmaking responsibility for the proposed repository outside DOE and makes DOE more accountable for its actions. Decisionmaking power over the proposal rests first with the President, then with the Governor or Legislature of the State of Nevada, potentially Congress (assuming the President decides to approve and there is a notice of disapproval from the Governor or the legislature of Nevada), and ultimately with the Nuclear Regulatory Commission. DOE could construct, operate and monitor, and eventually close a repository only in accordance with licensing and continuing regulation by the Nuclear Regulatory Commission and under standards developed by the Environmental Protection Agency to protect the public from releases from radioactive material.

The Nuclear Waste Policy Act of 1982 also established an independent review body, the Nuclear Waste Technical Review Board (see Section 1.3.2.1 of the EIS). The Nuclear Waste Technical Review Board consists of scientists and engineers with distinguished careers in disciplines within the range appropriate for the repository proposal, and who are independent of DOE. The Nuclear Waste Technical Review Board has power to investigate DOE's activities with regard to the repository, determine the technical and scientific validity of DOE's activities, and issue independent reports stating their conclusions to Congress and to the Secretary of Energy.

The EIS process for the proposed Yucca Mountain Repository has been structured to provide detached input to the EIS and public scrutiny of the EIS results. In addition, DOE retained a contractor not involved previously in the Yucca Mountain Project to assist in preparing the EIS and, thus, offer a means to evaluate independently the available information from the site characterization program, design information, and information and opinions offered by the public, state and local government, and Native American tribes. Public hearings and public review of the Draft EIS and the Supplement to the Draft EIS provided interested parties with the opportunity to examine the assumptions, analyses, and conclusions in those draft documents, as well as the opportunity to provide input on how these issues and other concerns should be addressed in the Final EIS.

Under the Nuclear Waste Policy Act of 1982 or any other law, DOE has no independent power to approve a site or to build and operate a repository at Yucca Mountain. The NWPA established a time sequence that places all approval and licensing decisions in the future and ensures that the EIS would be completed before any such decisions could be made. No decisions on matters within the scope of this EIS have been made.

If DOE determined that the Yucca Mountain site was not suitable, the NWPA empowers the Secretary of Energy to stop the site evaluation, order restoration of the site, and report to Congress on other recommended approaches for disposal of the materials (see Chapter 7 of the EIS for more details). In other words, the Secretary of Energy and DOE cannot approve the site but can reject it.

DOE believes that this EIS was prepared using the best available data and methods of analysis. Consistent with National Environmental Policy Act and the NWPA, DOE has prepared the EIS to provide a site-specific assessment of the Proposed Action.

Comment - 111 comments summarized

Commenters indicated that it is difficult to trust the people (that is, DOE) who created the situation (radioactive waste contamination) and who now propose scenarios for cleaning it up. They further stated that even if DOE had sound plans, the plans would not work and DOE would not be accountable for its actions (for example, conduct a satisfactory performance confirmation program).

Commenters expressed a general lack of trust in DOE and its contractors based on past mistakes and flaws in various programs. Commenters accused DOE of secrecy, misinformation, lack of reliable documentation and recordkeeping, performance of nuclear experiments on humans, dishonesty, and lack of ethics or regard for human health and the environment. Commenters alleged that DOE has not been responsive to public concerns and has usurped the rights of the people. Commenters expressed the opinion that DOE has not shown recent or historic concern for or interest in the public, future generations, workers, or the environment. Commenters cited both specific and general adverse impacts from past DOE programs and operations, and charged that DOE has demonstrated general abuse of responsibility.

Response

For more than 50 years, the U.S. Government and various commercial organizations have engaged in nuclear activities for defense, power generation, and related purposes. These activities have resulted in the production of spent nuclear fuel and high-level radioactive waste, which are long-lived, highly radioactive materials. Management and disposition of these materials in a manner that ensures that the materials do not adversely affect the public health and safety and the environment for this or future generations poses challenging long-term problems.

DOE and its predecessor agencies have had general responsibility for Federal programs involving nuclear materials. Although many of these programs were in the national interest, their legacy materials must be isolated and monitored in the interest of public safety.

DOE is aware of public criticisms of its operations, both ongoing and historic, and is working to rectify and eliminate adverse environmental impacts from past programs, and to ensure that it conducts its current activities without environmental insult. DOE continues to incorporate lessons learned from past waste management practices and the knowledge gained from research and development in new management programs.

DOE is committed to protecting the safety and health of its workers, the public, and the environment. Policy and conduct of operations emphasize safety and environmental considerations above other goals. In fact, DOE has established performance monitoring and site stewardship programs that accomplish multiple goals related to the Department's obligation to protect public health and safety and the environment. Furthermore, DOE intends to design, construct, and operate facilities in a safe manner, relying on lessons learned from the last 40 years of spent nuclear fuel management. In addition, DOE is evolving toward greater openness, as demonstrated by recent releases of information regarding past programs and practices, such as those associated with worker exposures to hazardous and radioactive materials.

Several aspects of the overall process created by the NWPA have had the effect of locating decisionmaking responsibility for the proposed repository outside DOE. Decisionmaking power over the proposal rests (in hierarchical order) with the President, the Governor or Legislature of the State of Nevada, potentially Congress (assuming a notice of disapproval from the Governor or the Legislature of Nevada), and ultimately with the Nuclear Regulatory Commission as the licensing authority. While DOE would construct, operate and monitor, and eventually close a repository, it could do so only in accordance with licensing and continuing regulation by the Nuclear Regulatory Commission and under standards developed by the Environmental Protection Agency. DOE would be held accountable for its actions in the construction and operation of a repository.

The NWPA establishes an independent review body, the Nuclear Waste Technical Review Board (see Section 1.3.2.1 of the EIS). The Board consists of distinguished scientists and engineers with expertise in the disciplines required to ensure safe operation of the proposed repository. As an authority independent of DOE, the Board has power to investigate DOE activities regarding the repository, determine the technical and scientific validity of DOE activities, and issue independent reports and conclusions to Congress and the Secretary of Energy. The Board has consistently shown confidence in, and respect for, the opponents of the project and provided a forum for opponents to voice their views and have DOE address them.

In response to the lack of trust expressed by some members of the public, the Secretary of Energy places great emphasis on openness and public involvement. It is DOE policy that the business of the Department must be open to the full view of those whom it serves, consistent with applicable laws, regulations, and contracts. This policy challenges the Department and its contractors to perform to a new standard of openness and service. DOE will incorporate public input in its decisions when appropriate and feasible, and will provide feedback to the public on its reasoning.

For example, the EIS process for the proposed Yucca Mountain Repository has been structured to provide input to the EIS and public scrutiny of the EIS results. Public hearings and public review of the Draft EIS and the Supplement to the Draft EIS by public stakeholders, agencies, Tribal Nations, and others during the comment periods comprise an important part of the process. The review periods provided interested parties the opportunity to examine the assumptions, analyses, and conclusions in the EIS draft and the Supplement and the opportunity to provide input on how DOE should address these issues and other concerns in the Final EIS. This process improves the quality of the EIS and is crucial to the decisionmaking process.

DOE provided the public, agencies, Tribal Nations, and others with the Draft EIS, Supplement to the Draft EIS, and supporting documents and data. During the public comment periods, the Department made these documents available in its reading rooms and other public locations throughout the country. Information on the availability of the references cited in the Final EIS can be found in the DOE Reading Rooms listed in Appendix D or on the Internet at the Yucca Mountain Project web site at *http://www.ymp.gov*.

Commenters had the opportunity to send written comments, make oral comments, and submit facsimile comments over a toll-free telephone line, and to attend one or more public hearings in locations across the United States. DOE has considered all issues raised during the public comment periods.

12 (1399)
Comment - EIS000294 / 0005
The assumptions that are in this EIS are completely cooked, they're completely massaged. And even then, the doses that are pictured in this EIS exceed every possible radiation limit.

Response
DOE did not write the EIS or base its analyses on a manipulation of information, data, and assumptions. DOE prepared this assessment of the potential environmental impacts associated with the Proposed Action and the No-Action Alternative in accordance with the National Environmental Policy Act, the Council on Environmental Quality and Departmental implementing regulations, and various guidance. Further, the Department has provided the EIS and its supporting information, data, and analyses to the public for review. The health and safety analyses described in Chapters 4 and 5 indicate that the impacts of the Proposed Action would be within applicable standards and limits.

12 (1614)
Comment - EIS000104 / 0002
[A DOE contractor] just finally admitted that they used this dry cask scenario that everybody's been talking about to build it out of six-inch thick stainless steel, and they finally admitted that it cracked open. The reason they admitted it cracked open was because when they very foolishly tried to bolt it shut, the thing exploded. It had hydrogen gas in there. When I talked to the [contractor] people and I said, "Hey, what is this? You guys are supposed to be the technical experts on this job," and what they said was, "well, we can't be a technical expert because DOE doesn't have anybody that can understand what we're doing, and so every time we try to do something, we get an argument, so we just give up and take the paycheck and go." That's a fatal flaw through this whole project and that needs to be in the EIS. I got a similar answer from [another contractor]...Another example of the problems that we have is this cask that split open violates the Nelson limits. The Nelson limits -- I've asked for months from the DOE and Yucca

Mountain to tell me what they are, and they can't find it. NRC doesn't have anybody that can find them. The National Academy of Science doesn't have anybody that can find them, and this kind of thing needs to be addressed in the EIS that we have fatal flaws in the -- in the whole system and under the NEPA laws, that's required to be in there up front for the public. The people that use the Nelson limits that by the way predicted this cask would crack in two to six months, so they failed their -- either they covered it up for the last four and a half years or the Nelson limits failed. The thing supposedly lasted five years before it split open. The people that know about these Nelson limits are industrial engineers, chemical engineers, mechanical engineers, people that work in industry, and that's only about a third of the engineers in the country. Two-thirds work for the government and for government contractors, so you won't find anybody in your contractors, you won't find anybody in the government that even knows what I'm talking about. That's a fatal flaw in this whole process, and it violates the NEPA laws because anything other than having somebody who knows what they're doing is pure speculation, and that also needs to be mentioned in the EIS.

Response
DOE is unsure what this comment meant by the "Nelson limits," although it appears that the issue may reflect a general concern regarding casks rather than a specific critique of EIS information. DOE believes (1) that the EIS information regarding casks is accurate and (2) that casks used in connection with the proposed action would both meet applicable standards and be protective of public health and safety.

12 (7259)
Comment - EIS001832 / 0006
In a traditional DEIS that compares a number of alternatives to a proposed action, as long as each category of impacts is characterized in common terminology, the reader is given a relative yardstick by which to evaluate alternatives against one another. However, this DEIS is not, and can not, be a comparison of multiple alternatives. This DEIS is unique in evaluating, as mandated by Congress, the environmental impacts of the building and operating a repository at Yucca Mountain and the impacts of not taking that action. Accordingly, DOE should provide some measure of comparison of the environmental impacts in order that the postulated impacts can be better understood as they relate to the decision-making process.

We recommend that DOE facilitate the synthesis of results by using common terminology to depict each of the 13 categories of impact (i.e. low - moderate -high; 0 to 10 with 10 being most severe; or some other method). This scale should be defined in commonly understood terms. Examples should be provided of things that regularly occur in our world and where they fit onto each segment of the scale. For radiological risks, DOE should provide comparisons to both other radiological and nonradiological risks. Care should be taken to include facilities and activities that have common characteristics with Yucca Mountain wherever possible (i.e., where there is a broad societal need for action to be taken). Secondly, having applied a common scale to all impacts, DOE should then summarize the results in a manner that places Yucca Mountain risks in perspective.

Response
DOE believes that the discussion of impacts is forthright and informative, both for the public and for decisionmakers.

The EIS quantifies impacts on environmental resources to the extent practicable. These impacts are then compared to relevant regulatory standards as appropriate to provide perspective on the significance of the impact. For example, for radiological impacts, the EIS presents information in terms of a dose to the maximally exposed individual and to populations. These numbers are then compared to the relevant standard. The EIS also presents expected health consequences from dose rates. To aid understanding, Appendix F of the EIS provides a human health impacts primer with more analytical details.

While the use of a numeric scale such as suggested by the commenter could have some utility, it also creates a potential for confusion. Different readers might attach different importance to impacts in certain areas. The use of a common scale in different disciplines could result in adding totals for impacts in different areas, although a 3 in aesthetic impacts might not have equal weight with a 3 in human health impacts.

12 (7276)
Comment - EIS001106 / 0018
Ethics and principles: The YMP DEIS is indifferent to the principles of environmental and moral ethics expressed in the National Environmental Policy Act. Also lacking is a unifying environmental goal and a strategy for the DOE to achieve it for the YMP. A commitment on the part of the DOE is needed to assure the protection of environmental quality and the achievement of moral and civil ethical principles. This includes openness and informing all of the stakeholders in the YMP and related regional activities about the full nature of costs and benefits of the Yucca Mountain Program.

Response
While the NWPA can be the basis for establishing goals and overall strategy, the EIS provides a comprehensive assessment of environmental issues and addresses the potential mitigation of unavoidable impacts, factors in the views of Native Americans, and is sensitive to the concerns raised by the public through numerous comments and opposing viewpoints.

A major emphasis of the EIS process is to promote public awareness of the proposed actions and provide opportunities for public involvement. The actions that DOE has taken to facilitate and encourage public participation in the EIS process are described in Section 1.5.1 of the EIS. DOE's proposal to construct and operate a geologic repository at Yucca Mountain for the disposal of commercially generated spent nuclear fuel and DOE spent nuclear fuel and high-level radioactive waste is consistent with the NWPA.

From early in the Yucca Mountain Project, the Nuclear Waste Technical Review Board has performed independent reviews of the project, as mandated by the Nuclear Waste Policy of 1982. The Board has consistently provided a powerful forum for stakeholders to express and to have DOE address their views. The public comment period for the Draft EIS was extended beyond that required by DOE's National Environmental Policy Act implementing regulations to allow stakeholders sufficient time for independent review.

DOE's objectives are transparent and are clearly stated at the beginning of the EIS. Congress has identified in the NWPA a national need to deal with the problems associated with spent nuclear fuel and high-level radioactive waste. Congress has identified a potential solution, disposal of these materials at Yucca Mountain in the NWPA. Congress has established DOE's objectives: to evaluate the suitability of the site, to prepare a recommendation for the President, and to prepare an EIS to accompany the recommendation.

12 (7283)
Comment - EIS001106 / 0019
The intent of the NEPA [National Environmental Policy Act] process is that unbiased environmental documents be prepared before a proposed action is tailored. Because of the legislative nature of the Yucca Mountain Project and its exposure to powerful external and internal interests, this intent of NEPA has not been possible. In particular, the DOE has violated the ethical principle of avoiding biases in the conduct of EIA [Environmental Impact Assessment] for the YMP. To avoid these faults the YMP DEIS should adopt both life cycle EIA and regional strategic EIA on a regional basis.

Response
DOE disagrees with the comment's supposition that its National Environmental Policy Act (NEPA) evaluation of the proposed repository at Yucca Mountain is biased. DOE estimated the long-term costs of the repository and did so consistent with the long-term strategic goals established by the NWPA. DOE has attempted to avoid bias by considering views that are inconsistent with its own, and by discussing the use of incomplete and unavailable information – the uncertainties in the analyses. For example, in Section 2.5 of the EIS, DOE acknowledges the receipt of input from a number of organizations that in some cases departs from its own interpretations. DOE reviewed this input and evaluated findings for inclusion in the EIS. If the information represented a substantive view, DOE made efforts to incorporate that view in the EIS and identify its sources. If DOE did not incorporate the information, it attempted to identify and address the opposing view. Nevertheless, DOE provisions of the process for evaluating the Yucca Mountain site provide a strong guarantee of the integrity of the process and the independence and sufficiency of the EIS.

Furthermore, the Nuclear Waste Policy Act of 1982 established an independent review body, the Nuclear Waste Technical Review Board, which consists of scientists and engineers with distinguished careers in disciplines appropriate for the repository proposal. The Board investigates DOE activities, determines their technical and scientific validity, and issues independent reports stating their conclusions to Congress and to the Secretary of Energy.

Decisionmaking for the project rests in the future, first with the President, and then with the Governor and Legislature of Nevada and with Congress. The Nuclear Regulatory Commission would have to issue a construction authorization before DOE could proceed. DOE does not have independent authority under the Nuclear Waste Policy Act or any other law to approve a site, or to build and operate a repository for spent nuclear fuel and high-level radioactive waste. Therefore, if the repository was approved and licensed, DOE would construct and operate it, but only in accordance with a license issued by the Nuclear Regulatory Commission and under standards developed by the Environmental Protection Agency.

12 (8838)
Comment - EIS000216 / 0009
We believe that we can rely on the expertise of DOE to provide the details of the repository design, the Nuclear Waste Technical Review Board to provide impartial oversight of the program, and the Nuclear Regulatory Commission to protect the public health and safety.

Response
Thank you for your comment.

12 (10354)
Comment - EIS001371 / 0002
There is an irony in the Department of Energy's (DOE) promotion of the transport of high level radioactive waste on trains and trucks to the western United States in the 1990's when they officially discouraged transport of the low level radioactive waste at DOE's Weldon Spring Sites Remedial Action Project in St. Charles County in the 1980's. When the citizens' organization pressed for removal of the Weldon Spring radioactive wastes DOE officials told the citizens "it would be a greater risk to the St. Charles County communities and others all along the route to wherever it would be taken by train or truck transport." They say it would be far safer to keep it where it was already located.

Response
DOE is following its mandates under the NWPA and is only evaluating transportation of waste to the proposed repository at Yucca Mountain. The NWPA establishes a process leading to a decision by the Secretary of Energy on whether to recommend that the President approve Yucca Mountain for development as a geologic repository. In the Act, Congress recognized the permanent disposal of spent nuclear fuel and high-level radioactive waste as a national problem. Congress focused national efforts on deep geologic disposal and directed DOE to evaluate whether Yucca Mountain is a suitable candidate site for a repository. The EIS analyzes the potential impacts of transporting spent nuclear fuel and high-level radioactive waste to the repository.

12 (10489)
Comment - EIS002138 / 0004
This DEIS lists the materials, table A-8, volume 2, page A-17 to be stored. They are careful on this table not to list the half-life of the elements. This is an example how DOE presents a report which on the surface the general public receives a feeling that it must be good. Look how thick it is. DOE is very careful not to blatantly lie, but they come very close. I guess in a legal sense, DOE is puffing.

Response
The half-lives of the elements are presented in Table A-8 of the Final EIS. In Section 5.1 of the EIS, DOE acknowledges that there are more than 200 radionuclides in the waste inventory that it could dispose of at Yucca Mountain. However, to perform impact calculations efficiently, the EIS evaluated a reduced number of radionuclides as explained in Appendix I. The EIS analysis of long-term performance focused on the nine radionuclides that would contribute most to total radiological dose, as calculated in the performance assessment models. Table 5-2 lists the average radionuclide inventory per waste package for the performance assessment calculations together with their half-lives.

The Nuclear Waste Policy Act of 1982 established an independent review body, the Nuclear Waste Technical Review Board, which consists of scientists and engineers with distinguished careers in disciplines appropriate for the repository proposal. The Board investigates DOE activities, determines their technical and scientific validity, and issues independent reports stating their conclusions to Congress and to the Secretary of Energy.

12 (10754)
Comment - EIS002145 / 0001
I believe everybody here, whether they're pro or con, should read this article. It's very interesting. I believe that -- and I've heard a lot of people say DOE is full of liars. Well, both sides have their share of liars, the pro and the con.

Response
Thank you for your comment.

12 (11184)
Comment - EIS000249 / 0003
And as I look at Yucca Mountain and the moving target as it were of what its mission is, and how it is going to accomplish it, and I look at the people who are going to receive this waste, and the parties that are engaged in this process, I am beginning to have the feeling that we are having a much bigger Pit Nine rolling down the tracks.

Response
DOE acknowledges the commenter's views. While there is no doubting the scale and complexity of the proposed Yucca Mountain Repository, there is no basis for a comparison with the low-level waste disposal problems of Pit Nine at the Idaho National Engineering and Environmental Laboratory. The disposal strategies and waste forms are entirely different. The disposal procedure for a repository at Yucca Mountain and the nature of the waste inventory are stated in Section 2.1 and Appendix A, respectively, of the EIS. Appendix A reflects DOE's best estimates of the volumes and characteristics of all wastes that would be transported to the repository, as well as details on the sources of the material, present storage conditions, and final disposal forms.

Comment - EIS001887 / 0402
Actions proposed and taken by the U.S. government often are contrary to the aims and intent of NEPA [National Environmental Policy Act]. Among the reasons is the indifference of civil servants and agency bureaucrats to matters of ethics and principles. Another reason is ignorance of the environment, the concepts of sustainability and ecosystem management, and the pervasiveness of pollution. Most important is the lack in some federal agencies of unifying goals and strategies for perceiving, pursuing, and realizing NEPA's principles and long-range purposes. The bureaucrats within federal agencies need to be seriously and effectively committed to assuring that high qualities for the environment and for productive and healthful personal and civic life are achieved and sustained. This includes a responsibility to inform the public and interest groups of what is at stake and how adverse environmental consequences can be averted over time. Above all, it means that government agencies and bureaucrats need to be honest with the public about the true nature and ultimate balance of costs and benefits from proposed actions.

Response
NEPA does not prohibit activities that harm the environment; rather, it requires Federal agencies to disclose the extent of such environmental harm, and environmental benefits, to the public and to agency decisionmakers. Consistent with NEPA, DOE has done so in its presentation of potential environmental impacts in the EIS, and through the public comment process.

The EIS process has been structured to provide detached input to the EIS and public scrutiny of the EIS results. An independent contractor was selected to assist DOE in preparing this EIS. Several independent assessments of the EIS have been performed to validate its results. Public hearings and public review of the Draft EIS and the Supplement of the Draft EIS provided interested parties including opponents and proponents of the Proposed Action with the opportunity to examine the assumptions, analyses, and conclusions in these documents and the opportunity to provide input on how these issues and other concerns should be addressed in the Final EIS.

DOE believes that it has assembled a well-trained, ethical, and independent team of experts to prepare the EIS. Chapter 13 lists preparers and their expertise.

DOE's objectives are transparent and are clearly stated at the outset of the EIS. Congress has identified in the NWPA a national need to deal with the problems associated with spent nuclear fuel and high-level radioactive waste. Congress has also identified a potential solution, disposal of these materials at Yucca Mountain. Congress has established DOE's objectives: to evaluate the suitability of the site, to prepare a recommendation for the President, and to prepare an EIS to accompany the recommendation.

Comment - EIS001887 / 0403
The procedural requirements of NEPA [National Environmental Policy Act] are meant to force attention to the Act's purpose of producing environmental documents for the NEPA process through application of the discipline of EIA [Environmental Impact Assessment]. Thus, EIA is to be conducted by federal agencies before strategic decisions about a project have been made and not simply tailored to fit the project once a decision has been made to proceed with the action. In this context, NEPA is better served if environmental documentation is based on life-cycle EIA. This approach addresses a project's full life cycle from cradle to grave, including the fate of all pollutants and residuals and the full social, economic, and resource implications. NEPA also is better served when EIA is conducted in a strategic format that coordinates similar actions over time in a regional context. The intent of the NEPA process is that unbiased environmental documents be prepared before a proposed action is tailored. The information and insights resulting from the EIA process is meant to be integrated into the final design and implementation of the action. Because of the legislative nature of the YMP [Yucca Mountain Project] and its exposure to powerful external and internal interests, this intent of NEPA has not been possible. In particular, DOE has violated the ethical principle of avoiding biases in the conduct of EIA for the YMP. To avoid these faults, the YMP DEIS should adopt both life cycle EIA and strategic EIA on a regional basis.

Response
From this comment, DOE assumes that a "cradle-to-grave" approach would require consideration and analysis of the entire nuclear waste cycle, from production of nuclear fuel and associated waste to its ultimate disposal as spent nuclear fuel and high-level radioactive waste. The National Environmental Policy Act and implementing regulations require an EIS to evaluate the direct and indirect impacts of an agency's proposal and alternatives to that proposal, as well as impacts from connected or similar actions. In the context of the Proposed Action to construct, operate and monitor, and eventually close a repository at Yucca Mountain, analyses related to the production of nuclear fuel are not connected to a decision on the development of a repository or related to the implementation of such an action. Furthermore, other DOE EISs have addressed portions of the nuclear fuel cycle on a programmatic or project-specific basis.

As suggested by this comment, Chapter 8 of the EIS considers the potential for cumulative impacts in the region. The analysis considered past, present and reasonably foreseeable future activities that could occur in the same time and geographic vicinity as the Proposed Action.

DOE disagrees with the comment's supposition that DOE wrote the EIS to support previously made decisions. Decisionmaking for the project rests in the future, first with the President, and then with the Governor and Legislature of Nevada and Congress. The Nuclear Regulatory Commission would need to issue a construction authorization before DOE could proceed. DOE does not have independent authority under the Nuclear Waste Policy Act or any other law to approve a site, or to build and operate a repository for spent nuclear fuel and high-level radioactive waste. Therefore, if the repository was approved and licensed, DOE would construct and operate it, but only in accordance with a license issued by the Nuclear Regulatory Commission and under standards developed by the Environmental Protection Agency.

DOE has attempted to avoid bias by considering views that are inconsistent with its own, and by discussing the use of incomplete and unavailable information – the uncertainties in the analyses. For example, in Section 2.5 of the EIS, DOE acknowledges the receipt of input from a number of organizations that in some cases departs from its own interpretations. DOE reviewed this input and evaluated findings for inclusion in the EIS. If the information represented a substantive view, DOE made efforts to incorporate that view in the EIS and identify its sources. If the information was not incorporated in the analyses, DOE attempted to identify and address the opposing view.

Nevertheless, provisions of the process for evaluating the Yucca Mountain site provide a strong guarantee of the integrity of the process and the independence and sufficiency of the EIS.

Furthermore, the Nuclear Waste Policy Act of 1982 established an independent review body, the Nuclear Waste Technical Review Board, which consists of scientists and engineers with distinguished careers in disciplines appropriate for the repository proposal, and who are independent of DOE. The Board investigates DOE activities, determines their technical and scientific validity, and issues independent reports stating their conclusions to Congress and to the Secretary of Energy.

12 (12104)
Comment - EIS001887 / 0404
NEPA [National Environmental Policy Act] is meant to further environmental values and ethics present in our society that are supported by a majority of citizens. The values reflect concern about long-term physical environmental quality and the quality of the human environment in the face of material growth. Under NEPA, the process of EIA [Environmental Impact Assessment] also is meant to enhance the congruence of future actions with broad environmental goals that protect the environment for future generations. This means providing assurance of the widest range of beneficial uses of the environment without degradation, risk to health, and other undesirable consequences. A particular loser in the NEPA process for the YMP [Yucca Mountain Project] has been long-term quality of the human environment regarding future generations. The DEIS in particular condones sacrificing the Yucca Mountain region for the future. The inherent biases of those responsible for the DEIS weigh heavy on the project because independent outside review of the EIA process was limited. Those opposed to the YMP were viewed by DOE with a lack of confidence when the opposite situation was in fact the case. This also was true of the contractors who executed EIA for the YMP and compromised their ethics and objectivity on behalf of DOE.

To achieve good EIA as intended by NEPA, expertise must be assembled and allowed by agency bureaucrats to remain involved throughout the entire process and to participate as part of an interdisciplinary team. An agency's legal staff also should be part of the team and should be involved from start to finish with the NEPA process. Strategies and tactics taken by one component of the team must be understood and agreed to by the entire team. Participants must be educated in the substantive purposes of NEPA as well as in the procedural ones, and they must be trained properly to write satisfactory impact statements that all stakeholder groups can understand. Above all else, a good sense of professional ethics must be practiced by all participants in the EIA process. As a whole, DOE has a poor record regarding environmental ethics, an indifference to environmental quality, and lacks openness to the public. The YMP is being conducted in this characteristic manner, where civil servants and bureaucrats ignore the higher precept of NEPA and environmental ethics. The DEIS includes no sense of unifying goals and strategies for achieving national environmental policy and informing and educating people about DOE's objectives which remain hidden and unopen.

Response
The analysis in Chapter 5 of the EIS concludes that the Proposed Action would not prove detrimental to long-term environmental quality and that regional productivity and viability would not be affected.

DOE does not agree with contentions that it is biased. Nevertheless, DOE notes that provisions of the process for evaluating the Yucca Mountain site provide a strong guarantee of the integrity of the process and the independence and sufficiency of the EIS.

The Nuclear Waste Policy Act of 1982 established an independent review body, the Nuclear Waste Technical Review Board. The Board consists of scientists and engineers with distinguished careers in disciplines within the range appropriate for the repository proposal, and who are who are independent of DOE. The Board has power to investigate DOE activities in regard to the repository, determine the technical and scientific validity of DOE activities, and to issue independent reports stating their conclusions to Congress and to the Secretary of Energy.

The EIS process has been structured to provide detached input to the EIS and public scrutiny of the EIS results. An independent contractor was selected to assist DOE in preparing this EIS. Several independent assessments of the EIS have been performed to validate its results. Public hearings and public review of the Draft EIS and the Supplement to the Draft EIS provided interested parties including opponents and proponents of the Proposed Action with the opportunity to examine the assumptions, analyses, and conclusions in these documents and the opportunity to provide input on how these issues and other concerns should be addressed in the Final EIS.

If DOE determined that the Yucca Mountain site was not suitable, the NWPA empowers the Secretary of Energy to stop the site evaluation, order restoration of the site, and report to Congress on other recommended approaches for disposal of the materials. In other words, the Secretary of Energy and DOE cannot approve the site but can reject it.

DOE believes that it has assembled a well-trained, ethical, and independent team of experts to prepare the EIS. Chapter 13 lists preparers and their expertise.

DOE's objectives are transparent and are clearly stated at the outset of the EIS. Congress has identified in the NWPA a national need to deal with the problems associated with spent nuclear fuel and high-level radioactive waste. Congress has also identified a potential solution, disposal of these materials at Yucca Mountain. Congress has established DOE's objectives: To evaluate the suitability of the site, to prepare a recommendation for the President, and to prepare an EIS to accompany the recommendation.

Comments Outside the Scope of the Environmental Impact Statement and the Yucca Mountain Site Characterization Project

13. COMMENTS OUTSIDE THE SCOPE OF THE ENVIRONMENTAL IMPACT STATEMENT AND THE YUCCA MOUNTAIN SITE CHARACTERIZATION PROJECT

13 (5)
Comment - 213 comments summarized
Commenters expressed their opinions regarding the need for and use of nuclear power. Most were opposed. Many of the commenters stated that there would be no nuclear waste problem if there were no nuclear power. Others stated that nuclear power is uneconomical and unsafe. Commenters stated that a moratorium on the mining of uranium, the construction of new powerplants, weapons facilities, and nuclear testing areas should be enacted immediately and advocated energy conservation; the use of alternative energy technologies, primarily from renewable sources such as geothermal, solar, wind, hydrogen, biomass, and hydropower; and DOE's financial support and promotion of education, research, and implementation in these areas. The use of clean coal technology was also recommended.

A small number of commenters supported the use of nuclear power; some cited economic benefits, including jobs, or stated that nuclear powerplants do not emit greenhouse gases and other conventional air pollutants that are emitted from fossil-fueled power plants.

Response
The United States depends on nuclear power as an energy source to produce electricity. At present, approximately 20 percent of the electricity in the United States is generated by nuclear power. In accordance with the Atomic Energy Act, the Nuclear Regulatory Commission is responsible for licensing, regulating, and overseeing commercial nuclear powerplants, including the generation and interim storage of spent nuclear fuel at the reactor sites. Therefore, the Commission, not DOE, has authority over the Nation's nuclear power industry.

The National Energy Policy envisions a comprehensive long-term strategy that uses leading-edge technology to produce an integrated energy, environmental, and economic policy (DIRS 156756-Cheney 2001).

DOE is committed to the development and responsible use of all types of energy, and supports energy education and conservation activities. DOE actively promotes these efforts through its many outreach programs. The DOE Office of Energy Efficiency and Renewable Energy is leading the Nation's efforts in the study of alternative energy technologies, including geothermal, wind, solar, hydrogen, biomass, and hydropower. For information on the Office's activities, please visit its web site at http://www.eren.doe.gov or write to U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, 1000 Independence Ave., S.W., Washington, DC, 28585.

Comment - 11 comments summarized
DOE received comments on the reprocessing of spent nuclear fuel—both in favor of and opposed to reprocessing. Reprocessing is the chemical separation of spent reactor fuel into uranium, transuranic elements, and fission products. One commenter stated that the United States Government should reconsider the policy that deferred indefinite recycling of commercial spent nuclear fuel and noted that other countries such as France and the United Kingdom currently reprocess fuel. Others in support of reprocessing stated that the material to be emplaced at Yucca Mountain is not waste but rather yet-to-be-recycled fuel. Other commenters opposed to reprocessing stated that a firm commitment should be made against the reprocessing of irradiated/spent nuclear fuel and others stated that reprocessing adds to radiological contamination.

Response
The scope of this EIS is limited to an analysis of the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, and the No-Action Alternative.

At present, commercial spent nuclear fuel is not reprocessed in the United States . While materials disposed of in the proposed repository could have the potential to be an economic resource, it has been a long-standing policy of the United States to promote international nonproliferation efforts by not reprocessing nuclear material. The Carter

Administration cancelled the breeder reactor commercialization and plutonium recycle programs in this country on April 7, 1977.

In 1993, President Clinton reemphasized the U.S. policy, stressing the need to avoid increasing the accumulation of material that has the potential for use in nuclear weapons.

The policy further states that the United States does not encourage the use of civilian plutonium and, accordingly, does not engage in plutonium reprocessing for either nuclear power or nuclear explosive purposes.

Comment - 18 comments summarized
DOE received comments about activities involving DOE and commercial nuclear sites around the United States, conditions in the environments around those sites, potential health effects from activities or conditions at those sites, and other governmental activities not related to the proposed geologic repository at Yucca Mountain.

Response
This EIS analyzes the potential environmental impacts of constructing, operating and monitoring, and eventually closing a geologic repository at Yucca Mountain for the disposal of spent nuclear fuel and high-level radioactive waste, and the No-Action Alternative. The EIS also analyzes the potential impacts of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain from 72 commercial and 5 DOE sites across the United States. Activities or conditions at other DOE or commercial nuclear sites, or that are within the purview of other governmental organizations, are outside the scope of this EIS. Comments and questions are of great concern to DOE and should be directed to the governmental organizations or corporations having authority over those projects or activities.

13 (72)
Comment - 12 comments summarized
DOE received comments opposed to the interim storage of spent nuclear fuel on Native American lands in the Western United States, in particular, the Private Fuel Storage Facility proposed for Skull Valley, Utah.

Response
Private Fuel Storage, L.L.C., which is owned by eight U.S. nuclear power generating utilities, has applied to the Nuclear Regulatory Commission for a license to receive, transfer, and possess spent nuclear fuel from commercial nuclear reactors at a privately owned spent nuclear fuel storage installation on the Reservation of the Skull Valley Band of Goshute Indians near Tooele, Utah. This facility would store spent nuclear fuel pending the availability of a DOE facility to accept the material permanently. The Commission is the lead agency for preparing the EIS for this proposed facility, and the Bureau of Indian Affairs, Bureau of Land Management, and the Surface Transportation Board are cooperating agencies. DOE is not involved in this proposal or in the preparation of the EIS. However, DOE has considered the Private Fuel Storage Facility to be a reasonably foreseeable future action that is analyzed as part of the cumulative impacts associated with the Proposed Action of the repository EIS (see Chapter 8).

The *Draft Environmental Impact Statement for the Construction and Operation of an Independent Spent Fuel Storage Installation on the Reservation of the Skull Valley Band of the Goshute Indians and the Related Transportation Facility on Tooele County, Utah* (DIRS 152001-NRC 2000), was published for public comment in June 2000.

13 (131)
Comment - 10 comments summarized
Commenters expressed their opposition to the production and testing of nuclear weapons. Reasons for their opposition include philosophical grounds and concerns about environmental contamination and wastes generated from nuclear weapons production and testing. Commenters also expressed opinions that the money used to maintain the U.S. nuclear arsenal could be better spent eliminating the arsenal, solving nuclear waste disposal issues, or on humanitarian causes.

Response
The United States no longer manufactures new-design nuclear weapons. DOE, under the Stockpile Stewardship and Management Program, is responsible for maintaining the safety and reliability of the United States nuclear weapons stockpile. The *Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management* (DIRS 103217-DOE 1996) describes DOE responsibilities, and analyzes the potential environmental impacts of proposed changes to the Nuclear Weapons Complex to support this mission.

This EIS analyzes the potential environmental impacts of constructing, operating and monitoring, and eventually closing a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, as well as the No-Action Alternative. Chapter 8 evaluates the cumulative impacts of stockpile stewardship and management activities at the Nevada Test Site, including subcritical testing of weapons components.

13 (211)
Comment - 10 comments summarized
Some commenters expressed dissatisfaction with the way members of their Congressional delegations, local political entities, other publicly funded organizations, or tribal councils conduct their business or themselves. In particular, issues related to adequate involvement and representation, campaign contributions, and project funding were raised.

Response
This EIS analyzes the potential environmental impacts of constructing, operating and monitoring, and eventually closing a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, as well as the No-Action Alternative. Commenters may submit their concerns about how members of Congress or other individuals or organizations conduct their business or represent their constituents directly to them.

13 (227)
Comment - 8 comments summarized
DOE received comments regarding civil disobedience and the use of peaceful, nonviolent protest. Some commenters wanted to assure DOE that there would be peaceful protests of spent nuclear fuel and high-level radioactive waste shipments to the proposed repository. Other commenters were concerned that peaceful protests could turn violent by response actions, citing incidents outside the United States as examples; expressed the opinion that these protests occurred and will continue to occur because the public has been excluded from the decisionmaking process; or questioned why the Draft EIS does not discuss the effect of civil disobedience on shipments to the repository.

Response
DOE recognizes that many persons in the United States oppose the manufacture, use, storage and transportation of nuclear materials and radioactive waste. DOE also recognizes the possibility of civil protests against these activities. DOE anticipates that if a repository were to be approved, any activities related to the implementation of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, including the related transportation, would occur in a peaceful manner. Although activities occurring outside the United States such as those cited by the commenters are outside the scope of this EIS, they do illustrate potential concerns. Section 6.2.4.2.3 and Section J.1.4.2.1 of this EIS consider the impacts of hypothetical, successful sabotage attempts on a cask en route to the repository. While acts of civil disobedience would unlikely involve breaching a cask, this analysis considers the maximum reasonably foreseeable consequences of such activities.

In transporting spent nuclear fuel and high-level radioactive waste to the proposed repository at Yucca Mountain, DOE organizations would work with representatives of other Federal, state, local, and Tribal governments and law enforcement agencies, as appropriate, to ensure that shipments progress as safely as possible. Personnel from these organizations will receive training, as appropriate, that includes responses to protests and other civil actions. DOE will also work with these organizations and its nongovernmental stakeholders to minimize the potential for confrontations.

DOE has included the public in the decisionmaking process, and will continue to do so. DOE made the Draft EIS available in more than 35 locations (public Reading Rooms and libraries) in 17 states and the District of Columbia, and on the Internet at http://www.ymp.gov/deis.htm; and mailed copies to stakeholders and others requesting one. Public hearings were held in 21 locations from California to Washington, D.C. DOE accepted comments through the mail, via the Internet, and in person at the public meetings. Because the Supplement to the Draft EIS focused primarily on matters involving repository design, the Department held three public hearings in Nevada during the comment period. More than 13,000 comments received on the Draft EIS and approximately 1,900 comments received on the Supplement to the Draft EIS are answered in this Comment-Response Document. DOE will continue public involvement activities with its stakeholders, including citizens groups and the media, and the general public, throughout the life of this project.

13 (618)
Comment - EIS000181 / 0005
The administration should also seek ways to streamline and economize the ridiculous EIS process, including by seeking new legislation if need be. DOE should become more of an action agency.

Response
The NWPA requires that DOE prepare an EIS for the construction, operation, and closure of a geologic repository at Yucca Mountain. DOE prepared this EIS consistent with the process-related requirements of the NWPA and the National Environmental Policy Act, and the Council on Environmental Quality and DOE regulations implementing the National Environmental Policy Act. The regulations that implement the National Environmental Policy Act establish a process, described in Section 1.5 of this EIS, that begins with scoping, followed by preparation of a draft EIS for public distribution and comment. The process culminates with preparation of a final EIS that includes responses to comments received on the Draft EIS. The NWPA also discussed in Section 1.5, influences the scope of this EIS. In addition to assisting in decisionmaking, a major emphasis of the EIS process is to promote public awareness of proposed actions and to provide opportunity for public involvement. For this reason, DOE does not believe it necessary to seek legislation to modify the process.

13 (1138)
Comment - EIS000270 / 0025
Factors that give rise to public concerns about and opposition to approval of the Yucca Mountain site include:

Omitting impacts of political and economic changes affecting the commercial nuclear and defense industries with respect to their continued safe management of all radioactive wastes.

Response
This EIS analyzes the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, and the No-Action Alternative. Issues related to the management of radioactive wastes by the commercial nuclear and defense industries are beyond the scope of this EIS.

13 (1205)
Comment - EIS000272 / 0002
We feel as a state (Georgia) -- and I know that the governor has indicated this to the Department of Energy very recently, within the last month, to the Secretary of Energy, that we have significant issues with transportation. We're looking at the possibility of nuclear -- of plutonium, weapons-grade plutonium, being shipped across the state coming from the west back to the east, to the Savannah River plant, if the plutonium fuel fabrication plan goes forward at the Savannah River Site, as well as the immobilization of that fuel. So the governor is highly concerned about the question of waste being brought into our state and about who's going to pay the bill for the training, what level of training is going to be necessary for these kinds of unanticipated and never-before-experienced holocaust type of accidents and emergencies that can emerge from this, potentially.

Response
This EIS analyzes the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain. Although issues related to the transportation of surplus weapons-usable plutonium through the State of

Georgia as part of the DOE Surplus Plutonium Disposition Program are beyond the scope of this EIS, DOE evaluated such potential impacts in detail in the Surplus Plutonium Disposition EIS (DIRS 118979-DOE 1999). Chapter 4 of that EIS describes transportation impacts, with detailed analyses in Appendix L of that document. In addition, comments from the State of Georgia Department of Natural Resources that included a number of transportation concerns, and the associated responses, are in the Comment Response Document (Volumes III and IV) of the Surplus Plutonium Disposition EIS.

13 (1243)
Comment - EIS010093 / 0002
The answer folks isn't unfettered energy policy "same oh same oh" but significant energy conservation. Dim the lights, auto time lighting switches, etc., etc. Solar or wind, energy accountability. Shut (text cut off).

Response
Thank you for your comment. DOE is committed to the development and responsible uses of all types of energy, including renewable energy sources such as geothermal, wind, solar, hydrogen, biomass, and hydropower. DOE's Office of Energy Efficiency and Renewable Energy is responsible for leading the Nation's efforts in the study of renewable energy sources. For information on the Office's activities, please visit its web site at http://www.eren.doe.gov, or write to U. S. Department of Energy, Office of Energy Efficiency and Renewable Energy, 1000 Independence Ave., S. W., Washington, DC, 28585.

13 (1548)
Comment - EIS000357 / 0007
Page 1-6. 1.2.2.2. How was the spent nuclear fuel from the "55 university- and government-owned test reactors" transported to Hanford and Savannah River? What was the accident record?

Response
University and government-owned spent nuclear fuel being considered for disposal in Yucca Mountain is transported to the Idaho National Engineering and Environmental Laboratory, not the Hanford Site. Section 1.2.2.2 discusses the small quantity of spent nuclear fuel that is generated from research conducted by approximately "55 university- and government owned test reactors." Transportation of university and government-owned test reactor fuel to the Idaho National Engineering and Environmental Laboratory for consolidated storage is an ongoing process that DOE is conducting in accordance with the Record of Decision for the *Department of Energy Programmatic Spent Nuclear Fuel Management and the Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs* (DIRS 103205-DOE 1995). This activity is outside the scope of this EIS, which analyzes the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, and analyzes the No-Action Alternative.

In the more than 2,900 shipments over the past three decades, there has not been an accident involving the transportation of spent nuclear fuel or high-level radioactive waste that has resulted in the release of radioactive contents from the package. The *Department of Energy Programmatic Spent Nuclear Fuel Management and the Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Environmental Impact Statement* (DIRS 101802-DOE 1995) includes historical data regarding shipments of spent nuclear fuel. For more recent information regarding the transportation of radioactive materials, please visit the National Transportation Program's web site at www.ntp.doe.gov.

13 (1906)
Comment - EIS000464 / 0002
But first I would like to talk about so-called burial or dry cask burial, or otherwise known as vitrification. Russia was first to try dry cask vitrification in their Ural Mountain nuclear dump. It exploded in the 1950s because heat is continually being generated along with hydrogen gas. Temperatures can rise to 5,000° and you will have a thermal explosion. There is now a 100-mile-radius dead zone in the Ural Mountains. No one is allowed near the place.

Then Dr. Roy told me France tried vitrification and found it a failed technology. It simply will not work. Nothing can contain the most corrosive element in the universe, high-level nuclear waste. It is going to leak out or explode or both.

Response
The commenter could be referring to an explosion of an underground liquid radioactive waste storage tank at the Mayak nuclear complex on September 29, 1957, following a failure of the tank cooling system. These tanks contained liquid nuclear processed waste, not spent nuclear fuel or immobilized (vitrified) high-level radioactive waste. An accident of a similar nature could not occur at the proposed Yucca Mountain Repository because DOE would emplace only waste in a stable, solid form.

With regard to vitrification efforts in France, the Waste Act of 1991 established a legislative framework for disposition of high-level and long-lived intermediate-level wastes and initiated a 15-year research program in three areas:

1. Separation and transmutation of long-lived isotopes in waste
2. Disposition in deep geological formations (via underground research laboratory tests)
3. Immobilization processes and long-term surface storage.

According to the 1991 Act, the French government will submit an overall assessment of the three research areas (including immobilization processes) to Parliament by 2006 (DIRS 156712-National Research Council 2001).

DOE has successfully demonstrated vitrification technology at a number of facilities in the DOE Complex, and has implemented the technology at the West Valley Demonstration Project in New York State and at the Defense Waste Processing Facility at the Savannah River Site in South Carolina. The Department is also planning to use vitrification for tank waste at the Hanford Site in Washington State.

13 (2004)
Comment - EIS000528 / 0001
I recently attended a meeting concerning Nuclear Waste at Yucca Mountain at C.O. Bastian school in Caliente, NV. At that meeting a statement was made indicating that the people in Lincoln County had been made aware of and are kept updated on the issue of Nuclear Waste Storage in Yucca Mountain. This is not true. The people stating, or in charge of this have a committee, but have masked it from the public by calling it the Impact Alleviation Committee. I recently polled twenty people and only two out of the twenty knew what this committee was or what it did. I am sure that if this was named the Nuclear Waste Impact Alleviation Committee that all of the people I asked would have known and more than two or three people would show up to their meetings. Local residents poorly attend the meeting because they are not advertised and results not published of the meeting.

Response
The Impact Alleviation Committee is a Lincoln County and City of Caliente organization that is neither accountable to nor represents DOE. The Impact Alleviation Committee conducts and advertises its meetings in accordance with its own practices and procedures.

13 (2072)
Comment - EIS000765 / 0002
The first comment may be stretching the scope of this forum somewhat, as it relates to the management of the nation's surplus weapons plutonium. Thank God we have this problem because it means that we've reduced our stockpile of operational nuclear weapons. However, I am not in favor of any plan of disposal of this plutonium, some 50 metric tons, in a manner that would forever preclude its possible use by future generations as a mixed-oxide reactor fuel. The technologies for producing energy are now undergoing rapid advances, but our need for energy is also increasing and must be met. But of equal importance is our need for energy that does not consume carbon fuels and discharge carbon dioxide into the atmosphere. It is possible, according to some scientists, that we will experience a global warming crisis in the future. If that occurs, our future generations may need every bit of non-fossil fuel energy they can lay their hands on. This plutonium is a national resource. Let's not throw it away.

Response
Thank you for your comment. DOE evaluated the disposition of 50 metric tons (55 tons) of plutonium declared surplus to national defense needs in its *Surplus Plutonium Disposition Final Environmental Impact Statement* (DIRS 118979-DOE 1999). The Record of Decision for that EIS specified that approximately 33 metric tons (36 tons) of the surplus plutonium would be fabricated into mixed-oxide fuel for use in domestic commercial nuclear

reactors; but that approximately 17 metric tons (19 tons) will be immobilized for direct disposal (65 *FR* 1608, January 11, 2000).

13 (2628)
Comment - EIS000714 / 0004
Per SCIENTIFIC AMERICAN May '96 the DOE now admits that enormous amounts of the highly radioactive liquids and solids were pumped or dumped into the ground and estimates that throughout all the weapons complexes, billions of cubic meters of soil, groundwater and surface water are contaminated.

Charges for criminal violations should be brought against the DOE/AEC for past, present and planned future damage of the highest order to the United States and its injured citizens - damage that has been deadly and that may last for thousands of years.

Response
DOE has long acknowledged that its activities and those of its predecessor agencies in the production of nuclear weapons resulted in the contamination of facilities and the surrounding environment at many of its sites around the country. The Department is spending billions of dollars to clean up those sites, and will continue those efforts until all sites have been cleaned up to specified standards. DOE's goal is to have completed cleanup at more than 90 percent of its sites by 2006. At most sites, DOE will continue long-term surveillance and monitoring activities to ensure the protection of human health and the environment (DIRS 107294-DOE 1998).

13 (2790)
Comment - EIS000882 / 0003
We need more money spent on research to make use of the high level radioactive waste and contain plutonium that is in the waters in Southern Nevada.

Response
Thank you for your comment. The scope of this EIS is limited to an analysis of the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain. Other issues concerning high-level radioactive waste, plutonium, or other materials are beyond the scope of this EIS.

13 (2793)
Comment - EIS000887 / 0003
If it's so safe we should require the heads of the DOE to live within 10 miles of the site for the rest of their lives. Do we have any takers? I think NOT!

Response
This EIS evaluates the potential environmental impacts of constructing, operating and monitoring, and eventually closing a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, including potential health effects to the general public. This EIS identifies the maximally exposed individual as being a resident located on the southern boundary of the land withdrawal area. Section 4.1.7.5.3 of the EIS discusses potential health effects to this maximally exposed individual, as well as to the general population. Analyses indicate that the likelihood of the maximally exposed individual incurring a latent cancer fatality from repository activities over a 70-year lifetime would be about 0.000016 to 0.000031 (1.6 to 3.1 in 100,000) under the flexible design repository operating modes. The estimated total number of latent cancer fatalities in the exposed population over 115 to 341 years for the range of repository operating modes would range from 0.46 to 2.0. During the time the project would be active the estimated number of cancer deaths unrelated to the project would range from about 30,000 to 89,000 in the exposed population.

I thought the [there] was a ban on nuclear weapons. Lets not store the waste on the earth to poison what Mother Nature has left us.

Response
The NWPA states that the Federal Government has the responsibility to dispose of spent nuclear fuel and high-level radioactive waste that has accumulated and continues to accumulate across the United States. It also identified the Yucca Mountain site in southern Nevada as a potential location for a monitored geologic repository and directed DOE to characterize the site for suitability. As required by the NWPA, the EIS analyzes a Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain.

Comment - EIS000926 / 0007
What about the Waste Isolation Plant in Carlsbad, New Mexico where testing is done for safe disposal of nuclear waste - radioactive waste. Why have we not heard about this???

Response
DOE operates the Waste Isolation Pilot Plant to dispose of transuranic waste left from research and production of nuclear weapons. This waste is different from the spent nuclear fuel and high-level radioactive waste that DOE would dispose of Yucca Mountain. For more information about the Waste Isolation Pilot Plant, please see the *Waste Isolation Pilot Plant Disposal Phase Final Supplemental Environmental Impact Statement* (DIRS 148723-DOE 1997) or visit the Plant's web site at *http://www.wipp.carlsbad.nm.us/wipp.htm*.

Comment - EIS001287 / 0001
We do appreciate the Department of Energy's attempt to thoughtfully and carefully devise a long-range plan for the disposal of 70,000 metric tons of nuclear waste. While we believe there are major problems with the YMP [Yucca Mountain Project], we are even more worried about the disposal of nuclear wastes in many other nations. In countries lacking democratic traditions there will be no environmental impact statements, no public hearings, no openness in the process for siting and burial. Worldwide, there will be hundreds of thousands of metric tons to be disposed of, in coming decades. Many nations will not do this safely and effectively. Many people will die and their land will be poisoned, for all practical considerations, forever. This makes the continued development of nuclear power, as well as nuclear weapons, seem reckless and irresponsible. Added to these concerns is the prospect that spent nuclear fuel can be reprocessed into weapons-usable materials. Thus nuclear power is likely to fuel the proliferation of nuclear weapons around the globe. Pandora's box has been opened. The YMP is an attempt to close the box. It's a better attempt than we anticipate elsewhere, but not without problems.

Comment - EIS001127 / 0002
We collectively have created this problem. Let me note however that the source of this problem is really not the electric industry or the Department of Energy. Rather it is the arms industry. Nuclear weapons are the source of the problem. Atoms for Peace, under President Dwight Eisenhower, became the focus of a governmental effort to find some redeeming qualities to nuclear fission. While the government was busy building nuclear warheads, our government sought to sell Atoms for Peace to the public. A variety of laws then made nuclear power attractive, and profitable, to the electric utilities. Today we collectively live with the results of the decisions made by our government to encourage nuclear production of electricity. I think all of us in this room know that there is a significant hazard in handling and storing of waste. Where we differ, I think, is over the level of confidence we place in our ability to handle it safely.

Comment - EIS001202 / 0007
I demand legislation providing for reduction of energy company inventories. If their cooling ponds are full, each rod taken gives them more storage space for new production, at unbelievable continuing expense to the public. This [is] charity to energy power utilities. We in Northeast Ohio have already given.

Response
Ratepayers and utilities are paying the cost of disposal of the spent nuclear fuel generated by the nuclear power industry. The Nuclear Waste Policy Act of 1982 specifies that the Federal Government is responsible for providing for the permanent disposal of spent nuclear fuel and high-level radioactive waste, and that the costs of this disposal should be the responsibility of the generators and owners of the spent nuclear fuel and high-level radioactive waste. Commercial utilities pay a fee of 1mil (one-tenth of 1 cent) per kilowatt-hour of electricity generated by nuclear energy to cover disposal costs for commercial spent nuclear fuel. The Federal Government pays for waste generated and owned by the United States from taxpayer revenues as appropriated by Congress.

Utility fees go into the Nuclear Waste Fund where unused portions earn interest. Since passage of the Nuclear Waste Policy Act of 1982, utilities and their ratepayers have paid approximately $9.8 billion into the Nuclear Waste Fund to pay for the development of a repository for the disposal of spent nuclear fuel and high-level radioactive waste. By the end of Fiscal Year 1999, the program had spent approximately $6 billion for the purposes specified in the Act. With accrued interest, the value of the Nuclear Waste Fund was $8.5 billion at the end of Fiscal Year 1999. The most recent review showed that approximately 70 percent of disposal-related costs would be paid from the Nuclear Waste Fund, and approximately 30 percent, to cover the cost of Federally owned spent nuclear fuel and high-level radioactive waste, would come from taxpayer revenues. Thus, the private commercial utilities are "paying their fair share" of repository program costs along with taxpayers. However, the cost estimates in the EIS do not consider and are not sensitive to the source of funding (see Sections 2.1.5 and 2.2.3 of the EIS).

Comment - EIS001471 / 0001
Thanks very much. Just to pick up where I was at. I did want to talk some more about the history of actual shipments of high-level waste, and again go back to Germany where there was a shipment of high-level waste sent from Germany to France for reprocessing. And upon its return to the border between France and Germany it was discovered to be 3,000 times the permissible level of radiation on the surface of the casks. So there was a contamination event.

And this information was kept from the public for a considerable period of time and created quite a scandal when it was finally released. And so that's another example of things going wrong with high-level waste transportation.

Response
DOE is uncertain about the incident to which the commenter is referring, but there were a few incidents in 1997 involving German, Swiss, and United Kingdom shipments to France in which external surface contamination was in excess of routine contamination limits. Shipments were temporarily halted but resumed in 1998. Investigations

determined that there were no radiological consequences to workers or the public, but did reveal an absence of cleanliness in Electricite de France reprocessing plants. Monitoring, inspection, and other measures were increased in response to these incidents. A working group comprised of experts from all four countries was formed in 1998 to ensure future safety of spent fuel transportation. The common opinion of the working group was that the corrective measures implemented following the incidents allow safe spent fuel transportation (DIRS 156709-SNSI 1998).

DOE appreciates the commenter's concern that incidents could occur during the transport of spent nuclear fuel and high-level radioactive waste. However, the DOE safety record demonstrates that transportation of these materials can and does occur safely. There has never been an accident involving the transportation of spent nuclear fuel or high-level radioactive waste in the United States that resulted in the release of radioactivity from the cask. With regard to the potential for shipping casks with surface contamination, each facility that ships such materials has rigorous procedures to minimize the possibility that a cask with external contamination above allowable limits could leave the site. In addition, casks shipped to Yucca Mountain would not be opened between the shipping location and the repository site. Procedures at the repository would ensure that if a cask arrived with external contamination above allowable limits, it would be segregated and decontaminated prior to acceptance for emplacement or return to the point of origin.

Comment - EIS001535 / 0004
What will happen to the tremendous amount of dangerous, so-called "low level wastes" that these nuclear power generating facilities generate?

Response
Utilities dispose of low-level radioactive waste in accordance with their operating licenses, Nuclear Regulatory Commission regulations, and the provisions of the Low-Level Radioactive Waste Policy Act. The nuclear industry uses privately operated low-level radioactive waste disposal facilities; this Act requires the development of more such facilities. It also requires that states form regional compacts for the purpose of developing low-level radioactive waste disposal sites by regions. If approved, the geologic repository proposed for Yucca Mountain would be used for the disposal of spent nuclear fuel and high-level radioactive waste, not low-level radioactive waste.

Decisions are going to be made. Just like before when the lights were out, we have to make sure that the lights will stay on in Nevada. Such as other parts of the country too, the lights must stay on. We must start a national energy policy. And like Mr. Bush has said, and to quote Mr. Bush, science will determine what will happen with a national energy policy. Science will also determine where the greatest site in America is for the storing of spent nuclear fuel.

Response
This EIS analyzes a Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, and analyzes the No-Action Alternative.

13 (5218)
Comment - EIS001322 / 0001
If the proposed disposal is estimated to be safe, why not have the nuclear industry take full responsibility - full liability - for any harm involved? It's their mess - why should taxpayers take the risk for them? Our subsidizing their risk gives them an unfair competitive advantage over other energy sources.

Response
Taxpayers are not subsidizing utilities' costs for disposal of spent nuclear fuel. Taxpayers would, however, fund the cost for disposal of spent nuclear fuel and high-level radioactive waste that belongs to the Federal Government. The Nuclear Waste Policy Act of 1982 specifies that the Federal Government is responsible for providing for the permanent disposal of spent nuclear fuel and high-level radioactive waste, and that the costs of this disposal should be the responsibility of the generators and owners of these materials . Commercial utilities pay a fee of 1 mil (one-tenth of 1 cent) per kilowatt-hour of electricity generated by nuclear energy to cover disposal costs for commercial spent nuclear fuel. The Federal Government pays for waste generated and owned by the United States from taxpayer revenues as appropriated by Congress.

Utility fees go into the Nuclear Waste Fund where unused portions earn interest. Since passage of the Nuclear Waste Policy Act, utilities and their ratepayers have paid approximately $9.8 billion into the Nuclear Waste Fund to pay for the development of a repository for the disposal of spent nuclear fuel and high-level radioactive waste. By the end of Fiscal Year 1999, the program had spent approximately $6 billion for the purposes specified in the Act. With accrued interest, the value of the Nuclear Waste Fund was $8.5 billion at the end of Fiscal Year 1999. The most recent review showed that approximately 70 percent of disposal-related costs would be paid from the Nuclear Waste Fund and 30 percent from taxpayer revenues. Thus, the private commercial utilities are "paying their fair share" of repository program costs along with taxpayers. However, the cost estimates in the EIS do not consider and are not sensitive to the source of funding (see Sections 2.1.5 and 2.2.3 of the EIS).

Comment - EIS010235 / 0008
Will hasty acceptance of this evolving design influence other countries to adopt this untested model, due to the United States' powerful international status?

Response
The repository design has evolved to reflect ongoing evaluations and other influences such as public comments and design and performance-related reviews by external organizations, such as the Nuclear Waste Technical Review Board. This EIS analyzes the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain. The extent to which the international community would adopt engineering designs evaluated for the Yucca Mountain site, is speculative and outside of the scope of this EIS.

13 (5642)
Comment - EIS010100 / 0003
Can we really afford the cost and dangers of nuclear power in the long run? Cleanup costs are unbearable to many like us (U.S.) in the Cold Water Creek Florissant Valley that used to be flowers not radioactive waste there/here now.

Response
The Nuclear Waste Policy Act of 1982 states that the Federal government has the responsibility to dispose of spent nuclear fuel and high-level radioactive waste that has accumulated and continues to accumulate across the United States. The Act identifies the Yucca Mountain site in southern Nevada as a potential location for a monitored geologic repository and directed DOE to characterize the site for suitability. As required by the Act, the EIS analyzes a Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain.

Comment - EIS000815 / 0007
Although not a part of this DEIS, the United States and the international community need responsible programs for appropriate control and disposition of weapons source materials, i.e., natural and depleted uranium, including that remaining from uranium enrichment. During the final two decades of the Cold War, weapons plutonium was produced in reactors at the SRP/SRS from these materials. An article in the March 2, 1999 issue of The New York Times by Matt Wald discusses plans by the Department of Energy (DOE) to turn depleted uranium into salable goods, but does not mention that depleted uranium "targets" can be used for production of weapons plutonium in any neutron source, i.e., research reactor, fusion device, medical isotope production reactor, commercial nuclear power plant, etc., or in an accelerator. Moreover, plutonium produced in targets would be much easier to recover, because most of the intensely radioactive fission products are in the reactor fuel. These materials should be stored under appropriate controls for eventual destruction through use in advanced nuclear power plants for production of electricity or other important and valuable purposes. The planned compromise by the US of important policies against use of commercial nuclear power plants for production of nuclear weapons materials makes this need all the more compelling.

Response
Management of the materials mentioned in this comment is not within the scope of this EIS. However, DOE manages all strategic materials (that is, the quantity of plutonium and highly enriched uranium material reserved for future weapons use) in accordance with strict security procedures, and protects them commensurate with the impact of the loss, theft, compromise, or unauthorized use of the material, as determined by vulnerability and risk analyses.

Comment - EIS010134 / 0002
We have Senator Murkowski, who was elected in 1980, and Senator Domenici, who was elected in 1972, who were the proponents of the 1987 nuclear bill -- of the repository bill. All it was was an ending bill to them. They just didn't want this stuff in their states.

We have Vice President Cheney and Bruce Babbitt, who either was a hypocrite when he was in the Clinton administration or he's a hypocrite today, I'm not sure which one he is, saying that nuclear energy is clean, safe and economic. Boy, would I love to debate that.

Clean? Sure it's clean if all you look at is a smoke stack. What about this toxic nuclear waste that they want to transport through 41 states over 28 years, six convoys a day? I mean, that's nuts. That ain't clean.

Safe? Well, I guess we have to forget about Three Mile Island and Chernobyl, then it's safe.

Economical? This industry in 1954 when we decided to use nuclear power to produce electricity our government gave you, all of us, the liability for the waste. What other industry do we go out and collect their garbage? Do we collect garbage off the auto manufacturers? That belongs -- that responsibility was theirs. It should never have been ours, so we were sold out in '54. They got a lot of power today, but we were sold out in '54.

And in the meantime they passed the Price-Anderson Bill which limited their liability, their liability in the event of an accident. And all the while they began subsidies and tax breaks, research and development moneys.

Economical? They made a statement when they first started producing nuclear power it's going to be too cheap to meter. You know what, now it's too expensive to use.

So you can't trust your government. Please don't have blind faith in them. As far as I'll give you another reason why you shouldn't have blind faith or you're a veteran -- Agent Orange, posttraumatic syndrome, Gulf War Syndrome.

Nuclear veterans -- they stood, they made them stay in the pits. They said when the concussion comes back, we're going to give you these nice glasses. You can get up and look at this nice show. It's very pretty. And they have the God damn nerve to put those troops there, and when they got sick they didn't pay them.

They didn't pay them of course with Agent Orange. For 20 years after the war they didn't even recognize them. Posttraumatic syndrome, today they don't recognize it. They say they're phonies. Gulf War Syndrome, they jerked those poor guys around with talking about one syndrome when it was 12 different things and they knew it was 12 different things.

So don't just have blind faith in your government, because they do lie to you. What about the miners at the Test Site? Now, we talk about people with protected jobs. These guys all the while they said oh, it's safe. I got a nice job. I'm making 60,000 a year. All of a sudden they got sick now. They want compensation and they're getting compensation.

You know, they didn't give the veterans compensation at the same time. They gave them compensation. So don't trust your government. Don't have blind faith in anything that's done in government.

Response
Thank you for your comment.

Comment - EIS010162 / 0002
What is the government doing? They put 55 metric tons at SRS. And what did our friend from Savannah River say from South Carolina? That's the most -- second most polluted place in the country. And I read volumes on it and it's criminal what they have done to SRS. Next to Hanford it is number two. There's no question about it.

Response
When Congress passed the NWPA, it affirmed that the Federal Government is responsible for the permanent disposal of spent nuclear fuel and high-level radioactive waste. DOE has long acknowledged that its activities and those of its predecessor agencies in the production of nuclear weapons resulted in the contamination of facilities and the surrounding environment at many of its sites around the country. The Department is spending billions of dollars to clean up those sites, and will continue those efforts until all sites have been cleaned up to specified standards.

13 (7352)
Comment - EIS001573 / 0004
The Department of Energy has an inherent number of interests and should not be the lead agency on the development of a permanent repository. Let me give you one good example. I'm an attorney and I represent a number of clients in Michigan in a federal court action pending in Kalamazoo U.S. District Court to stop a ridiculous experiment in the use of mixed oxide plutonium fuel in Canadian reactors. Part of the scheme involves the burning of about 34 tons of nuclear weapons, decommissioned weapons material, that has been converted into fuel in about half a dozen commercial nuclear power reactors in the south eastern United States. 34 tons of plutonium translates into several thousand tons of spent fuel, once that material is burned up in those reactors.

So, in effect, the Department of Energy is directly sponsoring and, in fact, has entered into contracts with several different utility companies to commence the burning of decommissioned nuclear weapons in American reactors to produce a far more radioactive material than otherwise exists in the form of decommissioned nuclear weapons grade material.

At present, if it weren't burned in reactors, that material could be immobilized in a ceramic [glass] type of fashion, could be far less expensively stored, could be far less expensively insulated and isolated from saboteurs, from anyone who might want to make the bomb or make nuclear fuel out of it. Nonetheless, the Department of Energy is going ahead officially, formally and contractually to make high-level, heavily irradiated spent fuel, ultimately, out of it.

Response
The NWPA specifically directs DOE to be the lead agency in developing a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste. As part of its responsibilities, DOE has prepared this EIS, which analyzes the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close, a geologic repository at Yucca Mountain. Other DOE activities, such as those related to the disposition of surplus plutonium from dismantled nuclear weapons, are outside the scope of this EIS. The Department is responsible for the Surplus Plutonium Disposition Program.

DOE evaluated the potential environmental impacts of the Surplus Plutonium Disposition Program in the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement* (DIRS 103215-DOE 1996) and the *Surplus Plutonium Disposition Final Environmental Impact Statement* (DIRS 118979-DOE 1999). The Surplus Plutonium Disposition EIS evaluates the disposition of 50 metric tons (55 tons) of surplus plutonium by fabricating as much as 33 metric tons (36 tons) into mixed-oxide fuel and irradiating that fuel in commercial nuclear power reactors and immobilizing as much as 17 metric tons (19 tons) in glass at the Defense Waste Processing Facility at the Savannah River Site. DOE has contracted with a consortium formed by Duke Engineering & Services, COGEMA, Inc., and Stone & Webster (DCS) to design, construct, and operate the mixed-oxide fuel fabrication facility and to irradiate the fuel in Duke Power Company's Catawba and McGuire reactors. This activity is independent of the one-time shipment of a small amount of mixed-oxide fuel [nine fuel rods containing less than 120 grams (4.2 ounces) of plutonium] to Canada in January 2000 under the Parallex Project. The latter activity was evaluated in the *Environmental Assessment for the Parallex Project Fuel Manufacture and Shipment* (DIRS 157153-DOE 1999).

Both the spent mixed-oxide fuel and immobilized plutonium are in the inventory of spent nuclear fuel and high-level radioactive waste that DOE would place in a monitored geologic repository at Yucca Mountain. The National Academy of Sciences has determined that both waste forms meet the Spent Fuel Standard. Waste forms meeting that standard would offer major nonproliferation and arms reduction benefits compared with leaving the material in storage in weapons-usable form (DIRS 100018-National Research Council 1995). There will not be a substantial increase in the amount of spent nuclear fuel generated by using the plutonium as mixed-oxide fuel because that fuel would replace mostly traditional low-enriched uranium fuel. Under the Preferred Alternative in the Surplus Plutonium Disposition EIS, the use of mixed-oxide fuel made from surplus plutonium would generate approximately 199 more low-enriched uranium fuel assemblies than would the use of only low-enriched uranium fuel in the designated commercial nuclear reactors (DIRS 118979-DOE 1999).

13 (8019)
Comment - EIS000817 / 0070
Two things happened that I think are relevant during the interim -- the MOX transport mess in Michigan with the Parallex Project for one. If that is representative of the way citizens and NEPA regulations are going to be treated in future radioactive shipments, then I foretell disaster. If things are going to be done in secret, without full notification of local authorities and citizens, then there is bound to be more and more opposition. Certainly an EIS was required for Parallex and not an EA. You can't segment such a huge project. It was all handled very badly.

Response
This EIS analyzes the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain. Activities conducted for the Parallex Project are outside the scope of this EIS. However, DOE believes that it has evaluated the potential environmental impacts of the Parallex Project in the Environmental Assessment for the Parallex Project Fuel Manufacture and Shipment (DIRS 157153-DOE 1999), for which it issued a Finding of No Significant Impact. Although the Environmental Assessment evaluated the fabrication and transport of as much as 26.8 kilograms (59 pounds) of mixed oxide fuel, DOE made a one-time shipment of less than 120 grams (4.2 ounces) of plutonium in nine fuel rods to the Atomic Energy of Canada, Limited, test reactor at Chalk River, Ontario.

DOE has kept the public informed of its activities related to the Parallex Project, including holding four public meetings in Michigan to discuss its decision to use Sault Saint Marie, Michigan, as the crossing point from the United States into Canada. These meetings were held between October 26, 1999, and November 1, 1999, before the shipment of the mixed oxide fuel in early January 2000. Participants discussed modes of transport in the United States and Canada and other issues.

13 (8244)
Comment - EIS002286 / 0004
The DOE has not solved the waste problem permanently. Therefore, they should use their money-making industry that, you know, is involved in it. They are all getting paid to decide whether or not Yucca Mountain is going to go forth or not. They have decided, even if it does go forth, there is still going to be waste out there. What are we going to do with all the other waste? They say the site is for 70,000 metric tons. They have already said there's going to be over a hundred some odd metric tons. That's if the reactors continue for ten more years. What's going to stop them from making more reactors, and what's going to stop all the medical waste and all the waste attributed to weapons production?

Response
When Congress passed the Nuclear Waste Policy Act of 1982, it affirmed that the Federal Government is responsible for the permanent disposal of spent nuclear fuel and high-level radioactive waste. Radioactive medical wastes are classified as low-level radioactive waste, which would not be emplaced in the proposed repository. Congress envisioned more than one repository, prohibiting the Nuclear Regulatory Commission from approving a license for the emplacement of more than 70,000 metric tons of heavy metal (MTHM) in the first repository until a second repository is in operation [NWPA, Section 114(d)]. The total projected inventory of spent nuclear fuel and high-level radioactive waste is more than 70,000 MTHM. Emplacement of more than 70,000 MTHM at Yucca Mountain would require legislative action by Congress unless a second repository was in operation.

The National Energy Policy recommends the safe expansion of nuclear energy by establishing a national repository for nuclear waste, and by streamlining the licensing of nuclear powerplants (DIRS 156756-Cheney 2001). Moreover, it is reasonably foreseeable that Congress would take such a legislative action. Chapter 8 of this EIS analyzes cumulative impacts from the disposal at Yucca Mountain of all spent nuclear fuel and high-level radioactive waste projected to be produced through 2046 for which DOE would retain ultimate responsibility.

13 (8265)
Comment - EIS001950 / 0005
Even the current movement of LLRW is threatening all the people in the communities along current transportation routes. I have heard of 3 incidents involving waste trucks heading toward the test site in the last past 6 months. All

occurred within 150 miles of the test site boundaries, one involving a rip in the side of the truck and "Loss of Material."

Response

DOE acknowledges that incidents occur during the transport of radioactive materials, but emphasizes that occurrences have been rare and impacts have been minimal. In addition to using only shipping containers and contractors certified or licensed for transport of these materials, DOE and contractor personnel receive training in their handling and transport. DOE responds immediately to such incidents, thoroughly investigates their causes, and incorporates lessons learned into programs and procedures to reduce or minimize the potential for future occurrence.

This comment cites incidents during the transport of low-level radioactive waste. While not minimizing the seriousness of incidents involving such waste, DOE would transport spent nuclear fuel and high-level radioactive waste in containers that are much more robust than the Type A containers used for low-level waste. In addition to meeting the standards for Type A containers, Type B containers must provide a high level of assurance that, even in severe accidents, they would maintain their integrity with essentially no loss of the radioactive contents or serious impairment of the shielding, and maintain subcriticality capability. The DOE safety record demonstrates that transportation of spent nuclear fuel and high-level radioactive waste can occur safely. There has never been an accident involving transportation of these materials in the United States that resulted in a release of radioactive contents.

13 (8352)

Comment - EIS001627 / 0004

The space available for storage of spent nuclear fuel at the generating stations is limited. Even if some utilities are able to expand their own storage facilities, there will come a point when no additional storage is available and the operators will have to shut the reactors down permanently. As generation is taken off the market, the available supply is diminished and the prices for the remaining energy sources will increase. This will hit customers hard who are trying to replace the power lost with the closing of nuclear generators.

Response

In passing the Nuclear Waste Policy Act in 1982, Congress affirmed that the Federal Government is responsible for the permanent disposal of spent nuclear fuel and high-level radioactive waste. To that end, Congress, in the Nuclear Waste Policy Amendments Act of 1987, had directed the Secretary of Energy to determine whether to recommend that the President approve the Yucca Mountain site for development of a repository for the permanent disposal of these materials.

Comment - EIS000817 / 0159

P. 7-43. I have not seen this NRC EIS for relicensing plants and wonder how they evaluated unloading casks and loading a replacement cask. I'd really like to see that, and frankly don't know how they did it since no cask has ever been unloaded. Surely if they relicense plants, this will have to be done. Relicensing any plant for 20 years would be a grave mistake and put an extra burden on waste storage by allowing more to be created -- following the major mistake all through nuclear history by creating more with no plan workable as to what to do with it forever! Pools are getting old, reactors are getting brittle -- it is a dangerous business to keep these aging plants going, I think. More and more waste creation makes decommissioning more and more of a problem and pushes it to future generations. Renewables are ready! Let's use them instead.

Response

Section 7.3 of the EIS states, "DOE based its estimates of the potential impacts from continued storage of commercial spent nuclear fuel on a representative site. The results of the analysis described in the previous section are consistent with the Nuclear Regulatory Commission's (NRC's) findings in its *Generic Environmental Impact Statement for License Renewal of Nuclear Plants* (DIRS 101899-NRC 1996). The Commission's EIS is available on the Yucca Mountain web site at http://www.ymp.gov, as well as in the reading rooms and libraries identified in Section D.8 of this EIS. For additional information concerning that EIS, please contact the Commission directly.

DOE is committed to the development and responsible use of all types of energy, including renewable energy sources such as geothermal, wind, solar, hydrogen, biomass, and hydropower. DOE's Office of Energy Efficiency and Renewable Energy is responsible for leading the Nation's efforts in the study of renewable energy sources. For information on the Office's activities, please visit its web site at http://www.eren.doe.gov, or write to U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, 1000 Independence Ave., S.W., Washington, DC, 20585.

Comment - EIS002283 / 0002
One of my concerns is an issue called DU rounds. I am trying to get to the bottom and find out what these depleted uranium rounds are. I know we processed close to two million rounds of depleted uranium rounds now and turned them into weapons, and I am real concerned because I hope that's not what they are planning on doing with an awful lot of the rest of the nuclear waste. You know, that two million rounds of this stuff, we are talking about disposal of 70,000 tons.

I have a real ugly feeling knowing the history of the government and corporations like Wachenhut [Wackenhut Services, Inc.] that this is not good news. Those rounds -- you can't tell me that those rounds are safe. I just don't buy it. I don't buy it a bit.

Response
The rounds mentioned in the comment are nonexplosive metals fabricated from depleted uranium. Depleted uranium is the material, primarily uranium-238, remaining after the removal of the fissile isotope uranium-235 from uranium ore. In the United States, it occurs most often as depleted uranium hexafluoride, a compound of uranium and fluorine. The *Final Programmatic Environmental Impact Statement for Alternative Strategies for the Long-Term Management and Use of Depleted Uranium Hexafluoride* (DIRS 152493-DOE 1999) describes the DOE depleted uranium inventory. DOE does not plan to dispose of depleted uranium in the proposed repository at Yucca Mountain.

Comment - EIS001837 / 0034
The United States must get out of the business of producing massive quantities of enriched uranium (U.S. Enrichment Corporation) and selling it overseas. This act is akin to producing tobacco for foreign sales. You are hurting the children and the future of mankind. You know that it is harmful to the health so stop producing it and stop selling it overseas. Nuclear activist Jeff Wright exposed what the U.S. Enrichment Corporation is doing and this friend of PARDs is in jail today because our government has denied him his right to speak and redress the government over these issues, using as their excuse meeting disruption when he inadvertently goes over the meager three minutes which the officials allow citizens in this San Bernardino County to redress government.

Comment - EIS001971 / 0002
I spent a portion of autumn, 1999 in the Minnesota State Archives reviewing the record of the second site process with which Minnesota was fiercely engaged from 1983-1987. From the reports, comments and testimony submitted to the federal government (NRC, DOE & Congress) by Minnesota's Nuclear Waste Council and state agency staff, I got an excellent perspective on the interplay of political, technical and strategic factors in the siting process. A number of the critiques and recommendations that Minnesota made during that period could still be applied. Unfortunately, limited time and resources prevent me from utilizing insights from that review. My conscience has been sharpened, however, by reliving the 5-7 years when Minnesota faced, with similar resistance and fears, the prospect that Nevada now faces. During that time, Minnesota reviewed federal reports on primary and secondary containment, site characterization, and transportation. The state grappled with state's rights issues, even submitting an amicus brief on Nevada's suit, and attempted to support standards that Minnesotans knew that they might have to live with. I am well aware of the unresolved issues and inadequacies of the process.

And most of my remarks today -- tonight are going to be taken from this article in the Las Vegas Sun dated Sunday, December 5, 1999, so this is very recent.

I don't suppose you can see it, but this is a picture, and you can see that it's highly technical. It says: "Engineers on-duty inside the live control room at the Calvert Cliffs Nuclear Plant in southern Maryland -- southern Maryland, Calvert Cliffs would send its solid waste to Yucca Mountain under a current proposal," and they've titled this called The Day of Reckoning, and I scratched out reckoning and I called it the Day of Infamy.

"Nuke plants running out of space as they wait for Yucca decision" and they start out by telling you how beautiful it is back in -- in Calvert Cliffs County, Maryland that you can -- oh, you can see the green forest and they're awash in red and gold and rust and the white-tailed deer dart into the woods and a bald eagle soars and sea breezes blow. "This beautiful setting seems a strange place to find one of the nastiest substances on earth, but nestled in this former Maryland tobacco farm is the state's only nuclear power plant where two 850 megawatt nuclear reactors generate electricity for 450,000 households and 35 to 40 tons of highly radioactive nuclear waste a year.

"The waste at Calvert Cliffs like any other produced by 103 reactors at 72 plants nationwide spent uranium fuel rods stored in pools of water inside the plant. The waste in a sample of the radioactive material bound for permanent storage Nevada." They've already decided that.

"Under a current proposal, Calvert Cliffs and the rest of the nation's plants want to store their waste in a single site, a geologic repository inside Yucca Mountain.

"The plants are running out of space," said Steven Ungelsbee, spokesman for the Nuclear Energy Institute, the industry's powerful lobbying arm." Get that word "lobbying" in there.

"The day of reckoning is here, and the glimpse inside Calvert Cliffs offers insight into the nuclear industry's campaign to make Nevada a nuclear burial ground." I wonder if they're talking about people. And you know, we hear from our opposition all the time how safe this stuff is. Okay. Can't see this picture, and by the way, I have a lot of these Xeroxed, so anyone that wants to come up get one afterwards, I'll be glad to share them with you.

Comment - EIS010129 / 0002
When an airplane crashes it makes the news because it's, you know, a lot of people dying at the same time. But the same amount of people can die in the same day in a bunch of car accidents all around the country. So in some way this Yucca Mountain thing puts all of the problems of the nuclear waste that we all have to face because we're all using electricity, we're all benefiting from this environmental degradation and these problems, this cancer causing horrible stuff, this nuclear radioactive waste, we're all benefiting from that in our use of electricity.

It's a communal problem deal. We need to deal with it. And Yucca is that symbol of putting it all in one place like in an airplane crash versus car accidents or other methods of death that people have devised for themselves. So that is one reason I think that the people have gathered and are trying to do something about it. But we need to continue regardless of whatever happens to Yucca Mountain, we all need to focus on our lifestyle choices and our responsibility as other people said tonight.

And I'd also like to make the statement that the process needs to continue, that the freedom of speech forum needs to continue and it needs to be expanding to a real process where people have a say so in what we're going to do with our communal problem of nuclear waste.
And so this also is all sort of a warning, my statement, because we live in the most powerful empire that the world has ever known, having so much control over the rest of the planet. And this empire, the United States, has also been -- it doesn't just exercise its power and control through the threat of nuclear weapons and whatever else it can come up with and maintain the policy of our economy being God in this country.

But the United States, in addition to controlling the rest of the planet and having that influence, it also has done a masterful job of keeping us people in the United States from finding true fulfillment and love, because it behooves the interest of those who are in charge to control and to dominate the rest of the planet. And it behooves them to confuse the rest of us in the United States and make sure that this process does not go anywhere in terms of the people's voice having a say so in what we do with our communal problem of nuclear waste.

Comment - EIS001888 / 0404
[Clark County summary of comments it has received from the public.]

Environmental justice with regard to transportation must be considered in the NTS [Nevada Test Site] EIS.

Response
This comment is one of many the Clark County government collected over several years. The date of this comment, May 3, 1996, and its subject matter suggest that it was intended as a comment on the *Draft Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada*. DOE published the Final EIS on the Test Site in August 1996 (DIRS 101811-DOE 1996).

DOE is committed to the principles expressed in Executive Order 12898, "Federal Actions to Address Environmental Justice in Minority and Low-Income Populations." The Department believes that its treatment of environmental justice in this Yucca Mountain EIS, in the Nevada Test Site EIS, and in all of its documents prepared under the National Environmental Policy Act adheres to these principles and is fair and appropriate.

Comment - EIS002102 / 0004
In only 50 years of the nuclear age, nuclear waste has leaked out of its containment at the Hanford Nuclear Reservation in the State of Washington and is leaking into the Columbia River. Strontium-90 has been found where salmon spawn, and the prevailing current will make [its] way down the Columbia River and down the West Coast of the U.S. coast, high-level nuclear waste. Radioactive environmental contamination will threaten the health and gene pool of thousands of future generations and Dr. Jay Gould's book, "The Enemy Within" -- he cites breast cancer rates were going down prior to 1945. Then with the first atom bomb explosion, breast cancer rates went up yearly.

Response
DOE acknowledges that past activities at its sites produced environmental contamination, and understands the concern that continued or future activities at those sites could result in harmful health effects in the public. Although the scope of this EIS is limited to an analysis of the construction, operation and monitoring, and eventual closure of a geologic repository at Yucca Mountain, the issue of radiological exposure and its relationship to cancer and other health effects is pertinent and important.

The Environmental Protection Agency and Nuclear Regulatory Commission have established dose limits to ensure there would be no impacts to public health and safety that would pose an unacceptable societal risk. No containment, natural or engineered, can be guaranteed indefinitely. Some radionuclides or potentially toxic chemicals could eventually enter the environment outside the repository. However, long-term performance assessment (modeling) analysis shows that the combination of the natural barriers of the site and engineered barriers would keep such a release small enough to pose no serious impact on the health and safety of people or the environment.

The results of this analysis, described in Chapter 5 of the EIS, indicate that impacts for the 10,000-year evaluation period would be low and that health effects would be thousands of times less than natural incidences of health problems in the population. The impacts predicted by the analysis would be much lower than the Environmental Protection Agency or Nuclear Regulatory Commission limits. Appendix I of the EIS, the *Viability Assessment of a Repository at Yucca Mountain* (DIRS 101779-DOE 1998), and supporting documents contain details of the analysis methodology.

Comment - EIS002170 / 0008
As they say, “humans, we could have been so great...but we suck.”

Too bad all of this wasn’t thought about before we jumped into this nuclear age. Too bad our species doesn’t have foresight and believes itself to be the caretakers of this beautiful planet. We certainly aren’t well adapted to the job even if it were ours, which it isn’t.

Do something right. I know everyone is thinking of trying to mitigate a bad situation. Think, think, think before any action is taken.

Response
Thank you for your comment.

13 (10728)
Comment - EIS000123 / 0002
DOE, with the Atomic Energy Commission, the Manhattan Project, when they got rid of the waste over there, they just dumped it over there.

They thought they were doing the proper methods over burial over at that area, just like we think we’re properly taking care of the nuclear waste now, but looking back in retrospect, this is out of an article that I wrote some years ago.

“It’s been fifty short years since the Manhattan Project was transferred to the Suburban Forest Reserve District and thirty years since its reactors, the related waste were buried.

“Scientists haven’t much knowledge about what lies below the earth. Records of buried waste are grossly incomplete and standards about what is considered dangerous have changed dramatically since then.

“Ironically scientists know so little about how our nuclear pioneers lived and worked here that they might as well have been digging into Inca ruins, not debris from a nuclear age library.”

Response
DOE recognizes that as science and engineering advance, better techniques and designs evolve. If there was a decision to implement the Yucca Mountain Repository, the design would incorporate the best science and engineering available, and would be in compliance with Nuclear Regulatory Commission and other applicable requirements. DOE would monitor the repository performance for at least 50 years after emplacement of the spent nuclear fuel and high-level radioactive waste to detect any anomalies.

13 (10777)
Comment - EIS000250 / 0011
And it is also the case that the nuclear industry is one of the most hugely subsidized industries in the history of the world in an economy that is supposed to be based on free market principles. It is really an insult to the people of this country that the industry receives the degree of subsidies that it does.

Response
Ratepayers and utilities are paying the cost for the disposal of commercial spent nuclear fuel, not the Federal Government. Commercial utilities pay a fee of 1 mil (one tenth of 1 cent) per kilowatt-hour of electricity generated by nuclear energy to cover disposal costs for commercial spent nuclear fuel. The scope of this EIS is to analyze the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste.

13 (10920)
Comment - EIS000244 / 0005
The impressive thing to me about, and I have seen films of this although I have never been in any of the demonstrations, is to see how powerfully strong these casks or storage containers are that they have been subject to train accidents and earthquakes and highway accidents and derailments, fire, et cetera, and puncture tests, and it seems like they pass all these tests very, very well. They really are very, very stout.

Response
As noted in this comment, casks for the transportation of spent nuclear fuel and high-level radioactive waste would be extremely robust and would be a major factor in ensuring the safety of the transportation of these materials. As discussed in Section J.1.4.2.1 of the EIS, nearly 100 percent of rail and truck accidents under the Proposed Action would not result in any release of radioactive material. Cask specifications and the stringent tests required to demonstrate that they meet these specifications are at 10 CFR Part 71. In addition to the testing requirements to demonstrate that the casks can withstand normal conditions of transport (10 CFR 71.71), there are even more rigorous requirements for testing (10 CFR 71.73) to demonstrate that the casks can withstand hypothetical accident conditions. Tests for normal conditions of transport subject the cask to heat, cold, reduced and increased external temperature, vibration, water spray, free drop, corner drop, compression, and penetration. Tests for hypothetical accident conditions include free drop (from a greater height than the normal condition test), crush, puncture, thermal (fire), and immersion.

13 (10946)
Comment - EIS000467 / 0008
As far as the necessity for the environment and jobs that nuclear power provides, nuclear energy industry ads are being challenged for being inaccurate in the newspapers and on the radio claiming to be emission free.

In the Great Lakes alone there are emissions emitted into the Great Lakes, uranium mining in the Great Lakes all of which has contributed to a growing inventory of radionuclides in the Great Lakes. All stages of the nuclear fuel chain are involved in this as well.

Response
Thank you for your comment.

13 (10958)
Comment - EIS001424 / 0003
The jobless/unemployment rate in the region of Southern Ohio (and Paducah, Ky.) is going to increase. About 22 percent of USEC's (United States Enrichment Corporation) workforce is scheduled for lay-off. USEC/DOE Portsmouth Gaseous Diffusion Plant located in Pike County of Ohio is the second largest employer in its congressional district. USEC/DOE Paducah Gaseous Diffusion Plant, Paducah, Ky. is the largest single employer in its congressional district. President of the Paper, Allied-Industrial, Chemical and Atomic Workers representing workers at Piketon, Ohio is quoted as saying:

'We will attempt to find transition work with the Department of Energy and seek an enhanced benefit package' for the people scheduled to lose their jobs beginning In July. ("USEC To Lay Off 850 Workers in Ohio, Kentucky," THE LEDGER INDEPENDENT, 4/4/00, A-4.)

What "transition" work is to be available from the Department of Energy has not yet been made public within the region. One hopes for clean-up funds for both Portsmouth and Paducah which employs union workers--rather than fund more studies and surveys! DOE Yucca Mountain must consider agency regulatory obligation to determine the suitability of the HLRW "permanent" repository. Privatizing the functions of former DOE sites--and DOE functions--appears to create swift changes in circumstances (i.e., social, economic, and technical regional benefits) in a global, competitive marketplace. International "understandings" and cooperative efforts appear to be subject to bottom line corporate profits and losses.

Bethesda, Md. based USEC was a federal agency set up to enrich uranium for commercial nuclear plants. It was privatized in 1998 to better compete in a global marketplace. Since being taken public in 1998, the company's stock price has fallen from $14.25 to $5.87 in trading Thursday. USEC officials say while the company is profitable, it is losing money on the Russian contract. The deal was set up by the U.S. government to keep Soviet-era warhead uranium away from rogue nations and terrorists. USEC has bought the uranium equivalent to 3,000 warheads. [The Ledger-Independent, 4/4/00, pg. A-4.]

Response
This EIS analyzes potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, as well as the No-Action Alternative. Comments related to the Portsmouth and Paducah Gaseous Diffusion Plants are outside the scope of this EIS. However, DOE shares the commenter's concerns about continued employment and the economic health of communities surrounding former DOE sites. To that end, DOE established its Office of Worker and Community Transition that (1) establishes policy and provides funding for contractor work force restructuring activities; (2) develops policy for contractor labor relations, oversees the collective bargaining process, and assists field organizations in labor/management relations; (3) establishes policy for community transition and allocates funding to mitigate economic impacts; (4) assists field organizations reduce the costs of maintaining the DOE infrastructure; and (5) provides information and opportunities for participation in the decisionmaking process affecting the contractor work force and adjacent communities.

Developing and operating the proposed repository at Yucca Mountain would increase jobs in the region of influence. Section 4.1.6 of this EIS describes potential socioeconomic impacts from performance confirmation, construction, operation and monitoring, and closure activities.

13 (11056)
Comment - EIS000475 / 0011
According to LOW-LEVEL RADIOACTIVE WASTES, STATES ARE NOT DEVELOPING DISPOSAL FACILITIES, GAO/RCED-99-238 no disposal facility for commercially generated low-level radioactive waste has been sited in the past 18 years despite the "compact" regional system and $600,000.00 spent. Common "obstacles and impediments" in the siting process include:

...the controversial nature of nuclear waste disposal, which often manifests itself in the form of skepticism about and/or opposition to disposal facilities by members of the public and political leaders at all levels of government, Ref.: LOW-LEVEL RADIOACTIVE WASTES, GAO/RCED-99-238, Sept. 99, page 5.

Opening the LLRW market to private industry could result in construction of operating facilities which would meet the needs of the commercial LLRW generators.

Response
Thank you for your comment. This EIS analyzes a Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, as well as the No-Action Alternative.

13 (11083)
Comment - EIS000309 / 0001
In other words, you work with the life giving natural resources rather than with life taking manmade resources. And if you never can catch up to the guide to tell him yourself and if the assistants are mostly unresponsive, you will just need to stop following them and work instead with the people around you to find a new direction in the light.

Response
Thank you for your comment.

13 (11149)
Comment - EIS000320 / 0001
I remember World War II, where we had about four to six million people killed. And for us who were in that war, when we looked at the atomic bomb, we thought, “At least the war’s going to be ended. Hurrah, you know, we’re going to save lives.” That’s one factor. The other factor is that I look at all the benefits that come from nuclear radiation. The woman talked about a small child that died from an inoperable cancer. I had a relative and two friends who were cured of cancer using irradiation. Approximately 3,000 people are saved each year treating cancer with radiation.

How many gas and chemical containers go down the railroad tracks that could be just as detrimental or more detrimental than radiation?

We keep talking about the potential accidents that could possibly happen if a cask should be ruptured. And yet we kill about 56,000 people per year in the United States with cars. Why don’t we outlaw cars? That’s a given, that’s a proven fact: every year we kill 55,000. But we may kill some people in a nuclear incident? I have a hard time comprehending that.

Response
Thank you for your comment and recognition that the risk of a potential accident from transporting spent nuclear fuel is extremely low.

13 (11457)
Comment - EIS010080 / 0005
They [nuclear-energy producers] sued the DOE and won in the Supreme Court and now they’re suing the EPA. The DOE and the EPA are you and me again! These same energy producers are holding our economy and us hostage. They could be manipulating power production and pipeline access to create an artificial shortage. Why are their profits doubling and tripling?

Response
Private commercial utilities and their ratepayers have paid approximately $9.8 billion in the Nuclear Waste Fund to pay for the development of a repository for the disposal of spent nuclear fuel and high-level radioactive waste. The Nuclear Waste Policy Act of 1982 specifies that the Federal Government is responsible for providing for the permanent disposal of spent nuclear fuel and high-level radioactive waste, and that the costs of this disposal should be the responsibility of the generators and owners of spent nuclear fuel and high-level radioactive waste. Commercial utilities pay a fee of 1 mil (one-tenth of 1 cent) per kilowatt-hour of electricity generated by nuclear energy to cover disposal costs for commercial spent nuclear fuel.

13 (11458)
Comment - EIS010080 / 0004
Ever since then, generous Congresses have given this industry subsidies and tax breaks, research and development funding and subsidized education. Congress also passed the Price Anderson bill, to limit liability in the event of a nuclear accident, while we have no insurance coverage.

Response
This EIS analyzes the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, as well as the No-Action Alternative. The Price-Anderson Act provides liability coverage for commercial activities operating under a license from the Nuclear Regulatory Commission and DOE activities. The Price-Anderson Act establishes a system of private insurance and Federal indemnification that generally ensures that up to $9.43 billion is available to compensate for damages suffered by the public from a “nuclear incident,” regardless of who causes the damage. The EIS has been revised to include more details about indemnification under the Price-Anderson Act (see Section M.8 of the Final EIS).

13 (11509)
Comment - EIS000454 / 0003
Jobs are very important, but clean, safe, morally acceptable jobs are what's important, not just any job. I very much support union members in their concern for jobs. But not just any job will do. If we get together and demand decent, morally acceptable jobs, maybe there will be enough of us together.

Response
Thank you for your comment.

13 (11735)
Comment - EIS010032 / 0001
We need two nuclear waste repositories with fast breeder reactors for recycling fuel rods, pellets and warhead material. They should be centrally located for closer access by eastern and western nuclear facilities; i.e., in coal mines of Wyoming and Kentucky for example. Coal mines are naturally radioactive. More radioactive heavy metal is released into the environment by burning coal than all the spent fuel rods now in storage. Each coal fired power plant releases 74 pounds of uranium U-235 every year which could be surreptitiously recapture [sic] enough material for two nuclear bombs. We have to get real and inform the public about the facts, soon.

Response
The scope of this EIS is limited to an analysis of the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, as well as the No-Action Alternative. The construction of nuclear waste repositories with fast breeder reactors for recycling fuel rods, pellets, and warhead material are beyond the scope of this EIS.

13 (12298)
Comment - EIS010138 / 0001
I would also request that the Department of Energy, when it does its Yucca Mountain tours, quit referring to the Amargosa area as the Amargosa Desert where nothing lives. 30 million people are fed by the milk that is produced in Amargosa. 25 percent of our state's milk production is produced in Amargosa. It's a vibrant, living community and they deserve better.

Response
Thank you for your comment.

13 (12368)
Comment - EIS010139 / 0004
I do have a good question. I know the S&ER was printed on recycled paper, I thank you for doing that. How much of it was post consumer recycled? There's a question.

Response
The Science and Engineering Report (DIRS 153849-DOE 2001) was printed on paper of at least 20-percent postconsumer recycled content.

13 (12583)
Comment - EIS000815 / 0005
Most of the waste generated at DOE's Hanford, WA site is in a form and configuration that provides reasonable assurances of safe, long-term isolation from the biosphere. The Hanford site is a desert with seven inches of annual rainfall. It is bordered on two sides by the Columbia River and surrounded by tens of thousands of square miles of desert. Physical and chemical tests of soils conducted during the 1950s and 1960s showed that the combination of dryness and ion exchange capacity of the soils would preclude significant transport of intensely radioactive materials until after full decay. Moreover, attempts to recover wastes from soil and old tanks would result in needless radiation exposure to workers, and compromise the integrity of stored wastes. Finally, although small amounts of radioactivity might move with ground water into the Columbia River, which flows alongside the Hanford site, the amounts would be much less than those released from routine operations during the 1950s and 1960s. These releases were monitored, and there was no indication of adverse consequences to humans or other life forms.

Operations to remove wastes from the soil and waste tanks at Hanford should be discontinued, except where there is evidence of danger. However, continuing surveillance should be maintained, in connection with other nuclear activities for the benefit of humans.

Response
The *Final Environmental Impact Statement for the Tank Waste Remediation System* (DIRS 103214-DOE 1996) evaluates the management of DOE Hanford Site wastes in soils and tanks. The purpose of this EIS is to provide information on potential environmental impacts that could result from a Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at the Yucca Mountain site.

13 (12874)
Comment - EIS010297 / 0001
I would like to have my patent considered for the Yucca Mountain Project, for the storage and dispossal [disposal] of your low level and high level Nuclear Waste, toxic chemicals and/or spent fuel. I also feel that to proceed with a full patented device, rather than a patent pending device, is the way that I would like to proceed. This device I believe will solve most of your problems at Yucca Mountain.

Response
Thank you for your comment. The scope of this EIS is limited to an analysis of the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive was at Yucca Mountain, and the No-Action Alternative. The commenter can contact the United States Patent and Trademark Office for information at http://www.uspto.gov/ or contact them by telephone at 1-800-786-9199 or 703-308-4357.

Comment - EIS010236 / 0005
The electric power industry should make way for truly clean ways of generating electricity - solar, wind, hydrogen and hydrogen fuel cells. The longer nuclear and fossil fuel generators are subsidized by the federal government, the longer these great new technologies will be delayed.

Response
Ratepayers and utilities are paying the cost for the disposal of commercial spent nuclear fuel, not the Federal Government. Commercial utilities pay a fee of 1 mil (one-tenth of 1 cent) per kilowatt-hour of electricity generated by nuclear energy to cover disposal costs for commercial spent nuclear fuel. The Federal Government pays for waste generated and owned by the United States from taxpayer revenues as appropriated by Congress. The scope of this EIS is to analyze the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste.

Comment - EIS010246 / 0010
The SDEIS reveals that Yucca Mountain would be the world's first solar and wind powered atomic waste dump. This begs the question: couldn't renewable energy be used to generate electricity in the first place, so that nuclear power can be phased out and no more high-level nuclear waste generated?

Response
The scope of this EIS is limited to an analysis of the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, and the No-Action Alternative. DOE is committed to the development and responsible use of all types of energy, including renewable energy sources such as geothermal, wind, solar, hydrogen, biomass, and hydropower. DOE's Office of Energy Efficiency and Renewable Energy is responsible for leading the Nation's efforts in the study of renewable energy sources. For information on the Office's activities, please visit its web site at http://www.eren.doe.gov, or write to U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, 1000 Independence Ave., S.W., Washington, DC 28585.

Comment - EIS010129 / 0005
So there's also an opportunity that we have because despite the fact that we're in this most powerful empire in the history of the world, there's a weakness and that is that the United States still allows freedom of speech. And so if we don't exercise that and start listening to each other and go beyond just the freedom of speech and into dialogue and into further action based on the wisdom that we can come up with communally, then we can do a good job of taking care of each other despite the powers that be in the United States.

Response
Thank you for your comment.

Comment - EIS010161 / 0002
I also forgot to mention at the DOE hearings in '93 in Concord I told of having heard of missing plutonium at the Concord Naval Weapons Station, which occurred at the time of the murder of Lieutenant Commander Peter Herlin in the aftermath of the Brian Wilson maiming where he lost his legs to a weapon train there. It was an unsolved murder.

My point here about that is the fact that none of my comments appeared in the environmental impact report on the use of Concord weapons station as a trans shipment point. And not so much the theory, the rumor, because I just presented it, having heard it from three different military sources, but the fact that my comments were not in that environmental impact report, not even as this lunatic thinks that these soldiers told him when the lieutenant commander was murdered that there was also missing plutonium from the base.

Response
The scope of this EIS is limited to an analysis of the potential environmental impacts of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste at Yucca Mountain, and the No-Action Alternative. Other issues identified by the commenter are beyond the scope of this EIS.
