ACRONYMS AND ABBREVIATIONS

To ensure a more reader-friendly document, the U.S. Department of Energy (DOE) limited the use of acronyms and abbreviations in this environmental impact statement. In addition, acronyms and abbreviations are defined the first time they are used. The most common acronyms and abbreviations used in the text of this document are listed below.

CFR	Code of Federal Regulations
DOE	U.S. Department of Energy (also called *the Department*)
EIS	environmental impact statement
EPA	U.S. Environmental Protection Agency
FR	*Federal Register*
LCF	latent cancer fatality
MTHM	metric tons of heavy metal
NEPA	National Environmental Policy Act, as amended
NRC	U.S. Nuclear Regulatory Commission
NWPA	Nuclear Waste Policy Act, as amended
PM_{10}	particulate matter with an aerodynamic diameter of 10 micrometers or less
$PM_{2.5}$	particulate matter with an aerodynamic diameter of 2.5 micrometers or less
REMI	Regional Economic Models, Inc.
RMEI	reasonably maximally exposed individual
Stat.	United States Statutes
TSPA	Total System Performance Assessment
U.S.C.	United States Code

UNDERSTANDING SCIENTIFIC NOTATION

DOE has used scientific notation in this EIS to express numbers that are so large or so small that they can be difficult to read or write. Scientific notation is based on the use of positive and negative powers of 10. The number written in scientific notation is expressed as the product of a number between 1 and 10 and a positive or negative power of 10. Examples include the following:

Positive Powers of 10
$10^1 = 10 \times 1 = 10$
$10^2 = 10 \times 10 = 100$
and so on, therefore,
$10^6 = 1,000,000$ (or 1 million)

Negative Powers of 10
$10^{-1} = 1/10 = 0.1$
$10^{-2} = 1/100 = 0.01$
and so on, therefore,
$10^{-6} = 0.000001$ (or 1 in 1 million)

Probability is expressed as a number between 0 and 1 (0 to 100 percent likelihood of the occurrence of an event). The notation 3×10^{-6} can be read 0.000003, which means that there are three chances in 1,000,000 that the associated result (for example, a fatal cancer) will occur in the period covered by the analysis.

Transportation Modes, Routes, Affected Environment, and Impacts

8. TRANSPORTATION MODES, ROUTES, AFFECTED ENVIRONMENT, AND IMPACTS

DOE received many comments stating that the transportation portions of the Draft EIS did not provide sufficient information or analysis, and that the analyses relied on incomplete and outdated information. Commenters concluded, therefore, that the transportation-related analyses were inadequate, and substantively and legally deficient.

DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in the State of Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was recommended and approved, at some future date DOE would issue a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), in Nevada DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event DOE selected heavy-haul truck as its mode of transportation in the State of Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

Nevertheless, because of the public's interest in transportation in general and in the related information and analyses, the Department has included in this Final EIS descriptive information (for example, Appendix, M, *Supplemental Transportation Information*), and maps and tables that show the analyzed routes and estimated health and safety impacts for each state through which the shipments would pass. Appendix M provides general background information about transportation-related topics, such as transportation operations, cask testing requirements, and emergency response.

DOE has revised the analyses to respond to comments and to reflect new information that has become available since publication of the Draft EIS. For example, as requested by commenters, DOE has analyzed the effects of different mixes of rail and truck shipments and has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data. In addition, new information has led DOE to revise, for instance, the transportation accident analyses to reflect the Nuclear Regulatory Commission document *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000).

Many of the following comments indicate dissatisfaction with the adequacy of the transportation analyses. However, for ease of reading and to facilitate understanding of the Department's responses in this chapter, DOE has elected not to repeat the above response. Rather, the reader is referred to this chapter introduction for additional information.

Comment - 56 Comments Summarized
Commenters stated that spent nuclear fuel and high-level radioactive waste could be transported safely to Yucca Mountain, with negligible radiological impacts to public health and safety and the environment. As evidence for this belief, commenters cited such things as the safe record of nuclear-materials transportation over the past 50 years; stringent shipping regulations; extensive testing and certification of shipping casks; robust cast construction; careful training of drivers; special safety features of trucks; and sophisticated tracking of shipments and communications.

Response
The results of the analyses presented in Chapter 6 and Appendix J of the EIS are consistent with the observations of the commenters.

8 (3801)
Comment - EIS001282 / 0003
The Draft Environmental Impact Statement fails to provide essential details about the modes and routes of transportation of the spent nuclear fuel and high-level radioactive waste. The public deserves full disclosure about the amounts, frequency, and types of materials that would pass through the cities where they live, work, and enjoy recreational activities.

Response
In response to public comments, Appendix J of the EIS has been revised to provide state-by-state maps of routes used in the analysis. These maps contain tables that show the numbers of shipments originating in and passing through each state by mode and provides the impacts from the shipments in each state. These numbers should be considered preliminary, as there are many factors that could cause the modes and routes to change, including waste generator site operations, trading of pickup allocations, selection of a different transportation mode for shipments by the site operator, or recommendation of alternate routes by states and tribes. Impacts in individual states could be different if the actual routes from generator sites to Yucca Mountain are different from those analyzed. However, it is not likely that the total impacts from transportation would be changed significantly or that any particular route connecting an origin/designation pair would present a significant difference in impact from any other.

DOE used two analytical scenarios—mostly legal-weight truck and mostly rail—as the basis for estimating the number of shipments of spent nuclear fuel and high-level radioactive waste from 72 commercial and 5 DOE sites. DOE selected the scenarios because, about 10 years before the proposed start of operations at the repository, it cannot accurately predict the actual mix of rail and truck shipments (mode) that would occur from the 77 sites. Similarly, routes used in the analysis of transportation impacts are highways and rail lines that DOE anticipates it could use for shipments to the repository. However, at this time, about 10 years before start of operations at the repository, specific routes have not been determined. Until such time as a repository site is approved, specific routes and the number of shipments along those routes cannot be determined. Additional discussion of routing can be found in Section M.3 of the EIS.

Comment - EIS001286 / 0007
In addition to concerns about packaging degradation, we must raise concerns about degraded fuel. DOE must study the fuel from the Perry plant and other nuclear power plants that have fuel rods leaking radioactivity. According to some scientists, this leaking fuel poses a serious threat to public safety and violates the operating licenses. Although it is a violation of federal regulations and a severe health risk for nuclear plants to continue operating with known fuel damage, the plants continue to operate with leaking reactor cores. This leaking fuel has been attributed to debris fretting or to undetected manufacturing defects-the fuel has pin point holes, bad end cap welds and axial cracks. GE believes that the root cause of the failures is undetected manufacturing defects, possibly exacerbated by the Perry operating practice of using control rod movement rather than flow control for minor power adjustments. What is going to happen when this fuel hits the road? DOE should evaluate fuel for undetected defects.

Response
The EIS does consider the issue of degraded fuel. Fuel with identified leaks would be shipped to the site in disposable canisters that have been sealed at the site of generation. These canisters wold be placed directly in the

disposal container (which becomes the waste package after it is filled, sealed and tested) without being opened at the repository.

DOE recognizes that some fuel rods would have undetected flaws and that there might be releases to the interior of the transportation canisters and casks. However, the shipping casks would be sealed during transportation and leaks to the exterior of the cask are highly unlikely. The surface handling facilities at the repository are designed to contain any contamination that might be released during transportation. Chapter 2 and Chapter 4 address surface facility operations and wastes generated from decontamination of canisters used in transportation, as well as the management of wastes from the treatment of water in the fuel handling pools.

Degraded fuel rods should have no impact on transportation in terms of radiation exposures or potential releases of radioactive materials associated with accidents or sabotage.

Finally, the studies of long term performance of the repository do assume some cladding failure at the beginning of the analysis period. This is further discussed in Section K.2.1.4 of the EIS.

The issues raised by the commentator concerning the risks of continued operations of nuclear powerplants with known fuel damage is not a subject of this EIS, nor is it a subject that is under the control of the Department of Energy. Operating commercial nuclear reactor licenses and safety concerns are the purview of the Nuclear Regulatory Commission.

8 (6949)
Comment - EIS000390 / 0003
An adequate environmental review of the proposed repository program must absolutely address the deadly nature of the waste to be shipped and buried, yet DOE barely touches on the radiological risks posed by highly irradiated nuclear fuel. Information on the total activity (in curies) and the surface dose rate (in rems per hour) of the assemblies of irradiated fuel is essential for the assessment of risks posed by the transportation and burial of radioactive waste, yet DOE does not provide such data.

According to the State of Nevada, a typical assembly from a pressurized water reactor will contain, even after 26 years of cooling, 31,000 curies of cesium-137 and 21,000 curies of strontium-90, and is a powerful source of penetrating gamma and neutron radiation. One unshielded assembly would have enough radiation to give a person standing next to it a dose of at least 100 rem per minute. After only two minutes of such exposure, cancer risk would roughly double, and symptoms of radiation sickness would probably appear. Ten minutes exposure would be enough to deliver a speedy but painful death to virtually all people exposed. Furthermore, shipping waste as fresh as five years old to the repository is contemplated, and should therefore have been included in the DEIS as a possible scenario, one which would carry even greater radiological risk.

Response
DOE did not estimate the consequences for persons or the environment that could be exposed to bare spent nuclear fuel outside shipping casks because transportation accidents severe enough to eject spent nuclear fuel from shipping casks are not reasonably foreseeable. Bare spent nuclear fuel assemblies represent a powerful source of penetrating radiation. However, because of its high radiation dose rate, heavy shielding, which can include several feet of water shielding, concrete structural shielding for remote-operated hot cells, or massive metal containers such as shipping casks, is always provided for spent nuclear fuel. During shipment, spent nuclear fuel and high-level radioactive waste would be contained within heavily shielded shipping casks that comply with Nuclear Regulatory Commission (NRC) regulations for performance under normal conditions of transportation and accidents. The shipping casks provide the shielding necessary to reduce the radiation dose rate emitted from the shipping cask to safe levels under both normal and accident conditions. Chapter 6 of the EIS presents DOE estimates of risks and consequences of accidents in transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain using such NRC certified shipping casks. DOE estimated the risks and consequences using information from an NRC study (DIRS 152476-Sprung et al. 2000), which analyzed performance of casks and spent nuclear fuel contents in severe transportation accidents. Although the NRC study evaluated a range of severe accidents, including very unlikely ones that would release radioactive materials from shipping casks, it did not project even the most extreme accidents would eject spent nuclear fuel from a shipping cask where persons or the environment could be directly exposed.

The commenter pointed out that the assumptions used in the EIS for the age and radiological characteristics of spent nuclear fuel in the maximum reasonably foreseeable accident scenarios could understate the transportation risks. It is true that DOE could ship some spent nuclear fuel that is more radioactive than the 26 year-old pressurized water reactor spent nuclear fuel analyzed in the scenario. Based on comments received and DOE's additional review of technical documents and conduct of hazard analyses, the basis for the transportation impact analysis has been revised to consider commercial spent nuclear fuel that has median hazard. Spent nuclear fuel having median hazard would be discharged from a reactor approximately 14 years before shipment to Yucca Mountain. The radionuclide inventories of the representative spent nuclear fuel used in the analysis are presented in Tables A-8 and A-9 of the EIS. If any 5-year old or 10-year old spent nuclear fuel were to be shipped to the repository, it would be a small fraction of the total shipments. This is a case in which "average" data is used in the EIS as opposed to bounding assumptions. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing accident scenarios. Other elements of the impact analyses (for example, radiation dose rates, atmospheric dispersion modeling, release fractions) are such that the transportation impact results presented in the EIS are bounding yet not so conservative that the true differences among alternatives are masked.

8 (8491)
Comment - EIS010150 / 0005
Clearly there are other aspects of the Draft Environmental Impact Statement that has changed and will continue to change since the draft was released. Transportation significantly needs to be rewritten, and hearings on this issue need to be held in the communities that would be affected, some of which were not identified by the draft but now are likely to be affected by transportation.

To conclude, from the perspective of public health and safety, these issues should be of serious concern because we do not know at the end of the day, we do not have an assessment of the environmental impacts of the repository proposal.

Response
The Draft EIS discussed ongoing site characterization activities and design evaluations, and the potential for resulting changes to repository design. Since DOE issued the Draft EIS, it has acquired an improved understanding of the interactions of potential repository features with the natural environment, and the advantages of a number of design features (such as titanium drip shields) to enhance waste containment and isolation. DOE issued the Supplement to the Draft EIS to provide the updated information to the public. While aspects of the design have evolved, the basic elements of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain (such as transportation of spent nuclear fuel and high-level radioactive waste) remain unchanged. For this reason, the Supplement focused on the most recent design enhancements, including various operating modes to manage heat generated by emplaced spent nuclear fuel and high-level radioactive waste.

Because the Supplement focused primarily on matters involving repository design, the Department held three public hearings in Nevada during the comment period. Commenters nationwide were encouraged to submit comments at public hearings and by mail, facsimile, and the Internet during the comment periods. DOE used means comparable to those used for the Draft EIS (advertisements, releases, announcements) to notify the public.

DOE believes that the EIS adequately analyzes the environmental impacts that could result from either the Proposed Action or the No-Action Alternative. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts that could occur, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist.

8 (9209)
Comment - EIS002140 / 0006
Area 5. We're bringing in nuclear waste like crazy out there. I can remember working in Area 5 when certain shipments came in from submarines, so on and so forth and we couldn't even get near it. When the guys with guns would come out, we'd unload it and bury it in Area 5. It's been going on for years and years. This is -- shipping nuclear waste to Yucca Mountain is not a new thing.

Response
The comment is correct that the Nevada Test Site is a disposal site for low-level radioactive waste from around the DOE complex, and will continue to fulfill that role in the future. Chapter 8 of the EIS discusses how impacts from these disposal activities could contribute to cumulative impacts related to the proposed repository at Yucca Mountain.

The *Final Waste Management Programmatic Environmental Impact Statement For Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (DIRS 101816-DOE 1997) and the *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DIRS 101811-DOE 1996) and their respective Records of Decision describe low-level radioactive waste disposal at the Nevada Test Site.

8 (9662)
Comment - EIS002074 / 0007
With respect to transportation, too, I might also add that the maps that were given out in the handouts today and also the maps that are inclusive in the EIS, they clearly illustrate county boundaries and state boundaries, but they don't illustrate tribal boundaries. And so we may recommend that the maps be expanded, especially due to the special relationships and recognition that's given, that are afforded to tribes, that those boundaries be indicated in there as well as to give a clear and concise picture.

Response
In response to public comments, DOE has revised Appendix J of the EIS to include maps of the rail and truck routes, the number of shipments, and the impacts for each state through which spent nuclear fuel and high-level radioactive waste shipments was analyzed. These are estimates used for analyzing transportation impacts; the actual routes and number of shipments made through a state could be different depending on the routes actually. Native American lands within each state are indicated on both the state transportation maps in Appendix J and on the national transportation maps used throughout the EIS.

8 (10992)
Comment - EIS001952 / 0006
PUCO's [Public Utilities Commission of Ohio] transportation director has also just described the planning, strategy sessions, and citizens surveys for future land use and zoning currently being implemented (from 600 residents of Brown County selected from voter registration records). PUCO has issued grant which Ohio State University (OSU) is currently implementing. The implementation phase currently in progress Brown County most certainly indicates that transportation routing decisions have, in fact, already been made. Full participation by the public, as described by PUCC, appears to be re-invented as meetings to which the public is invited where questions and/or objections may be stated after-the-fact and too late to do any good.

Response
In the context of the letter that included this comment, the commenter is describing the actions of the Public Utilities Commission of Ohio in relation to the routing of spent nuclear fuel and high-level radioactive waste shipments through Brown County, Ohio, to the proposed repository at Yucca Mountain. Section 6.2 of the EIS discusses the transportation of these materials from the 77 generator sites to the State of Nevada.

The comment mentions public participation "as described by PUCO." Typically, the Department of Energy uses Federal publications (for example, the *Federal Register*) and public media (for example, newspapers, web sites, and radio and television stations). Individuals and organizations can add their names to the DOE mailing list to receive notifications of information availability and upcoming events. DOE has no control over how or when other organizations choose to notify their stakeholders.

8 (12090)
Comment - EIS002307 / 0004
Section 6 of the DEIS is incorrect in the evaluation of transportation risks because the DEIS uses outdated models (RISKIND and RADTRAN4) to compute the risk factors.

Response
The RISKIND code has been used widely and is generally accepted as appropriate for estimating the consequences of transportation accidents that could release radioactive materials. RADTRAN 5 was used for the analyses in the Final EIS.

8 (12273)
Comment - EIS010096 / 0017
Figure 2-4 of the SUPPLEMENT TO THE DRAFT EIS refers only to direct rail access and heavy-haul access to the site. The text on Page 2-12 refers to legal-weight trucks. It is not clear if DOE anticipates legal-weight trucks being used to transport waste directly to the Yucca Mountain site.

Response
Even though DOE has expressed a preference for rail, both nationally and in Nevada, the repository design would facilitate the ability to receive spent nuclear fuel or high-level radioactive waste delivered by legal-weight truck.

8 (12415)
Comment - EIS010279 / 0004
Although transportation issues were not discussed in the Supplement to the Draft EIS, the DOE recently informed the Timbisha Shoshone Tribe that the proposed *Carlin/Caliente Bonnie Claire Option* for a rail corridor to Yucca Mountain goes right through the Scottys Junction Trust Parcel of the Tribe (see attached map). Let it be on record that the Timbisha Shoshone Tribe strongly opposes this proposed rail corridor because of its potential threat to the land, the safety of tribal members, and the adverse effects it would have on the Tribe's economic development. The inadequate, small scale map in the DEIS (p. 6-42) did not show this occurrence even though *The Timbisha Shoshone Tribal Homeland: A Draft Secretarial Report to Congress to Establish a Permanent Tribal Land Base and Related Cooperative Activities* indicated the location of the proposed Trust land parcel (p. 35) and was published in April 1999, three months before the publication of the DEIS for Yucca Mountain.

Response
The Department acknowledges the Timbisha Shoshone Tribe's opposition to the Bonnie Claire option of the Carlin and Caliente Corridors. At this time, DOE has not identified a preference for a specific rail corridor within Nevada. DOE would identify a preferred corridor only if the Yucca Mountain site were approved under the NWPA, and then only after consultation with affected stakeholders, particularly the Timbisha Shoshone Tribe.

Section J.3.1.3 of the EIS contains a discussion of the land-use conflicts with each of the evaluated rail corridors, including the Bonnie Clare Alternate. Detailed corridor maps included in this section show the Timbisha Shoshone Trust Lands and the proposed alignment.

8.1 General Opposition to Transporting Spent Nuclear Fuel and High-Level Radioactive Waste

8.1 (170)
Comment - 589 comments summarized
Commenters stated their opposition to the transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain by rail, heavy-haul truck, or legal-weight truck. In many cases, reasons for the opposition were not specified or were very broad in scope. Examples include broad, nonspecific impacts to the environment and ecosystem; generic accidents with catastrophic consequences; incidental and cumulative radiation exposure to millions of people along the transport routes during decades of transport; sabotage and terrorist attacks; and natural disasters.

Many commenters expressed opposition to spent nuclear fuel and high-level radioactive waste transport through specific neighborhoods, cities, heavily populated areas, specific states, and other areas. Reasons for the opposition included the proximity of potential routes to specific structures and areas such as private residences, schools, hospitals, lakes, rivers, and Native American tribal lands. Some commenters stated that the EIS does not provide adequate detail regarding transportation risks along designated nationwide routes and specific cities and communities. Others were opposed because of the disproportionate share of shipments that would travel through a particular neighborhood, city, or state. Still others were opposed because they believe their quality of life would be adversely affected due to the large number of shipments over many years.

Commenters were also opposed to spent nuclear fuel and high-level radioactive waste transport because of site-specific concerns about emergency preparedness training, cleanup costs after an accident, and predicted damages to property values if an accident occurred.

Response

Based on the results of the impact analyses presented in Chapter 6 and Appendix J of the EIS, as well as the results published in numerous other studies and environmental impact analyses cited in the EIS, DOE is confident that spent nuclear fuel and high-level radioactive waste could be and would be safely transported to Yucca Mountain. DOE believes, as the EIS reports, that the potential impacts of this transportation would be so low for individuals who lived and worked along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured. The analysis presented in the EIS factored in the characteristics of spent nuclear fuel and high-level radioactive waste, the integrity of shipping casks that would be used for transportation, and the regulatory and programmatic controls that would be imposed on shipping operations (see Appendix M). The EIS analytical results are supported by numerous technical and scientific studies that have been compiled through decades of research and development by DOE and other Federal agencies of the United States, including the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as by the international community, including the International Atomic Energy Agency.

DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. For instance, DOE selected the RADTRAN 5 computer program to estimate radiological impacts to populations from incident-free transportation and from accidents. RADTRAN, which was originally developed by Sandia National Laboratories in the late 1970s, has been used in many other DOE EISs, and it has undergone periodic review and revision. In 1995, a review of RADTRAN 4 (immediate predecessor of RADTRAN 5) demonstrated that it yielded acceptable results when compared to “hand” calculations. More recently, a review found that RADTRAN 5 overestimates the measured radiation dose to an individual from moving radiation sources.

To ensure that the EIS analyses reflect the latest reasonably available information, DOE has either incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relied on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data.

Transportation by legal-weight truck would involve shipments along Interstate System highways, beltways, and bypasses, where available, in accordance with U.S. Department of Transportation regulations (49 CFR 397.101). These regulations allow states and tribes to designate alternate routes in accordance with U.S. Department of Transportation guidelines (49 CFR 397.103). Thus, states and tribes would have the opportunity to designate eligible routes that they prefer to be used.

There are no Federal regulations pertaining to rail routes for shipment of spent nuclear fuel or high-level radioactive waste. The shipper and railroad companies (carriers) determine rail routes based on best available trackage, schedule efficiency, and cost-effectiveness. This includes selecting routes that result in minimum time in transit, minimum interchanges, and maximum use of mainline tracks. The routes must be submitted in advance to the Nuclear Regulatory Commission for approval. In addition, DOE has developed operational protocols (see Section M.3 of the EIS) that include guidelines for selecting rail routes. DOE applied the guidelines in identifying routes for analysis in the EIS.

Section 6.2.4 of the EIS provides results of analyses from postulated transportation accidents and Section J.1.4 provides details of the methods and data used in the analyses. The analysis of impacts to populations along shipment routes assumed that an accident could occur at any location along the route. Given the number of shipments, traffic accidents probably would occur, although DOE does not believe that any of the accidents would be severe enough to result in the release of radioactive material, primarily because of the structural integrity of the casks in which the material would be transported.

"Real-life" transportation accidents involve a myriad of collisions, such as with other vehicles and obstacles, that could result in fires and explosions, inundation or burial of a cask containing spent nuclear fuel and high-level radioactive waste. These accidents would be initiated by a variety of events including human error, mechanical failure, or natural causes, such as earthquakes or landslides. Accidents could occur in different places such as mountain passes, urban areas, on Interstate Highways in rural areas, or rail switchyards.

The combinations of accident conditions, initiating events, and locations is very large. Analyzing an extensive array of accident scenarios is neither practical nor meaningful. However, it is meaningful to analyze a range of reasonably foreseeable accident scenarios that consider, in effect, common initiating events and conditions having similar characteristics. Thus, for example, the EIS analyzes the impacts of various collision accidents in which a cask would be exposed to a range of impact velocities (see Section J.1.4.2.1).

The EIS also analyzes a maximum reasonably foreseeable accident, an accident with a probability of occurrence of about 3 in 10 million per year. To put this in perspective, this accident would occur once in the course of about 5 billion legal-weight truck shipments. In this scenario, a truck cask, not involved in a collision, would be engulfed in a fire with temperatures between 750°C and 1,000°C (1,400°F to 1,800°F) (see Section 6.2.4.2 of the EIS). The conditions of the maximum reasonably foreseeable accident analyzed in the EIS envelop conditions reported for the Baltimore Tunnel fire (a train derailment and fire that occurred in July 2001 in a tunnel in Baltimore, Maryland). Temperatures in that fire were reported to be as high as 820°C (1,500°F), and the fire was reported to have burned for up to 5 days.

DOE could decide to use a dedicated train that carried only the material to be shipped to Yucca Mountain, or could elect to move the spent nuclear fuel and high-level radioactive waste by general freight. If the material was shipped as general freight, the position of the spent nuclear fuel or high-level radioactive waste car in the train would be regulated by 49 CFR 174.85. This regulation requires that railcars placarded "radioactive" must be separated from a locomotive, occupied caboose, or carload of undeveloped film by at least one nonplacarded car, and it may not be placed next to other placarded railcars of other hazard classes.

Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000, all). DOE has concluded that the models used for analysis in the Draft EIS relied on assumptions about spent nuclear fuel and cask response to accident conditions that caused an overestimation of the resulting impacts. Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents. (Of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials.) This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS reports the potential consequences for accidents that could release radioactive materials.

The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection and safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the physical protection and safeguards regulation are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. The cask safety features that provide containment, shielding, and thermal protection also provide protection against sabotage. The casks would be massive. The spent nuclear fuel in a cask would typically be only about 10 percent of the gross weight; the remaining 90 percent would be shielding and structure.

It is not possible to predict whether sabotage events would occur, and if they did the nature of such events, nevertheless, DOE examined various accidents, including an aircraft crash into a transportation cask. The consequences of both the maximum reasonably foreseeable accident and the aircraft crash are presented in the EIS for the mostly truck and mostly rail transportation scenarios and can provide an approximation of the types of consequences that could occur from a sabotage event. In addition, DOE analyzed the potential consequences of sabotage against a truck or rail cask (see Section 6.2.4.2.3 of the EIS). The results of this analysis indicate that the risk of the maximally exposed individual incurring a fatal cancer would increase from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the terrorist attack of September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions the Department would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for addressing emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures (63 *FR* 23753; April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

The Price-Anderson Act establishes a system of financial protection (compensation for personal injury and property damage, including loss of use of property) for the public in a nuclear accident, regardless of who causes the damage. The Price-Anderson Act would indemnify any person held liable for damage, including cleanup of released radioactive materials. Persons indemnified would include DOE contractors, subcontractors, suppliers, state, local or tribal governments, emergency response workers, health care workers, other workers, victims, and other citizens who might be held liable. See Section M.8 of the EIS for a discussion of the Price-Anderson Act.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since the scoping process for this EIS to enable DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were scientific and social studies performed in the past few years that relate directly either to Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty.

- Much of the uncertainty is irreducible.

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as serious accidents, would not expect such accidents to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in the Final EIS.

8.1 (259)
Comment - 125 comments summarized
Many commenters expressed general opposition to the transportation of spent nuclear fuel and high-level radioactive waste through Nevada. A summary of the comments is as follows:

- Many were opposed to transportation near certain types of structures or areas, including schools, hospitals, businesses, lakes, rivers, and Native American tribal reservations.

- Some commenters were more specific, stating that the EIS does not provide adequate detail about the risks and impacts of spent nuclear fuel and high-level radioactive waste transport to specific towns and cities in Nevada and of impacts to areas through which the largest number of shipments would pass. Specific areas and issues mentioned by commenters include:

  - The Las Vegas Valley, including impacts on tourism
  - Impacts to communities near Yucca Mountain
  - The effects on property values along transportation routes
  - Impacts of using specific routes such as State Route 160 in Pahrump Valley
  - Impacts to specific communities such as the town of Enterprise;
  - Impacts to land use and access across a branch rail line

Impacts of heavy-haul truck shipments from Caliente and the feasibility of using U.S. 95 because of steep grades, curves with a radius of less than 240 meters (800 feet), and critical side slopes and steep dropoffs that would increase the probability of accidents and complicate subsequent clean up

- Some commenters were opposed to the Caliente and Caliente-Chalk Mountain Corridors through Garden Valley, stating that the use of existing roads would be less wasteful and better from an environmental standpoint.

- The hot springs near the northern end of the Carlin Corridor, as well as the seasonal playa lakes in the area, were cited as reasons not to select the Carlin Corridor. Other commenters, however, said that the Carlin Corridor would be the best because it would avoid many towns and cities in Nevada.

Some questioned the overall suitability of roads and highways in Nevada to transport spent nuclear fuel and high-level radioactive waste, including the potential for transportation accidents. Many commenters had specific concerns about the use of the Las Vegas Beltway for truck shipments to Yucca Mountain. These concerns included:

- The possibility that the Beltway would not meet Interstate Highway System standards until 2023, which is many years after shipments would begin and the use of the U.S. Highway 95/I-15 interchange (the "Spaghetti Bowl") while the Beltway is being completed

- The costs of accelerated construction of the Beltway;

- The future population that would be exposed to spent nuclear fuel and high-level radioactive waste shipments along and near the Beltway, including expected heavily populated residential and commercial areas along the beltway in the City of North Las Vegas and in the Summerlin area on the west side of Las Vegas, and the use of projected traffic volumes on the Beltway in the future.

- Figure S-12 incorrectly shows secondary roads not extending to the vicinity of the Las Vegas Beltway when these roads already extend well beyond the beltway.

Others commenters were concerned about terrorist attacks, sabotage, and security issues; inexperienced drivers; evacuation measures; emergency response; radiation exposure; compensation for injuries; advance notice of shipments; local control of routing and time-of-day restrictions; bad weather; and the presence of Native American tribal populations along the routes.

Response

Based on the results of the impact analyses presented in Chapter 6 and Appendix J of the EIS, as well as the results published in numerous other studies and environmental impact analyses cited in the EIS, DOE is confident spent nuclear fuel and high-level radioactive waste can be and would be safely transported to Yucca Mountain. DOE believes, as the EIS reports, that the potential impacts of this transportation would be so low for individuals who live and work along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured. The analysis presented in the EIS factored in the characteristics of spent nuclear fuel and high-level radioactive waste, the integrity of shipping casks that would be used for transportation, and the regulatory and programmatic controls that would be imposed on shipping operations (see Appendix M). The EIS analytical results are supported by numerous technical and scientific studies that have been compiled through decades of research and development by DOE and other Federal agencies, including the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as by the international community, including the International Atomic Energy Agency.

DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. For instance, DOE selected the RADTRAN 5 computer program to estimate radiological impacts to populations from incident-free transportation and from accidents. RADTRAN, which was originally developed by Sandia National Laboratories in the late 1970s, has been used in many DOE EISs, and it has undergone periodic review and revision. In 1995, an independent review of RADTRAN 4 (immediate predecessor to RADTRAN 5) demonstrated that it yielded acceptable results when compared to "hand" calculations. More recently, an independent review found that RADTRAN 5 overestimates the measured radiation dose to an individual from moving radiation sources.

To ensure that the EIS analyses reflect the latest reasonably available information, DOE has either incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relied on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data.

Spent nuclear fuel and high-level radioactive waste can be harmful to human health and the environment because they emit radiation as the elements in them decay. For this reason, Nuclear Regulatory Commission and U.S. Department of Transportation regulations, as well as DOE's own internal Orders, specify containment, shielding, thermal, and nuclear safety requirements for shipping containers (casks). These regulations are designed to preclude even a remote chance of direct exposure. In addition, spent nuclear fuel and high-level radioactive waste are not easily dispersed; they do not readily dissolve in water; they are not liquids or gases that can be easily spilled or leaked, and radiation from them does not make other materials radioactive. Spent nuclear fuel and high-level radioactive waste are solids. They are hard, tough, and dense ceramics, metals, or glasses contained within tough metal barriers.

The shipping casks used to transport these materials are massive, with design features that comply with strict regulatory requirements to ensure that the casks are fault-tolerant. That is, the casks must perform their safety functions even when damaged. Numerous tests and extensive analyses, using the most advanced analytical methods available, have demonstrated that these types of shipping casks would provide containment and shielding even under the most severe kinds of accidents. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000, all). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents. (Of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials.) This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS reports potential consequences for accidents that could release radioactive materials.

Although the risk of releasing radioactive materials from a shipping cask in an accident would be small, the U.S. Department of Transportation requires highway shipments to use preferred routes that reduce time in transit (49 CFR 397.101). The Department of Transportation regulations provide for states and tribes to designate alternate preferred routes. These regulations require a state or tribe to consider overall public safety in designating routes that would be in lieu of or in addition to routes specified by the Department of Transportation regulations. For example, under current Federal regulations, before DOE highway shipments of spent nuclear fuel and high-level radioactive waste could use U.S. 95 through Mineral County, Nevada, the State would need to designate this route as an alternate route. The Department of Transportation requirements and the planned completion of the Las Vegas Beltway led DOE to assume, for purposes of analysis in the EIS, that legal-weight truck shipments would not enter the Spaghetti Bowl interchange of Interstate-15 and U.S. 95. Nevertheless, to assess how potential impacts would be different from those of using the Las Vegas Beltway, DOE analyzed the impacts for legal-weight trucks to travel through the Spaghetti Bowl interchange (see Section J.3.1.3 of the EIS for an analysis of the impacts of using different routes in Nevada). DOE did not analyze transportation by heavy-haul trucks through the Spaghetti Bowl interchange because use of the interchange would not be practical. The high volume of traffic through the interchange combined with the slow progression of the trucks through the turns and the over-length configurations of the vehicles would create excessive disruptions of traffic flow.

DOE revised maps in the EIS to represent streets and roads correctly in the Las Vegas Valley and illustrate that many extend to and beyond the Las Vegas Beltway.

The U.S. Department of Transportation routing requirements, along with regulatory requirements to limit radiation dose external to a shipping cask, would help to ensure that radiation doses to persons residing along the routes would be low. The analysis in Chapter 6 of the EIS for the mostly legal-weight truck scenario estimates the dose to persons who would drive alongside the trucks as they traveled on the highways, who would be stopped in locales where truck shipments stopped, and who lived along the routes that would be used. In response to public comments, DOE forecasted growth in populations along routes to estimate potential impacts that could occur in the future when shipments would occur. However, the estimated dose to an individual living along a route would not change with changes in population—only the integrated dose to the whole population would change. The dose for a maximally exposed individual who lived along a route would be an average of about .25 millirem per year. This is about 400 times less than the maximum dose permitted for members of the public in 10 CFR Part 20 (100 millirem).

Based on public comments, the Final EIS includes estimated public health along transportation routes. This analysis accounted for factors such as the locations of intersections, commercial establishments and residences, and traffic signals. The impacts of incident-free transportation would be so low for individuals who lived and worked along the routes that these individual impacts would not be discernible even if the doses could be measured. The total impacts of transportation would be similar for different routes that might be used.

To calculate the potential impacts to a maximally exposed individual, DOE used information and assumptions from a report sponsored by the City of North Las Vegas, Nevada, because DOE believes it to be the only source of the information (DIRS 155112-Berger Group 2000). However, DOE considers the exposure assumptions presented in the report to be extreme and very unlikely to occur (see text box in Section 6.2.1 of the EIS for additional information). The DOE analysis of dose, using information and assumptions presented in the report, estimated a maximally exposed individual in Nevada would receive a dose of about 530 millirem over 24 years. This is an annual dose of about 22 millirem, which is about 6 percent of a 1-year exposure to natural background radiation, and 22 percent of the limit for members of the public listed in Nuclear Regulatory Commission regulations (10 CFR Part 20). A dose of 530 millirem would increase an individual's risk of a fatal cancer by about 1 chance in 4,000 over the person's lifetime. For perspective, an individual's lifetime risk of a fatal cancer from all other causes is about 1 in 4. So, even using the unlikely exposure assumptions contained in the Berger Group report shows that the dose to a maximally exposed individual would be well below that received from natural background radiation, would not be discernible, and would not add measurably to other impacts that an individual could incur.

Nuclear Regulatory Commission and U.S. Department of Transportation regulations (10 CFR Part 73 and 49 CFR Part 173, respectively) include requirements to ensure the physical security and protection of shipments from diversion and attack. For the Final EIS, DOE reexamined, for both rail and truck casks, the consequences of an attack that results in a release of material (in other words, the cask's shield wall would be penetrated) (see Section 6.2.4.2.3 of the EIS), and estimated consequences exceeded those presented in the Draft EIS. Differences in the consequences between the Draft EIS and the Final EIS are due to using "representative" spent nuclear fuel (rather than "typical" fuel in the Draft EIS) and an escalation of impacts to represent population growth to 2035. In addition, in the Draft EIS the consequences of the sabotage event were bounded by those of the maximum reasonably foreseeable accident.

The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection and safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the physical protection and safeguards regulation are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. The cask safety features that provide containment, shielding, and thermal protection also provide protection against sabotage. The casks would be massive. The spent nuclear fuel in a cask would typically be only about 10 percent of the gross weight; the remaining 90 percent would be shielding and structure.

It is not possible to predict whether sabotage events would occur, and if they did the nature of such events, nevertheless, DOE examined various accidents, including an aircraft crash into a transportation cask. The consequences of both the maximum reasonably foreseeable accident and the aircraft crash are presented in the EIS for the mostly truck and mostly rail transportation scenarios and can provide an approximation of the types of consequences that could occur from a sabotage event. In addition, DOE analyzed the potential consequences of sabotage against a truck or rail cask (see Section 6.2.4.2.3 of the EIS). The results of this analysis indicate that the risk of the maximally exposed individual incurring a fatal cancer would increase from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the terrorist attack of September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

Although DOE anticipates accidents would occur in transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain, it does not anticipate that an accident would lead to a release of radioactive materials from a shipping cask. Nevertheless, the Price-Anderson Act provides for indemnification of liability up to $9.43 billion to cover claims that might arise from an accident in which radioactive materials were released or one in which an authorized precautionary evacuation was made (see Section M.8 of the EIS for a more complete discussion of the Price-Anderson Act). If the damage from a nuclear incident appeared likely to exceed that amount, the Price-Anderson Act contains a Congressional commitment to thoroughly review the particular incident and take whatever action is determined necessary to provide full and prompt compensation to the public.

U.S. Department of Transportation regulations in Volume 49 of the Code of Federal Regulations and DOE's own Transportation Practices (see Appendix M of the EIS) would apply to shipments of spent nuclear fuel and high-level radioactive waste. Included are requirements for training of transportation personnel who are responsible for the safety of shipments, safety of vehicles, shipping documentation, financial responsibility of transportation carriers, emergency response notification, driving and parking requirements (including DOE requirements for transportation during severe weather conditions), and other requirements.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions the Department would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for addressing emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) of the NWPA (63 *FR* 23753; April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) policy and procedures.

In addition, DOE would employ satellite tracking and, in accordance with Nuclear Regulatory Commission regulations, provide advance notification to state, tribal (subject to Nuclear Regulatory Commission approval), and local officials for each shipment of spent nuclear fuel. DOE maintains a national radiological emergency response capability that is available to assist states and tribes in the event of a transportation accident (see Appendix M of the EIS).

DOE investigated the potential impacts of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain would have on multiple resource areas not related to human health and safety: land use; air quality; biological resources and soils; hydrology; cultural resources; socioeconomics; noise; aesthetics; waste management; utilities, energy, and materials; and environmental justice (see Chapter 6 of the EIS). The Department concluded that the impacts in these resource areas from nationwide transportation (outside Nevada) would not be discernible because shipments would use existing highways and railroads and would contribute only minimally to the volume of national transportation (0.007 percent of railcar kilometers and 0.008 percent of truck kilometers). Although radiological health and traffic fatality impacts would be adverse, because these potential impacts nationwide would not be high for any individual or identifiable group, including Native American tribes, DOE also concluded that transportation of these materials would not raise environmental justice concerns.

As discussed in the EIS, to provide for transportation of rail casks to Yucca Mountain, DOE could construct a branch rail line in one of five candidate rail corridors or could work with the State of Nevada to upgrade one of five highway routes for heavy-haul trucks and, in that case, construct an intermodal transfer facility. For three of the candidate routes for heavy-haul trucks and for purposes of analysis of socioeconomic impacts of heavy-haul truck shipments in Nevada, DOE assumed availability of loaned funds from sources external to Nevada to assist in accelerating construction of the Las Vegas Beltway, if needed. Heavy-haul truck shipments would not travel through the Spaghetti Bowl interchange of Interstate-15 and U.S. 95 in Las Vegas. For the three alternative routes that would pass through the Las Vegas Valley, these trucks would need to use a section of the Las Vegas Beltway to transit from Interstate-15 to U.S. 95 before continuing to Yucca Mountain. DOE's analysis of potential impacts in Section 6.3.3.1 considered the likelihood that large, heavy-haul trucks would affect traffic flow on roads that they would use, including causing delays to traffic on the Las Vegas Beltway. These shipments would be made under permits issued by the State of Nevada that would contain restrictions designed to minimize the effects on traffic of the large trucks.

In its evaluation of potential impacts of constructing a branch rail line in each rail corridor and of upgrading highways for use by heavy-haul trucks and constructing an intermodal transfer station in Nevada, DOE considered the potential impacts that could occur both to the natural environment and to communities, such as Caliente, that would be nearby (see Sections 6.3.2 and 6.3.3 of the EIS). For example, in the Garden Valley west of Pioche in northeastern Nye County, DOE biologists found the Welsh's catseye plant, classified as a sensitive species by the Bureau of Land Management, about 2.7 kilometers (1.7 miles) from a potential alignment of the Caliente Corridor (DIRS 104593 CRWMS M&O 1999). In this area, DOE identified potential variations in the Caliente Corridor alignment that could avoid a sensitive environmental feature or other feature that could affect the engineering or construction of the route. In the Carlin Corridor, DOE identified numerous springs within 5 kilometers (3 miles) of the alignment of a branch rail line. At the north end of this corridor, DOE biologists identified a hot spring approximately 0.5 kilometer (0.31 mile) east of Nevada Route 306 about 5 kilometers south of Interstate-80. DOE would locate the alignment of a branch rail line to minimize the potential to affect springs and wet areas.

If a corridor was selected for construction of a branch rail line, DOE would conduct field studies along the corridor that would identify sensitive ecological, and cultural resources, and specific land uses to be avoided. DOE would minimize land-use impacts and would avoid private land to the maximum possible extent. DOE would determine how to best avoid detrimental impacts; for example, in some areas, fences could be recommended to protect livestock and open culverts could allow access to both sides of the track.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since the scoping process for the EIS to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were scientific and social studies conducted in the past few years that relate directly either to Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty.
- Much of the uncertainty is irreducible.
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as serious accidents, would not expect such accidents to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

Comment - EIS000253 / 0002
The DEIS does not adequately detail proposed shipping routes or the training and equipment necessary for local emergency response personnel in communities along the routes. COPEEN is concerned about the number of shipments that would travel along the I-70 corridor. These shipments would pass through communities that are already overburdened by exposure to numerous hazardous and toxic materials. These Northeast Denver communities are lower-income communities of color who are exposed to higher than average environmental hazards-shipments to Yucca Mountain would only increase their exposure. COPEEN demands that the Department of Energy propose alternative transportation routes. Additionally, COPEEN expects to see detailed training and community education plans regarding the Yucca Mountain shipments. Local emergency response personnel must be adequately trained on how to handle a situation should one arise.

Response
Appendix J in the EIS includes state maps of the routes used in the analysis of national transportation. Although these are the routes that were used to analyze potential impacts, these are not necessarily the routes that would be used for the transport of high-level radioactive waste and spent nuclear fuel to a repository at Yucca Mountain. As stated in the EIS (see Section 2.1.3.2.2), a truck carrying a shipping cask of high-level radioactive waste or spent nuclear fuel would travel to the repository in accordance with U.S. Department of Transportation regulations

(49 CFR 397.101), which require the use of preferred routes. These routes include the Interstate Highway System, including beltways and bypasses. Alternate routes could be designated by states and Native American tribes following Federal regulations (49 CFR 397.103) that require consideration of the overall risk to the public and prior consultation with affected local jurisdictions and with any other affected states and tribes. The highway routes that would be used would be selected in accordance with these Federal transportation regulations and would not be selected by DOE. However, in accordance with Federal regulations, states, including Colorado, may propose alternate routes to better meet local or regional conditions. The process for selecting and approving routes, including state and tribal consultation, is described in Section M.3 of the EIS.

DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. To reach this conclusion, DOE considered whether sites are able to handle larger (rail) casks, distances to suitable railheads, and historic precedent in actual shipments of fuel, waste, or other large reactor-related components. DOE also has considered relevant information published by knowledgeable sources such as the Nuclear Energy Institute and the State of Nevada. The analysis has confirmed DOE's belief that the mostly legal-weight truck and mostly rail scenarios provide the range (lower and upper bound) of environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

The potential environmental justice impacts of transportation activities are discussed in Section 6.1.2.12 of the EIS.

In response to comments, the EIS has been revised and now provides information about emergency response capabilities in Appendix M. With respect to emergency response training, as required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for assessing the need for and training for public safety officials of appropriate units of local government and Native American tribal governments through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would institute this training before beginning shipments to the repository. In the event of an incident involving high-level radioactive waste or spent nuclear fuel, the transportation vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities, if requested, to respond to such an incident. However, state and tribal governments have a primary responsibility to respond to and protect the public health and safety in their jurisdictions in accidents involving radioactive materials. The EIS does not include detailed training and community education plans. Such plans would be developed by state, local, and tribal agencies and governments.

Comment - EIS000432 / 0006
The next problem I have with the proposal is the transportation. The idea of having radioactive waste on our highways does not seem like a good one. If an accident occurred in a major city and the radioactive waste was spilled what would happen? I didn't find any information on what the DOE or the government would do if this occurred. All I found was possible impacts that didn't make sense. From 1 to 4 traffic fatalities would be likely to occur due to traffic accidents? That's what the DOE said. But if a traffic accident occurred and radioactive waste was spilled I think there is a much higher potential for deaths. Furthermore, the DOE is planning on 49,500 trucks shipments from different plants across the country to the Yucca Mountain site in Nevada. With this many trucks on the highways I think there is substantial potential for an accident; along with trucks they have proposed to use railways as a source of transportation. Maybe the railways might be safer, but if there are 300 shipments there is a possibility for a major accident as well.

Response
Although, given the number of shipments, traffic accidents would be probable, DOE does not believe that any accident would result in the release of radioactive material, primarily because of the structural integrity of the casks in which the material would be transported. The EIS contains a discussion of potential impacts from accidents in both the mostly legal-weight truck scenario and the mostly rail scenario (see Section 6.2.4.2). Though an accident resulting in release of radioactive material is not expected to occur, the Department analyzed the maximum reasonably foreseeable accident that would involve the release of radioactive material from a transportation cask. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). DOE has concluded that the models used for analysis

in the Draft EIS relied on assumptions about spent nuclear fuel and cask response to accident conditions that caused an overestimation of the resulting impacts. Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments of spent nuclear fuel in the United States over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

Comment - EIS000359 / 0002
There's also been a lot of discussion this afternoon, as is correct to have this amount of discussion, on nuclear waste transportation. It's the issue that affects most of the country, with highways and railroads going past all of our communities. And I think all parties can agree that public health and safety and protection of the environment are vitally important. And that is a primary goal that I saw in the Draft Environmental Impact Statement.

Response
Chapter 6 and Appendix J of the EIS does provide a comprehensive analysis of worker and public health and safety and Section 6.3 provides a comprehensive assessment of potential environmental impacts. The results are that impacts would be small for national and Nevada transportation of spent nuclear fuel and high-level radioactive waste.

The Department agrees that sufficient information on public health and safety and environmental protection of the national and Nevada transportation and their potential impacts is provided in the EIS to support current decisionmaking.

8.1 (2218)
Comment - EIS000621 / 0008
Will the Crescent Valley airport be restricted? It goes right into the quarter mile corridor.

Response
Until DOE selected a corridor and determined the alignment of a route in that corridor, it would be unclear if there was a potential for repository-related transportation activities to affect specific land uses. On the other hand, DOE would consider existing uses both in its selection among the alternative corridors and the final alignment of the route in the corridor. The Department would endeavor to minimize the consequences of its routing decisions on existing uses in the selected corridor. It is unlikely that restrictions would be placed on use of the Crescent Valley airport because of DOE shipments on a branch rail line in the Carlin Corridor.

8.1 (2265)
Comment - EIS000394 / 0002
The transportation of spent nuclear fuel and high-level waste from the various points of generation to a national repository is of keen interest to Georgia. Public acceptance of transportation of spent nuclear fuel in the U.S. is not a given, as media reports of recent and upcoming shipment campaigns will attest. Public acceptance of the risks of transporting spent nuclear fuel and high-level radioactive waste, however small or large they are, or are perceived to be, is critical to the success of this program. A strong, credible education and public outreach program is essential to achieving some measure of public acceptance for this program, as is the existence of knowledgeable emergency response personnel at the state and local level, armed with both the training and equipment which would be required to respond to a transportation incident involving spent nuclear fuel or high-level radioactive waste.

Response
DOE conducted 21 public hearings across the nation to solicit input on this EIS during a 199-day comment period. In addition to announcements in the *Federal Register*, the Department placed advertisements for each hearing in local or regional newspapers and provided notices to local media outlets, public service announcements on radio and television stations, and notices to state senators and congressional representatives, governors, mayors, and county commissions. As part of continuing its efforts to inform the public about the Proposed Action, DOE placed maps of

the routes analyzed in the EIS on the Yucca Mountain Project web site and added them to the Final EIS. (As noted throughout the EIS, the analyzed routes might not be the routes used for shipment to the repository. DOE would identify actual routes about 5 years before shipments would begin.)

A major element of the Yucca Mountain Project has been to ensure that stakeholders, the media, and the public have an opportunity to participate in and acquire the information they need to make informed decisions about the project. This effort focuses on building and maintaining relationships with stakeholders, the public, and the media through regular interaction and provision of project information. The program develops public information products, including permanent and portable field exhibits, information materials, exhibits and models, audiovisuals, electronic media, publications, and public outreach announcements. These sources are available at science centers in Las Vegas, Pahrump, and Beatty, Nevada; on the Yucca Mountain and Office of Civilian Radioactive Waste Management Internet sites (*www.ymp.gov* and *www.rw.doe.gov*); through public meetings and hearings on Yucca Mountain topics; and during public tours of the Yucca Mountain site, as well as by specific inquiries and requests for information materials. DOE provides speakers and technical experts to local, state, national, and international technical groups, community groups, professional organizations, students, and other audiences on Yucca Mountain topics, and has created programs and materials to enhance the awareness of area educators and students on issues related to the disposal of spent nuclear fuel and high-level radioactive waste. Information on Yucca Mountain public outreach activities is available at 1-702-295-1312 or 1-800-225-6972.

As to emergency response capabilities, DOE is required by Section 180(c) of the NWPA to provide technical and financial assistance to states and Native American tribes to support training for emergency responders. Part of this support is the determination of needed training that is based on plans developed by responsible jurisdictions. Additional information on Section 180(c) requirements and other emergency response capabilities and responsibilities are provided in Sections M.6 and M.5 of the EIS.

DOE believes that sufficient information on transportation of spent nuclear fuel and high-level radioactive waste has been and continues to be provided to the public and responsible authorities. The Department also believes that sufficient information on emergency preparedness training and equipment is provided in the EIS to support current decisionmaking.

8.1 (2315)
Comment - EIS000571 / 0002
In the previous session I was informed that this waste would be traveling over the Donner overpass. Well, what happens to the people, because there are houses by the Donner overpass?

So what happens if, say, a truck or something else is traveling down the road and perhaps they wreck or they derail, depending on what it is, and these tubes go down rolling down the hill? They are going at very fast speed when they are going down the hill, and they are round. Perhaps they are going 60, 70 miles down the hill and they crash into a tree or something. What happens if they crack [casks] and somehow this radioactivity gets out into our public and then it will start harming people.

Response
Section J.1.2 of the EIS provides maps and tables that indicate the number and routing that DOE used for analysis in the EIS of shipments from 77 sites in the United States to Yucca Mountain. Many tables in this section indicate the origin, miles to be shipped, and number of shipments that the Department has estimated would originate in and pass through each state. The tables in the maps include potential impacts in each state associated with a national campaign to transport high-level radioactive waste and spent nuclear fuel to the proposed repository at Yucca Mountain (see Section 6.2.3). Section 6.3.1.3 discusses the impacts to maximally exposed persons along a legal-weight truck route. The estimated impact would be about 6 millirem. The average background radiation dose in the United States is about 300 millirem, indicating that the maximally exposed person receives a small dose and the dose to the average person along a legal-weight truck route would be much smaller.

The EIS contains a discussion of potential impacts from accidents in both the mostly legal-weight truck scenario and the mostly rail scenario (see Section 6.2.4.2). Though an accident resulting in release of radioactive material is not expected to occur, the Department analyzed the maximum reasonably foreseeable accident that would involve the release of material from a transportation cask. Since the publication of the Draft EIS, the Nuclear Regulatory

Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). DOE has concluded that the models used for analysis in the Draft EIS relied on assumptions about spent nuclear fuel and cask response to accident conditions that caused an overestimation of the resulting impacts. Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

Comment - EIS000935 / 0001
I live in Kirkland between two railroads only one mile apart from each other. I feel a great threat to my life and for my family. I do not want to see another Times Beach story of evacuation. Not even a Francis Howell episode. These town were destroy[ed] by Gov. contamination. Has not Missouri had enough radioactive or chemical problems.

This is the Madrid fault area for earthquakes. Train derailment is going to happen.

There should be another alternative.

The unsinkable Titanic sank. The construction of the cast could shield us but not 100%.

Response
A transportation accident that would involve the release of radioactive material from a transportation cask is not expected to occur during the transportation campaign. The Department analyzed the maximum reasonably foreseeable accident that would involve the release of material from a transportation cask. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). DOE has concluded that the models used for analysis in the Draft EIS relied on assumptions about spent nuclear fuel and cask response to accident conditions that caused an overestimation of the resulting impacts. Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

Although it is extremely unlikely, the EIS does include a discussion of potential impacts from accidents (including those induced by an earthquake) in both the mostly legal-weight truck scenario and the mostly rail scenario (see Section 6.2.4.2).

Comment - EIS000642 / 0003
Will mining claims be divided and access restricted? There are many claim holders out here, people who are looking for additional mineral deposits. We feel that it is inadequately addressed in the EIS.

Will the Cortez Mine be given its own railroad overpass to continue its daily operations? As one can see on the map on the wall, the corridor goes right through their operations. They have a mill on each side of the valley, and these things are inadequate. They have not been addressed in the EIS, the Draft EIS.

Response
If the repository proposal proceeds, final corridor selection and alignment would be necessary before determinations could be made regarding the nature and locations of crossings and other facilities. Alignment decisions could result in route locations that do not impede the operation of existing facilities.

At this time, definitive information is not available on specific tracts of land that could be required for a given transportation alternative. For any land that would be required or otherwise affected, the Department would fairly compensate landowners under Federal acquisition procedures. Should DOE be required to exercise its right of eminent domain, it would do so pursuant to applicable laws and regulations.

8.1 (3297)
Comment - EIS000986 / 0003
In addition, the DOE informs me that it will take approximately 24 years to complete all the waste shipments from these commercial and DOE facilities to the repository at Yucca Mountain. Given that extensive period of time and the thousands of required shipments, it is highly unlikely that this transport will be completed within an accident. Our region simply cannot afford to have this waste travel through the area. The risks to the public health are much too great.

Response
The risks of transporting spent nuclear fuel and high-level radioactive waste to a repository have been analyzed and the results of the analyses are presented in Chapter 6 of the EIS. The conclusions reached are that the risks and impacts are almost negligible. Of the thousands of shipments of spent nuclear fuel completed over the last 30 years, none has resulted in an identifiable injury from the release of radioactive material.

The EIS acknowledges that transportation accidents are likely to occur during the transport of radioactive materials to the proposed Yucca Mountain Repository. In Section J.1.4.2.3.2, the EIS estimates the number of accidents under the mostly legal-weight truck shipping scenario and accidents under the mostly rail scenario. A recent study concluded that only a tiny fraction of all accidents, less than one in 10,000, would be severe enough to cause a failure in a spent nuclear fuel shipping cask (DIRS 152476-Sprung et al. 2000). The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. Based on these statistics, DOE does not expect an accident to occur that would result in a radiological release and subsequent environmental cleanup. For additional information on the regulations, practices, and equipment which have contributed to this safety record and would be followed and utilized in the future, see Appendix M.

8.1 (4121)
Comment - EIS002239 / 0007
Looking at the mostly truck scenario, a hundred percent truck; and mostly rail, 95 percent truck. Neither of those is realistic.

What's realistic -- and if you look at realistic, I'm relating it not just to this document, but to the way the Department of Energy has planned to privatize the transportation system. Private sector corporations have to be able to make money moving this stuff.

When you look at all of those considerations, it's most likely that about 60 percent of the waste can be moved by rail, and 40 percent will move by truck. We have got a scenario where we have modeled this -- we call it the current capabilities scenario.

The Draft EIS fails to bound the full impacts of transportation. Now, this may sound strange until you actually model it, but a combination of 60 percent rail and 40 percent truck actually has more impact than 100 percent either way, and that's because you have more routes in more states, more Indian tribes and more counties affected; and at the very least, the amount of expenditures and concerns we have for emergency response training goes up.

Response
The EIS considers two national transportation scenarios, mostly legal-weight truck and mostly rail (see Sections 2.1.3.2.1 and 6.2). As shown in Section J.3.1.3, these scenarios illustrate the broadest range of operating conditions

relevant to potential impacts to human health and the environment. Sensitivity studies, described in this section, indicate that there is little difference in impacts for a wide variety of alternative legal-weight truck routes. The Department does not anticipate that either the mostly legal-weight truck or the mostly rail scenario represents the actual mix of truck or rail transportation modes it would use. Rather, these two scenarios represent the two extremes in the possible mix of transportation modes. The analysis of the potential impacts associated with each of these scenarios provides DOE with an envelop of impacts to understand all of the potential impacts associated with Proposed Action and to make future decisions regarding a transportation mode. DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. As stated in the EIS, DOE has identified mostly rail as the preferred national mode of transportation.

8.1 (4440)
Comment - EIS001038 / 0007
He [Senator Richard Bryan of Nevada] cited DOT statistics that "over a 10 year period there were more than 99,000 transport accidents releasing hazardous materials." Accidents happen. And where? So far, most of the country can only guess.

Response
The EIS contains a discussion of potential impacts from accidents in both the mostly legal-weight truck scenario and the mostly rail scenario (see Section 6.2.4.2). Though an accident resulting in release of radioactive material is not expected to occur, the Department analyzed the maximum reasonably foreseeable accident that would involve the release of materials from a transportation cask. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). DOE has concluded that the models used for analysis in the Draft EIS relied on assumptions about spent nuclear fuel and cask response to accident conditions that caused an overestimation of the resulting impacts. Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

8.1 (4663)
Comment - EIS001372 / 0006
Another critical component of the Yucca Mountain Project is the transportation issue. Nearly 100,000 metric tons of nuclear waste on as many as 79,300 truck and 12,600 rail shipments would travel by rail and highway through 43 states, within a half-mile of 52 million people in casks that have not been fully or safely tested for a 30 year period. There are a great many concerns about this aspect of the proposal. First, according to government figures, approximately 50-260 accidents would occur and 250-900 "incidents" would be expected over the 30-year period. How can we afford to even have one accident occur during the transportation of high-level radioactive waste! We cannot! It is evident from reading the DEIS that this aspect is very shortsighted.

Response
As stated in Section 2.1.3.2 of the EIS, under the mostly legal-weight truck scenario about 53,000 shipments of spent nuclear fuel and high-level radioactive waste would travel on the Interstate Highway System over a 24-year period. For the mostly rail scenario, approximately 9,600 railcars would travel on the nationwide rail network over the same period. Although traffic accidents would be probable given the number of shipments, DOE does not believe any accident would result in the release of radioactive material, primarily because of the structural integrity of the casks in which it would transport the material. In the more than 2,700 shipments involving spent nuclear fuel over the past 3 decades, there has not been a release of radioactive materials to the environment.

The EIS discusses potential impacts from accidents under the mostly legal-weight truck and mostly rail scenarios (see Section 6.2.4.2). Approximately five traffic fatalities could occur in transporting spent nuclear fuel and high-level radioactive waste under the mostly legal-weight truck scenario during the 24 years of operation and 350 million kilometers (220 million miles) of highway travel. In the mostly rail scenario, there could be approximately three traffic and train accident fatalities. The maximum reasonably foreseeable accident would involve the release of material from a transportation cask. The shipping casks used to transport these spent nuclear fuel and high-level radioactive waste are massive and tough with design features that comply with strict regulatory requirements that ensure the casks perform their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents. This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

With respect to costs associated with an accident involving nuclear waste, the Price-Anderson Act, as discussed in Section M.8 of the EIS, establishes a system of financial protection for persons who might be liable for or injured by a nuclear accident or incident. The Price-Anderson Act provides liability coverage to DOE activities (including transportation) involving spent nuclear fuel, high-level radioactive waste, and transuranic waste. Specifically, the Act establishes a system of private insurance and Federal indemnification that generally ensures that as much as $9.43 billion is available to compensate for damages suffered by the public, regardless of who causes the damages. The liability of all responsible parties is limited to the amount of coverage provided by the Price-Anderson system. State, local, and tribal governments cannot be required to provide additional compensation. Price-Anderson indemnification would apply to the operators of a repository at Yucca Mountain and to transporters of nuclear waste from commercial and DOE sites to the repository.

In addition to Price-Anderson indemnification, the Motor Carrier Act of 1980 and its implementing regulations (49 CFR Part 387) require vehicles carrying spent nuclear fuel or high-level radioactive waste to maintain financial responsibility of at least $5 million, which would be available to cover public liability from a non-nuclear incident and for environmental restoration. Federal law does not require rail, barge, or air carriers of radioactive materials to maintain liability coverage, although these carriers often voluntarily carry such insurance. Regardless of whether the carrier had insurance, an incident involving these carriers would be subject to state law applicable for any type of accident.

The Nuclear Regulatory Commission would certify casks used for the transport of spent nuclear fuel and high-level radioactive waste (10 CFR Part 71). Section M.4 of the EIS provides more details on the Commission testing and certification program for transportation casks.

8.1 (5912)
Comment - EIS001622 / 0028
Some routes leading to the Nevada Test Site/Yucca Mountain area are heavily traveled tourist and recreational routes. These routes can be greatly impacted by increased truck traffic. Increased truck traffic (especially those hauling nuclear waste) could influence the safety, reliability and congestion characteristics of these routes. Additionally, none of these non-Interstate routes are suitable for the safe and efficient transport of HLNW. None of these routes were designed for heavy trucks, high truck volumes, or quick emergency response.

Response
The EIS analyzed the potential impacts in Nevada of the mostly legal-weight truck scenario and the use of heavy-haul trucks under the mostly rail scenario (see Section 6.3). Under the mostly legal-weight truck scenario, highway shipments would be restricted to specific routes that satisfy the regulations of the U.S. Department of Transportation (49 CFR Part 397). Because the State of Nevada has not designated preferred alternate routes, only one combination of routes for legal-weight truck shipments would satisfy U.S. Department of Transportation routing regulations (Interstate-15 to U.S. 95 to Yucca Mountain). Legal-weight truck shipments in Nevada of spent nuclear fuel and high-level radioactive waste to the Yucca Mountain site would be a very small fraction of the total traffic [less than 1.2 million kilometers (750 thousand miles) per year for legal-weight truck shipments in Nevada in comparison to an estimated 1.2 billion kilometers per year of commercial vehicle traffic on Interstate-15 and U.S. 95 in Southern Nevada].

DOE recognizes that use of heavy-haul trucks would require upgrading of some Nevada highways, and has included the potential environmental impacts and costs of such upgrades in the EIS (see Section 6.3.3). Upgrades would include reconstruction of some highway sections, new turnout lanes at frequent intervals, widening of highway shoulders, and improvement of road surfaces.

With respect to quick emergency response, as required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states and tribes for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions DOE would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would institute this training before beginning shipments to the repository. In the event of an incident involving high-level radioactive waste or spent nuclear fuel, the transportation vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities as appropriate to mitigate such an incident. Additional information on the requirements and implementation of Section 180(c) is provided in Sections M.6 and M.7 of the EIS.

8.1 (6092)
Comment - EIS001265 / 0001
This plan has already been implemented so your next step is to discuss the safest way to transport this nuclear waste through your "valley." This should be your primary reason for meeting and discussion. Being realistic about this is the only way to be, all the yes's and no's mean nothing they are only words it is action to assure the safety of this transportation that counts.

Response
DOE has made no decision regarding the proposed monitored geologic repository at Yucca Mountain. After the EIS has been completed, the Secretary of Energy will decide whether to recommend approval of the development of a monitored geologic repository at Yucca Mountain to the President.

The Secretary of Energy will consider the potential impacts associated with transportation of high-level radioactive waste and spent nuclear fuel when determining whether to recommend Yucca Mountain as the site of the monitored geologic repository. Although no transportation decisions would be made until after completion of the Site Recommendation process, DOE believes that the EIS provides the information necessary to make decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments), as well as the choice among alternative rail corridors in Nevada.

With respect to transportation safety, DOE agrees that the ability to safely transport high-level radioactive waste and spent nuclear fuel to the proposed repository is an integral part of the determination on whether to recommend Yucca Mountain as a site for a repository. The protocols to be used by the Regional Servicing Contractors are listed in Section M.3 of the EIS. These protocols meet the statement made by DOE in Section 2.1.3.2 that the transportation of spent nuclear fuel and high-level radioactive waste would comply with all applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission.

8.1 (6565)
Comment - EIS001632 / 0052
Section 6.2.1: This section describes how the EIS bounds the impacts to human health, safety and the environment from transportation by examining the two extremes of transportation possibilities mostly rail and mostly legal-weight truck. Based on DOE's analysis, EPA [the Environmental Protection Agency] agrees with DOE's overall assessment that radiological impacts to the public from transportation of wastes to Yucca Mountain will be small.

Response
Thank you for your comment.

8.1 (6793)
Comment - EIS001905 / 0005
The highway routes used in the DEIS make Ohio a major corridor state for truck shipments to Yucca Mountain. Three of the principal truck routes from Eastern reactors enter Ohio from Pennsylvania on I-90, I-80, and I-76;

converge on the Ohio Turnpike (I-80/I-90) at Elyria; and then continue west through Indiana, Illinois, and Iowa on I-80. These routes traverse the Cleveland and Toledo metropolitan areas, and more than 300 miles on rural Ohio interstate highways. Under the mostly truck scenario, proposed action, about 11,200 truck shipments of high-level nuclear waste (about 22% of the total) traverse Ohio over 24 years. Under the mostly truck scenario, modules 1 & 2, about 18,900 truckloads of high-level nuclear waste (about 20% of the total) traverse Ohio over 39 years. Under either scenario, an average of 1.3 trucks per day would travel through Ohio every day for decades.

Response
Considering the number of shipments described in Section 6.1.1 of the EIS and potential routes of shipments described in Section J.1.2, only a fraction of the total volume of spent nuclear fuel and high-level radioactive waste (especially that currently located in the Northeastern United States) would travel through Ohio. Appendix J of the EIS contains maps of individual states and tables for each state listing the number of shipments that DOE estimates would originate and pass through the state and the impacts of those shipments. Assuming the 22 percent figure used by the commenter is correct, less than two additional truck shipments would pass through Ohio on a daily basis. Given the amount of truck travel that already occurs on U.S. highways, including those in Ohio, the additional daily truck shipments would not be expected to cause additional impacts as a result of incident-free transportation.

The EIS addresses the potential impacts associated with a national campaign to transport high-level radioactive waste and spent nuclear fuel to the proposed repository at Yucca Mountain (see Section 6.2.3). DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered whether sites are able to handle larger (rail) casks, distances to suitable railheads, and historic precedent in actual shipments of fuel, waste or other large reactor-related components. DOE also has considered relevant information published by knowledgeable sources such as the Nuclear Energy Institute and the State of Nevada. The analysis has confirmed DOE's belief that the mostly legal-weight truck and mostly rail scenarios provide the range (lower and upper bound) of environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

8.1 (6795)
Comment - EIS001905 / 0006
Rail shipments to Yucca Mountain would also heavily impact Ohio. The DEIS evaluated four rail routing scenarios using the INTERLINE model. Under the DEIS routing scenarios, two major streams of rail shipments to Yucca Mountain converge in Cleveland, at the interchange of Conrail mainlines from Buffalo and Harrisburg. A smaller number of shipments travel the Norfolk Southern from Cleveland to Chicago, the Norfolk Southern from West Virginia to Kansas City via Portsmouth, and the CSXT from Pennsylvania to Chicago via Youngstown and Akron. Rail shipments along these routes total almost 1,000 route miles in Ohio. Under the mostly rail scenario, proposed action, about 2,700 rail shipments (about 25% of the total) traverse Ohio over 24 years. Under the mostly rail scenario, modules 1 & 2, about 4,200 rail shipments (about 21% of the total) traverse Ohio over 39 years.

Response
Considering the number of shipments described in Section 6.1.1 of the EIS and potential routes of shipments described in Section J.1.2, only a fraction of the total volume of spent nuclear fuel and high-level radioactive waste (especially that currently located in the Northeastern United States) would travel through Ohio. Appendix J of the EIS contains maps of individual states and tables for each state listing the number of shipments that DOE estimates would originate and pass through the state and the impacts of those shipments. Given the amount of rail traffic that already occurs on U.S. railways, including those in Ohio, the additional rail shipments would not be expected to cause additional impacts as a result of incident-free transportation.

DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments of spent nuclear fuel and high-level radioactive waste. To determine this mix, DOE considered whether sites are able to handle larger (rail) casks, distances to suitable railheads, and historic precedent in actual shipments of fuel, waste or other large reactor-related components. In addition, DOE considered relevant information published by knowledgeable sources such as the Nuclear Energy Institute and the State of Nevada. The analysis has confirmed DOE's belief that the mostly legal-weight truck and mostly rail scenarios provide the range (lower and upper bound) of environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

The EIS addresses the potential impacts associated with a national campaign to transport high-level radioactive waste and spent nuclear fuel to the proposed repository at Yucca Mountain (see Section 6.2.3).

Comment - EIS001337 / 0045
During EIS scoping, Lincoln County and the City of Caliente provided DOE with evidence that rail condition can affect accident rates. Reference to County and City sponsored research regular assessments of rail condition along the UP mainline[13] was provided to DOE. The County and City encouraged DOE to an assessment of pre-waste shipment track condition and use within the DEIS. The DEIS is silent on the issue of existing rail condition and implications of rail condition for transportation safety.

[13] ETS Pacific, Inc., Pilot Study and Analysis of 46 Mile Rail Corridor in Lincoln County, Nevada, prepared for the Board of Lincoln County Commissioners, October 1986. See also ETS Pacific, Inc., Condition Update of 46 Mile Rail Corridor in Lincoln County, Nevada, prepared for the Board of Lincoln County Commissioners, June 1989.

Response
DOE recognizes that rail conditions could affect accident rates. The analysis in the EIS used state-specific accident rates and data from a recent Nuclear Regulatory Commission study (see Section J.1.4.2.3.1 of the EIS) of the adequacy of its transportation regulations in 10 CFR Part 71 to estimate the likelihood and severity of transportation accidents. The data from these studies are based on national data collected from actual accidents. Thus, the analysis presented in the EIS uses data derived from accidents where unique local conditions were contributing factors, including the Union Pacific mainline in Nevada.

Comment - EIS001957 / 0025
Section 6.0 Environmental Impacts of Transportation -- The NPS [National Park Service] objects to transportation of nuclear waste materials in and near the boundaries of its management units. Hazardous waste contamination of park land from ancillary transportation is already a major problem. Each year millions of dollars and unnecessary employee time is expended on these issues. These costs drain important funding from areas and projects necessary for the maintenance of park units. The possibility of the spill or inadvertent release of radionuclides within or neighboring a park unit is unacceptable.

State highways adjoin or are adjacent to Death Valley and Great Basin NP's [National Parks] and Lake Mead NRA [National Recreation Area]. Any accidental spills arising from transportation will directly affect the parks. Not only will park resources be affected, but park emergency response staff will be necessarily deployed. The proposed Yucca Mountain transportation plan does not provide for adequate trained emergency response staff or other resources to deal with highway accidents affecting the parks. Relying on NPS [National Park Service] staff to respond to highway accidents involving high-level nuclear waste is unacceptable.

For example, California Highway 127 parallels the drainage of the Amargosa River over a great distance in proximity to Death Valley NP [National Park]. Flow measurements published by the U.S. Geological Survey give evidence of periodic surface flows in that drainage. Flows may originate at Oasis Valley, Forty Mile Wash, or a host of other locations and continue to the terminus of the system at Badwater Basin in the park. The draft EIS provides neither any discussion of the outcome should an accident occur releasing material into the park along this route, nor a risk analysis of this possibility.

The supplemental EIS must address this omission with regard to both Nevada State Highway 95 and California State Highway 127, identifying and assessing scenarios for Great Basin NP [National Park] and Lake Mead NRA [National Recreation Area] (in addition to Death Valley NP [National Park]).

Response
Transportation of spent nuclear fuel and high-level radioactive waste is an integral part of the ultimate disposition of these wastes in a geologic repository and the EIS addresses the potential impacts associated with a transportation

campaign (see Chapter 6). In determining whether to recommend the Yucca Mountain site to the President, the Secretary of Energy would take transportation impacts, including potential impacts to national parks and recreation areas, into account.

Transportation by legal-weight truck would involve shipments along Interstate System highways in accordance with U.S. Department of Transportation regulations (49 CFR Part 397). These regulations limit shipments of hazardous materials such as nuclear waste to Interstate System highways and require shippers to use beltways and bypasses where available. DOE recognizes that even an incident-free transportation campaign could adversely affect people who live, work, or recreate near transportation routes. DOE also recognizes the potential for transportation accidents and analyzed impacts resulting from transportation accidents in the EIS, including contamination of water and food. Given the number of shipments, traffic accidents would be probable. DOE does not believe that any accident would result in the release of radioactive material, primarily because of the structural integrity of the casks (see Section M.5 of the EIS for a discussion of cask safety and testing) in which the material would be transported. In the more than 2,700 shipments involving spent nuclear fuel over the past 3 decades, there have been four accidents, with no release of radioactive materials to the environment.

As required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions DOE would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. D OE would institute this training before beginning shipments to the repository. In the event of an incident involving high-level radioactive waste or spent nuclear fuel, the transportation vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities as appropriate to mitigate such an incident. Additional information on the elements and implementation of Section 180(c) of the NWPA act is provided in Section M.6 of the EIS.

8.1 (7485)
<u>Comment</u> - EIS001775 / 0002
I sat through four hours of the hearing this morning eager to learn all I could about this project. What I did learn was alarming. Those who have knowledge of nuclear waste and know what questions to ask could not get their questions answered. You kept saying that congress did not require you to address a number of issues. When you were asked about transportation, you said congress told you didn't have to address it. Excuse me? To us here in the midwest, this is about transportation, the transportation of deadly nuclear waste through our streets and cities where our families live, over the rivers where we get our drinking water.

<u>Response</u>
Transportation of spent nuclear fuel and high-level radioactive waste is an integral part of the ultimate disposition of these wastes in a geologic repository and the EIS addresses the potential impacts associated with a transportation campaign (see Chapter 6 and Appendix J of the EIS). In determining whether to recommend the Yucca Mountain site to the President, the Secretary of Energy will take transportation impacts into account.

Transportation by legal-weight truck would involve shipments along Interstate System highways in accordance with U.S. Department of Transportation regulations (49 CFR Part 397). These regulations limit shipments of highly radioactive materials such as nuclear waste to Interstate System highways and require carriers to use beltways and bypasses where available. DOE recognizes that even an incident-free transportation campaign could adversely affect people who live or work near transportation routes. Section 6.2.3.1 of the EIS presents the number of latent cancer fatalities from legal-weight truck transport of spent nuclear fuel and high-level radioactive waste for the 24-years of operation. DOE also recognizes the potential for transportation accidents and analyzed impacts resulting from transportation accidents in Section 6.2.4. Although, traffic accidents would be probable given the number of shipments, DOE does not believe that any accident would result in the release of radioactive material, primarily because of the structural integrity of the casks in which the material would be transported. In the more than 2,700 shipments involving spent nuclear fuel over the past 3 decades, there have been four accidents, with no release of radioactive materials to the environment.

The EIS states that approximately five traffic fatalities could occur in the course of transporting high-level radioactive waste and spent nuclear fuel under the mostly legal-weight truck scenario during the 24 years of operation and 350 million kilometers (220 million miles) of highway travel. In the mostly rail scenario, there could be approximately three traffic and train accident fatalities. Though an accident resulting in release of radioactive material is not expected to occur, DOE analyzed the maximum reasonably foreseeable accident would involve the release of material from a transportation cask. The shipping casks used to transport these spent nuclear fuel and high-level radioactive waste would be massive and tough with design features that complied with strict regulatory requirements that ensure the casks performed their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that, of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each with less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

8.1 (8925)
Comment - EIS001028 / 0001
I am concerned about the danger inherent in transporting vast amounts of radioactive waste through 43 states over a period of 25 years through population centers such as St. Louis.

I am not satisfied that the NRC [Nuclear Regulatory Commission] has conducted satisfactory tests to determine the safety of transporting the waste. Amy Shollenberger, senior policy analyst for Critical Mass, has charged that the NRC is relying on computer-simulated tests, rather than on tests of real transportation containers. She recommends that the NRC change it testing methods to ensure it gets an accurate idea of the dangers involved.

Response
To transport spent nuclear fuel or high-level radioactive waste to the proposed repository, DOE would use shipping casks that met Nuclear Regulatory Commission regulations (10 CFR Part 71). DOE is required to comply with these regulations. The extent to which the Nuclear Regulatory Commission should reexamine the methodology it uses to certify casks as adequately protective of public health and safety is beyond the scope of the EIS. However, Section M.4 of the EIS provides additional information about the modeling and testing and the safety of transportation casks for spent nuclear fuel and high-level radioactive waste.

Section 6.2.3 of the EIS describes the impacts of transporting spent nuclear fuel and high-level radioactive waste on national highways and rail lines, including transport through urban, suburban, and rural populations. Section J.1.2.2 describes the basis for and methods used to determine the number of miles, speeds, and populations in each of these three areas for each route used in the analysis. These data were used in the analysis for public collective, public resident, and maximally exposed individual doses recorded in Section 6.2.3.

8.1 (9411)
Comment - EIS001888 / 0106
Maps presented in the DEIS are also fundamentally misleading. No national routes are depicted in the report. Many of the people who are most affected by the program, therefore, will not be aware of the impact based on the report's contents.

Response
Appendix J of the EIS includes maps of each state through which shipments of spent nuclear fuel and high-level radioactive waste could originate or pass. The maps identify the routes used in the analysis of national transportation. In addition, the maps contain tables listing the number of shipments that DOE estimates would originate in and pass through the state along with the impacts for each state based on the numbers and routes of shipments. The impacts in each state were estimated using route specific information such as projected number of shipments, along-route populations; route lengths in urban, suburban, and rural areas; and state-specific accident rates. Although these are the routes that were used to analyze potential impacts, these are not necessarily the routes that would be used for the transport of high-level radioactive waste and spent nuclear fuel to a repository at Yucca

Mountain. As stated in Section 2.1.3.2.2 of the EIS, a truck carrying a shipping cask of high-level radioactive waste or spent nuclear fuel would travel to the repository in accordance with U.S. Department of Transportation regulations (49 CFR 397.101), which require the use of preferred routes. These routes include the Interstate Highway System, including beltways and bypasses. Alternate routes could be designated by states and Native American tribes following Department of Transportation regulations (49 CFR 397.103) that require consideration of the overall risk to the public and prior consultation with affected local jurisdictions and with any other affected states and tribes. The highway routes would be selected in accordance with these Federal transportation regulations and would be approved by the Nuclear Regulatory Commission.

DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered whether sites are able to handle larger (rail) casks, distances to suitable railheads, and historic precedent in actual shipments of fuel, waste or other large reactor-related components. DOE also considered relevant information published by knowledgeable sources such as the Nuclear Energy Institute and the State of Nevada. The analysis has confirmed DOE's belief that the mostly legal-weight truck and mostly rail scenarios provide the range (lower and upper bound) of environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

8.1 (9495)
Comment - EIS001888 / 0155
[Summary of comments noted by Clark County Nuclear Waste Division staff at various citizens' meetings.]

One person felt that it was a good thing because it would bring high paying trucking jobs to the community. He didn't think there was a radiological risk and cited his knowledge of a mine in Canada that was so radioactive that it made the stuff that would be coming to Yucca Mountain looks like spit - the stuff in Canada was magnitudes of times greater in radioactivity. He said that if we didn't want the waste shipped here, Canada would take it there and reap the economic benefits.

Response
Chapter 6 and Appendix J of the EIS provides a comprehensive analysis of worker and public health and safety risks. The results are that impacts would be small for national and Nevada transportation of spent nuclear fuel and high-level radioactive waste.

8.1 (9557)
Comment - EIS001888 / 0230
Other data is also apparently flawed. In 1998, Clark County received geographic data files from DOE. These data files were for the proposed implementing alternatives through Nevada to Yucca Mountain. Cartographers from Clark County's Geographic Information Systems Department found that the files provided by the DOE incorrectly located major features (e.g. Interstate 15).

Response
Appendix J of the EIS contains state maps for all states where shipments of spent nuclear fuel and high-level radioactive waste could originate or through which they could pass. The maps include numbers of shipments, alternative routes, and impacts by state. The routes designated on the maps are those used for the impact analysis in the EIS and are similar to the results given in Chapter 6. The impacts in each state were estimated using route specific information such as projected number of shipments, along-route populations; route lengths in urban, suburban, and rural areas; and state-specific accident rates.

8.1 (9594)
Comment - EIS001888 / 0268
Maintenance Facilities and Support Operations

Hazardous materials transporters currently have elaborate, effective agreements for managing maintenance and support operations. These agreements have served the HAZMAT [hazardous materials] industry well for many years, however, it is not clear that the same institutional architecture will be adequate to service the specialized equipment used to transport SNF [spent nuclear fuel]. The DEIS should provide a clear description of arrangements that will be made to provide en route maintenance and support.

Response
The EIS includes a discussion of TRANSCOM, the satellite-based transportation tracking and communications system that DOE developed to provide continuous tracking and communication with truck and rail shipments of radioactive materials (see Section 2.1.3.2). In addition, the EIS describes the procedures that would be used by the Regional Servicing Contractors to perform the planning and implementation of legal-weight truck and rail shipments nationally and with Nevada. Section M.3 lists the protocols that the Regional Servicing Contractors would use to carry out planning, tracking, acquisition of casks, from shippers, en-route management, emergency management, response to weather and other unexpected conditions, and postshipment reviews, maintenance and record keeping. All of these activities would be performed in compliance with all applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission, as stated in Section 2.1.3.2.

8.1 (10039)
Comment - EIS001888 / 0526
[Clark County summary of comments it has received from the public.]

The UP mainline is the major link between So. CA & Midwest. Freight transport was 8.7 Million in 1994 up from 6 million in 1990. 80% through traffic, 15% off-loaded & 5% onloaded. This could be hurt by the repository.

Response
As indicated in Section 6.1.1 of the EIS, the proposed shipment of nuclear waste to a repository at Yucca Mountain would involve up to 400 rail shipments per year, over a 24-year period, under the mostly rail transportation scenario. Under the mostly legal-weight truck scenario, there would be approximately 13 additional rail shipments per year (see Section 6.1.1). Because not all rail shipments would travel on the same routes or through the same rail transfer points, the actual number of shipments passing a particular point would be less than the total estimated. This relatively small additional amount of traffic on the rail lines would not be expected to adversely affect existing rail shipments. The extent to which shippers might be reluctant to ship products because of the existence of spent nuclear fuel and high-level radioactive waste on the rail lines is speculative and was not analyzed by DOE.

8.1 (10104)
Comment - EIS002168 / 0001
Where is waste from Cleveland and the East Coast currently being shipped?

Response
Section 2.1.3.2 of the EIS identifies the nuclear utility and Department of Energy sites from which shipments of spent nuclear fuel and high-level radioactive waste would be shipped. Figures in this section identify the Interstate Highway System and national rail system in relation to these sites. Spent nuclear fuel and high-level radioactive wastes are currently mostly stored onsite at 72 commercial locations and 5 DOE sites.

8.1 (10291)
Comment - EIS000936 / 0003
Transporting material from current locations to Yucca Mt. exposes people along the truck routes to potential disastrous accidents. It seems we want to shift the problem from its current locations to another place at tremendous potential damage along the way while gaining nothing from it. So why do it?

Response
The Nuclear Waste Policy Act of 1982 gives the Federal Government the responsibility to dispose permanently of spent nuclear fuel and high-level radioactive waste to protect the health and safety and the environment. The decision to evaluate and use, if suitable, a geologic repository at Yucca Mountain for the disposal of spent nuclear fuel and high-level radioactive waste was a national policy initiative embodied in the Nuclear Waste Policy Amendments Act of 1987. Through the passage of that Act, Congress redirected DOE's implementation of the original Act in several ways, including directing DOE to study only the Yucca Mountain site to determine its suitability as a repository. The Act does not direct DOE to examine any other methods of disposal.

In 1980, the Department published the *Final Environmental Impact Statement, Management of Commercially Generated Radioactive Waste* (DIRS 104832-DOE 1980). This EIS examined both geologic disposal and alternatives to geologic disposal, including deep seabed disposal, ice sheet disposal, disposal in deep boreholes, transmutation, and disposal in outer space. The Record of Decision for this EIS concluded, in agreement with the National Academy of Sciences, that deep geologic disposal was the preferred alternative, and that the alternatives to geologic disposal other than continued storage were not technologically viable at the time. The Department agrees with the National Academy of Sciences and therefore does not consider continued storage a solution. Continued storage is viable and safe, but simply postpones the decision to the future in the hope that technology to solve the problem would be developed.

8.1 (10374)
Comment - EIS001371 / 0007
Legal trucks weights are 80,000 pounds per single unit, and there are tandem units which compound the problems. Interstates are built to withstand that weight, and the fees the trucks must pay help the states maintain their highways. Not knowing how heavy the illegal trucks are makes it impossible to gauge speed and other risk factors which could make that truck more prone to an accident. How can DOE calculate the impact of a collision of 80,000 pound tractor trailer? Not to mention the additional risk of possible drug use. These are risks that every motorist takes every time they get on interstate highways. Just the size and the speed of the interstate trucking industry creates and unthinkable environment for DOE to even consider shipping the most hazardous waste in the world through the heartland of America.

Response
In analyzing the potential for transportation accidents involving legal-weight trucks, DOE used national truck accident data (see Section J.1.4.2.3.1 of the EIS). Thus, the analysis has taken into account current conditions on the Nation's highways, including human factors (for example, drug use), as discussed in Section J.1.4.2.1. This risk analysis is contained in Section 6.2.4. Overweight (heavy-haul) trucks would not be used on national highways. They would be used in Nevada under the mostly rail scenario where branch rail lines do not exist to complete transportation to Yucca Mountain.

The EIS states that approximately four traffic fatalities could occur in the course of transporting high-level radioactive waste and spent nuclear fuel under the mostly legal-weight truck scenario during the 24 years of operation and 350 million kilometers (220 million miles) of highway travel. The maximum reasonably foreseeable accident would involve the release of material from a transportation cask. The shipping casks used to transport these spent nuclear fuel and high-level radioactive waste would be massive and tough with design features that complied with strict regulatory requirements that would ensure the casks performed their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

8.1 (10625)
Comment - EIS002220 / 0010
"Armed guards and radiation experts escort a truck transporting a nuclear waste cask from an indoor storage pool at Calvert Cliffs Nuclear Power Plant to an outdoor storage bunker nearby."

Now, you tell me that it's safe and it takes armed guards and radiation experts to escort one truck, one truck, and folks, they're not talking about bringing this for one year. They're talking about 30 years, folks.

You think they're not going to have a whole bunch of accidents in 30 years? And you know if they get it out there, it won't be 30 years because they'll keep generating it back East and they'll be shipping it out to the west. It won't be just 30 years.

Response

The EIS includes a discussion of TRANSCOM, the satellite-based transportation tracking and communications system that DOE developed to track truck and rail shipments of radioactive materials (see Section 2.1.3.2). In addition, Appendix M of the EIS describes the protocols and procedures that would be used for both legal-weight truck and rail shipments. Appendix M describes the protocols and regulations that would be implemented to ensure safe transport of radioactive materials.

While spent nuclear fuel and high-level radioactive waste could continue to be generated, there is a statutory limit (Nuclear Waste Policy Act of 1982) on the mass (weight) of waste that can be emplaced in the first repository (70,000 metric tons of heavy metal). Given this limit, the shipment of spent nuclear fuel and high-level radioactive waste would occur over a 24-year period.

Transportation by legal-weight truck would involve shipments along inter Interstate System highways in accordance with U.S. Department of Transportation regulations (49 CFR Part 397). These regulations limit shipments of highly radioactive materials such as nuclear waste to Interstate System highways and require carriers to use beltways and bypasses where available. DOE recognizes the potential for transportation accidents and analyzed impacts resulting from transportation accidents in Section 6.2.4.2. Given the number of shipments, traffic accidents would be probable. DOE does not believe that any accident would result in the release of radioactive material, primarily because of the structural integrity of the casks in which the material would be transported (see Section M.4 for additional information on cask safety and testing). In the more than 2,700 shipments involving spent nuclear fuel over the past 3 decades, there have been four accidents, with no release of radioactive materials to the environment.

Section 6.2.4.2 of the EIS states that approximately 5 traffic fatalities could occur in the course of transporting high-level radioactive waste and spent nuclear fuel under the mostly legal-weight truck scenario during the 24 years of operation and 350 million kilometers (220 million miles) of highway travel. In the mostly rail scenario, there could be approximately 3 traffic and train accident fatalities. The maximum reasonably foreseeable accident would involve the release of material from a transportation cask. The shipping casks used to transport these spent nuclear fuel and high-level radioactive waste are massive and tough with design features that comply with strict regulatory requirements that ensure the casks perform their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

As required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions DOE would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would institute this training before beginning shipments to the repository. In the event of an incident involving high-level radioactive waste or spent nuclear fuel, the transportation vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities as appropriate to mitigate such an incident. Additional information on emergency response and implementation of Section 180(c) of the NWPA is provided in Appendix M of the EIS.

8.1 (10887)
Comment - EIS000762 / 0003
After considerable effort and a frustrating trial and error exercise, the State of Nevada managed to extract DOE's shipment routes, modes, and shipment numbers from the raw data contained in draft EIS reference materials. (One Nevada transportation consultant employed to assist with the review of the draft EIS likened it to breaking the Japanese military codes during World War II.)

Under DOE's shipping scenario, Utah would be the most heavily affected corridor state for truck shipments to Yucca Mountain. Yet the DEIS makes no particular reference to transportation impacts in Utah. Three major truck routes to Yucca Mountain traverse Utah:

I-15 from Idaho to Arizona (405 miles in Utah);
I-80, I-215, and I-15 from Wyoming to Arizona (381 miles in Utah); and
I-70 and I-15 from Colorado to Arizona (364 miles in Utah).

Depending upon the scenarios evaluated in the draft EIS, between 43,000 and 80,000 truck shipments traverse Utah over 24 years. Under either scenario, an average of 5 to 6 trucks per day would travel through Utah every day for decades. Additionally, Utah would be impacted by about 300 rail cask-shipments of naval reactor spent fuel and about 2,500 truckloads of miscellaneous radioactive wastes during the same time period. (See Table 1 for additional detail on the truck shipments scenario.)

Response
Section J.1.2 of the EIS provides maps of each state, including Utah, and tables that indicate the number and routing of shipments from 77 sites in the United States to Yucca Mountain. Many tables in this section indicate the origin, miles to be shipped, and number of shipments originating in and passing through each state. The impacts in each state were estimated using route specific information such as projected number of shipments; populations along route; route lengths in urban, suburban, and rural areas; and state-specific accident rates. The tables in Section J.1.3 list potential impacts in each state associated with a national campaign to transport spent nuclear fuel and high-level radioactive waste to the proposed repository at Yucca Mountain (see Section 6.2.3).

As stated in Section 2.1.3.2.2 of the EIS, under a mostly legal-weight truck scenario about 53,000 shipments of high-level radioactive waste and spent nuclear fuel would travel on the Interstate Highway System during a 24-year period. Most of these shipments would traverse Utah.

8.1 (11177)
Comment - EIS000232 / 0010
The first you can do right now. You are sitting just a few meters from the railroad tracks over which you propose to transport high-level nuclear waste. Now, transport yourself back in time to New Years Eve 1910. Floodwaters would be twisting those railroad tracks to pretzels. Millions of tons of rock would be raining down from the hillsides onto the railroad. You would be sitting up to your necks in mud the consistency of pancake batter.

The second should wait until tomorrow as you commute back to Las Vegas. Try to envision making the trip on that narrow, curvy road between here and Alamo in a truck that's 270 feet long, has forty wheels, two engines and two drivers, and weighs almost 300 thousand pounds.

Then go back to Washington DC and tell someone they need to re-think their transportation plan.

Response
Shipments of spent nuclear fuel by rail have taken place for over 4 decades without an accident that resulted in breaching of the transportation casks. Over the years, rail safety has improved dramatically using the latest technology (communications, weather reports, etc.) to assist in controlling train traffic to adjust to weather-related problems.

Regarding the comment on using heavy-haul truck on the Caliente-Las Vegas route, most of the road segments are negotiable with a heavy-haul truck at a speed of 40 to 64 kilometers (25 to 40 miles) per hour. This assumes that identified road upgrades have been implemented. At present, approximately 40 heavy-haul vehicles with payloads in excess of 68 metric tons (75 tons) that are permitted by the Nevada Department of Transportation travel this segment of U.S. 93 each year.

8.1 (11384)
Comment - EIS002230 / 0005
The controversy of such transportation has focused on the adequacy of the Nuclear Regulatory Commission system for shipping the casks, the potential consequences of transportation accidents, and the routes that nuclear waste shipments are to follow.

Response
As stated in Section 2.1.3.2 of the EIS, DOE would comply with all applicable regulations of the Nuclear Regulatory Commission and U.S. Department of Transportation for the transportation of spent nuclear fuel and high-level radioactive waste. These regulations were promulgated to protect public health and safety. DOE recognizes the potential for transportation accidents and analyzed impacts resulting from transportation accidents in Section 6.2.4.2. In response to comments, the EIS has been revised (Section 6.2.4.2) to describe the maximum reasonably foreseeable accident in terms of cask failure mechanisms, range of impact velocities, and temperature range for the accident. Based on the revised analyses, DOE has concluded in the EIS that casks would continue to fully contain spent nuclear fuel in more than 99.99 percent of all accidents. This means that there would be less than a 1 percent chance over 24 years of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain by truck of an accident that could result in a release of radioactive material from a cask. The chance of a rail accident that would cause a release from a cask is even less. The corresponding chance that such an accident would occur in any particular locale would be much less than 1 percent. Although given the number of shipments traffic accidents would be probable, DOE does not believe that any accident would result in the release of radioactive material, primarily because of the structural integrity of the casks in which the material would be transported. See Section M.4 for more information on cask safety and testing. In the more than 2,700 shipments involving spent nuclear fuel over the past 3 decades, there have been four accidents, with no release of radioactive materials to the environment.

In relation to shipping the casks, DOE expects to hire commercial companies to act as Regional Servicing Contractors in accordance with the NWPA, as amended. The process for procuring these contractors is described in Section M.3 of the EIS and the detailed protocols to be used in loading, shipping and generally managing the transportation activities are described in this section. These protocols are based on the processes developed and implemented for shipments to the Waste Isolation Pilot Project and comply with all applicable U.S. Department of Transportation and Nuclear Regulatory Commission regulations.

With respect to routes, Appendix J in the EIS includes state-by-state maps of the routes and the estimated number of shipments that would originate and pass through each state. These are the routes and shipments used in the analysis of national transportation. Although these are the routes that were used to analyze potential impacts, they are not necessarily the routes that would be used for the transport of high-level radioactive waste and spent nuclear fuel to a repository at Yucca Mountain. As stated in the EIS (see Section 2.1.3.2.2), a truck carrying a shipping cask of high-level radioactive waste or spent nuclear fuel would travel to the repository in accordance with U.S. Department of Transportation regulations (49 CFR 397.101), which require the use of preferred routes. These routes include the Interstate Highway System, including beltways and bypasses. Alternate routes could be designated by states and Native American tribes following Department of Transportation regulations (49 CFR 397.103) that require consideration of the overall risk to the public and prior consultation with affected local jurisdictions and with any other affected states and tribes. The highway routes that would be used would be selected in accordance with these Federal transportation regulations and would need to be approved by the Nuclear Regulatory Commission.

DOE believes that the mostly rail case, in which 95 percent of the spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. To determine this mix DOE considered whether sites are able to handle larger (rail) casks, distances to suitable railheads, and historic precedent in actual shipments of fuel, waste or other large reactor-related components. DOE also considered relevant information published by knowledgeable sources such as the Nuclear Energy Institute and the State of Nevada. The analysis has confirmed DOE's belief that the mostly legal-weight truck and mostly rail scenarios provide the range (lower and upper bound) of environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

8.1 (11533)
Comment - EIS002248 / 0003
If there is some kind of a breakdown in Needles on the railroad, there is no way to transport the shipment, except by highway, out of there. There's no other alternative. So you are going to have to use the roads as an alternative, at least, and it needs to be appraised in the environmental document.

Response
In the event of a breakdown on the railroad at Needles or any other location in the United States, the railroads would initiate their routine recovery procedures. The contractor making the shipment for DOE would have the responsibility to plan for and respond to disruptions, whether incident-free or involving incidents. DOE has defined a set of operational procedures that would be followed by the contractor. These procedures are discussed in more detail in Appendix M of the EIS.

8.1 (11573)
Comment - EIS002281 / 0003
I have heard that the government proposes that the waste be transported in unmarked vehicles, so that saboteurs couldn't know what is being transported.

Well, if the saboteurs don't know, how can emergency people know what's being transported? If this is true, boy, our tax dollars at work, folks.

Response
The shipments would have proper labels and vehicle placards (hazard identification) as required by U.S. Department of Transportation regulations (49 CFR Part 172. Further, DOE would use a satellite-based transportation tracking and communications system such as TRANSCOM to track all shipments. Using this system, DOE would monitor shipments to the repository and, consistent with requirements in Nuclear Regulatory Commission regulations, would provide state and tribal governments with information regarding shipments. In heavily populated areas, armed escorts would be required for highway and rail shipments. For additional details on notification, communication, tracking, security, and emergency response, see Sections M.3 and M.5 of the EIS.

8.1 (11621)
Comment - EIS002239 / 0001
Now, it's true that there are some specific routes that might be used for actual deliveries to Yucca Mountain, where the State of Nevada and the State of California have differences of opinion.

For example, we would like to use 127, 373, from Baker through Death Valley Junction. We think that's the least-risk route if there are going to be large numbers of truck shipments.

California, of course, sees it differently. Other routes that have been talked about are State Route 160 in order to avoid shipments through downtown Las Vegas. So I don't mean to say that there aren't still some controversies to be resolved over routing, but on the big routes, the routes that are going to be the cross Country feeders from the east to the west, we have known all along that the choices are I-70, I-80, and I-40, as DOE does. It's a rail shipment. They are the Union Pacific lines through Nebraska and Wyoming, or the Burlington Northern Santa Fe lines that come into California from Arizona.

Response
Sections 2.1.3.2.1 and 2.1.3.2.2 describe the national and Nevada shipping scenarios, respectively, analyzed by DOE for the actions proposed in the EIS. DOE would select highway modes and routes in consultation with responsible agencies and jurisdictions, and stakeholders and in accordance with U.S. Department of Transportation regulations in 10 CFR 397.101. In the absence of state and tribal designated alternate routes, these regulations require the use of Interstate System highways. The states and tribes can designate alternate routes in accordance with 10 CFR 397.103 that includes a provision for continuity of routes. Section 103(a) states in part:

"Designations must be preceded by substantive consultation with affected local jurisdictions and with any other affected States to ensure consideration of all impacts and continuity of designated routes."

Therefore, any differences of opinion between Nevada and California will have to be resolved by consultation if either or both States designate alternate routes.

8.1 (11677)
Comment - EIS000295 / 0002
Our good friends at the Nevada Agency for Nuclear Projects completed a study in 1995, which could have been used by the DOE in this analysis, which reveals that there are 821 waste shipments via rail through North Carolina, 917 shipments via rail through South Carolina, 3,866 waste shipments via rail and highway through Tennessee and 2,650 shipments via rail and highway through Georgia. Why did the DOE not use that to do a realistic analysis of these shipments?

Response
Section J.1.2 of the EIS provides maps and tables that indicate the number and routing of shipments from 77 sites in the United States to Yucca Mountain. Many tables in this section indicate the origin, miles to be shipped, and number of shipments originating in each state. The tables in Section J.1.3 include the potential impacts associated with a national campaign to transport high-level radioactive waste and spent nuclear fuel to the proposed repository at Yucca Mountain (also see Section 6.2.3).

DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. To reach this conclusion, DOE considered whether sites are able to handle larger (rail) casks, distances to suitable railheads, and historic precedent in actual shipments of fuel, waste, or other large reactor-related components. DOE also considered relevant information published by knowledgeable sources such as the Nuclear Energy Institute and the State of Nevada. The analysis has confirmed DOE's belief that the mostly legal-weight truck and mostly rail scenarios provide the range (lower and upper bound) of environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

8.1 (11801)
Comment - EIS000792 / 0001
I recently concluded the highly successful Napalm Recovery Outreach Effort, this after a shaky start similar to what is occurring with your project. As a Captain in the Naval Reserve, I spent 15 months managing the community relations outreach efforts as the Navy fought off opposition of the movement of napalm from our Fallbrook storage facility to Texas and then on to Louisiana. The napalm is moving east on a regular schedule now, with over one-third of the controversial product safely moved with no visible opposition along the way.

Your project is going down the same road that the initial effort of the [Department] of the Navy moved along in early 1998. Before it is too late, you should be talking to those that have had the experience, moving trains through the same area that you are now receiving complaints from.

I am now retired from the Navy and am in a position to offer your effort the many years of community relations experience I have, not only in the Navy on a variety of matters, but as a 44 year active resident (business and elected official) of the high desert portion of San Bernardino County.

Obviously I am watching your efforts daily in the headlines of our regional newspapers. Give me a call.

Response
DOE has spent considerable time and effort reaching out to Federal, state, tribal, and local agencies, and has provided information to the public in a variety of forums. Appendix C of the EIS delineates the interagency and intergovernmental interactions in which the Department has been involved for the Proposed Action. As the Yucca Mountain program moves forward, DOE will intensify these interactions and public outreach forums. Thank you for your offer of assistance.

8.1 (11811)
Comment - EIS001765 / 0001
I don't know if this material can be stored on site or not. If it can, I too would like to see that. But at this stage with the amount of money already spent, maybe it's better if we do move it. Now, how do you move it? It's got to go by

rail or highway, so it has to move through cities like ours. I'm sure safety is the number one priority of all involved in the moving. Somewhere along the line you have to trust others, and I'm sure that if moved, all will be concerned and careful.

Response
As stated in Section 2.1.3.2 of the EIS, the transportation of spent nuclear fuel and high-level radioactive waste would comply with all applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission. These requirements have been expressed in the protocols established for the Regional Servicing Contractors as outlined in Section M.3. DOE's goal is to provide safe transport and ultimate disposition of these wastes in a geologic repository, regardless of its location. As discussed in Section 2.2, while implementation of the No-Action Alternative (continued onsite storage) would not involve transportation, it would pose other risks. For example, the risks associated with sabotage and materials diversion in relation to the fissionable material stored at the 77 sites would be much greater than they would be if the fissionable materials were stored in a monitored deep geologic repository. Implementation of the No-Action Alternative (Scenario 1) would cost nearly $600 million per year for 9,900 years. DOE agrees, however, that the ability to safely transport high-level radioactive waste and spent nuclear fuel to the proposed repository is an integral part of the determination on whether to recommend Yucca Mountain as a site for a repository.

8.1 (11820)
Comment - EIS002031 / 0006
When moving nuclear waste material from the eastern coast what will the safety precautions be? How do we even know nuclear waste transportation is safe?

Response
Transportation by legal-weight truck would involve shipments along Interstate System highways in accordance with U.S. Department of Transportation regulations (49 CFR Part 397). These regulations limit shipments of hazardous materials such as nuclear waste to Interstate System highways and require shippers to use beltways and bypasses where available. There would be an estimated 3 latent cancer fatalities in the general public from incident-free legal-weight truck transport over the 24-year campaign and 1 latent cancer fatality from rail transport over the same period. DOE also recognizes the potential for transportation accidents and analyzed impacts resulting from transportation accidents in the EIS (see Section 6.6.2.4.2). Although, traffic accidents would be probable given the number of shipments, DOE does not believe that any accident would result in the release of radioactive material, primarily because of the structural integrity of the casks in which the material would be transported (see Section M.4). In the more than 2,700 shipments involving spent nuclear fuel over the past 3 decades, there have been four accidents, with no release of radioactive materials to the environment.

The EIS includes a discussion of TRANSCOM, the satellite-based transportation tracking and communications system that DOE developed to track truck and rail shipments of radioactive materials (see Section 2.1.3.2). In addition, the EIS describes the procedures that would be used by the Regional Servicing Contractors for both legal-weight truck and rail shipments in Section M.3. Additional information on transportation physical protection is provided in Section M.7.

As required by Section 180(c) of the NWPA, DOE would provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would institute this training before beginning shipments to the repository. In the event of an incident involving high-level radioactive waste or spent nuclear fuel, the transportation vehicle crew would notify local authorities and the central communications station monitoring the shipment. DOE would make resources available to local authorities as appropriate to mitigate such an incident. Additional information on the elements and implementation of Section 180(c) is provided in Section M.6 of the EIS.

8.2 Number of Shipments

8.2 (3255)
Comment - EIS000981 / 0003
What quantities of nuclear waste will be shipped via highway and on rail shipments? What is the quantity per shipment? What do the vehicles look like (trailer and rail) and what safety precautions will be taken to the transportation vehicles?

Response
See Table J-1 of the EIS for estimated numbers of shipments for the various inventory and national transportation analysis combinations. In response to public comments, DOE has included the maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Section J.4). Section J.4 includes potential health and safety impacts associated with shipments for each state through which shipments could pass. For the Proposed Action, the estimated number of truck shipments under the mostly legal-weight scenario would be 52,786 (with an additional 300 rail shipments) and under the mostly rail scenario there would be an estimated 9,646 rail shipments plus an additional 1,079 legal-weight truck shipments. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Truck shipments could be made using a cask that holds four spent nuclear fuel assemblies that would weigh about 2.7 metric tons (3 tons). The truck cask itself would weigh about 24 metric tons (26 tons). Rail shipments would be made using a cask that holds about 26 spent nuclear fuel assemblies that would weigh about 18 metric tons (20 tons). The rail cask itself would weigh about 140 metric tons (150 tons). Figures J-3 and J-4 of the EIS show these casks on a trailer and a railcar.

Many safety precautions are taken during the transport of spent nuclear fuel and include U.S. Department of Transportation and Nuclear Regulatory Commission requirements for driver training, packaging, placarding of vehicles, escorting, communications, security, and routing. Because of the public's interest in transportation in general, the Department has included Appendix M in the EIS. Appendix M provides background information about transportation-related topics, such as transportation operations, cask testing requirements, and emergency response.

8.2 (4408)
Comment - EIS001511 / 0001
The Department continues to respond to inquiries from reporters prompted by repository opponents fanning the public's fears of transportation disasters around the country. This is of course exacerbated by the state of Nevada's press releases pointing out that according to the DEIS nearly all spent fuel shipments from across the country will pass through Illinois in route to Yucca Mountain. If the proposed repository is established, the number of spent nuclear fuel shipments passing through Illinois undoubtedly will increase. However, the fiction fostered by the estimates of the frequency which these shipments will transit Illinois as presented in the DEIS needs to be corrected. While Illinois' extensive experience and expertise gained from its unique program for inspecting and escorting spent fuel shipments will make the transition to heavier shipment volume manageable, no constructive purpose is served by distorting the expected shipment load at this time.

Response
In response to public comments, DOE has included the maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-42 of the EIS for the representative Illinois routes analyzed). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-82 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would enter Nevada from Illinois in the mostly legal-weight truck scenario. The table also lists the estimated number of rail shipment through Illinois in the mostly rail scenario for each of the proposed Nevada rail corridors and heavy-haul truck routes.

If the Yucca Mountain site was approved, under the mostly legal-weight truck scenario, the total number of truck shipments through Illinois was estimated to be 38,549 over 24 years, which is approximately 4 truck shipments per day. There would be no rail shipments.

The estimated numbers of shipments entering Nevada from Illinois under the mostly rail scenario are less than the mostly legal-weight truck scenario. According to Table J-82, the number of rail shipments would range from 6,825 to 7,027, depending on the mode (rail or heavy-haul truck) and corresponding corridor/route selected in Nevada. This is less than 1 rail shipment per day over 24 years. In addition, there would be approximately 1,071 legal-weight truck shipments through Illinois. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use. Before such shipments began, states and tribes could designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified.

8.2 (7528)
Comment - EIS001723 / 0002
You've got to get the waste to the site from all over the country, Maine to Florida, California to Washington. Got to get here some way (passing through 43 states I'm told).

Right now, looks like your best plan is by truck. Rather impractical if you ask me. You are so vague about the use of rail, I don't know how heavily this aspect has been studied? You at least know, you will have to build some rail lines (one would go right through Pahrump, if you were to use the Jean Corridor). If this were the case, how many train loads of Nuclear Garbage would come through our town?

I don't know enough about trains to make a comment, but I'll bet it'll be more than one!

Response
In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-53 of the EIS for the representative Nevada routes analyzed). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-93 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would enter Nevada in the mostly legal-weight truck scenario. The table also lists the estimated number of rail shipments in Nevada in the mostly rail scenario for each of the proposed rail corridors and heavy-haul truck routes.

If the Yucca Mountain site was approved, under the mostly legal-weight truck scenario, the estimated total number of truck shipments in Nevada would be 52,786 over 24 years, approximately 6 truck shipments per day. In addition, there would be approximately 300 rail shipments over the 24-year period.

The estimated numbers of shipments in Nevada under the mostly rail scenario are less than the mostly legal-weight truck scenario. According to Table J-93, the number of rail shipments would be 9,646, no matter which mode (rail or heavy-haul truck) and corresponding corridor/route selected in Nevada. This is slightly more than 1 rail shipment per day over 24 years. In addition, there would be approximately 1,079 legal-weight truck shipments in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use. Before such shipments began, states and tribes could designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified.

8.2 (7530)
Comment - EIS001723 / 0003
All things being equal, let's say you decide the use of trucks are the best bet for transporting this garbage. What are we speaking of here? Let's speak only of what you refer to as "Light Haul" trucks. Most of us would recognize

these as what are commonly referred to as 18 wheelers. So, let's use them for our example. And let's use 40,000 lbs. Per load. I seem to remember this weight as being a "legal weight" in most states. We won't even speak of what you refer to as "Heavy Haul" trucks. That'll scare most folks right out of their skin!

OK, we've got 77,000 metric tons of garbage to move. Remember a metric ton is 2200 lbs., so we are to move 169,000,000 lbs. Of waste to Yucca Mountain. 40,000 lbs. Per load (bulk, not counting the weight of the canisters), does that come out to 4,840,000 truck loads? Even more, if you count the weight of the canisters!

Response
See Table J-1 of the EIS for estimated numbers of shipments for the various inventory and national transportation analysis combinations. In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Section J.4). Section J.4 includes potential health and safety impacts associated with shipments for each state through which shipments could pass. For the Proposed Action, the estimated number of truck shipments under the mostly legal-weight scenario would be 52,786 with 300 rail shipments, and under the mostly rail scenario there would be an estimated 9,646 rail shipments with 1,079 legal-weight truck shipments. A legal-weight truck is 36 metric tons (40 tons or 80,000 pounds), which includes the weight of the vehicle and the weight of the spent nuclear fuel and shipping casks.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.2 (9417)
Comment - EIS001888 / 0112
The DEIS did not describe the volumes of waste that may travel on each highway or rail route.

Response
In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Section J.4 of the EIS). Section J.4 includes potential health and safety impacts associated with shipments for each state through which shipments could pass.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use. Before such shipments began, states and tribes could designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified.

The amount of spent nuclear fuel and high-level radioactive waste destined for the repository is discussed in Appendix A of the EIS.

8.2 (9540)
Comment - EIS001888 / 0201
[Summary of comments noted by Clark County Nuclear Waste Division staff at various citizens' meetings.]

Questions were asked about the number of potential shipments.

Response
See Table J-1 of the EIS for estimated numbers of shipments for the various inventory and national transportation analysis combinations. In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Section J.4). Section J.4 includes potential health and safety impacts associated with shipments for each state through which shipments could pass. For the Proposed Action, the estimated number of truck shipments under the mostly legal-weight scenario would be 52,786 with 300 rail shipments, and under the mostly rail scenario there would be an estimated 9,646 rail shipments plus 1,079 legal-weight truck shipments.

8.2 (10072)
Comment - EIS001888 / 0548
[Clark County summary of a comment it received from a member of the public.]

A commenter stated that the number of shipments used for the impacts analysis should be estimated based on single assembly casks, in order to provide an upper bound on the number of shipments.

Response
Single assembly casks are generally necessary for shipments of spent nuclear fuel that have very short decay times, about 150 days, or are used when a few spent nuclear fuel assemblies must be moved. It is highly unlikely that single assembly casks would be used for shipments to the repository because shipments to the repository involve a large number of spent nuclear fuel assemblies and these assemblies have decay times of 5 years or more. Therefore, the numbers of truck and rail shipments were based on current generation casks that have the ability to hold more than one spent nuclear fuel assembly.

See Table J-1 of the EIS for estimated numbers of shipments for the various inventory and national transportation analysis combinations. In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Section J.4).

8.2 (10888)
Comment - EIS000762 / 0004
Rail shipments to Yucca Mountain would also heavily impact Utah. Under the routing scenarios DOE used in the draft EIS, rail shipments of highly radioactive materials will traverse Utah on four rail lines:

- The Union Pacific from Grand Junction, Colorado, to Southern Nevada (461 miles in Utah);
- The Union Pacific from Granger, Wyoming to Southern Nevada (390 miles in Utah);
- The Union Pacific from Pocatello, Idaho to Southern Nevada (381 miles); and
- From Colorado, Idaho, or Wyoming to Wells, Nevada, via Ogden.

Under the mostly rail scenarios, between 10,600 and 18,400 rail shipments traverse Utah over 24 years, which is an average of 8 to 9 rail casks per week every week for decades. Additionally, even with most shipments coming by rail, Utah would also be impacted by an average of two truck shipments per week during the same time period. (See Table 2 for additional information on rail shipments.)

The information presented above is not found anywhere in the draft EIS.

Response
In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-52 of the EIS for the representative Utah routes). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-89 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would enter Nevada from Utah on Interstate-15 in the mostly legal-weight truck scenario. The table also lists the estimated number of rail shipment through Utah in the mostly rail scenario for each of the proposed Nevada rail corridors and heavy-haul truck routes.

If the Yucca Mountain site was approved, under the mostly legal-weight truck scenario, the estimated total number of truck shipments through Utah would be 45,919 over 24 years, approximately 5 truck shipment per day. In addition, there would be approximately 300 rail shipments over the 24-year period.

The estimated numbers of shipments entering Nevada from Utah under the mostly rail scenario are less than the mostly legal-weight truck scenario. According to Table J-92, the number of rail shipments would range from 8,181 to 9,134 depending on the mode (rail or heavy-haul truck) and corresponding corridor/route selected in Nevada. This is slightly more than 7 rail shipment per week over 24 years. In addition, there would be approximately 1,079 legal-weight truck shipments through Utah, which is slightly less than 1 per week. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use. Before such shipments began, states and tribes could designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified.

8.3 Transportation Modes and Routes

8.3 (60)

Comment - 27 comments summarized

Commenters expressed concern and opposition to routing shipments of spent nuclear fuel and high-level radioactive waste through heavily populated areas and along some of the busiest and most congested freeways and rail lines in the United States, stating little or no effort has been made to avoid densely populated areas, reduce unnecessary risks to persons and property, or provide for the equitable distribution of shipping routes among a much larger number of possible routes. Commenters stated that DOE should coordinate closely with state and local governments to minimize transportation routing through populated areas.

A commenter stated that although routes would be selected in accordance with 49 CFR 397.101, these paths [the Interstate Highway System] have the highest population density. The commenter stated that DOE should have to consider an alternative that maximized the avoidance of dense urban areas.

Response

In response to comments on the Draft EIS, DOE prepared Appendix M to provide additional information on transportation regulations and the operational aspects of spent nuclear fuel and high-level radioactive waste transportation (see Sections M.2 and M.3 of the EIS). This information includes more details on how DOE would select transportation routes if the Yucca Mountain site received approval. The routes selected would comply with the applicable regulations in place at the time of shipment.

If there was a decision to proceed with the development of a repository at Yucca Mountain shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use. Before such shipments began, states and tribes could designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified.

Nevertheless, the representative highway routes identified for the EIS analysis conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, developed for transportation of Highway Route Controlled Quantities of Radioactive Materials, require such shipments to be on preferred routes selected to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or an alternate route designated by a state or tribal routing agency. Alternate routes could be designated by states and tribes under Department of Transportation regulations (49 CFR 397.103) that require consideration of the overall risk to the public and prior consultation with local jurisdictions and other states and tribes. Federal regulations do not restrict the routing of rail shipments. However, for the analysis, as discussed in Section J.1.1.3 of the EIS, DOE assumed routes for rail shipments that would provide expeditious travel and the minimum number of interchanges between railroads.

In response to public comments, DOE has included maps of the representative highway routes and rail lines it used for analysis in the EIS (see Section J.4). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass.

DOE chose candidate rail corridors in Nevada to maximize the use of Federal lands (except U.S. Air Force-controlled lands), provide access to regional rail carriers, and minimize, to the extent possible, obvious land-use conflicts. As discussed in Section 6.3.2.1, all of the candidate Nevada branch rail lines would require the use of mostly Federal land and very little private land.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. Section M.3 of the EIS contains more information on routing regulations and operational procedures and protocols DOE would use if the Yucca Mountain site was recommended and approved. Section M.3 also contains more detail on the proposed role of the Regional Servicing Contractors.

8.3 (146)
Comment - 10 comments summarized
Commenters stated that the EIS does not identify and analyze specific national transportation routes for rail and highway shipments. Instead, DOE performed a limited generic analysis of modes and routes that avoided analysis of specific conditions, impacts, and hazards along specific routes. Commenters stated transportation issues should be considered in separate transportation EISs for each area to fully evaluate the impacts of transportation of spent nuclear fuel and high-level radioactive waste. In conjunction with new EISs, commenters want DOE to hold hearings to inform, address safety concerns, and solicit comments from people that live near identified routes.

Response
If there was a decision to proceed with the development of a repository at Yucca Mountain shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, states and tribes could designate alternate preferred highway routes, and highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state and tribal designated alternate) that reduce time in transit. DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials.

Sections 6.2 and 6.3 of the EIS address the potential impacts of transporting spent nuclear fuel and high-level radioactive waste from facilities where it is generated to the proposed repository. Appendix J discusses the methods and data DOE used for these analyses. DOE based the analyses on representative routes, identified for purposes of analysis. Analyses in the EIS (Sections J.2 and J.3) demonstrate that the total transportation impacts would be essentially the same regardless of the routes used. These analyses indicate that because all shipments must comply with regulatory limits, the impacts would be principally proportional to the number of shipment miles. Accidents that would result in releases of radioactive materials from the casks would be extremely unlikely regardless of the routes because applicable transportation requirements prescribe that the casks must be able to withstand virtually all types of accidents without releasing their contents.

DOE believes that this EIS adequately analyzes the environmental impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

In response to public comments, DOE has added maps of the representative routes analyzed in the EIS to Appendix J (see Section J.4) . DOE used state-specific accident data in the analyses, which includes consideration of specific conditions and hazards along representative highway and rail routes.

Comment - 218 comments summarized
Commenters raised several issues about the adequacy of information and analyses in the EIS with respect to the selection of spent nuclear fuel and high-level radioactive waste transportation routes, as follows:

1. The EIS does not identify DOE's preferred transportation alternatives (mode and routes) or the maximum number of shipments that would pass through and near specific areas.

2. The EIS does not contain sufficient route-specific information on national routes to allow DOE to identify, compare, and bound the impacts of spent nuclear fuel and high-level radioactive waste transportation to make informed decisions. Commenters said that the generic transportation analyses in the EIS were inadequate, vague, and too ambiguous to support transportation-related decisions. Route-specific information requested by commenters included such things as rail and road conditions in specific cities and towns; incidental radiation exposure in specific cities and towns and the consequences of this exposure; likely places for accidents and their consequences; evaluation of specific and realistic modes and primary and secondary routes; the effects of accidents in highly populated areas, rural areas, areas where retrieval of a leaking cask would be difficult, and areas where accidents would be most likely; accidents that involve releases of radioactive materials; radiological impacts from rail cars that are parked on sidings for extended periods of time; impacts of using dedicated trains subject to speed restrictions; and bounding analyses that would allow individual communities and specific regions to compare the risks and impacts among routes and combinations of modes and routes.

3. The EIS does not contain sufficient route-specific information on alternative modes and routes in Nevada to allow DOE to identify, compare, and bound the impacts of spent nuclear fuel and high-level radioactive waste transportation and associated construction (including the siting and construction of an intermodal transfer station) to make informed decisions. Commenters said that the EIS should have acknowledged that impacts from spent nuclear fuel and high-level radioactive waste transportation would be concentrated in Nevada. Others noted that many communities in Nevada would be close enough to a branch rail line to require evacuation in the event of a severe accident or terrorist attack, yet the EIS did not describe specific impacts to Pahrump, Goldfield, and other Nevada towns. Moreover, the EIS did not list the assumptions regarding the acquisition of Nevada environmental permits, approvals, and rights-of-way; the engineering feasibility and construction requirements for transporting waste through Nevada; and the impacts to private property and grazing lands. Commenters wanted to know who would own, operate, and maintain the tracks in Nevada and whether the tracks would be fenced off from surrounding areas.

Commenters said that such route-specific information is required by the National Environmental Policy Act and by regulations of the Council on Environmental Quality. Because route-specific information is lacking, communities that would actually be affected by transport cannot begin to undertake emergency planning and preparedness and do not understand the impacts and costs to local programs. Moreover, local, state and tribal governments and their response agencies were unable to determine specific health, safety, and environmental impacts, or to develop mitigation measures. Some said that DOE had ample time to collect route-specific information for the Draft EIS, citing a DOE commitment in the 1986 Environmental Assessment of Yucca Mountain (DIRS 104731-DOE 1986) to do so and to involve responsible agencies and governmental bodies in the planning and analysis process. Some said that route-specific analyses should not be deferred to the future, requesting instead that a supplemental EIS be prepared that contains route-specific information and analyses (including field surveys, consultations, and engineering and environmental analyses). Others said that the EIS should be withdrawn and a new EIS prepared that contains route-specific information, contending that without such route-specific information and analyses, the public cannot comment on the EIS in a meaningful manner.

In contrast to the above, some commenters supported the level of detail contained in the EIS with regard to transportation.

Response

DOE believes that the EIS adequately analyzes the transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

1. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved, DOE would issue at some future date a Record of Decision to select a mode of transportation. If, for example, DOE selected mostly rail (both nationally and in Nevada), it would then identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. A similar process would occur in the event that DOE selected heavy-haul

truck as its mode of transportation in Nevada. DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In response to public comments, DOE has included, maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Section J.4). Section J.4 includes health and safety impact estimates associated with shipments for each state through which shipments could pass.

2. If there was a decision to proceed with the development of a repository at Yucca Mountain made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state and tribal designated alternate route) that reduce time in transit. DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials.

   DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

   To ensure that the EIS analyses reflect the latest reasonably available information, DOE has either incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relied on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data.

   Although the EIS analyses are based on the latest reasonably available information and state-of-the-art analytical tools, not all aspects of incident-free transportation or accident conditions can be known with absolute certainty. In such instances, DOE has relied on conservative assumptions that tend to overestimate impacts. For instance, DOE assumed that the radiation dose external to each vehicle carrying a cask during routine transportation would be the maximum allowed by U.S. Department of Transportation regulations. Similarly, DOE assumed that an individual, the "maximally exposed individual," would be a resident living 30 meters (100 feet) from a point where all truck shipments would pass. Under these circumstances, the maximally exposed individual would receive a dose of about 6 millirem from exposure to all truck shipments (6 millirem represents an increased probability of contracting a fatal cancer of 3 in 1 million). Although it can be argued that individuals could live closer to these shipments, it is highly unlikely that an individual would be exposed to all shipments over the 24-year period of shipments to the repository, even though DOE incorporated this highly conservative assumption in the analysis.

   However, in response to comments, DOE has considered locations at which individuals could reside nearer the candidate rail corridors and heavy-haul truck routes in Nevada as a way of representing conditions that could exist anywhere in potentially affected communities. For example, DOE assumed that a maximally exposed individual could reside as close as 4.9 meters (16 feet) to a candidate heavy-haul truck route. During the 24-year period of repository operations this maximally exposed individual would receive an estimated dose of about 29 millirem, resulting in an increased fatal cancer probability of 2 in 100,000.

   As stated in the EIS (see Section 2.1.3.2.2), a truck carrying a shipping cask of spent nuclear fuel or high-level radioactive waste would travel to the proposed repository in accordance with U.S. Department of Transportation regulations (49 CFR 397.101), which require the use of preferred routes that reduce time in transit. The highway routes DOE would use would be submitted to the Nuclear Regulatory Commission for final approval.

Further, the EIS contains a discussion of potential impacts from accidents in both the mostly legal-weight truck scenario and the mostly rail scenario (see Section 6.2.4.2). The accident analysis includes a description of the consequences of a release of radioactive material from a transportation cask, although such an event would be extremely unlikely. The EIS states that an accident involving a release from a transportation rail cask could result in approximately five latent cancer fatalities in an urban area. A severe accident in another population zone (for example, rural) would have lower consequences.

3. As stated above, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. The choice of a rail corridor or intermodal transfer station location and heavy-haul truck route within Nevada would not be based solely on the potential environmental impacts identified in the EIS. DOE would consider factors such as engineering feasibility, safety, input from the State of Nevada and surrounding communities, and cost in its decisionmaking. The extent to which the branch rail line, or parts of the branch rail line, would be fenced would be determined through additional consultations and appropriate National Environmental Policy Act reviews, including determinations on necessary mitigation measures.

At this time, DOE plans to use private industry, including railroads, to the maximum extent possible, to accomplish its transportation mission. Such an arrangement, however, would not jeopardize the relationships and agreements that have been developed between DOE and stakeholders. DOE would retain responsibility for policy decisions, stakeholder relations, final route selection, and implementing Section 180(c) of the NWPA. DOE would award contracts for acceptance of spent nuclear fuel and high-level radioactive waste and transportation services to those bidders whose proposals DOE considered to be most advantageous to DOE, with cost being only one of a variety of selection factors. One of the qualifications that must be met by a successful bidder would be to have performed a major transportation and logistics coordination project involving railroad, truck, or intermodal carriage of radioactive, toxic, or other types of hazardous materials within the past 10 years. DOE would require the transportation contractor to provide for maximum use of dedicated train service and advanced rail equipment features where this type of service or equipment can be demonstrated to enhance operating efficiency, dependability, or cost-effectiveness, or lessen the potential of adverse railroad equipment incidents.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) of the NWPA (63 *FR* 23753; April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) policy and procedures.

Comment - 6 comments summarized
Commenters stated that the EIS is deficient in its treatment of key transportation issues on a state level because it fails to evaluate a more likely and potentially heavier impact modal mix. Commenters stated the scenarios used in the EIS significantly underestimate the likely number of combined truck and rail shipments, the number and mileage of truck and rail routes, and the number of states affected by both rail and truck shipments. Commenters proposed a third transportation scenario based on the current capabilities of waste generators and storage sites, without investments to upgrade cask loading capabilities or upgrade near-site infrastructure.

Response
DOE evaluated the potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste from 5 DOE and 72 commercial sites to the proposed repository at Yucca Mountain. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at

least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments to a repository could begin, it is impossible to predict with a reasonable degree of accuracy the exact number of shipments that would be made by either truck or rail. For this reason, DOE evaluated two scenarios for moving the materials to Nevada: (1) transportation using mostly legal-weight trucks and (2) transportation using mostly rail. DOE analyzed these scenarios to ensure that it considered the range of potential environmental impacts associated with the transportation of spent nuclear fuel and high-level radioactive waste.

DOE believes that the mostly rail scenario, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste, or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada. In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Nevertheless, in response to comments DOE has analyzed the effects of different mixes of rail and truck shipments. The results of this analysis confirm DOE's estimate that the mostly rail and mostly legal-weight truck scenarios represent a reasonable range (lower and upper bound) of potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

DOE identified the mostly rail scenario to estimate the impacts that could occur if shipments to Yucca Mountain used rail transportation to the maximum practical extent and minimized use of legal-weight trucks. Correspondingly, DOE identified the mostly legal-weight truck scenario to estimate the greatest impacts that could occur if shipments to Yucca Mountain were made using legal-weight trucks to the maximum practical extent with only shipments of naval spent nuclear fuel being made by rail to Nevada. DOE used the CALVIN computer program (see Section J.1.1.1 of the EIS), along with data from owners of spent nuclear fuel and high-level radioactive waste collected by the Energy Information Agency and by DOE programs (see Appendix A), to estimate the number of legal-weight truck and rail shipments that would most likely be made. The CALVIN program, which uses information regarding the modal capabilities of shipping sites, and the data from owners (such as utilities) are the best tools available to DOE for estimating the number of shipments that could be made to Yucca Mountain.

To analyze the potential impacts of rail and truck shipments, DOE used the INTERLINE and HIGHWAY computer programs, respectively, to identify representative rail and highway routes that could be used for shipments from the 72 commercial and 5 DOE generator sites located across the continental United States (see Sections J.1.1.2 and J.1.1.3 of the EIS). The routes used in the analyses, which are illustrated on maps presented in Appendix J, originate in or cross 45 states and the District of Columbia. Not included are Montana, North Dakota, and Rhode Island, which are not crossed by highways or railroads identified by the analysis. Because of their geographic locations in relation to the locations of generator facilities and to likely transport routes, DOE believes that it is unlikely that shipments to Yucca Mountain would pass through these states. The INTERLINE and HIGHWAY computer programs are the best methods available for identifying representative rail and highway routes for analysis of impacts of transporting spent nuclear fuel and high-level radioactive waste.

Because transportation impacts would be proportional to the number of shipments, any mix of rail and truck shipments lying between the two extremes used in the analysis would have potential impacts that would be the sum of proportioned impacts of the two scenarios analyzed. For example, the transportation impacts of a 50-percent rail and 50-percent legal-weight truck scenario would be approximately the sum of 50 percent of the impacts presented in the EIS for the mostly rail scenario and 50 percent of the impacts for the mostly legal-weight truck scenario. Based on the results reported in the EIS, the transportation impacts for this example would lie between those for the mostly legal-weight truck and mostly rail scenarios. These impacts would be neither higher than those estimated for the mostly legal-weight truck scenario nor lower than those estimated for the mostly rail scenario. This would be the case for all possible scenarios (all combinations of rail and truck shipments that add to 100 percent) for legal-weight truck and rail transportation. Therefore, for transportation, the impacts estimated in Chapter 6 of the EIS for the mostly rail and mostly legal-weight truck scenarios consider the associated range of those that would be estimated for the different mixes of rail and legal-weight truck modes that could occur.

Section J.1.2.1.4 of the EIS discusses the sensitivity of analysis results to changes in the number of shipments. This change would occur, for example, if less material was included in each cask, causing the total number of shipments to increase. Using the information in this section, an increase of 50 percent in the number of truck shipments would result in a 50-percent increase in the estimated total distance traveled by legal-weight trucks and a 50-percent increase in impacts of incident-free transportation for this mode. For this eventuality, for the mostly legal-weight truck scenario discussed in the EIS, the public dose would increase from about 5,100 person-rem (2.6 latent cancer fatalities) to 7,700 person-rem (3.9 latent cancer fatalities). The impacts of constructing and maintaining a branch rail line or upgrading and maintaining a highway route for use by heavy-haul trucks and constructing and operating an intermodal transfer station would not be appreciably different for different mixes of rail and legal-weight truck modes that might be used.

Comment - 130 comments summarized
Commenters stated that DOE failed to identify transportation modes and the specific rail and highway routes analyzed in the EIS. The commenters observed that DOE actually selected specific routes for analysis in the Draft EIS using the HIGHWAY and INTERLINE models. The commenters note references to these data in Chapter 6 and Appendix J of the Draft EIS. Commenters stated that by not releasing this information, DOE failed to notify and inform the public of the potential impacts through their communities, provide the public an opportunity to determine the legal sufficiency of DOE's analysis, and participate in the review and public comment process. Commenters stated that DOE violated the National Environmental Policy Act by concealing crucial information that would permit affected communities to participate in the process, which should be grounds for declaring the EIS legally deficient and requiring DOE to revise and reissue a Draft EIS or issue a supplemental Draft EIS for a new round of public review and comment. Commenters stated that the attempt to publish route maps, which failed to identify shipment numbers, modal mix, and specific communities affected, 3 weeks before the end of the comment period (after 18 of the 21 public hearings had been conducted) in no way mitigated this deficiency in the Draft EIS. DOE's attempted concealment of the shipping routes is a deviation from DOE's past practice of identifying the most likely transportation routes in other National Environmental Policy Act documents, such as the Waste Isolation Pilot Plant EIS and its associated supplemental EIS.

Commenters indicated that they understand that the routes are preliminary and that states and tribes could identify alternate routes. However, DOE's argument that the routes could change is not an acceptable justification for refusing to include the specific routes used to analyze potential impacts. The commenters noted the purpose of a Draft EIS is to highlight preliminary information and examine all the alternatives available, not to withhold information.

A commenter stated that the nuclear community's greatest fear is that DOE will be forced to identify routes and then the controversy over Yucca Mountain will no longer be a Nevada issue, but will be a source of extreme and vocal outrage in hundreds of communities across the Nation. Commenters requested that the EIS identify specific primary, secondary, and emergency routes, seasonal route changes, casks, and time of day; establish baseline conditions along routes and use route specific data; provide a range of transportation-risk options and associated fiscal impact estimations, and honestly identify potential impacts along those routes, including socioeconomic and public perception.

One commenter stated that he could not believe that after 13 years DOE cannot tell the public exactly how, what time of day, and on what routes shipments would be transported. Failure to identify routes or even likely highway or rail transportation routes reduces public awareness and interest in the Draft EIS analysis and hampers overall meaningful input. Failure to identify likely routes means that the impacts on those specific communities, as well as states, have not been adequately evaluated and conceals the need to evaluate impacts to highly affected areas in the various states. A commenter stated DOE's decisionmaking process for choosing the safest available routes needs to be independent of Nevada's effort to convince the Nation that safe transportation is an impossible task. Others stated DOE needs to show a comparison of likely rail and truck shipment routes with similar information. One commenter noted that DOE will not delineate specific routes until approximately 4 years prior to shipment. However, for states and localities to access funds for providing training and getting proper equipment for responding to any accidents, DOE, by statute, has to designate what those transportation routes will be. The commenter believes the Department should identify the routes now so that communities can be assured emergency responders are trained.

A number of commenters suggested the EIS should include both maps and tables showing the specific routes and numbers of shipments expected on each route, as well as where the spent nuclear fuel and high-level radioactive waste shipped on each route would originate, and how many casks would be involved and disclose the variables and assumptions that are built into the computer models to identify routes.

Response

DOE has not attempted to conceal transportation routes. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway or rail lines would be used. For example, in the interim, state or Native American tribal governments could designate alternate preferred highway routes and new highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in the EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials. In response to public comments, DOE has included in the EIS maps of representative highway routes and rail lines that were used for the EIS analysis (see Figures 6-11 and 6-12).

In response to public comments, DOE has added Appendix M to the EIS to provide further information on topics concerning transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. These topics include liability for transportation accidents, emergency management, cask safety and testing, and transportation services acquisition and protocols.

As discussed in Sections J.1.2.2 and M.2.6 of the EIS, specific routes would be identified well before shipments in accordance with transportation protocols that would apply in the event of emergencies or other conditions that required deviation from the regular routes. As stated in the EIS (see Section 2.1.3.2.2) and noted above, a truck carrying a shipping cask of spent nuclear fuel or high-level radioactive waste would travel routes to the repository in accordance with U.S. Department of Transportation regulations (49 CFR 397.101), which require the use of preferred routes. These routes include the Interstate Highway System, including beltways and bypasses. Alternate routes may be designated by states and tribes following U.S. Department of Transportation regulations (49 CFR 397.103) that require consideration of the overall risk to the public and prior consultation with affected local jurisdictions and with any other affected states and tribes. The highway routes would be selected in accordance with these Federal transportation regulations and would be approved by DOE. As noted above, there are no Federal regulations pertaining to rail routes for shipment of spent nuclear fuel or high-level radioactive waste. The shipper and railroad companies (carriers) determine rail routes based on best available trackage, schedule efficiency, and cost-effectiveness. This includes selecting routes that result in minimum time in transit, minimum interchanges, and maximum use of mainline tracks. The routes would be submitted in advance to the Nuclear Regulatory Commission for approval. In addition, DOE has developed operational protocols (see Section M.3.2.1.2 of the EIS), that include guidelines for selecting rail routes. DOE applied the guidelines in selecting routes for analysis in the EIS. If the U.S. Department of Transportation promulgates rail routing regulations, DOE would change its operational protocols, as appropriate, to comply with the regulations.

DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience with actual shipments of nuclear fuel, waste, or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada. In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Nevertheless, in response to comments DOE has analyzed the effects of different mixes of rail and truck shipments. The results of this analysis confirm DOE's estimate that the mostly rail and mostly legal-weight truck scenarios represent a reasonable range (lower and upper bound) of potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

As stated in the EIS, 70,000 MTHM spent nuclear fuel and high-level radioactive waste would be shipped to Yucca Mountain under the Proposed Action. Section 6.1.1 of the EIS reports the number of cask shipments that would be required for each of the two shipment scenarios analyzed – mostly rail and mostly legal-weight truck. Numbers of cask shipments are tentative, as there are many factors that could cause them to change, including selecting different transportation casks for shipments, reactor operations, and a change in the utility's priority for shipping spent nuclear fuel to a repository. For example, a utility that initially could not load a rail cask might develop that capability.

The analysis in the EIS used state-specific accident rates and data from a Nuclear Regulatory Commission study of the adequacy of its transportation regulations in 10 CFR Part 71 to estimate the likelihood and severity of transportation accidents (DIRS 152476-Sprung et al. 2000). The data from these studies are based on national data collected from actual accidents. The national data (see Section J.1.4.2 of the EIS) includes accidents in which road hazards and other local conditions were contributing factors. Thus, the analysis presented in the EIS uses data derived from accidents in which unique local conditions were contributing factors. The EIS analyzes a maximum reasonably foreseeable accident, an accident with a probability of occurrence of about 3 in 10 million per year. To put this in perspective, this accident would occur once in the course of about 5 billion legal-weight truck shipments. In this scenario, a truck cask, not involved in a collision, would be engulfed in a fire with temperatures between 750°C and 1,000°C (1,400°F to 1,800°F) (see Section 6.2.4.2 of the EIS). The conditions of the maximum reasonably foreseeable accident analyzed in the EIS envelop conditions reported for the Baltimore Tunnel fire (a train derailment and fire that occurred in July 2001 in a tunnel in Baltimore, Maryland). Temperatures in that fire were reported to be as high as 820°C (1,500°F), and the fire was reported to have burned for up to 5 days.

DOE could decide to use a dedicated train that carried only the material to be shipped to Yucca Mountain, or could elect to move the spent nuclear fuel and high-level radioactive waste in general freight. If the material was shipped as general freight, the position of the spent nuclear fuel or high-level radioactive waste car in the train would be regulated by 49 CFR 174.85. This regulation requires that railcars placarded "radioactive" must be separated from a locomotive, occupied caboose, or carload of undeveloped film by at least one nonplacarded car, and it cannot be placed next to other placarded railcars of other hazard classes.

Local health and safety impacts of transporting spent nuclear fuel and high-level radioactive waste would be a fraction of national impacts discussed in Section 6.2.3 of the EIS. The population impacts in small communities would be much less than the population impacts in metropolitan areas, though the impacts to maximally exposed individuals would be comparable.

Section 6.2 of the EIS discusses socioeconomic and other potential impacts of national transportation of spent nuclear fuel and high-level radioactive waste. Because existing rail and highway systems would be adequate for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain, except under conditions where heavy-haul trucks would be used, infrastructure upgrades would not be necessary and therefore are not included in the analysis. The EIS assumes that sites identified as being served by a railroad would use rail and that sites that do not have rail service (for example, needing rail spur upgrades) would ship using heavy-haul trucks or barges to nearest railheads.

Nevertheless, DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since the scoping process for the EIS to enable DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty.
- Much of the uncertainty is irreducible.
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as serious accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

Comment - 51 comments summarized
Commenters stated that DOE did not reveal the process or timetable for selecting a preferred rail corridor or heavy-haul truck route or discriminating information for the alternatives. The commenters, in general, stressed the need for DOE to describe the process of selecting implementing alternatives. Several commenters requested a formal criteria document or comprehensive transportation plan describing the decision process, the criteria for selecting shipping routes, and a sound methodology for evaluating optional mixes of routes and transportation modes. Commenters noted a range of factors that should be part of the selection criteria including emergency response, population, accident rates, weather, seasonal road closures, infrastructure, health and safety, environmentally sensitive areas, and Native American tribal communities. One commenter noted that DOE should recognize (the commenter referred to Section 2.1.3.3.1 of the Draft EIS) and explain the role that states might play in routing. Another commenter stated that DOE should specifically address whether it would conduct additional National Environmental Policy Act analyses for every transport segment when route and mode mix was completed. Several commenters took issue with the role Regional Servicing Contractors or carriers could have in the route-selection process. Commenters stated that DOE needs to accept the responsibility for choosing the safest routes available and specify those routes to contractors and carriers rather than abrogating that responsibility and leaving it up to the railroads to decide routing issues.

Response
If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments to a repository could begin, it is impossible to predict with a reasonable degree of accuracy the exact number of shipments that would be made by either truck or rail. For this reason DOE evaluated two scenarios for moving the materials to Nevada: (1) transportation using mostly legal-weight trucks and (2) transportation using mostly rail. DOE analyzed these scenarios to ensure that it considered the range of potential environmental impacts associated with the transportation of spent nuclear fuel and high-level radioactive waste.

DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste, or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada. In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Nevertheless, in response to comments DOE has analyzed the effects of different mixes of rail and truck shipments. The results of this analysis confirm DOE's estimate that the mostly rail and mostly legal-weight truck scenarios represent a reasonable range (lower and upper bound) of potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

At this point, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, state or Native American tribal governments could designate alternate preferred highway routes, and highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route). DOE identified rail lines based on current rail practices, because there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials.

In response to public comments, DOE has included in the EIS maps of representative highway routes and rail lines used for analysis. In addition, potential health and safety impacts associated with shipments are provided for each state through which shipments could pass (see Section J.4 of the EIS).

In response to comments, DOE has added information to the EIS (see Section M.3.2.1.2) on the route-selection process and proposed operational protocols for shipments. Current planning is that contractors providing transportation services would prepare transportation plans that would include proposed routes and modes selected according to U.S. Department of Transportation regulations and Federal Railroad Administration policy. The Department would provide those plans to the states and tribes for comment. DOE would then make final route selections and provide them to the Nuclear Regulatory Commission. The EIS has been revised to include a description of this planning process.

Comment - 28 comments summarized
Commenters noted that Section 180(c) of the NWPA requires the Federal government to provide improvements in emergency response training and capability along routes designated for the transport of spent nuclear fuel and high-level radioactive waste. The commenters stated that the costs of providing and maintaining response capability should be estimated as part of the fiscal impact analysis necessary to compare and eventually designate spent nuclear fuel and high-level radioactive waste transportation corridors for the project. Others asked what would be the source of funding for state, local, and Native American tribal inspectors and enforcement, and who would pay and oversee state and local law enforcement and emergency response training. Others questioned when funding would become available. Commenters stated that, because some of the proposed routes are in isolated areas or the roadways are unsuitable for the transportation of spent nuclear fuel and high-level radioactive waste, it would be costly to safeguard residents in these areas. These commenters stated that the Draft EIS failed to address the significant fiscal and possible significant environmental impacts of meeting those obligations and that the counties and states would be "saddled" with meeting those obligations. Others stated that funding under the NWPA would be inadequate compared to the amount of money that would be needed by local jurisdictions to prepare for transporting spent nuclear fuel and high-level radioactive waste. Other commenters urged that Congress and DOE ensure adequate national assistance and appropriations to fund emergency management activities for state and local jurisdictions through which spent nuclear fuel and high-level radioactive waste would travel well before the first shipments occurred. Others noted that DOE had engaged in constructive discussions regarding financial assistance, but that there were no commitments made in the Draft EIS for such assistance. The Final EIS needs to describe both the appropriate level of preparedness for local jurisdictions and how funding would be administered.

Response
As discussed in the EIS, accidents involving spent nuclear fuel or high-level radioactive waste shipments could occur. However, of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. Thus, the likelihood that a first responder or other emergency personnel would become contaminated or eventually fall ill, even in very severe accidents, would be

remote. Of the thousands of shipments completed in the United States over the last 30 years, none has resulted in an injury through the release of radioactive materials. Because the transportation analyses in the EIS did not take credit for the mitigation aspects of emergency response activities, the cost of emergency response planning and preparedness is not included in the EIS, although DOE intends to provide assistance and funds for emergency response training.

Nevertheless, in response to comments DOE has revised the EIS by adding Appendix M to provide additional transportation-related information, including DOE funding for improvements in emergency response training and capabilities along the routes (see Section M.5). State and Native American tribal governments have primary responsibility to respond to and to protect the public health and safety in their jurisdictions from accidents involving radioactive materials. However, Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions the Department could transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for addressing emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) of the NWPA (63 *FR* 23753; April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) policy and procedures.

DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

8.3 (362)
Comment - EIS000043 / 0003
The Draft EIS does not analyze impacts associated with specific nuclear waste transportation routes even though it's intended that the document will be used at sometime in the future to select transportation modes and routes from 75 individual waste sites to Yucca Mountain.

Residents along potential transportation routes to Yucca Mountain, through 43 states and within one-half mile of more than 50 million people, are most knowledgeable about local hazards, yet their specific knowledge is co-opted by the generic treatment of transportation risks in the Draft EIS.

Response
DOE evaluated the potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste from 5 DOE and 72 commercial sites to the proposed repository at Yucca Mountain. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, state or Native American tribal governments may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state and tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

In addition, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

8.3 (377)
Comment - EIS000040 / 0003
It certainly casts doubt on the efficiency of the transportation problem when Mesquite does not even appear on the D.O.E. maps. Further, in Nuclear Regulatory Commission NURE6-1437, dated February 1999, the city is not mentioned and the planned route does not go through Overton as stated.

Response
Maps in the EIS that depict transportation routes and corridors include the City of Mesquite, where appropriate (for example, see Figure 6-13).

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state and tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

Comment - EIS000118 / 0003

The [Nye County] Commission has also said that the only possible heavy haul route and the preferable rail route is one that avoids Nye County communities and comes across the Test Site. The EIS says that that is not the preferred alternative and the reason why is because there's a problem within the federal family. Air Force doesn't want it, and so it's not preferred.

Response

Public comments during the EIS scoping period requested that DOE evaluate routes through the Nellis Air Force Range to Yucca Mountain. In response, DOE added an implementing alternative for the transportation of spent nuclear fuel and high-level radioactive waste by rail or by heavy-haul truck to the Yucca Mountain site across the Nellis Air Force Range (the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route analyzed in the Draft EIS).

During preparation of the Draft EIS, DOE consulted with various organizations and agencies, including the Air Force (see Appendix C of the EIS). In a letter dated March 1999, F. Whitten Peters, Acting Secretary of the Air Force, commented that the Air Force believes that there is no route through the Nellis Air Force Range that could avoid adversely affecting classified national security activities, leading to the imposition of flight restrictions and affecting the ability for testing and training. As a consequence, DOE listed the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route in the Draft EIS as "nonpreferred alternatives."

In comments on the Draft EIS, the Air Force restated its position that routes across the Nevada Test and Training Range would not be consistent with its national security uses. The Air Force concluded that use of such a corridor or route could adversely affect critical and sensitive national security activities.

In response, DOE reevaluated whether the Caliente-Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route should be eliminated from further evaluation. DOE met with the Air Force (see Appendix C of the EIS), considered the information they provided, and concluded that the Caliente-Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route implementing alternatives should remain identified as "nonpreferred alternatives" in this Final EIS.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (565)

Comment - EIS000106 / 0004

The EIS looks at a lot of transportation options, as Les mentioned, and it states that these are to bound future decisions on the specifics of transportation that were made in process, but what it doesn't do is tell what DOE would commit to regarding transportation.

Response

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures (63 *FR* 23753; April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action.

In addition, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

8.3 (577)
Comment - EIS000066 / 0001
The Division of Waste Management's main concern would be the routes used to transport the material. There are no permitted hazardous waste disposal sites for this type waste in Kentucky. The division may have further comments when the routes are finalized.

Response
DOE evaluated the potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste from 5 DOE and 72 commercial sites to the proposed repository at Yucca Mountain. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state and tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

The final routes would be selected following the requirements and protocols outlined in the Draft Request for Proposals for Regional Servicing Contractors (DIRS 153487-DOE 1998; see Section M.3.2.1.2 of the EIS). DOE and its shipping contractors would consult with the states and tribes along proposed routes for input into the route selection. DOE would submit selected routes to the Nuclear Regulatory Commission for approval.

In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-43 for the representative Kentucky routes). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass (see Table J-83).

As stated in Sections 1.1 and 1.2 of the EIS, the Yucca Mountain site in Nevada is the only site being considered as a geologic repository for disposal of spent nuclear fuel and high-level radioactive waste.

8.3 (675)
Comment - EIS000110 / 0004
I personally would favor rail because it's safer, but it is more expensive. My objection to the truck routes would be mostly because of the impact on the present highways.

As I said when I'm traveling over the mountain passes, I am frequently slowed down behind legal weight trucks going as slow as 15 miles an hour. Consider heavy haul trucks and increase that number by maybe an order of magnitude, you have a big problem.

Response
DOE believes that the mostly rail scenario, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada.

In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (937)
Comment - EIS010378 / 0002
NOW THEREFORE BE IT RESOLVED, that the City of Ely supports figure 2-4 of the White Pine County Comments to the Supplemental Draft SDEIS so long as figure 2-4 is amended to read that the Nevada Northern Railroad will be considered a primary route of shipment for any waste shipped through White Pine County to the Yucca Mountain Project Sight [Site].

Response
White Pine County is requesting clarification on the transportation modes that would be used to ship spent nuclear fuel and high-level radioactive waste to the site. The text and Figure 2-4 in the White Pine County comments are unclear on whether legal-weight trucks would have access to the site.

Depending upon how a shipment of spent nuclear fuel or high-level radioactive waste would be transported from the generator sites; one of three modes of transportation would be used in Nevada, rail, heavy-haul trucks, and legal-weight trucks. Legal-weight truck shipments could continue directly to the repository following routes that satisfy the regulations of the U.S. Department of Transportation (49 CFR Part 397).

Shipments arriving in Nevada by rail would travel to the repository either directly by rail or be transferred to heavy-haul trucks at one of three possible locations along Interstate-15 in Nevada and then travel along highways to the repository. A discussion of these scenarios along with maps of the candidate routes is found in Section 2.1.3.3 of the EIS.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (1009)
Comment - EIS000262 / 0005
Inyo County has a strong preference for a rail-focused option which offloads the bulk of the waste east of the site. Lincoln County, Nevada has already indicated its support for an intermodal transfer site within its jurisdiction. Development of this site would avoid reliance on transportation corridors in high-risk areas south and west of Yucca Mountain and place one of the major components of the project in a jurisdiction amenable to the operation.

<u>Response</u>
DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (1271)
<u>Comment</u> - EIS000221 / 0002
The draft EIS itself fails to identify the cross Country rail and truck routes used in DOE's transportation impact analysis, and fails to identify potential transportation routes to Yucca Mountain through California. The document further fails to provide a meaningful analysis of the potential impacts on California of rail and truck transportation to the proposed repository.

<u>Response</u>
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, state and tribal governments may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-34 of the EIS for the representative California routes). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-74 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would enter Nevada from California in the mostly legal-weight truck scenario.

If the Yucca Mountain site was approved, under the mostly legal-weight truck scenario, the estimated total number of truck shipments through California would be 6,867 over 24 years, which would be approximately 6 truck shipments per week. There would be no rail shipments.

The estimated numbers of shipments entering Nevada from California under the mostly rail scenario are less than the mostly legal-weight truck scenario. According to Table J-74, the number of rail shipments would range from 512 to 1,464 depending on the mode (rail or heavy-haul truck) and corresponding corridor/route selected in Nevada. This is slightly more than 1 rail shipment per week over 24 years, at most. In addition, there would be approximately 286 legal-weight truck shipments through California, which is slightly less than 1 per month. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.3 (1276)
<u>Comment</u> - EIS000221 / 0003
The DEIS evaluates a mostly truck scenario and a mostly rail scenario. Nevada believes that the final EIS must evaluate a third transportation scenario based on the current transportation capabilities of reactor and storage sites. Under the "current capabilities" scenario, there could be more than 26,000 truck shipments and more than 9,800 rail shipments through California. Under this scenario, California would receive an average of two truck shipments per day and four to five rail shipments per week for 39 years.

This potential level of shipments through California certainly constitutes a significant impact which should have been identified and evaluated in the draft EIS.

Response
As stated in Section 6.2 of the EIS, DOE analyzed two feasible scenarios – mostly rail and mostly legal-weight truck – for potential impacts of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Prior transportation analyses provide substantial evidence that truck, rail and barge modes of transportation that could be used would result in low environmental impacts (see DOE environmental impact statements listed in Table 1-1 of the EIS). Different mixes of modes from the two analyzed in the EIS (for example, a 50:50 or 60:40 truck/rail mix or a mix in which shipments from 32 commercial sites would use legal-weight trucks and shipments from 45 commercial and DOE sites would use rail) would result in impacts that would lie somewhere between those for the mostly legal-weight truck scenario and the mostly rail scenario (Section J.1.2.1.4 discusses how impacts would change for variations in the mix of transportation modes for shipments to Yucca Mountain). Thus, as mentioned above, DOE chose to analyze the mostly rail and mostly truck scenarios as a means of displaying the range of impacts that could result from different mixes of modes.

In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-34 of the EIS for the representative California routes). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-74 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would enter Nevada from California in the mostly legal-weight truck scenario.

If the Yucca Mountain site was approved, under the mostly legal-weight truck scenario, the total number of truck shipments through California was estimated to be 6,867 over 24 years, which is approximately 6 truck shipments per week. There would be no rail shipments.

The estimated numbers of shipments entering Nevada from California under the mostly rail scenario are less than the mostly legal-weight truck scenario. According to Table J-74, the number of rail shipments would range from 512 to 1,464 depending on the mode (rail or heavy-haul truck) and corresponding corridor/route selected in Nevada. This would be slightly more than 1 rail shipment per week over 24 years, at most. In addition, there would be approximately 286 legal-weight truck shipments through California, which would be slightly less than 1 per month.

DOE believes that the mostly rail scenario, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada. In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.3 (1779)
Comment - EIS000392 / 0004
Transportation: The DEIS fails to select a single route or mode choice for transporting high-level radioactive waste. The route choice through Nevada is especially important. Selection of a route through the State will have national effects.

The DOE failed to address these effects in the DEIS. The DEIS gives insufficient consideration of non-radiological impacts. The considerable impacts of on road surfaces, accident rates and infrastructure improvements caused by shipping radioactive waste must be defined.

Response
DOE evaluated the potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste from 5 DOE and 72 commercial sites to the proposed repository at Yucca Mountain. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available

approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved, DOE would identify for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In response to public comments, DOE has included state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Figure J-53 for the Nevada map). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass and illustrates how these estimates change based on the selection of Nevada routes and corridors (see Table J-93 for Nevada information).

Road surface damage associated with heavy-haul truck transport is given in *Road Upgrades for Heavy Haul Routes* (DIRS 154448-CRWMS M&O 1998). The costs for maintaining surface roadways is included in the $800-million Nevada estimate given in Section 2.1.5 of the EIS.

Accident rates for nonradiological accidents associated with transportation were acquired from Federal and state data files for the general routes identified in the EIS. How this information was acquired and used in the analyses are included in the following EIS sections:

- J.1.4.2.2, Methods and Approach for Analysis of Nonradiological Impacts of Transportation Accidents
- J.1.4.2.3, Data Used to Estimate Incident Rates for Rail and Motor Carrier Accidents
- J.1.4.2.4, Transportation Accidents Involving Nonradioactive Hazardous Materials
- J.2.4.3.2, Nonradiological Accident Risks for Barge and Heavy-Haul Truck Transportation

Infrastructure improvements in Nevada associated with rail transport are described in *Rail Alignment Analysis* (DIRS 131242-CRWMS M&O 1997). Infrastructure improvements in Nevada associated with heavy-haul truck transport are included in Section J.3.1.2 of the EIS, Tables J-37 through J-41. Additional information is included in *Road Upgrades for Heavy Haul Truck Routes – Design Analysis* (DIRS 154448-CRWMS M&O 1998).

Comment - EIS000616 / 0001
I'm not going to get into the philosophy of the federal storage area for all this waste. But should the site at Yucca Mountain be selected, I feel the safest transportation would be the rail corridors option. I don't think heavy hauling should be considered as a transportation option, and I just feel that that is an option that shouldn't be considered at all from a safety standpoint. I think the rail corridors, whichever one you select, would be the best and safest option anywhere in the United States.

And I do believe that should the corridors be selected, that multiple use should be allowed. I think the communities, the mines, the industry, and all that could be in partnership with the DOE on that, and they would support the communities.

Response
DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental

studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

DOE identified the potential for shared use in Section 8.4.2 of the EIS as a reasonably foreseeable future action. This section states "DOE would have to consider these impacts [of shared use] in any decision it made to allow shared use of the branch rail line." If the site is approved, then decisions regarding shared use would be made.

8.3 (2202)
Comment - EIS000613 / 0001
Today our focus is on DOE's failure to identify a preferred rail access corridor to Yucca Mountain in the DEIS. The Yucca Mountain site has no access to the national rail system. The nearest rail route is in Las Vegas, almost 100 miles away.

The DEIS identifies and describes four potential corridors, one-quarter mile in width, which DOE could use to construct a rail line connecting Yucca Mountain to the Union Pacific mainline in Southern Nevada: Valley modified is 98 miles; the Jean route is 112 miles; the Caliente Chalk Mountain, 214 miles; and the Caliente, 319 miles. The DEIS designates the Caliente Chalk Mountain corridor as a nonpreferred alternative. A fifth potential corridor, Carlin, which is 323 miles, would connect Yucca Mountain with the Union Pacific mainline in north central Nevada.

The DEIS fails to identify a preferred rail corridor, and sets forth no time table for selection of a preferred rail corridor, despite DOE's assertion that the information presented is sufficient to select a preferred corridor. The DEIS states:

"Although it is uncertain at this time when DOE would make any transportation related decisions, DOE believes that the EIS provides the information necessary to make decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments), as well as the choice among alternative transportation corridors." From page 6-1.

Referring specifically to the selection of implementing alternatives, such as alternative rail corridors in Nevada, the DEIS states:

"If and when it is appropriate to make such decisions, DOE believes that the EIS provides the information necessary to make these decisions." On page 6-2.

According to the DEIS, additional information, analyses, and consultations will be required "for selection of a specific rail alignment within a corridor." Page 6-1.

DOE's failure to designate a preferred rail access corridor in the DEIS violates the National Environmental Policy Act (NEPA). NEPA procedures are designated to "insure that environmental information (including information on the human environment as well as public health and safety) is available to public officials and citizens before decisions are made and before actions are taken." DOE's approach denies the affected public a meaningful opportunity to participate in the rail corridor evaluation process before DOE prepares the final EIS.

Moreover, DOE's refusal to narrow the choice of corridors extends the region of influence of the proposed action to 13 Nevada counties traversed by the five rail corridors and their existing mainline rail connections. Virtually the entire population of Nevada will be held hostage by DOE's indecision. Coupled with the absence of a time table, the resulting uncertainty, in and of itself, will cause adverse socioeconomic impacts for individuals, businesses and communities.

During the scoping process in December of 1995, the State of Nevada recommended the following process to DOE:

"The Draft EIS must present a technically credible methodology for comparative evaluation of rail spur route options. The State of Nevada believes that DOE should fully evaluate at least three feasible rail spur routes before selecting a preferred route."

Nevada also recommended specific criteria for the DEIS comparative route evaluation: Impacts on public health and safety; impacts on highly populated areas; engineering feasibility; impacts on surface and ground water resources, threatened and endangered species, and federal and state parks and refuges; cost of construction, recognizing that predictability of costs may be as important as least cost in ranking alternatives; avoidance of private lands, and potential for voluntary acquisition of private lands where necessary; impacts on Native American lands and cultural resources; potential conflicts with the U.S. Air Force facilities and operations; and economic development costs and opportunities, addressing both standard and special (risk-induced) socioeconomic impacts.

The DEIS does not reveal the process DOE plans to use in selecting a preferred rail corridor. The base line information provided in chapter 3, and the impact analysis provided in chapter 6 and appendix J, are particularly deficient regarding impacts on highly populated areas; engineering feasibility; construction costs, and cost uncertainties; potential for voluntary acquisition of private lands; impacts on Native American lands and cultural resources; and economic development costs and opportunities, including risk-induced socioeconomic impacts.

In conclusion, the State of Nevada believes that DOE's refusal to identify a preferred rail corridor in the DEIS makes a legally sufficient assessment of rail transportation risks and impacts impossible.

Response
DOE believes that EIS adequately analyzes the environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

National Environmental Policy Act regulations promulgated by the Council on Environmental Quality [see 40 CFR 1502.14(e)] require an agency to identify a preferred alternative in a Draft EIS if one exists and state that an agency must identify a preferred alternative in a final EIS unless another law prohibits expression of a preference. At the time the Draft EIS was issued, DOE did not have a preference for a national transportation mode or for transportation alternatives within Nevada, however DOE did identify the Proposed Action as its preferred alternative in the Draft EIS.

8.3 (2304)
Comment - EIS000614 / 0001
On page 1-3, the DEIS states:

"Although it is uncertain at this time when DOE would make any transportation-related decisions, DOE believes that the EIS provides the information necessary to make decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments), as well as the choice among alternative transportation corridors."

With respect to alternate rail corridors to Yucca Mountain, it is questionable whether DOE even has the authority to select such a corridor given that the majority of lands within the various alternative corridors are public lands under the management authority of the Bureau of Land Management.

It is at least arguable that the selection of rail route alternatives and specific alignments are subject to BLM's [Bureau of Land Management's] own environmental review and permitting process because they ultimately have the authority to grant a right-of-way for construction and operation.

We are uncertain as to what level of review or consultation took place with BLM as the alternative corridors were being developed. It does not appear that they are a cooperating agency.

The Final EIS should explain efforts to coordinate the review and selection of a proposed alternative route with BLM.

Response
As indicated in Section 3.2.2 of the EIS, a large percentage of the land through which any of the proposed rail corridors would pass is managed by the Bureau of Land Management. The Bureau was not a cooperating agency for the Yucca Mountain Repository EIS, but the interactions that the Department had with the agency are delineated in Section C.2.1.1. In addition, Appendix C does not include the many staff-level interactions that occurred between the Bureau and DOE and were necessary for the development of the EIS. Information exchanges have occurred frequently in the past and are ongoing. These range from DOE providing informal status reports to the Bureau providing specific data for analyses purposes such as Geographic Information System data for utility corridors.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada and the Bureau of Land Management. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (2455)
Comment - EIS000679 / 0003
We've said plan the transportation system to maximize use of rail. Only use trucks where absolutely necessary.

Here I give them credit for actually developing a plan to maximize use of rail, but in the Draft EIS, then, they looked at the results of their computer models and said, "Well, the risk of truck isn't that much different than rail, so we can do it either way."

We strongly disagree. It's a way to maximize use of rail, and that should be the policy that they follow.

Response
DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (3402)
Comment - EIS001393 / 0003
I request that DOE do an environmental impact statement on every route that such waste would travel along. People along the proposed routes have the right to know everything about the risks of transporting nuclear waste.

Response
DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. In addition, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines could be constructed or modified. In response to public comments, DOE has included state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

8.3 (3611)
Comment - EIS001031 / 0017
What routes do you propose to use? Have they been identified and studied for safety? Shouldn't the shipments be delayed until this is done and emergency response preparations are in place?

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions the

Department would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures (63 *FR* 23753; April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

8.3 (4233)
Comment - EIS001160 / 0048
Examples of possible "worst case" scenarios within should be considered within the FEIS as a means to bound impact assessment and to identify reasonable mitigation measures include:

1. Nevada's Governor designates U.S. 93 south from I-80 at Wendover through Ely to U.S. 6 then south to U.S. 95 then on to the Nevada Test Site as an alternate to transportation through Las Vegas via I-15. Direct impacts include residents and visitors in the County being exposed to risk of radiological exposure. Indirect impacts include enhanced public perception of risk and related area stigmatization.

2. Nevada's Governor designates U.S. 93 south from I-80 at Wendover through Ely to U.S. 6 then south to State Highway 318 through Lund to State Highway 376 to U.S. 93 then south to I-15 to U.S. 95 north to the Nevada Test Site. Direct impacts include residents and visitors in the County being exposed to risk of radiological exposure. Indirect impacts include enhanced public perception of risk and related area stigmatization.

Response
The impacts of using the two routes discussed by the commenter are presented in Section J.3.1.3 of the EIS. The results of these analyses show that the impacts of using these routes are not very different from using routes that go through Clark County, Nevada, both on a national level and on a Nevada level. In response to public comments, DOE has included state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Figure J-53 for Nevada map). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass (see Table J-93).

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents,

which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.3 (4341)
Comment - EIS001191 / 0004
The Draft EIS does not identify and specifically analyze particular routes for rail and highway shipments. It needs to be recognized that regular shipments of high-level radioactive waste over a 24-year period will have a major impact on communities along transportation routes, even if an accident never actually occurs.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included, state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

Based on the results of the impact analyses presented in Chapter 6 and Appendix J of the EIS, as well as the results published in numerous other studies and environmental impact analyses cited in the EIS, DOE is confident that spent nuclear fuel and high-level radioactive waste can be and would be safely transported to Yucca Mountain. DOE believes, as the EIS reports, that the potential impacts of this transportation would be so low for individuals who live and work along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured. The analysis presented in the EIS factored in the characteristics of spent nuclear fuel and high-level radioactive waste, the integrity of shipping casks that would be used in transport, and the regulatory and programmatic controls that would be imposed on shipping operations (see Appendix M of the EIS). The EIS analytical results are supported by numerous technical and scientific studies which have been compiled through decades of research and development by DOE and other Federal agencies of the United States, including the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as by the international community, including the International Atomic Energy Agency.

8.3 (4958)
Comment - EIS001301 / 0002
I wouldn't exactly think it is a good idea to transport by trucks. The best way to transport the nuclear waste is to transport it by trains. Trucks would be ok, but if a truck has a wreck everyone in that area is in big trouble. If the weather gets bad then don't send any waste that day or week or month.

Response
DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. Section M.3.2 of the EIS provides a discussion of the protocols and procedures that would be implemented by a Regional Servicing Contractor and its subcontractors under adverse weather or road conditions.

8.3 (5035)
Comment - EIS001520 / 0003
The specific transportation routes assumed for the analyses of transportation impacts should be identified in the EIS.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction (see Appendix M of the EIS). At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included, state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (5042)
Comment - EIS001520 / 0010
Appendix J of the draft EIS describes the use of the HIGHWAY and INTERLINE computer codes to project the specific transportation routes to be used for analysis of transportation impacts when moving radioactive waste to a Yucca Mountain repository. However, the draft EIS does not report what those transportation routes are. The Board recommends that the final EIS identify the specific transportation routes that are used for analysis of transportation impacts. If the DOE has identified preferred transportation routes, those also should be identified in the final EIS. If preferred transportation routes have not been identified, the final EIS should discuss when and how such identification will occur.

Response
Appendix J of the EIS includes maps of all rail and highway routes used in the analysis of impacts presented in Chapter 6 along with tables showing the number of shipments originating in and passing through each state. Although it is likely that some commercial spent-nuclear fuel would be transported to the Yucca Mountain site using standard highway (legal-weight) trucks, the EIS indicates that DOE plans to encourage potential transportation contractors to use rail to the extent practical, consistent with Departmental planning to procure transportation services.

As discussed in Appendix M of the EIS, specific routes would be identified approximately 4 years before shipments would occur. As stated in Section 2.1.3.2.2, a truck shipment of spent-nuclear fuel or high-level radioactive waste would use routes to the repository in accordance with U.S. Department of Transportation regulations (49 CFR 397.10), which require the use of preferred routes. These routes include the Interstate Highway System, including beltways and bypasses. Alternate routes would be designated by states and tribes following Department of Transportation regulations (49 CFR 397.103) that require consideration of the overall risk to the public and prior consultation with affected local jurisdictions and affected states and tribes. The highway routes that would be used would be selected in accordance with these Federal transportation regulations and would not be selected by DOE. There are no Federal regulations for the selection of rail routes for the shipment of radioactive materials. However, DOE has developed operational protocols (Section M.3 of the EIS) which include guidelines for selecting rail routes based on current best practice. DOE applied the guidelines in selecting the routes for analysis in the EIS. If the U.S. Department of Transportation promulgates rail routing regulations, DOE's operational protocols would change to comply with the regulations.

8.3 (5052)
Comment - EIS000999 / 0002
It is my understanding that current regulations that govern the shipment of spent nuclear fuel and high-level radioactive waste require the avoidance of major population centers. In spite of this requirement, all of the potential highway and rail routes depicted in the Environmental Impact Statement through Missouri go through either the metropolitan areas of St. Louis and Kansas City, or both. These two metropolitan areas have a combined population of over 4.3 million people.

I would like to go on record at this time in opposition to the shipment of spent nuclear fuel and high-level radioactive waste through Missouri and through this state's most urbanized population centers, St. Louis and Kansas City. The potential exposure of these concentrated populations to the risks associated with the shipment of material of this nature should preclude further consideration of routes that would involve these metropolitan regions in Missouri.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. The maps of highway routes through Missouri show only Interstate-70, the beltways around St. Louis and Kansas City would be used (see Figure J-47). Furthermore, the State has the authority to designate alternate routes in accordance with 49 CFR 397.103. As a consequence, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-47 of the EIS for the representative Missouri routes). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-87 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would enter Nevada after travelling through Missouri in the mostly legal-weight truck scenario. The table also lists the estimated number of rail shipment through California in the mostly rail scenario for each of the candidate Nevada rail corridors and heavy-haul truck routes.

If the Yucca Mountain site was approved, under the mostly legal-weight truck scenario, the estimated total number of truck shipments through Missouri would be 19,142 over 24 years, approximately 2 truck shipments per day. There would be an estimated 435 rail shipments, slightly more than 1 per month.

The estimated numbers of shipments entering Nevada after travelling through Missouri under the mostly rail scenario are less than the mostly legal-weight truck scenario. According to Table J-87, the number of rail shipments would range from 4,069 to 4,126 depending on the mode (rail or heavy-haul truck) and corresponding corridor/route selected in Nevada. This is slightly more than 3 rail shipment per week over 24 years, at most. In addition, there would be approximately 71 legal-weight truck shipments through Missouri.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

Comment - EIS001887 / 0070
Page 2-9; Section 2.1.1.4 - Nevada Transportation Scenarios and Rail and Intermodal Implementing Alternatives

Likewise, the Draft EIS fails to evaluate each of the rail spur and intermodal facility alternatives at the same level of analysis and with the same level of information. It also postpones the selection of a preferred rail spur, intermodal facility location, the identification of specific rail spur alignments, and the analysis of specific operational aspects and impacts of the rail/intermodal system to some future, undefined time. Nevada contends that there is sufficient information available now for DOE have to compared rail spur alternatives, identified a preferred alternative, identified a specific and clearly defined rail alignment within the preferred corridor, identified whether an intermodal transfer facility is needed, and, if needed, selected a preferred site for such a facility. Failing to undertake these analyses and present findings in the Draft EIS makes it impossible for potentially impacted citizens and communities to effectively participate in the NEPA [National Environmental Policy Act] process.

Response
Sections 6.3 and J.3 of the EIS describe the impacts and analyses for the five rail corridors and the five heavy-haul truck routes analyzed as alternatives for transporting large rail casks to the Yucca Mountain site. Based on public comments on the Draft EIS, DOE has acquired new information and analytical tools that contribute to an improved understanding of interactions between the potentially affected environment and proposed transportation activities in Nevada. This includes in part, newly identified potential land-use conflicts, additional information of biological resources and cultural resources, and new analyses for ground vibration and noise impacts on sensitive structures. See the introduction to Chapter 6 for additional information on changes from the Draft to the Final EIS. DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

8.3 (5678)
Comment - EIS001887 / 0300
SECTION 6. ENVIRONMENTAL IMPACTS OF TRANSPORTATION

DOE has not demonstrated the technical, economic, or environmentally acceptable feasibility of transporting spent nuclear fuel and high-level radioactive waste to the proposed site. Absent this demonstration, DOE violates the National Environmental Policy Act by deferring transportation related decisions. Specifically, if the proposed repository is approved based upon this EIS, DOE will begin to make a substantial commitment of resources to the proposed repository, even though the method of transportation to the site has not been determined. This could force a transportation related decision that results in unacceptable, adverse impacts. This is the scenario that the NEPA [National Environmental Policy Act] process is designed to avoid.

Response
DOE believes that the EIS adequately analyzes the environmental impacts of the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

8.3 (5687)
Comment - EIS001887 / 0304
On the bottom of page 6-1, the Draft EIS states: “Because the mode of transportation used to ship from each site would depend on several factors that DOE does not control (for example, future capabilities of shipping sites, rail service to shipping sites, and labor agreements), DOE recognizes that it cannot predict the specific transportation mode (truck or rail) of each shipment to the repository.” This statement is factually incorrect. The NWPA, as amended, makes DOE the shipper of record for all SNF [spent nuclear fuel] and HLW [high-level radioactive waste] shipments to the repository. As shipper of record, DOE is legally entitled to dictate the choice of mode for every shipment. Over the past decade, DOE contractor studies, such as the Near Site Transportation Infrastructure and Facility Interface Capability Assessment, have documented the technical factors which constrain modal choices at each commercial reactor site and estimated the cost of adding rail shipment capability at truck-only sites. DOE’s decision to make all transuranic waste shipments to the Waste Isolation Pilot Plant (WIPP) by truck, even though rail transportation to WIPP is feasible from major federal facilities such as Hanford and Savannah River, is a strong precedent for DOE control of repository transportation modal choice decisions. Moreover, DOE recently dictated not only the choice of mode (rail), but also the service option (dedicated trains), the port of entry (Concord), and the preferred route (Feather River Canyon) for the recent foreign research reactor SNF shipments to INEEL.

<u>Response</u>
It is the Department's opinion that the statement made in the EIS is correct. The shipments cited by the commenter were under the complete control of DOE. Waste Isolation Pilot Plant shipments are from one DOE site to another and the foreign research reactor spent nuclear fuel shipments are made by DOE contractors acting on DOE instructions. Shipments made under the NWPA are made under the terms of the Standard Contract for Disposal of Spent Nuclear Fuel and/or High-Level Radioactive Waste (10 CFR Part 961). Under the terms of this contract, which DOE has with each utility owning spent nuclear fuel, the utility has the right to specify the type of cask required. DOE has the responsibility to deliver a cask "suitable for use" at the utility site. Therefore, although a reactor's commercial nuclear facilities might have the capability to handle a large rail cask, the utility might prefer a truck cask and DOE would be required to accept the spent nuclear fuel using truck casks. In addition, under stipulations of the Regional Servicing Contractors Draft Request for Proposal, the Regional Servicing Contractors would work with utilities to determine the best way to service a site and integrate site planning into a regional servicing plan including modes and routes.

DOE believes that the mostly rail scenario, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada. In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.3 (5689)
<u>Comment</u> - EIS001887 / 0305
Page 6-2; Section 6 - Environmental Impacts of Transportation

The Draft EIS fails to identify a preferred rail corridor and sets forth no timetable for selection of a preferred rail corridor, despite DOE's assertion that the information presented is sufficient to select a preferred corridor. The Draft EIS states: "Although it is uncertain at this time when DOE would make any transportation-related decisions, DOE believes that the EIS provides the information necessary to make decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments), as well as the choice among alternative transportation corridors." (p. 6-1) Referring specifically to the selection of "implementing alternatives," such as "alternative rail corridors in Nevada," the Draft EIS states: "If and when it is appropriate to make such decisions, DOE believes that the EIS provides the information necessary to make these decisions." (p. 6-2) According to the Draft EIS, additional information, analyses, and consultations would be required "for selection of a specific rail alignment within a corridor." (p. 6-1)

DOE's failure to designate a preferred rail access corridor in the Draft EIS violates the National Environmental Policy Act (NEPA). NEPA procedures are designed to "insure that environmental information [including information on the human environment as well as public health and safety] is available to public officials and citizens before decisions are made and before actions are taken." DOE's approach for the Draft EIS denies the affected public a meaningful opportunity to participate in the rail corridor evaluation process before DOE prepares the Final EIS.

Moreover, DOE's refusal to narrow the choice of corridors extends the region of influence of the Proposed Action to thirteen Nevada counties traversed by the five rail corridors and their existing mainline rail connections. Virtually the entire population of Nevada will be held hostage by DOE's indecision. Coupled with the absence of a timetable, the resulting uncertainty, in and of itself, will cause adverse socioeconomic impacts for individuals, businesses, and communities.

During the scoping process in December, 1995, the State of Nevada recommended the following process to DOE: "The Draft EIS must present a technically credible methodology for comparative evaluation of rail spur route options. The State of Nevada believes that DOE should fully evaluate at least three feasible rail spur routes before selecting a preferred route." Nevada also recommended specific criteria for the Draft EIS comparative route evaluation: 1) impacts on public health and safety; 2) impacts on highly populated areas; 3) engineering feasibility;

4) impacts on surface and groundwater resources, threatened and endangered species, and federal and state parks and refuges; 5) cost of construction, recognizing that predictability of costs may be as important as least cost in ranking alternatives; 6) avoidance of private lands and potential for voluntary acquisition of private lands where necessary; 7) impacts on Native American lands and cultural resources; 8) potential conflicts with U.S. Air Force facilities and operations; and 9) economic development costs and opportunities, addressing both standard and special (risk-induced) socioeconomic impacts.

The Draft EIS does not reveal the process DOE plans to use in selecting a preferred rail corridor. The baseline information provided in Section 3 and the impact analysis provided in Section 6 and Appendix J are particularly deficient regarding impacts on highly populated areas; engineering feasibility; construction costs and cost uncertainties; potential for voluntary acquisition of private lands; impacts on Native American lands and cultural resources; and economic development costs and opportunities, including risk-induced socioeconomic impacts. Nevada believes that DOE's refusal to identify a preferred rail corridor in the Draft EIS makes a legally sufficient assessment of rail transportation risks and impacts impossible.

Response
As stated in Sections 1.1 and 2.1 of the EIS, transportation of spent nuclear fuel and high-level radioactive waste is an integral part of the Proposed Action and the EIS addresses the potential impacts associated with a national and Nevada campaign to transport radioactive waste to the proposed repository at Yucca Mountain (see Sections 6.2 and 6.3.1). DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

DOE's decisionmaking process with respect to a rail corridor selection in Nevada would take into account public health and safety; engineering feasibility; surface and groundwater resources, threatened and endangered species, Federal and State parks and refuges, cost of construction and maintenance, land use and ownership, cultural resources, potential conflicts with U.S. Air Force facilities and operations, and socioeconomic impacts. These factors are addressed for each of the five rail corridors in the EIS (see Section 6.3.2).

National Environmental Policy Act regulations promulgated by the Council on Environmental Quality [see 40 CFR 1502.14(e)] require an agency to identify a preferred alternative in a Draft EIS if one exists and states that an agency must identify a preferred alternative in a final EIS unless another law prohibits expression of a preference. At the time the Draft EIS was issued, DOE did not have a preference for a national transportation mode or for transportation alternatives within Nevada; however, DOE did identify the Proposed Action as its preferred alternative in the Draft EIS.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.3 (6051)
Comment - EIS001632 / 0054
EPA [the Environmental Protection Agency] appreciates that the actual shipments of waste will not likely occur for another 10 years and understands DOE's reluctance to provide additional information on likely routes for waste transport. However, EPA sees no reason why DOE cannot commit to making this information available as the time for shipments approaches. DOE is doing this now for shipments to the Waste Isolation Pilot Plant in New Mexico. Once DOE has greater certainty about the routes along which waste shipments will travel, the Department will also be able to update and expand upon, if needed, the environmental justice or other impact analyses which are route-specific.

Response
If the Yucca Mountain site was approved for development of a repository, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction (see Section M.6 of the EIS). In accordance with 10 CFR 73.37(a)(7), actual route selection and submission to the Nuclear Regulatory Commission would occur 1 or more years before a route's use for shipment (see Section M.3.2.1.2 for more information). At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified

representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included, state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

8.3 (6440)
Comment - EIS001632 / 0014
Page 2-40, Section 2.1.3.2, first paragraph: Please confirm whether only heavy-haul trucks will be used from commercial sites, or if legal-weight trucks may also be used.

Response
DOE believes that the mostly rail scenario, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, and the rest by legal-weight truck, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada. In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.3 (6493)
Comment - EIS001774 / 0008
When will a route-specific comprehensive plan with state and local fee permit programs be implemented and established?

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Department has issued a draft Request for Proposals requiring the Regional Servicing Contractor to prepare a transportation plan that describes the Contractor's operational strategy and delineates the steps it would implement to ensure compliance with all regulatory and other DOE requirements. Operational protocols and procedures would be developed with each generator by Regional Servicing Contractors as part of the planning process to be completed prior to initiation of transport of spent nuclear fuel or high-level radioactive waste from generators to the repository. Section M.3 of the EIS contains additional information on operational protocols required of the Regional Servicing Contractors.

This planning includes identification of proposed routes and associated routing considerations, coordination and communication with all participating organizations and agencies, including other Regional Servicing Contractor(s), DOE, state, tribal, and local governments, and interactions with appropriate Federal and state organizations. The route and mode determinations would be interactive.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste.

8.3 (7185)
Comment - EIS001337 / 0077
Page 2-54 Apex/Dry Lake and Sloan/Jean Routes. The assumption here that the northern and southern legs of the beltway would be available is inappropriate. This highway will be owned by Clark County and will not necessarily be available for use by heavy-haul shipments. The analysis of routing through the Las Vegas Valley should be confined to existing roadways (I-15, U.S. 95 etc.).

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

The U.S. Department of Transportation requirements and the planned completion of the Las Vegas Beltway led DOE to assume, for purposes of analysis in the EIS, that legal-weight truck shipments would not enter the Spaghetti Bowl interchange of Interstate-15 and U.S. 95. Nonetheless, to assess how potential impacts would be different from those of using the Las Vegas Beltway, DOE analyzed the impacts for legal-weight trucks to travel through the Spaghetti Bowl interchange (see Section J.3.1.3 of the EIS for an analysis of the impacts of using different routes in Nevada).

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

If DOE selected the Apex/Dry Lake heavy-haul truck implementing alternative, it would initiate additional engineering and environmental studies, including appropriate National Environmental Policy Act reviews. It would also initiate consultations with responsible Federal, State of Nevada, tribal, and local authorities on route-specific details, impacts, and mitigative measures, and the permitting process for overdimensional and overweight heavy-haul trucks. As stated in Section 2.1.3.2 of the EIS, DOE would comply with applicable U.S. Department of Transportation and Nuclear Regulatory Commission regulations and state and local requirements. This would include Nevada regulations and conditions of the heavy-haul truck permit issued by the Nevada Department of Transportation.

8.3 (7208)
Comment - EIS001337 / 0091
Page 3-98 Section 3.2.1.1. [and Page 3-120, 3rd full paragraph] The second paragraph of this section indicates that final transportation mode and routing decisions will be made on a site-specific basis during the transportation planning process, following a decision to build a repository at Yucca Mountain. This statement implies that the Secretary of Energy’s Site Recommendation to the President will be made prior to resolution of site-specific mode and routing decisions. This would seem contradictory to the guidance contained within existing 10 CFR 960 and inconsistent with the proposed revisions to 10 CFR 960, which infer the availability of EIS-based transportation information for use, by the Secretary in preparing a Site Recommendation to the President. In the event that site-specific transportation decisions are deferred until after a decision to build Yucca Mountain is made, such transportation decisions may not be made until 2005, the year DOE anticipates receiving a construction authorization (see Figure 2-9). Such a schedule will provide DOE with just five-years to complete necessary field

studies and surveys, complete environmental documentation, complete necessary final designs, construct necessary rail and/or highway infrastructure and provide necessary training and equipment to emergency first responders along selected routes. Lincoln County and the City of Caliente do not agree with a DOE decision to defer making site-specific transportation decisions until after a decision to build Yucca Mountain is made. The County and City recommend that the DEIS include a phased schedule for making site-specific transportation decisions which begins now so as to avoid decision-making under the pressure of unnecessarily tight time constraints. Further, the County and City do not agree with the apparent DOE assumption that if a repository site is approved for construction that transportation issues will be resolved and that a satisfactory transportation route and mode will be available to serve the site. Rather, the DEIS should include a schedule and approach to making transportation decisions which will enable minimization of related risks. The current approach described (or inferred) within the DEIS does not support risk minimization.

Response

DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (7290)
<u>Comment</u> - EIS001832 / 0029
Confidence in the robustness of this evaluation would be further bolstered if the following improvement was made in the FEIS:

DOE should address the fact that the mostly rail scenario is more likely than the mostly truck scenario. This is because most reactor sites, even those that do not now have the ability to handle rail casks, will likely modify cask handling capability to be able to handle 100 to 125 ton transportable storage systems. These upgrades will facilitate the use of rail casks for transportation. Nuclear Energy Institute would be pleased to provide examples of some sites that have upgraded or are in the process of upgrading sites and or plans.

<u>Response</u>
DOE believes that the mostly rail scenario, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada.

In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved, DOE would identify for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada.

8.3 (7623)
<u>Comment</u> - EIS001912 / 0080
Pg. 6-35 4th para. states, “Because the state of Nevada has not designated preferred routes.... Does this statement mean that the preferred alternative for highway route in the EIS would be I-15? If no, please explain.

<u>Response</u>
Section 6.3 of the EIS describes the general scenarios for transportation of spent nuclear fuel and high-level radioactive waste through Nevada to the proposed repository and their impacts. As stated in Section 6.3, without a preferred alternate route proposed and established by the State of Nevada, the U.S. Department of Transportation regulations would be the governing regulation for selecting a route. The Department of Transportation regulations identify that the Interstate Highway System is the preferred routing, with the remainder of the transport route to be the shortest distance from the Interstate Highway System. At present, these routing requirements for highway systems identify Interstate-15 and U.S. 95 to the proposed repository as the preferred route.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations (see Figure 6-11). DOE identified rail lines based on current rail practices, because there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

The U.S. Department of Transportation regulations provide for states and tribes to designate alternative preferred routes. These regulations require a state or tribe to consider overall public safety in designating routes that would be in lieu of or addition to routes specified by the Department of Transportation regulations. For example, under current Federal regulations, before DOE highway shipments of spent nuclear fuel and high-level radioactive waste could use U.S. 95 through Mineral County, Nevada, the State would need to designate this route as an alternate route.

8.3 (7823)
Comment - EIS001653 / 0020
With respect to rail and truck shipment routes in the EIS, has DOE eliminated all other routes from consideration? If not, why not? If they are not eliminated should they be included in the DEIS?

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction (see Section M.3.2.1.2 of the EIS). At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included, state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could traverse.

DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. In addition, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (8073)
Comment - EIS000406 / 0004
It does appear from the evaluation in the DEIS that the risk associated with rail transportation is less than the risks associated with truck transportation. Under the truck transportation alternative, more than 100,000 individual truck shipments will be made to Yucca Mountain compared to approximately 25,000 rail shipments. A Yucca Mountain DEIS which is structured to support a decision to choose one modal option over the others appears contrary to current DOE transportation planning guidance and policy direction. Recently, DOE issued its draft request for proposal for the acquisition of waste acceptance and transportation services for the Office of Civilian Radioactive Waste Management, otherwise known as the privatization proposal. Under this proposal, private shipping companies called regional servicing contractors would be selected to transport waste from generator sites to Yucca Mountain. As proposed, the regional servicing contractor would make modal and route decisions with guidance from DOE. In effect, regional servicing contractors could use multiple routes and modes for waste shipments. This approach seems somewhat inconsistent with the impact results and the approach taken in the DEIS where one modal option is compared against the other. Furthermore, DOE limited its discussion of highway transportation routes to one (I-15). The Final EIS should clarify the policy direction DOE intends to take and describe how that policy direction will be reflected in future Yucca Mountain transportation logistics and planning.

Response
DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

In addition, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Department has issued a draft Request for Proposals requiring the Regional Servicing Contractor to prepare a transportation plan that describes the Contractor's operational strategy and delineates the steps it would implement to ensure compliance with all regulatory and other DOE requirements. This includes identification of proposed routes and associated routing considerations, coordination and communication with all participating organizations and agencies, including other Regional Servicing Contractor(s), DOE, state, Native American tribal, and local governments, and interactions with appropriate Federal and state organizations. The route and mode determinations would be interactive. If, during the course of the mode or route determinations, one of the previously determined factors changed, the site-specific mode and route analysis would be reevaluated to ensure consistency. The Regional Servicing Contractor would consult with other Regional Servicing Contractor(s) as appropriate to ensure continuity and consistency of routes and to ensure trained emergency response personnel capability.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, because there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

8.3 (8126)
Comment - EIS001653 / 0078
Pg. 6-35 4th par states, "Because the state of Nevada has not designated preferred routes... Does this statement mean that the preferred alternative for highway route in the EIS would be I-15? If no, please explain.

Response
Section 6.3 of the EIS describes the general scenarios for transportation of spent nuclear fuel and high-level radioactive waste through Nevada to the proposed repository and their impacts. As stated in Section 6.3, without a

preferred alternate route proposed and established by the State of Nevada, the U.S. Department of Transportation regulations would be the governing regulation for selecting a route. The Department of Transportation regulations identify that the Interstate Highway System is the preferred routing, with the remainder of the transport route to be the shortest distance from the Interstate Highway System. At present, these routing requirements for highway systems identify Interstate-15 and U.S. 95 to the proposed repository as the preferred route.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

The U.S. Department of Transportation regulations provide for states and tribes to designate alternative preferred routes. These regulations require a state or tribe to consider overall public safety in designating routes that would be in lieu of or addition to routes specified by the Department of Transportation regulations. For example, under current Federal regulations, before DOE highway shipments of spent nuclear fuel and high-level radioactive waste could use U.S. 95 through Mineral County, Nevada, the State would need to designate this route as an alternate route.

8.3 (8449)
<u>Comment</u> - EIS001397 / 0017
The issue of new route construction is also barely touched. Issues of impact upon ground and surface waters, flood plains, and species habitat are barely addressed. Impacts on communities both Native and non-native, such as socioeconomic impacts on hunting, agriculture and tourism, emergency response needs, health concerns of frequent and repeated exposure, and transient worker man Camps in rural areas are not presented.

This information is so inadequate in the DEIS that unless it can be completely addressed before the final EIS of this study, a separate or supplementary study should be drafted that presents complete information once it is compiled and analyzed.

<u>Response</u>
As described in Sections 2.1.3.2 and 2.1.3.3 of the EIS, existing national highway and rail routes are adequate to support the transportation of spent nuclear fuel and high-level radioactive waste either to the repository (if legal-weight trucks are used) or to Nevada (if rail is used). If rail is used to bring large casks to Nevada, significant construction would be required only to support the construction of a branch rail line in one of the candidate corridors within Nevada. If heavy-haul truck was chosen as the mode in Nevada, Upgrades to existing highway routes, not new construction, as well as construction of an intermodal transfer facility, would be necessary. The environmental impacts of constructing branch rail lines in Nevada are presented in Sections 6.3.2 and J.3.4.2.

The EIS includes assessments of impacts of branch rail line construction and operation on land use and ownership (including access, hunting, mining, and ranching), water resources, biological resources (including endangered species), occupational health and safety, socioeconomics, noise, cultural resources, utilities and energy, flood plains, and other potential impact areas. The impacts presented in Section 6.3.2 of the EIS include the impacts of the rail construction worker camps, which would be transient and short-term and would be restored to predisturbance conditions following completion of the branch rail line.

The U.S. Department of Transportation routing requirements, along with regulatory requirements to limit radiation dose external to a shipping cask, help to ensure that radiation dose to persons who live along routes would be low. The analysis in Chapter 6 of the EIS for the mostly legal-weight truck scenario estimates the dose to persons who would drive alongside the trucks as they travel on the highways, who would be stopped in locales where truck shipments stop, and who live along the routes that would be used. The dose for an individual who lived along a route would be an average of about 0.02 millirem per year. This is 18,000 times less than average annual background radiation in the United States (360 millirem) and less than 1/500 of the dose from a chest x-ray.

In response to public comments, DOE has included, state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.3 (9403)
Comment - EIS001888 / 0101
The purpose of an EIS is to establish a basis for mitigation negotiations. To achieve this goal, an EIS must assign specific roles and responsibilities for actions that cause impacts and for those that ameliorate impacts. This was not achieved in the DEIS. For example, the DEIS failed to provide this information regarding an implementing alternative for transportation routing. At a minimum, it should have provided a specific schedule for the construction of a route to Yucca Mountain, and defined specific agency responsibilities for constructing, maintaining and operating the route to Yucca Mountain. None of this has been accomplished, and in view of these omissions, Clark County and other affected jurisdictions do not have sufficient information necessary to effectively understand effects and negotiate mitigation.

Response

As stated in Section 1.1 of the EIS, the purpose of the EIS is to provide information on potential environmental impacts that could result from the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at the Yucca Mountain site. Transportation of spent nuclear fuel and high-level radioactive waste is an integral part of the Proposed Action and the EIS addresses the potential impacts associated with a national and Nevada campaign to transport waste to the proposed repository (see Sections 6.2 and 6.3). DOE would consider the impacts of both the proposed repository and transportation, both nationally and within Nevada, in determining whether to recommend the Yucca Mountain to the President as a site for a geologic repository.

DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should a rail corridor be selected, other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, state, Federal, and Native American tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

Section 116(c) of the NWPA states that "the Secretary shall provide financial and technical assistance to [an affected unit of local government or the State of Nevada]… to mitigate the impact on such [an affected unit of local government or the State of Nevada] of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Any decision to provide assistance under Section 116(c) would be based in part on an evaluation of a report submitted by an affected unit of local government or the State of Nevada to document likely economic, social, public health or safety, and environmental impacts. If the proposed repository were to become operational, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

After a decision is made regarding the proposed repository and transportation modes and routes, local jurisdictions would be better able to identify the likely economic, social, public health and safety, and environmental impacts that would be the basis for a request for economic assistance under Section 116(c) of the Act. Because several years would elapse between approval of the repository and start of a transportation campaign, affected units of local governments and tribal governments would have sufficient time to request and receive funding.

8.3 (9553)
Comment - EIS001888 / 0226
The purpose of an EIS is to establish a basis for mitigation negotiations. To achieve this goal, an EIS must assign specific roles and responsibilities for actions, which cause impacts, as well as those which ameliorate impacts. The DEIS fails to provide this information. For example, there is no information about how an "implementing alternative" for a route through Nevada will be chosen, when construction will begin, what agency will oversee the construction, and how the route will be maintained. Clark County, and other effected jurisdictions do not have sufficient information necessary to understand potential impacts. The DEIS should have selected an "implementing alternative" to move waste through Nevada. It should have provided a specific schedule for the construction of a route to Yucca Mountain. The DEIS should have defined specific agency responsibilities for constructing, maintaining and operating the route to Yucca Mountain. None of this has been accomplished. Indeed, none of the information necessary to describe how an implementing alternative will be selected is provided in the DEIS.

Response
As stated in Section 1.1, the purpose of the EIS is to provide information on potential environmental impacts that could result from the Proposed Action to construct, operate and monitor, and eventually close a geologic repository for the disposal of spent nuclear fuel and high-level radioactive waste at the Yucca Mountain site. Transportation of spent nuclear fuel and high-level radioactive waste is an integral part of the Proposed Action and the EIS addresses the potential impacts associated with a national and Nevada campaign to transport waste to the proposed repository (see Sections 6.2.3 and 6.3.1). DOE would consider the impacts of both the proposed repository and transportation, both nationally and in Nevada, in determining whether to recommend the Yucca Mountain to the President as a site for a geologic repository.

DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. Should a rail corridor be selected, other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and Native American tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

Section 116(c) of the NWPA states that "the Secretary shall provide financial and technical assistance to [an affected unit of local government or the State of Nevada]… to mitigate the impact on such [an affected unit of local government or the State of Nevada] of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Any decision to provide assistance under Section 116(c) would be based in part on an evaluation of a report submitted by an affected unit of local government or the State of Nevada to document likely economic, social, public health or safety, and environmental impacts. If the proposed repository was to become operational, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

After a decision was made on the proposed repository and transportation modes and routes, local jurisdictions would be better able to identify the likely economic, social, public health and safety, and environmental impacts that would be the basis for a request for economic assistance under Section 116(c) of the Act. Because several years would elapse between approval of the repository and start of a transportation campaign, affected units of local governments and tribal governments would have sufficient time to request and receive funding.

8.3 (9576)
Comment - EIS001888 / 0250
There are conflicts between the proposed action analyzed by the DEIS and plans in Clark County, Nevada. The DOE's examination of these impacts was cursory and must be revised.

Response
DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and a rail corridor be selected, other transportation decisions, such as the selection of a specific rail alignment within the corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and Native American tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use. DOE would seek input from Clark County planning officials on any planning conflicts and potential mitigative measures needed due to transportation through Clark County, Nevada.

8.3 (9854)
Comment - EIS001888 / 0419
[Clark County summary of comments it has received from the public.]

Commenters believe that the EIS should be used to select specific transportation routes in consideration of the socioeconomics impacts from the public perception of risks. Socioeconomic impacts mentioned for analysis include interference with orderly and planned urban development, and unredeemable costs and burdens on local governments.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

Regarding costs and burdens on local governments, DOE is authorized to provide technical and financial assistance to affected units of local government to mitigate impacts associated with the repository. Section 116(c) of the NWPA states that "the Secretary shall provide financial and technical assistance to [an affected unit of local government or the State of Nevada]… to mitigate the impact on such [an affected unit of local government or the State of Nevada] of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Any decision to provide assistance under Section 116(c) would be based in part on an evaluation of a report submitted by an affected unit of local government or the State of Nevada to document likely economic, social, public health or safety, and environmental impacts. If the proposed repository were to become operational, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures. After a decision is made regarding the proposed repository and transportation modes and routes, local jurisdictions would be better able to identify the likely economic, social, public health and safety, and environmental impacts that would be the basis for a request for economic assistance under Section 116(c) of the Act. Because several years would elapse between approval of the repository and start of a transportation campaign, affected units of local government and tribal governments would have sufficient time to request and receive funding.

8.3 (9958)

Comment - EIS001877 / 0001

OCRWM's continuing systematic denial of the need to address transportation issues is a fundamental flaw which threatens to undermine the NWPA program. We are gravely concerned that the current draft EIS does not meet the requirements of the National Environmental Policy Act (NEPA) in assessing the transportation impacts involved with shipping radioactive waste to Yucca Mountain under the NWPA. In particular, the Committee finds that the EIS completely fails to provide an adequate analysis for the selection of transportation modes and routes.

As the Committee has stated many times in the past, mode and route analysis is one of the most crucial aspects of SNF [spent nuclear fuel] / HLW [high-level radioactive waste] transportation planning. The importance of conducting timely and defensible mode and routing analysis and selection is also reflected in WGA Resolution 99-014 passed last June by the Western Governors' Association. This resolution is included in Attachment A. Until DOE establishes mode and route selection methodologies which adequately address safety issues, further crucial steps in the development of a working transportation plan, such as the provision of funding to states and tribes under Section 180(c) of the NWPA, cannot be taken.

Response

DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included, state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

Comment - EIS000463 / 0005

Nevada has asked the Commission to reexamine the requirements for advance approval of routes. Currently the Commission has regulations requiring potential carriers and shippers to submit their routes for approval, and in 1980, and since 1980, the NRC [Nuclear Regulatory Commission] has been using a regulatory guidance document which identifies five types of routes that receive special evaluation, routes through highly populated areas, routes which would place the shipment or escort vehicle in a significantly tactically disadvantageous position, for example, tunnels which would prevent the escort vehicle from maintaining continuous surveillance of the shipment vehicle, routes with marginal safety design features, for example, two-lane routes, all too common, unfortunately, in rural Nevada, absence of guardrails, et cetera, routes with limited rest and refueling locations, also abundant in rural Nevada, and routes where responses by local law enforcement agencies when requested would be swift or timely, also, unfortunately, common in rural Nevada.

Nevada believes that the Commission should specifically require shippers and carriers to identify primary and alternative routes, which minimize highway and rail shipments through heavily populated areas. We are cognizant that this will force large numbers of shipments into rural areas where these other adverse conditions pertain.

We, therefore, also believe the Commission should adopt the route selection criteria in NUREG 0561 as part of the regulations that specifically require shippers and carriers to minimize the use of routes which fail to comply with those criteria.

Response
The commenter is referring to the State of Nevada's petition for rulemaking to the Nuclear Regulatory Commission to revise the regulations applicable to in-transit physical protection of shipment of spent nuclear fuel (10 CFR 73.37). The petition and comments on the petition, both pro and con, can be found at *http://ruleforum.llnl.gov/cgi-bin/rulemake* [click on Petition for Rulemaking (PRM-73-10) State of Nevada].

DOE would follow all applicable Nuclear Regulatory Commission regulations for in-transit physical protection of shipment of spent nuclear fuel, high-level radioactive waste, and all other types of material, which could be shipped to Yucca Mountain. DOE, as stated in the comments to the Commission on the State of Nevada petition, believes the current Commission regulations are adequate.

The complete DOE comment letter is available on the Internet site noted above.

In response to comments on the Draft EIS, DOE prepared Appendix M to provide additional information on transportation regulations and the operational aspects of spent nuclear fuel and high-level radioactive waste transportation (see Sections M.2 and M.3 of the EIS).

8.3 (10196)
Comment - EIS001888 / 0567
[Clark County summary of comments it has received from the public.]

Some commenters suggested specific rail or heavy haul routes or intermodal transfer stations, which should or should not be considered by the EIS.

Response
Section 6.3 of the EIS describes the general scenarios and their impacts for transportation of spent nuclear fuel and high-level radioactive waste through Nevada to the proposed repository. Under the rail scenario, DOE would construct and operate a branch rail line in Nevada. Based on previous studies (described in Section 2.3), DOE narrowed its consideration for a new branch rail line to five candidate corridors – Caliente, Carlin, Caliente-Chalk Mountain, Jean, and Valley Modified (see Figure 6-14). In addition, the EIS includes analyses for the Nevada heavy-haul truck scenario. Under this scenario, rail shipments would go to an intermodal transfer station where the shipping cask would transfer from the railcar to a heavy-haul truck. The heavy-haul truck would travel on existing roads to the repository. DOE considered three intermodal transfer station locations and five heavy-haul truck routes.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and a rail corridor be selected, other transportation decisions, such as the selection of a specific rail alignment within the corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews. During this process, DOE would initiate consultations with responsible local, State, Federal, and Native American tribal agencies, landowners, and other stakeholders to identify, acquire, and evaluate additional information and develop mitigative actions necessary to minimize potential impacts, including land use.

8.3 (10237)
Comment - EIS001888 / 0586
The DEIS does not meet the letter or the spirit of NEPA [the National Environmental Policy Act]. It does not provide the information that is needed to be able to assess the real impacts, not only to the citizens of Clark County, but to the nation as a whole. For example, no national transportation routes are suggested - how can an assessment of the environmental impacts be made? Likewise, in Nevada, so many routes and modes of transportation are made - time and resources do not allow an adequate assessment of environmental impacts along the routes.

Response
DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

In addition, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

In response to public comments, Appendix J of the EIS has been revised to provide state-by-state maps of routes used in the analysis. This is in addition to the route maps that were already included in the Draft EIS (see Section 2.1.3.2 for national routes and Section 2.1.3.3 for Nevada maps). These maps contain tables that show the numbers of shipments originating in and passing through each state by mode and provides the impacts from the shipments in each state.

8.3 (10311)
Comment - EIS002175 / 0004
Transportation. The DEIS fails to address the fact that the number of shipments and the amount of radioactive material that will be shipped is unprecedented in world history. About 90% of the volume would be spent fuel from nuclear power plants, and virtually none of this type of material has ever been shipped before.

Response
The United States has many years of experience in shipping spent nuclear fuel safely and efficiently. Of the thousands of shipments completed over the last 30 years, none has resulted in an identifiable injury through the release of radioactive material. Based on this experience, DOE believes that spent nuclear fuel will continue to be shipped safely and efficiently in the future. It is the Department's opinion that the EIS adequately analyzes potential impacts of the transportation alternatives.

8.3 (10348)
Comment - EIS001927 / 0006
DOE's extremely late release of transport route maps is inexcusable. Even these maps are still very vague. They have only been published on DOE's Yucca Mountain Project website, and certainly not everyone has ready access to the internet; they are hard to read (the highway route numbers are blurry); they are difficult to print because they involve so much memory; they do not show an overview of the entire nation; and they certainly do not show how many shipments would travel along a certain route, nor at what frequency.

Response
In January 2000 (during the public comment process for the Draft EIS), DOE posted state maps of the representative highway and rail line routes analyzed in the DEIS at *http://www.ymp.gov/timeline/eis/routes/routemaps.htm*. In response to public comments, DOE has included these state maps of representative highway routes and rail lines in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

8.3 (10911)
Comment - EIS001115 / 0005
Ohio's only presently operating nuclear electric generating power plants are located along Lake Erie in the Cleveland, Ohio vicinity. In order to keep operating as nuclear generators, both Davis-Bessie and Perry Power Plants require "solutions," i.e., where to dispose the High-level Radioactive Waste and considerable amount of Low-Level Radioactive Waste generated. It would seem rather obvious and logical that transportation routes for both High- and Low-level Radioactive Waste will be essentially the same whether by rail, truck, and/or "hybrid" alternative using some of both modes.

Response
The NWPA directed DOE to investigate and potentially develop a permanent geologic repository at Yucca Mountain for spent nuclear fuel and high-level radioactive waste. If the Yucca Mountain Repository was approved, it would be illegal to emplace low-level radioactive waste within the facility.

Low-level waste will be shipped to whichever low-level waste disposal facility the utilities have a contract with for this service. The routes for these shipments of low-level radioactive waste will depend on the destination and some segments might coincide with the routes for shipment of spent nuclear fuel to Yucca Mountain. Additional information on low-level waste transportation can be found in Appendix M of the EIS.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included, state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Figure J-41 for Ohio map). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass (see Table J-81 for Ohio impacts).

8.3 (10957)
Comment - EIS001424 / 0002
DOE is considering alternate transportation routes for HLRW as well as legacy waste and "excess/surplus" nuclear weapons materials, during the same time frame that the Appalachian Regional Commission (ARC) is implementing an Appalachian Intermodal Transportation Study in three Local Development Districts (LDD's). One of these LDD's is OVRDC [the Ohio Valley Regional Development Commission] (which includes Pike County of Ohio, location of the Portsmouth Gaseous Diffusion Plant). Project goal is to:

Increase industrial/commercial traffic along the Ohio River that will establish intermodal facilities and economic activities. Such growth can result in the creation of new jobs and provide a wide array of economic, social, and community benefits to the region.

Information goals from this study (funded through ARC) are to be used to provide "the necessary research and database for us (OVRDC) to seek more substantial funding through the U.S. Department of Transportation Intermodal Planning grant program." (OVRDC Winter 2000 Newsletter, pgs. 1 & 3.) Newsletter also indicates building partnerships with public and private entities representing air, highway, and rail modes of transportation that would be vital to any Ohio River focus activity is included in grant proposal submitted to ARC by OMEGA (Ohio Mid-Eastern Governments Association). Where does Mr. Miller, OVRDC, and ARC/DOE plan to include Brown County "people in-put" in this process, and when??? DOE cannot fall to include projects and their goals funded through ARC in agency decision-making process. What regulations and standards apply to transportation of radioactive materials by air mode? Are "private entities" exempt from DOE, U.S. EPA [Environmental Protection Agency], and NRC [Nuclear Regulatory Commission] regulations, standards and applicable federal laws? Is DOE considering transport of HLRW [high-level radioactive waste], LLRW [low-level radioactive waste], Mixed Waste, and/or recycled or unrecycled "surplus nuclear materials" by air transport mode as alternative to threat of accident, incident, and sabotage posed by rail and/or truck mode?

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Department has issued a draft Request for Proposals requiring the Regional Servicing Contractor to prepare a transportation plan that describes the Contractor's operational strategy and delineates the steps it would implement to ensure compliance with all regulatory and other DOE requirements. This includes identification of proposed routes and associated routing considerations, coordination and communication with all participating organizations and agencies, including other Regional Servicing Contractor(s), DOE, state, Native American tribal, and local governments, and interactions with appropriate Federal and state organizations. The route and mode determinations would be interactive. If, during the course of the mode or route determinations, one of the previously determined factors changed, the site-specific mode and route analysis would be reevaluated to ensure consistency. See Section M.3.2.1.2 of the EIS for more information on route selection.

The weight of spent nuclear fuel and heavily shielded shipping casks would make transportation by air very expensive. In addition, use of air transportation would not eliminate use of land transportation. Shipments would still have to travel from generator sites to nearby airports and from an airport in Nevada to Yucca Mountain by a land transportation mode. Finally, regulatory requirements in 10 CFR Part 71 regarding air transportation of plutonium in excess of 20 curies, could preclude air transportation of spent nuclear fuel that could contain as much as 20,000 curies of plutonium per MTHM or 40,000 curies of plutonium per truck cask. Regulations in 10 CFR Part 71 address requirements prescribed by Congress regarding air transport of plutonium.

Shipments of spent nuclear fuel and high-level radioactive waste made by private entities are not exempt from U.S. Department of Transportation and Nuclear Regulatory Commission transportation regulations, which include packaging, transporting, and handling radioactive materials for all modes of transportation, and include standards for labeling, shipping papers, placarding, loading, and unloading, allowable radiation levels, and limits for contamination of packages and vehicles, among other requirements. In addition, the regulations specify training for personnel who perform handling and transport of hazardous materials, liability insurance requirements for carriers, and safety requirements for vehicles and transport operations. More details on transportation regulations are in Section M.2 of the EIS.

8.3 (10980)
Comment - EIS001115 / 0002
The so called "Golfer's Highway" from Detroit, Michigan to Charleston, South Carolina promoted years ago by the Ohio turnpike Commission is apparently being constructed in pieces and parts. The Ohio Department of Transportation recently (November 1999 in Batavia, Ohio) held hearing on a major highway construction project in the vicinity of Stonelick Lake, Clermont County, near Eastgate/Cincinnati. Should this project, by whatever name, be completed prior to DOE's selection of a truck transport route and/or as transportation to Yucca Mountain is occurring, the directly affected public along the route and motorists using the route will have no means to realize that they are sharing a highway with high-level radioactive waste transporting trucks! The route proposed years ago for "The Golfer's Highway" transversed Ohio North to South, including the Greater Cincinnati and Northern Kentucky area (with detour from the Eastgate Area of Cincinnati to Piketon, Ohio along OH State Route 32). I am most interested in the route along State Route 32 as it is within 5 miles or so of my residence. During local Ohio Turnpike Commission and other discussion "upgrades" to State Route 32 included closing off numerous local access

roads in Brown and Adams Counties of Ohio, including most local access roads in the vicinity of Sardinia and Macon, Ohio.

It would seem likely that motorists traveling the same highway routes at commercial trucks destined for Yucca Mountain would notice the over-size semi trucks, but that recognition would not necessarily provide any clue to motorists as to what was being transported. Neither would travelers stopped at restaurants and road-side rest areas have knowledge as to what radiation dose they were receiving during routine shipment (minus unintentional release and accident scenarios).

The public along the selected routes would not have means of determining what was being transported multiple times in, near, or through their communities nor the potential risks to which they were being exposed. Southern Ohio and Northern Kentucky residents have had little opportunity to become informed and issue comments on what could be of extreme interest to them so far in this process. Should DOE response to concerns raised in the Cleveland vicinity be selection of alternative routing, the public last-to-know and with least- opportunity-to-object would be “notified” too late to serve any meaningful purpose in DOE decision-making process. Decision to avoid (in areas with public comments in objection) would require selection of available alternative highways (existing at the time shipments are scheduled to begin).

Absence of comment from local emergency management, police, and fire responders in the Southern half of Ohio and Northern Kentucky seems considerable omission during DOE decision-making process.

Response

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included, state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Figure J-41 for Ohio map). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass (see Table J-81 for Ohio impacts).

The trucks used to transport the nuclear waste to Yucca Mountain would not be oversize or overweight (with the exception of heavy-haul trucks used in Nevada to transport rail casks). They would be placarded in accordance with U.S. Department of Transportation regulations (49 CFR 172.507, 172.527, and 172.556). Motorists and public safety officials would be able to recognize the shipments from the “Radioactive” placard found on all sides of the vehicle. Additional information on the marking of shipments can be found in Section M 2.2 of the EIS.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (11532)
Comment - EIS002248 / 0002
I owe a lot to the paper [San Bernardino Sun] for their little map and showing that it's only going to be a railroad track through [San Bernardino] Needles and not a highway because that made me look real closely at the document and ask questions.

And I -- I now believe that this document, just based on that fact that there is no road proposed for use through Needles, renders the document to be deficient. And it needs to be revised and recirculated again for the same review period that was circulated the first time.

Response
In response to public comments, DOE has added Section J.4 to the EIS to provide state-by-state maps of routes used in the analysis in the EIS. This is in addition to the route maps already included in the EIS (see Section 2.1.3.2 for national routes and Section 2.1.3.3 for Nevada maps). These maps contain tables that show the numbers of shipments originating in and passing through each state by mode and provides the impacts from the shipments in each state.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states and tribes may designate alternative preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

8.3 (11765)
Comment - EIS000512 / 0003
This is the first time I've ever visited Denver. And I am amazed, I'm amazed that with all of the work and energy and brilliant people involved that the solution for this waste is to truck it through on those high overpasses through this heavily populated area.

I've never been back east. I've never even seen overpasses like that, curves that go way up in the air.

Then the density of the population here. This is also one of the biggest cities I've ever seen. I stayed downtown last night, and I know the population of the downtown area is at least half minority, you know. And surely a place like the mousetrap, which I saw for the first time today, is much closer to those minority areas than they are to your all-white suburbs.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states or tribes may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11 of the EIS). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

Fourteen states—Alabama, Arkansas, California, Colorado (where Denver is located), Delaware, Iowa, Kentucky, Nebraska, New Mexico, Ohio, Tennessee, Texas, Utah, and Virginia—have designated alternative or additional preferred routes (DIRS 104789-Rodgers 1998)

DOE has addressed environmental justice issues (minority or low-income populations) in Section 6.2.5 of the EIS for national transportation, and Sections 6.1.2.12 and 6.3.4 for Nevada. DOE has concluded that transportation impacts on the population are low and that there would be no disproportionate impacts on these populations. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (12209)
Comment - EIS000478 / 0011
The greater latent cancer fatality risk of truck-based transportation suggests that the DOE use rail transportation as frequently as possible.

Response
DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (12255)
Comment - EIS001157 / 0001
The DEIS addresses actions that the Department of Energy (DOE) proposes to take to develop a geologic repository at Yucca Mountain and to transport the material from 77 sites around the country to Yucca Mountain. The material to be stored at the proposed Yucca Mountain geologic repository will have to be shipped there. It is our belief that the transport of these materials cannot be separated from the site itself. Therefore, the DEIS should include the proposed routing.

The DEIS statement that the actual route would have to be addressed in a separate environmental impact statement (EIS) is not acceptable. Delaying such an important part of the environmental analysis is not reasonable, especially given the legislative exemptions to the National Environmental Policy Act (NEPA) that have already been accorded to the Yucca Mountain project.

Response
DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

Comment - EIS001905 / 0003
Full release of all information to the public
On December 6th 1999, I and several of my colleagues in the House of Representatives sent a letter to the Secretary of Energy asking for important information regarding the routes of nuclear waste transport. From our reading of the DEIS, DOE had produced routes of transport to evaluate the impacts of nuclear waste transport, but had failed to release the routing. The DOE’s response to date has been mediocre. I am aware that you have released data files on your website that explain the routes. These files are not advertised and not readily understood by the general public, thus they do nothing to inform the general public. I also understand that you have released maps of likely nuclear waste transport for each state at www.gov/timeline/eis/routes/routemaps.htm. I applaud you for this. However, in the previous letter I and several colleagues also requested a 180 day extension and a second hearing opportunity for those communities that did not have the information necessary to be fully aware of DOE actions. The release of the maps occurred on January 21, 2000, only 19 days before the original end of the comment period on February 9, 2000. The extension to February 28, 2000, increased the time to comment on these routes to only 38 days. Thus, the ability for the American public to understand where the waste may travel and comment on these routes was severely curtailed. To correct this problem, the DOE must publish a Supplemental DEIS that focuses on the nuclear waste transportation routes. A 180-day review period should be required for the supplemental DEIS. It will not be sufficient to include the routes in the FEIS without the 180-day comment period.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, state or tribes may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In January 2000 (during the public comment process for the Draft EIS), DOE posted state maps of the representative highway and rail line routes analyzed in the Draft EIS at *http://www.ymp.gov/timeline/eis/routes/routemaps.htm*. In response to public comments, DOE has included these state maps of representative highway routes and rail lines in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

DOE distributed 3,400 copies of the Draft EIS to stakeholders and held 10 public hearings throughout Nevada and 11 public hearings elsewhere across the country during a 199-day comment period (August 13, 1999 through February 28, 2000). During the comment period, DOE encouraged stakeholders to offer comments on the document at the public hearings and by mail, facsimile, and the Internet. In May 2001, DOE issued the *Supplement to the Draft Environmental Impact Statement for a Geologic Repository for the Disposal of Spent Nuclear Fuel and*

High-Level Radioactive Waste at Yucca Mountain, Nye County, Nevada, which it distributed to more than 4,000 stakeholders. The Department encouraged these stakeholders to submit comments during a 45-day comment period, which it later extended to 57 days (May 4 through July 6, 2001).

8.3 (12671)
Comment - EIS000648 / 0002
The need to pit rural people and urban people against each other, and to say we have to avoid Las Vegas, so the rurals need to take the impact. I think that it's an unfair, inequitable, and an unsafe proposition to do the roll of the dice. The risk analysis says that the rurals have to take the risk because it's to unsafe for urban areas. We're all citizens here. We're all in the same boat. The EIS, with is bounding analysis, says let's look at what we can do to the urban area, and that's the worst thing we could do. The rurals are the backup position.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states or tribes may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

As described in the EIS, risks to people living in rural or urban areas as a result of a transportation campaign would be primarily associated with transportation accidents. The EIS contains a discussion of potential impacts from accidents in both the mostly legal-weight truck scenario and the mostly rail scenario (see Section 6.2.4.2). For mostly legal-weight truck transportation, Section 6.2.4.2.1 describes the maximum reasonably foreseeable accident, which could cause 0.55 latent cancer fatalities in an urban area. Severe accidents in less urban areas would have smaller consequences. Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low.

8.3 (12688)
Comment - EIS001887 / 0037
The Draft EIS fails to identify the specific transportation routes for spent fuel and HLW [high-level radioactive waste] shipments from specific reactor and generator locations to Yucca Mountain, despite the fact that these routes were identified as part of the analyses contained in the transportation appendix. DOE, in effect, has chosen to hide the routes and simply report the results of the analyses in a generic fashion. The half-hearted and inadequate attempt to publish a set of route maps three week[s] before the end of an extended comment period (and after 18 of 21 public hearings had already been conducted without any notice to the public about likely routes and potentially impacted communities) in no way mitigates this extraordinary and fundamental deficiency in the Draft EIS. The maps themselves fail to contain information about shipment numbers, modal mix, and specific communities impacted.

One can only conclude that the failure to disclose specific nuclear waste shipping routes in the Draft EIS is intentional and designed to serve a political objective of suppressing public interest in the project and participation in the public hearings, especially those in states other than Nevada. Nevada believes that DOE has violated the National Environmental Policy Act by concealing crucial information used in the Draft EIS. Absent this information, persons affected by the transportation impacts of the Proposed Action have no way of determining the substantive and legal sufficiency of DOE's analysis. Such concealment of information can only diminish public confidence in DOE's ability to safely transport these highly radioactive materials and, of itself, renders the Draft EIS fundamentally deficient.

Response

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states or tribes may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In January 2000 (during the public comment process for the Draft EIS), DOE posted state maps of the representative highway and rail line routes analyzed in the DEIS at *http://www.ymp.gov/timeline/eis/routes/routemaps.htm*. In response to public comments, DOE has included these state maps of representative highway routes and rail lines in Appendix J of the EIS (see Section J.4). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

DOE believes, however, that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

8.3 (12752)

Comment - EIS000990 / 0003

Under the DEIS mostly truck scenario, DOE's preferred Nevada route to Yucca Mountain is I-15, the Las Vegas Beltway (I-215), and US 95. Using the HIGHWAY model, DOE contractors generated national routes from the 77 shipping sites to connect with the Las Vegas Beltway. These national routes are not revealed in the DEIS, but they are disclosed in the DEIS references, which can be accessed on the worldwide web at www.ymp.gov/timeline/eis/trwl999udata.

The routes used for the mostly truck impact analysis in the DEIS correspond to actual cross Country routes to I-15 and the Las Vegas Beltway. These routes generally are I-80 for shipments from the Northeastern and North Central states, I-70 for shipments from Southeastern and Midwestern states, and I-10 and I-40 for shipments from South Central and Southwestern states. Shipments from the Pacific Northwest and Idaho use I-84 and I-15. Shipments from Arizona and California use I-5, I-10, and I-15. [See CRWMS M&O 1999, Chapter 4, file bt-map.prn. The origin-destination distances generated in miles in this file correspond to the origin-destination distances given in kilometers in DEIS Table J-11]. The DEIS compares the transportation impacts calculated for the preferred route with impacts for six potential alternative routes identified by the State of Nevada to minimize shipments through the Las Vegas Valley. [See Table J-48].

The routes used in the DEIS make Missouri one of the more heavily affected corridor state for truck shipments to Yucca Mountain, but the DEIS make no specific reference to transportation impacts in Missouri. One of the major truck routes to Yucca Mountain enters Missouri on I-270 from Illinois, travels through the St. Louis area to connect with I-70 at St. Charles, follows I-70 to I-435 in Kansas City, Missouri, and reconnects with I-70 through Kansas, Colorado, and Utah. According to the DEIS references, this route travels 250 miles in Missouri. Truck shipments using this route are presented in Table 1. Under the mostly truck scenario, proposed action, more than 18,000 truck shipments of SNF [spent nuclear fuel] and HLW [high-level radioactive waste] (about 37% of the total) traverse Missouri over 24 years. Under the mostly truck scenario, modules 1 & 2, 29,000 truckloads of SNF, HLW, and other radioactive wastes requiring geologic disposal (about 30% of the total) traverse Missouri over 39 years. Under either scenario, an average of two trucks per day would travel through St. Louis and Kansas City every day for decades. Additionally, Missouri would be traversed by up to 1,000 truckloads of greater-than Class C low level radioactive wastes from commercial reactors to Yucca Mountain during the same time period.

Response

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states or tribes may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-47 of the EIS for the representative Missouri routes). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-87 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would enter Nevada after travelling through Missouri in the mostly legal-weight truck scenario. The table also lists the estimated number of rail shipment through California in the mostly rail scenario for each of the proposed Nevada rail corridors and heavy-haul truck routes.

If the Yucca Mountain site was approved, under the mostly legal-weight truck scenario, the estimated total number of truck shipments through Missouri would be 19,142 over 24 years, approximately 2 truck shipments per day. There would be an estimated 435 rail shipments, slightly more than 1 per month.

The estimated numbers of shipments entering Nevada after travelling through Missouri under the mostly rail scenario are less than the mostly legal-weight truck scenario. According to Table J-87, the number of rail shipments would range from 4,069 to 4,126 depending on the mode (rail or heavy-haul truck) and corresponding corridor/route selected in Nevada. This would be slightly more than 3 rail shipment per week over 24 years, at most. In addition, there would be approximately 71 legal-weight truck shipments through Missouri.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved and mostly rail was selected as the preferred mode (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. Should a rail corridor be selected, additional engineering and environmental studies would be conducted as a basis for detailed design and for appropriate National Environmental Policy Act reviews.

8.3 (12980)
Comment - EIS010303 / 0009
As it was pointed out in the House Energy and Water Development Appropriations Bill 2002 Report, Nuclear Waste Disposal, the DOE has an "exemplary safety record in the shipping of commercial and naval nuclear fuel" (p.3). The DOE has proven that it can safely transport spent nuclear fuel and high-level nuclear waste from plant sites across the nation. Yet, instead of moving forward with a more assertive approach in educating the public and working with state and local officials in the development of transportation routes to Nevada and other states, the DOE is deferring its transportation planning until the completion and final selection of the permanent repository.

Response
If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.3.1 STATE ROUTE 127, HOOVER DAM, NEVADA DEPARTMENT OF TRANSPORTATION ALTERNATIVES

8.3.1 (20)
Comment - 9 comments summarized
Commenters expressed concern about routing shipments of spent nuclear fuel and high-level waste over Hoover Dam, also referred to as Boulder Dam, and through Boulder City, Las Vegas, and the Spaghetti Bowl interchange of I-15/515 and U.S. 93/95 during peak travel times. One commenter stated that before any spent nuclear fuel and high-level radioactive waste should be allowed near Nevada, shipments must avoid contact (or proximity) with any waterways or populated areas and stated a highway needs to be built that circumvents the Dam and does not go through cities. Commenters expressed the hope that shipments would not be routed over the Dam and stated DOE should avoid the use of certain routes such as the Spaghetti Bowl.

Response
For truck transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain, a motor carrier could use only routes that comply with the requirements contained in U.S. Department of Transportation regulations (49 CFR 397.101). The regulations require use of routes designated as preferred routes that reduce time in transit; these preferred routes are Interstate System highways, Interstate System beltways and bypasses, and state or tribal designated preferred routes. The only exceptions are for pickup and delivery routes used to travel to and from a nearest preferred route.

If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, states or tribes could designate alternative preferred highway routes, and highways and rail lines could be constructed or modified. Therefore, for purposes of analyses presented in Sections 6.2 and 6.3 of the EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations. DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials.

Unless the States of Nevada and Arizona both designated U.S. 93 as a preferred route from Kingman, Arizona, to Las Vegas, Nevada, shipments of spent nuclear fuel and high-level radioactive waste would not cross Hoover Dam. Because DOE assumed that the Las Vegas Beltway would be available when shipments began in 2010, the analysis in Chapter 6 did not use highway routing that would pass through the Spaghetti Bowl interchange (Interstate-15/515 and U.S. 93/95) in Las Vegas. However, to evaluate the sensitivity of impacts to potential alternative routing of highway shipments in southern Nevada, DOE evaluated impacts that would occur if shipments traveled through the Spaghetti Bowl interchange (see Section J.3.1.3 of the EIS).

Federal regulations for highway routing of shipments do not include time-of-day travel restrictions or restrictions regarding travel on routes that cross waterways. However, DOE protocols do include consideration of time-of-day travel through urban areas. For additional information regarding DOE policies, procedures, and protocols for transportation, see Section M.3 of the EIS.

8.3.1 (195)

Comment - 12 comments summarized

Commenters stated that the Draft EIS was deficient because it did not analyze two routes identified by the Nevada Department of Transportation in 1989 (known as the A and B routes) for the transportation of spent nuclear fuel and high-level radioactive waste within Nevada. Others stated that alternative routing within Nevada could have higher impacts than those analyzed in the EIS. Alternative routing in the event of an accident or bad weather should also be addressed.

Response

As described in Section J.1.1.2, the analyses in the EIS used highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations require the shipments of radioactive material to be made on preferred routes to reduce time in transit. A preferred route is an Interstate System highway, bypass or beltway, or a route selected by a state or tribal routing agency. The regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (A and B pass through White Pine County) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3). However, these are not yet formally designated alternative preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes, including Nevada Department of Transportation routes A and B, as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base Case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario. The various impacts would generally be small for all cases, but for routes A and B they should be about a factor of 1.5 times greater than the route used for the EIS analysis. All direct environmental factors are addressed for Nevada transportation in the EIS (see Section 6.3.2).

Section M. 3.2.1.4 of the EIS includes information on the procedures to be used in the event of adverse weather or road conditions.

8.3.1 (608)
Comment - EIS000140 / 0002
DOE failed to address direct and indirect effects of legal-weight truck shipments through White Pine County, including implications for emergency first response and emergency medical services.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transportation) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (A and B pass through White Pine County) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario. The various impacts are generally small for all cases, but for routes A and B the impacts are about a factor of two larger than the route used for the EIS analysis.

With respect to emergency planning, Section M.6 of the EIS contain additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753; April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty
- Much of the uncertainty is irreducible, and
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.3.1 (641)
Comment - EIS000141 / 0005
The Draft EIS fails to consider unique local conditions along the NDOT [Nevada Department of Transportation] B Route which may increase the probability of severe accidents, and which could exacerbate the consequences of a severe accident or terrorist attack resulting in a release of radioactive materials. There are numerous mountain passes, such as White Horse Pass, Currant Summit, Black Rock Summit, Sandy Summit, and Warm Springs Pass. Near-route terrain frequently includes drop-offs into deep canyons or river valleys that would make response to an accident or attack, and recovery of the cask, damaged or not, quite difficult. Route proximity to surface water and groundwater resources is a major concern. DOE has failed to address the implications of route-specific conditions for accident prevention, emergency response, and the economic costs of cleanup and recovery.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario. The various impacts are generally small for all cases, but for route B the impacts are about a factor of two larger than the route used for the EIS analysis.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

With respect to emergency planning, Sections M.5 and M.6 of the EIS contain additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments, and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $9.4 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 of the EIS included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

8.3.1 (1006)
Comment - EIS000262 / 0002
Without detailed information on likely primary and secondary routes in California and the staging of shipments, it is impossible for Inyo County to evaluate the impacts of the shipping campaign on our area.

At present, State Route 127 is being utilized for shipment of low-level nuclear waste to the Nevada Test Site and may be used for shipment of transuranic waste from the Test Site to the Waste Isolation Pilot Plant. This makes State Route 127 a likely candidate for eventual shipments of high-level radioactive waste.

Section 180(c) of the NWPA calls for Federal action to provide improvements in emergency response training and capability along routes designated for the transport of high-level nuclear waste and spent fuel. The virtual absence of emergency response capability on Route 127 and the isolated character and the current configuration of this roadway promise to make compliance with this part of the Act an involved and expensive exercise on the part of the Federal Government.

Other necessary improvements will include complete reconstruction of some sections of the roadway and the construction, equipping and staffing of emergency response stations. The County and the State will be saddled with significant new costs to safeguard their residents. The EIS fails to address, in any manner, the significant fiscal and possibly significant environmental impacts of meeting these obligations. These impacts too, are inseparable from the issue of the repository itself and need to be quantified by the EIS.

Response

As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes C and E include the use of California 127) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and in Nevada, based on the mostly legal-weight truck scenario.

Sections M.5 and M.6 of the EIS contain additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction.

The transportation analyses (with the exception of that for the Nevada branch rail line) consider shipments on existing highway infrastructure that would not require upgrading. Where upgrading is required for safe transport or maintenance to keep roads and railroads safe, the necessary funding would be made available to responsible jurisdictions.

8.3.1 (1014)
Comment - EIS000254 / 0004
Here are a few of the issues not even addressed in the DEIS on the Carlin route in regard to Crescent Valley:

- Lifestyle -- Social, economic, and quiet enjoyment of your property.
- Wildlife -- Wildlife corridors, range areas, viewing, rearing, grazing and hunting impacts.
- Ranchers -- Cattle ranging, rearing, feeding, security.
- Railroad crossings -- Locations? At grade? Safety? Security, noise.
- Water/Floodplains -- No mention of lake bed at Crescent Valley. Flash flooding, washouts, culverts, bridges, dam effect of railroad and impact of backup water to Crescent Valley town and valley landowners.
- Earthquake -- Is lakebed or valley soil subject to the liquefaction effect in case of earthquake? Note associated railroad impacts.
- Railroad Ownerships -- Who will own railroad? Who will own the land?
- Mitigation -- For all of the above must be stated.

Response
In its evaluation of potential impacts of constructing a branch rail line in each rail corridor in Nevada, DOE considered the potential impacts that could occur both to the natural environment and to communities, such as Crescent Valley, that would be nearby (see Section 6.3.2 of the EIS). For example, in the Carlin Corridor, DOE identified numerous springs within 5 kilometers (3 miles) of the alignment of a potential branch rail line. At the north end of this corridor, DOE biologists identified a hot spring approximately 0.5 kilometer (0.3 mile) east of Nevada Route 306 about 5 kilometers (3 miles) south of Interstate-80. DOE would locate the alignment of a branch rail line to minimize the potential to affect springs and wet areas. DOE would determine how to best avoid detrimental impacts, for example, in some areas, fences could be recommended to protect livestock and open culverts could allow access to both sides of the track.

In its assessment of potential land-use impacts, DOE considered the differences between land-use types, land disturbances, land ownership, and the creation of barriers. The assessment compared proposed uses of land for Yucca Mountain transportation purposes to existing or other proposed land uses to estimate the magnitude and context of potential conflicts. If an action would result in continuing a current land use either due to little or no impact or through mitigation, the effects were considered insignificant or small. For example as discussed in Chapter 6, the impacts to livestock and Bureau of Land Management grazing allotments could be mitigated through the use of fencing, overpasses, and underpasses, which could provide a water source to animals cut off from current sources. With these mitigating measures, the impacts would be lessened and considered small. If an action could result in departures from existing uses, and mitigation could not remedy the conflict, the effects could be more substantial. For example, as discussed in the Carlin Corridor sections of Chapter 6 (see Section 6.3.2.2.2), the Bonnie Claire Alternate passes directly through the portion of the newly estimated Timbisha Shoshone Homeland near Scottys Junction. Should this alternate be chosen, the construction of a branch rail line could limit or enhance economic development in the Timbisha Shoshone Trust Lands parcel and could limit the use for housing be restricting access. Factors considered included the uniqueness of a geographic area; presence of historic, scientific, and cultural resources; potential effects on endangered species; and compliance with Federal, State, or local law. Based on information available, potential land-use impacts associated with Yucca Mountain transportation activities could be minimized through judicious alignment of the branch rail line or through mitigation. Overall, the land-use impacts are not substantial because of the use of various optional and alternate routes in the corridor, mitigation measures, and the judicious routing of the branch rail line in the corridor.

Additional information about impact reduction features, procedures, and safeguards, and mitigation measures under consideration are included in Chapter 9 of the EIS. Chapter 9 identifies ongoing studies that could eventually influence mitigation measures related to the project plan and design. For example, Section 9.3 discusses mitigation measures intended to address impacts from the possible construction of a branch rail line.

If the Yucca Mountain site was approved, and rail was selected as the transportation mode, then decisions regarding ownership and shared use would be made. Line ownership, however, would not affect potential environmental impacts.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved, DOE would issue at some future date a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment in a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

8.3.1 (1155)
Comment - EIS000261 / 0003
The southeast [Inyo] County has recently seen several highway accidents involving non-nuclear hazardous waste. One incident with a leaking toxic waste truck resulted in the responders being exposed to toxic levels of waste, followed by hospitalization and ongoing medical treatment. The time delay in getting toxic waste expertise into the region was the reason for the severity of the incident. In another area, a hazardous waste truck failed to negotiate a turn near a rest stop, rolled over and crushed a picnic facility. Our confidence in truck transportation for dangerous materials on remote, narrow, two-lane roads is not high. The DEIS is silent on this issue.

State Highway 127 itself is not an engineered route; most of it originated as an historic wagon trail that was paved over a period of time. Inyo County's recent survey of the route from its junction in the south with Interstate 15 at Baker to its junction with U.S. Highway 95 in the north revealed many unbanked, unsigned high-speed turns, numerous blind rises where visibility is limited, sustained grades in excess of modern standards, and dozens of washes crossing both over and under the pavement. The route passes through four towns, two of which include sharp 90-degree turns in the middle of town.

In the event of an incident, there are few alternate routes useful to diverting commercial and passenger traffic around accident or cleanup sites. For long sections of 127, there is no alternate route whatsoever.

There are approximately 1,000 acres of land in the vicinity of Death Valley Junction that is proposed for release to the Timbisha-Shoshone Tribe for their use. If developed to mixed residential and commercial uses, this territory could host an unknown number of additional residents and contribute significantly to traffic on Route 127.
The status of this corridor with respect to Yucca Mountain shipments is not addressed in any meaningful fashion by the EIS. We don't see any mitigation in the EIS to compensate for the hazard which the waste would impose upon responders, travelers or residents of the region. Conditions on possible primary and secondary routes in California are not evaluated and no attempt is made to develop and weigh alternatives for getting nuclear waste originating in California into Yucca Mountain.

As it stands, the isolation and current configuration of southeast County roadways cannot reasonably and safely support the demands of a 25-year nuclear waste transport campaign. The EIS provides insufficient information to allow us to assess repository operations on County residents or determine our risk in the larger context of the entire national transportation effort.

Unless State Route 127 is officially dismissed from consideration for the transport of high-level waste and spent nuclear fuel, the DEIS at minimum needs to be amended to evaluate risks associated with the route, propose measures to offset those risks, and identify the expected source of funding of these measures.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote

public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes C and E include the use of California 127) as alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider the conditions of State Route 127 that were identified by the commenter, such as high accident rates in specific areas (for example, unbanked, unsigned high-speed turns; blind rises; limited visibility; and sustained grades in excess of modern standards), during the process of selecting and designating alternative preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

The transportation analyses (with the exception of that for the Nevada branch rail line) consider shipments on existing highway infrastructure that would not require upgrading. Where upgrading is required for safe transport or maintenance to keep roads and railroads safe, the necessary funding would be made available to responsible jurisdictions.

Section 9.3 of the EIS describes management actions to mitigate the potential for environmental impacts from transportation of spent nuclear fuel and high-level radioactive waste to the repository. California State Route 127 is currently not a preferred route so DOE has not determined how these risks would be mitigated. As mentioned above, DOE would not designate preferred highway routes based on the information in the EIS alone. Additional environmental and engineering studies would be conducted before such a decision was made. DOE anticipates that potential mitigation measures, which might include infrastructure upgrades, would be considered as a part of these additional studies.

8.3.1 (1172)
Comment - EIS000229 / 0005
The DEIS generally fails to identify and evaluate credible HHT [heavy-haul truck] routing options. Nevada acknowledges that DOE has accurately classified the Caliente Chalk River HHT route as a "non-preferred alternative" in response to national security issues raised by the Air Force. [p. 6-110] Since concurrence by the Secretary of the Air Force would be required, DOE should eliminate this route from further consideration. DOE's other HHT route options are unrealistic and unwise. The DEIS continues to consider HHT routes using I-15, the Las Vegas Beltway, and US 95 and through Las Vegas, in spite of repeated advice from Clark County and state agencies that these routes are not even acceptable for LWT [legal-weight truck] shipments. In 1994, NDOT [Nevada Department of Transportation] notified the California Highway Patrol that: "Because I-15 goes through the heart of Las Vegas, Nevada, is interested in selecting a preferred route... bypassing Las Vegas." Absent action by California to designate SR 127 or other routes avoiding I-15 into Las Vegas, NDOT stated its intention to "recommend to the State Transportation Board the designation of Nevada SR-160 as the preferred route and to undesignate I-15

between the Utah-Nevada Stateline and Las Vegas as a preferred route." DOE should eliminate HHT routes through Las Vegas from further consideration.

Response

DOE has reevaluated whether the Caliente-Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route should be eliminated from further evaluation. DOE met with the Air Force (see Appendix C of the EIS), considered the information provided, and concluded that the Caliente-Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route implementing alternatives should remain identified as "nonpreferred alternatives" in this Final EIS.

DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

As stated in Section 6.3 of the EIS, U.S. Department of Transportation regulations (49 CFR Part 397) govern highway shipments of spent nuclear fuel and high-level radioactive waste. This regulation describes the process that state or tribal routing authorities are to follow to designate alternative preferred routes. The State of Nevada has proposed alternative routes to DOE, which evaluated them in the EIS (see Section J.3.1.3). However, DOE is unaware of the State submitting alternate preferred routes to the Nuclear Regulatory Commission for approval. Until this happens, the Department would continue to consider alternatives through Las Vegas using the Interstate Highway System as required in Federal routing regulations for legal-weight and heavy-haul trucks.

For heavy-haul truck routes, DOE has chosen to analyze alternative routes in addition to the Interstate-15 and -215 (the partially complete Las Vegas Beltway) routing options. DOE will continue to consider the implementing alternatives (described in Section 6.3 of the EIS) that avoid the Las Vegas Valley. The Department is unaware that any State or Native American routing agency is in the process of, or has selected, a preferred route bypassing Las Vegas, such as State Route 160.

8.3.1 (1346)

Comment - EIS000382 / 0001

State Route 127 is about 50 miles long in Inyo County. It goes from the Inyo/San Bernardino County line all the way up to the Nevada border up by Longstreet. 127 is a poor highway for truck traffic. It's got flat-graded curves, sharp curves, and it's only a two-lane roadway. My opinion is that it's unsuitable for increased truck traffic.

I'm familiar with the hazardous material spills on that highway. I handled many of them, and I know what it takes to take care of a situation like that. Currently, in that part of the county there is no fire department, as was talked about. So there's not even the manpower to close the highway. We can't even put one person at each end of the truck spill to close the thing down. There's no trained manpower.

Shoshone only has one resident [police] officer. The next one would be Death Valley, and you're talking about 45 minutes away. Baker, California, on numerous occasions, has volunteered to come up and help, but you're talking about 57 miles from Shoshone to Baker. They are too busy with everything that happens on the 15. Pahrump has volunteered to come over on occasion. They have more than they can handle on State Route 160. So it's not reasonable to expect these people to help us out. Pretty much we're on our own, and there's no training, and the roadway is just not designed for this type of activity. So I would oppose any type of secondary use of State Route 127, all 50 miles of it in Inyo County, for any kind of HAZMAT [hazardous materials] transportation like this.

Response

As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes C and E include the use of California 127) as alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

At present, State Route 127 is not a preferred highway, so DOE could not use it for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. If the State of Nevada or California designated this highway as an alternative preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. As noted above, the States of Nevada and California would have the opportunity to designate alternative preferred routes. The regulations require a state or tribe to select routes in accordance with the Federal guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, local jurisdictions, and Native American tribes would be required. The affected routing authorities would consider the conditions of State Route 127 the commenter identified (that is, flat-graded curves, two lanes) and other conditions during the process of selecting and designating alternative preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

The comment mentions several potential highway upgrades necessary to improve the safety of transporting spent nuclear fuel and high-level radioactive waste on State Route 127. The transportation analyses (with the exception of a branch rail line) considered shipments on existing highways that would not require upgrading. Where upgrading would be required for safe transport or maintenance would be required to keep roads and railroads safe, the necessary funding would be made available to responsible jurisdictions.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Regional Servicing Contractor would be required to provide detailed written procedures for how it would respond to an incident and arrange for repair/replacement of equipment or recovery, as appropriate. In accordance with ANSI N14-27 (DIRS 156289-ANSI 1987), the carrier is expected to provide appropriate resources for dealing with the consequences of an accident, isolating and cleaning up contamination, and maintaining working contact with the responsible governmental authority until the latter has declared the incident to be satisfactorily resolved and closed. Section M.3 of the EIS contains more detail on the proposed role of the Regional Servicing Contractor.

Sections M.5 and M.6 of the EIS contain additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would to transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction.

8.3.1 (1440)

Comment - EIS000353 / 0003

Section 6.2.4, accident scenarios. Page 6-32. It identifies that approximately four traffic fatalities would occur during the course of transporting the spent nuclear fuel and high-level waste under the mostly legal-weight trucks scenario during the 24 years of operation nationwide.

Well, that seems like it's an extremely small number. And, in addition, it does not discuss the injuries due to accidents. White Pine County, with 105 miles of rural, two-lane roads, where automobiles and lightweight trucks travel at high speed, it is likely there will be a number of accidents related to the nuclear waste shipments. White Pine County needs more assurance and assistance from the DOE to be able to have communications equipment, medical facilities, emergency response personnel to provide the necessary care for any injured person.

Response

Section J.1.4.2.3 of the EIS provides the sources of data used in the transportation accident analysis, which included accident fatality rates developed by Saricks and Tompkins (DIRS 103455-1999) to perform the traffic fatality calculations on a state-by-state basis. DOE did not calculate nonradiological traffic injuries in the EIS. However, to provide some perspective, the route length provided by the commenter and the number of shipments, accident rates, and fatality rates in Nevada were used to estimate the nonradiological accident impacts in White Pine County. The accident and fatality rates used were 3.8×10^{-7} accidents per kilometer and 1.67×10^{-8} fatalities per kilometer, respectively (DIRS 103455-Saricks and Tompkins 1999). DOE assumed that 45,919 legal-weight truck shipments would travel along this route (from the EIS, Figure J-10). DOE also assumed that loaded and empty return truck shipments would use this highway. Using these data, a total of between 5 and 6 accidents would occur along this 170-kilometer (105-mile) stretch of highway over 24 years, or about one every 4 years. The probability of a traffic fatality occurring was calculated to be about one in four accidents over the 24-year period.

As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes A and B are through White Pine County) as alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada designate one of these other routes as an alternative preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultations with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and in Nevada, based on the mostly legal-weight truck scenario. The various impacts are generally small for all cases, but for routes A and B the impacts are about a factor of two larger than the route used for the EIS analysis.

Section M.6 of the EIS contains additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would to transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. Should the State of Nevada designate Nevada Alternative Routes A or B as a preferred highway, White Pine County would be eligible for technical assistance and funds provided by Section 180(c).

In addition, there is a Federal Radiological Program outlined in the Federal Radiological Emergency Response Plan and the Federal Radiological Monitoring and Assessment Plan. These plans outline the policies, procedures, roles, and responsibilities of Federal, tribal, state, and local agencies in planning for and responding to emergencies involving releases or suspected releases of radiological materials from government and commercial facilities or operations.

8.3.1 (1441)
Comment - EIS000353 / 0004
Section 6.3.1, impacts of Nevada mostly legal-weight transportation scenario. The EIS identifies there will be an average of 2,100 legal-weight truck shipments per year along with the accompanying escorts. The EIS only considers changes to the traffic level on I-15 and I-95. However, as I stated previously, it is felt that most likely these shipments will be routed around Clark County and Las Vegas. This means as most of the shipments will be coming from the East, they will be coming through Ely and White Pine. This will present a significant increase in the truck traffic in Ely and the County, and the impact of this increase in traffic needs to be addressed in the EIS.

During the EIS scoping meetings, it was stated regularly that the EIS will cover the extremities, extremes, and impacts of any variation in traffic will be less than that considered in the EIS. If the legal-weight shipments come on U.S. 93 from I-80, the EIS needs to address this. It needs to address it as far as Nevada. It needs to address it as far as Nevada's affected counties are concerned.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes A and B pass through White Pine County) as alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultations with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses, including transport through Ely and White Pine Counties. Tables J-47 and J-48 include descriptions of impacts of the other routes evaluated in the EIS. Because these other routes have not been formally designated by the State of Nevada as alternative preferred routes and because the routes follow existing highways and would require no additional land acquisition, the EIS focuses on quantifying the impacts to human health and safety and the potential for accidents along these other routes.

8.3.1 (1456)
Comment - EIS000142 / 0007
The contradictory nature of the omission of any substantive discussion of impacts in White Pine County is also apparent when one considers DOE's selection of transportation routes and related impacted corridor communities within the DEIS. The third paragraph on Page 6-35 of the DEIS includes the following statement: "Because the State of Nevada has not designated alternative preferred routes, only one combination of routes for legal-weight truck shipments would satisfy U.S. Department of Transportation routing regulations, (I-15 to U.S. Highway 95 to Yucca Mountain)." DOE elected not to consider the impacts or a region of influence along the State of Nevada identified candidate alternate routes. However, the first full paragraph of Page 2-44 contains the following statement: "The EIS analysis assumed that the proposed Interstate bypass around the urban core of Las Vegas, (the Las Vegas Beltway) would be operational before 2010." DOE could have just as easily assumed that the State of Nevada would designate one or both alternative routes it identified to keep waste shipments out of the Las Vegas urban core. The failure of DOE to include an assessment of the impacts of the State of Nevada identified alternative legal-weight routes as a serious deficiency of the DEIS.

The likelihood that the State of Nevada will designate alternative routes for legal-weight trucks that avoid the Las Vegas Valley is borne-out in the State's acquiescence to the use of routes through White Pine County to transport low-level radioactive waste (LLRW) across Nevada to the Nevada Test Site. As DOE is aware, the use of northern highway routes for LLRW has effectively shifted any transportation risks from the Las Vegas area to rural northern Nevada counties.

Failure of the DEIS to consider the impacts of legal-weight truck transportation through White Pine County is made worse by Tables J-47 and J-48 which demonstrates that risks of transporting spent fuel and high-level radioactive wastes through the County are significantly greater than the risks for the Base Case (routes allowed by current U.S. Department of Transportation regulations for Highway Route Controlled Quantities of Radioactive Materials). The fact that LLRW is also being transported on a route through White Pine County raises the specter of significant cumulative impacts.

The Final EIS must evaluate the direct, indirect, and cumulative impacts of transporting all forms of radioactive wastes through White Pine County.

The National Environmental Policy Act (NEPA) requires federal agencies to consider "connected actions". Construction and operation of a repository at Yucca Mountain will result in spent nuclear fuel and high-level radioactive waste being transported through Nevada (and in all likelihood by legal-weight truck in the short-term). The prospect of transportation of spent nuclear fuel and high-level radioactive waste through the Las Vegas Valley will trigger a decision by the Governor of Nevada to designate alternative routes. Therefore, the Final EIS must consider the impacts of State of Nevada identified alternative routes as a connected action pursuant to NEPA.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote

public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes A and B pass through White Pine County) as alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

Use of the northern Las Vegas Beltway, currently under construction, would be consistent with the definition of a preferred route given above, whereas the Nevada Department of Transportation alternative routes, which use non-Interstate System highways for a large fraction of the travel distance in Nevada, would not automatically meet the definition of a preferred route.

In any event, alternative routing options within Nevada were analyzed in the EIS in Section J.3.1.3. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations are equivalent to the data collected for the base case routes (that is, routes currently allowed by DOE regulations). The environmental impacts of the base case and six Nevada Department of Transportation routes are presented in Table J-48. Thus, DOE did not exclude the Nevada Department of Transportation routes from consideration in the EIS. Therefore, all direct environmental factors are addressed for Nevada transportation in the EIS (see Section 6.3.2).

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty
- Much of the uncertainty is irreducible, and
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

Section 8.1.1 of the EIS discusses the cumulative past and present actions occurring in Nevada that would be additive to actions related to the proposed repository and its associated transportation of spent nuclear fuel and high-level radioactive waste. These actions include activities of the Nevada Test Site, Nellis Air Force Base, management of low-level radioactive waste, Native American activities, other DOE waste management, and regional mining activities and enterprises, among others. Impacts of all of these activities on the environment are assessed and accumulated in accordance with National Environmental Policy Act regulations.

8.3.1 (1543)
Comment - EIS000357 / 0002
Increased motor vehicle traffic. It is very difficult to evaluate impact on communities in the major zone of influence. I was unable to find any quantification of how many actual legal-weight truck haul loads could be expected through Ely on U.S. 93 or State Route 318 scenario. The table on J-7 might indicate around 1,500 shipments from the Idaho National Engineering and Environmental Laboratory, 800 shipments from Hanford that might use a route through Ely as an alternate to interstate routes spread over a 20-year period. And these are shown on Table J-4.

It would be useful if there was analysis of some key points like Ely, apparently a relatively low-impact area with about 350 shipments of high-level radioactive waste a year, Table J-4, as opposed to, perhaps, high-impact Mesquite with, perhaps, an average of 1,700 shipments a year of commercial spent nuclear fuel. Figure J-10.

Response
Section 6.3.1.3 of the EIS presents the human health and safety impacts of transporting spent nuclear fuel and high-level radioactive waste on current preferred highways and six other routes based on a 1989 Nevada Department of Transportation study. These other routes include two that involve transport through Ely and White Pine County (see Table J-46, Cases 5 and 6). However, because these other routes have not been formally designated by the State of Nevada as alternative preferred routes and because the routes follow existing highways and would require no additional land acquisition, the EIS focuses on quantifying the impacts to human health and safety and the potential for accidents along these other routes.

Should the State of Nevada designate the highway route through Ely on U.S. 93 or State Route 318 as an alternate preferred routes and not be preempted, Ely and White Pine County could expect to see a majority of the legal-weight truck shipments of spent nuclear fuel from nuclear powerplant sites in the eastern, midwestern, and northwestern United States. This constitutes a vast majority of the spent nuclear fuel shipments. Figure J-10 shows that approximately 45,919 shipments per year would enter Nevada at Mesquite over 24 years or about 1,900 shipments per year. Approximately this number of shipments could be diverted from entering Nevada at Mesquite to entering Nevada at Wendover and traveling through Ely on U.S. 93 or State Route 318, assuming no shipments would enter Nevada on Interstate-15 at Mesquite.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began through a jurisdiction. At this time many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, states and tribes may designate alternate preferred highway routes, and highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.3.1 (2399)
Comment - EIS000674 / 0003
The bottom line is NDOT [Nevada Department of Transportation] has already said when shipments start big time, they're not going to allow shipments on I-15 between the Utah border and the west side of Las Vegas. They just haven't had to take that decision yet.

Similarly all these routes are going to have problems with the NRC [Nuclear Regulatory Commission]. In my statement, and I won't read this, the NRC has identified five criteria that they advise their staff to avoid.

When people want to ship spent fuel, they got to go to the NRC first and get a route approval for routes that will make it difficult for terrorists and saboteurs to take down a shipment. None of the routes in the EIS comply with those criteria.

Specifically we need to say a few things about the Caliente/Chalk Mountain route. Forgive me if I say Chalk River because Chalk River's a famous nuclear facility in Canada and those of us who work in that field, it's just hard sometimes. I've made the mistake about three times in the last week.

First of all, the most difficult part of this route that we're talking about is between here [Lincoln County] and Rachel. You go out here to mile post 93, drive through Oak Springs Summit to mile post 77 and you'll see sixteen miles where a whole lot of road improvement--probably double-landing, guard rails, everything. The same thing at Hancock Summit for fifteen miles, and there's another ten miles in there and some of it goes through fragile environment like around Crystal Springs.

So, (A) it's going to be difficult and expensive to upgrade; (B) there will be environmental impacts.

Response

As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F as alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultations with affected states, tribes, and local jurisdictions would be necessary.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS. The data needed to characterize these routes to support the impact calculations are equivalent to the data collected for the base case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

The Nuclear Regulatory Commission would review routes proposed by DOE after the selection process identified in Section M.3.2.1.2 of the EIS and would involve Regional Servicing Contractors and Federal, state, tribal, and local responsible authorities.

DOE recognizes that use of the highways in Nevada could require upgrades, particularly if heavy-haul trucks were used (see Section J.3.1.2 of the EIS). However, as stated in Section 6.2, the Department believes that the use of existing roads for legal-weight truck transportation would not cause additional environmental impacts because there would be no changes in the rights-of-way for those roads.

8.3.1 (4191)
Comment - EIS001160 / 0009
Failure of the DEIS to consider the impacts of legal-weight truck transportation through White Pine County is made worse by Table J-48 which demonstrates that risks of transporting spent fuel and high-level radioactive wastes through the County are significantly greater than the risks for the Base Case (routes allowed by current Department of Transportation regulations for Highway Route Controlled Quantities of Radioactive Materials). The fact that LLRW is also being transported on a route through White Pine County raises the specter of significant cumulative impacts.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (A and B pass through White Pine County) as alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario. The various impacts are generally small for all cases, but for routes A and B the impacts are about a factor of two larger than the route used for the EIS analysis.

The low-level waste shipments through White Pine referred to by the commenter did not begin until the summer of 1999, after the Draft EIS was published. Prior to that time, the low-level waste shipments traveled over Hoover Dam and through the Las Vegas Valley on the way to the Nevada Test Site low-level waste disposal areas. Routing low-level waste shipments around Las Vegas and Hoover Dam was a voluntary action by the carrier, although DOE and stakeholders influenced it. This action does not necessarily set precedence for spent nuclear fuel and high-level radioactive waste shipments to Yucca Mountain, which must follow much more stringent routing requirements than low-level waste shipments.

Section 8.4 of the EIS provides the results of cumulative impact analyses conducted to ensure that the environmental impacts of the Proposed Action and other potential actions that involve the same regions or resources are provided to decisionmakers. The information is used to minimize or avoid adverse consequences and to develop an appropriate mitigation strategy and enable DOE to monitor its effectiveness. The health and safety impacts of low-level waste shipments to Nevada Test Site disposal areas are included in Table 8-58 of the EIS, which lists cumulative impacts (see "Nevada Test Site expanded use" in the table). The table does not identify impacts to specific populations (that is, for specific routes) for any of the categories listed in the table. However, the collective incident-free radiation doses to the public and workers from transporting low-level waste to Test Site disposal areas (150 person-rem in Table 8-58 for entire trips, including inside and outside Nevada) are small in relation to the cumulative radiation doses in Nevada for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain (approximately 2,000 to 4,000 person-rem in Table J-48). Therefore, the cumulative incident-free radiation dose impacts in Nevada of transporting low-level waste, spent nuclear fuel, and high-level radioactive waste are not significantly different than the impacts of shipping spent nuclear fuel and high-level radioactive waste alone. It is unlikely that any additional mitigation or monitoring would be required beyond that for spent nuclear fuel and high-level radioactive waste transportation.

For nonradiological traffic fatalities, the fatality rates for shipments of all three materials are approximately the same because they are all shipped on heavy combination trucks, from which the accident rates were derived. The cumulative impacts of the increased legal-weight truck traffic on the existing highway infrastructure would be evaluated in detail during the route identification and selection process to be implemented in the next several years.

8.3.1 (4200)
Comment - EIS001160 / 0017
The DEIS should estimate the number of expected transportation incidents/ accidents which might be expected to occur within White Pine County over the 24 year shipping campaign. This information could be easily derived from U.S. Department of Transportation incident/accident reports prepared for other shipments of spent nuclear fuel and high-level radioactive wastes. There have been incidents and accidents in the past. There will be such occurrences in the future. White Pine County is concerned that any single transportation incident or accident, even assuming no release of radioisotopes to the accessible environment, could be widely covered by the media, with perceived risks amplified and area stigma a result.

Response
To provide some perspective, the route length [170 kilometers (105 miles)] and the number of shipments, accident rates, and fatality rates in Nevada were used to estimate the nonradiological accident impacts in White Pine County. The accident and fatality rates used were 3.8×10^{-7} accidents per kilometer and 1.67×10^{-8} fatalities per kilometer, respectively (DIRS 103455-Saricks and Tompkins 1999). DOE assumed that 45,919 legal-weight truck shipments would travel along this route (from the EIS, Figure J-10). DOE also assumed that loaded and empty return truck shipments would use this highway. Using these data, a total of between 5 and 6 accidents would occur along this 170-kilometer stretch of highway over 24 years, or about one every 4 years. The probability of a traffic fatality occurring was calculated to be about one in four of the accidents over the 24-year period.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty
- Much of the uncertainty is irreducible, and
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents,

which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.3.1 (4211)
Comment - EIS001160 / 0025
The DEIS does not adequately address issues raised and substantiated by White Pine County during the scoping process. For example:

Alternatives to be considered should include construction and use of a hazardous cargo route around the City of Ely. The DEIS does not consider the benefit, feasibility or cost of this alternative.

The risks associated with use of U.S. Highways 93 and 6 and State Highway 318 through the County should be compared against the risks of using other routes (i.e. I-15 to U.S. 95). Although Table J-48 provides a summary of risks for each route, there is no analysis of the data in this table. In fact, Table J-48 reveals that the risks of transporting waste through White Pine County are significantly greater than through the Las Vegas Valley. The detailed analysis of routes through the Las Vegas Valley then do not bound the range of expected impacts the text in Chapter 6 implies. Table J-48 makes clear that specific impacts of transportation through White Pine County should have been included within the DEIS.

Response
The commenter mentions a potential highway upgrade as an alternative that could improve the safety of transporting spent nuclear fuel and high-level radioactive waste through White Pine County; that is, a hazardous cargo bypass around the City of Ely. The transportation analyses (with the exception of that for the branch rail line) considered shipments on existing highway infrastructure that would not require upgrading. Where upgrading was required for safe transport or maintenance to keep roads and railroads safe, the necessary funding would be made available to responsible jurisdictions.

As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (A and B pass through White Pine County) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario. The various impacts are generally small for all cases, but for routes A and B the impacts are about a factor of two larger than the route used for the EIS analysis.

8.3.1 (4219)
Comment - EIS001160 / 0036
The DEIS does not adequately address issues raised and substantiated by White Pine County during the scoping process. For example:

It is imperative that the repository EIS includes an exhaustive evaluation of the environmental consequences of waste transport through White Pine County. Because of the unique attributes of the County and its communities, the analysis must be specific to these geographic areas. A generic assessment of transportation risks will not facilitate identification of specific impacts and will preclude consideration of mitigation options necessary to alleviate such effects. The DEIS includes only a cursory assessment of transportation impacts in White Pine County. Socioeconomic, environmental, land use, etc. is not assessed. Measures to mitigate impacts of transportation through White Pine County are not included within the document.

The repository EIS must consider these significant differences in risk (estimated by UNLV-TRC[(6)] as being significantly greater in White Pine County) and address appropriate methods for managing risks in the County to a level commensurate with other areas of the Nation. Table J-48 of the DEIS confirms that risks of transporting waste through White Pine County are significantly greater than other routes involving Interstate highways. The DEIS does not address methods for managing transportation risks in White Pine County.

[(6)] Highway Routes, Parentela, Emelinda, et. al., Risk Analysis for Spent Nuclear Fuel Transportation Through White Pine County: University of Nevada-Las Vegas, Transportation Research Center, prepared for White Pine County Nuclear Waste Project Office, UNLV/TRC/RR-95/9, November 1995.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (A and B pass through White Pine County) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-47 and J-48 present the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario. The various impacts are generally small for all cases, but for routes A and B the impacts are about a factor of two larger than the route used for the EIS analysis.

The comment expressed concern about proposed measures to offset or mitigate the risks associated with transporting radioactive waste to Yucca Mountain. As stated in Section 3.2.2 of the EIS, legal-weight truck shipments would use existing highways that would require no new land acquisition and no new construction. Thus, the EIS focused on potential impacts to human health and safety along existing highways.

8.3.1 (4232)
Comment - EIS001160 / 0047
A variety of discrepancies within the DEIS text and tables and inconsistencies in data presented in the document exist. Several of the risk computations use assumptions that do not appear to be consistent with known references, and reasonable expectations. Examples of these problems with the DEIS are included within the specific comments which follow. Several of the "worst case scenarios" do not appear to be "worst case" for White Pine County. Using known intersections, traffic conditions, established weather patterns and road usage, County reviewers were able to develop several worst case scenarios that meet or easily exceed the ones listed in the DEIS. Examples of possible "worst case" scenarios which should be considered within the FEIS as a means to bound impact assessment and to identify reasonable mitigation measures include:

Accident Scenarios

1. Legal weight truck loaded with spent fuel collides with double-trailer on U.S. 6 immediately south of the City of Ely water supply at Murry Springs. Both vehicles engulfed in flames. Fire of sufficient heat and duration to destroy cask seals resulting in breach of containment. Direct impacts include environmental contamination, closure of U.S. 6 and enhanced public perception of risk and related area stigmatization.

2. Legal weight or heavy-haul truck loaded with spent fuel collides with double-trailer gasoline tanker at intersection of U.S. 93 and State Route 375 near Crystal Springs in Lincoln County. Both vehicles engulfed in flames. Fire of sufficient heat and duration to destroy cask seals resulting in breach of containment. Indirect impacts in White Pine County include reduction of vehicular traffic along U.S. 6 and U.S. 93 through the County and related reductions in visitation to Great Basin National Park and other destination locations within the County.

3. Legal weight truck loaded with spent fuel collides with double-trailer tanker on U.S. 93 thirty miles north of Ely. Both vehicles engulfed in flames. Fire of sufficient heat and duration to destroy cask seals resulting in breach of containment. Direct impacts include environmental contamination, closure of U.S. 93 and enhanced public perception of risk and related area stigmatization. Economic and fiscal consequences of road closure.

DOE is also encouraged to give serious consideration to the scenario presented by Ms. Elizabeth Risden, a White Pine County resident, at the October 19, 1999 DEIS hearing in Ely.

Response
As discussed in Section 6.2.4.2 of the EIS, the National Environmental Policy Act requires assessment of reasonably foreseeable impacts from proposed agency actions. In its various EISs, DOE has defined a reasonably foreseeable accident as one that has a frequency of occurrence of at least once in 10 million years (1×10^{-7} per year). The concept of a maximum reasonable foreseeable accident is sometimes misinterpreted as being a "worst-case" accident.

"Real-life conditions" such as those raised by the commenters would involve various types of collisions (such as airplanes and military trucks with explosives), various natural disasters, specific locations (such as mountain passes), or various infrastructure accidents (such as track failure) in effect constitute a combination of cask failure mechanisms, impact velocities, and temperature ranges, which the EIS does evaluate. DOE has revised the EIS to describe the maximum reasonably foreseeable accident in terms of cask failure mechanisms, range of impact velocities, and temperature range.

In the Draft EIS, DOE considered six categories of increasingly severe and unlikely accident scenarios. The analyses hypothesized one accident scenario to represent each category, along with a corresponding projection of the amount of radioactive material a transportation cask could release. The analyses estimated impacts of postulated releases in three population zones – urban, suburban, and rural – and under two weather conditions – slowly dispersing conditions and moving air conditions. The analyses also estimated impacts from an unlikely but severe accident scenario called a maximum reasonably foreseeable accident.

DOE has revised the transportation accident analyses in the EIS to reflect new information. For example, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). DOE has concluded that the models used for analysis in the Draft EIS relied on assumptions about spent nuclear fuel and cask response to accident conditions that caused an overestimation of the resulting impacts.

Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low.

In evaluating the potential impacts of transportation accidents in the EIS, DOE conservatively assumed that no emergency response would occur and evaluated the full impacts of the accident on the surrounding population. The analysis of impacts of transportation accidents in the EIS (Section J.1.4.2.1) does not take credit for emergency response efforts to reduce exposures to individuals. Therefore, the impacts consider the range of what might happen regardless of the emergency response capabilities of jurisdictions along transportation routes. If responders followed standard emergency response procedures, such as avoiding the downwind smoke of a major fire, exposures would be low. However, because DOE could not predict what type of emergency response would be available, it could not factor any mitigation of impacts as a result of such measures into the EIS analysis.

8.3.1 (4240)
Comment - EIS001160 / 0055
Although White Pine County is a remote rural area, the topography, climate, population concentration, existing transportation systems and economic condition are unique and must be considered in any decision on transportation routing for hazardous materials. The absence of any data in the DEIS concerning this is particularly disconcerting for the County's emergency first responders. Besides transportation issues, it is a fact that White Pine County is downwind of Yucca Mountain and its residents have had health problems from testing conducted at the NTS [Nevada Test Site]. County residents would probably prefer the no action alternative where wastes are stored at their current locations. The DEIS should consider baseline health and public perceptions of risk.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and Highway 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes A and B are through White Pine County) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to

Yucca Mountain. Should the State of Nevada designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-43 and J-44 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario. The various impacts are generally small for all cases, but for routes A and B the impacts are about a factor of two larger than the route used for the EIS analysis.

Sections M.5 and M.6 of the EIS contain additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. Should the State of Nevada designate Nevada Alternative Route A or B as a preferred highway, White Pine County would be eligible for technical assistance and funds provided by Section 180(c).

As stated in Section 3.2.2 of the EIS, legal-weight truck shipments would use existing highways that would require no new land acquisition and no new construction. Thus, the EIS focused on potential impacts to human health and safety along existing highways.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents,

which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.3.1 (4298)
Comment - EIS001160 / 0107
Page 6-31, Section 6.2.4.2.1, Paragraph 2 states "The accident risk for legal-weight truck shipments dominates the total risk. . . " If this is the case and shipments through White Pine County are even a remote possibility, then detailed analysis of such shipments through White Pine County should be addressed in the DEIS.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes A and B are through White Pine County) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada designate one of these other routes as an alternative preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultations with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternative preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario. The various impacts are generally small for all cases, but for routes A and B the impacts are about a factor of two larger than the route used for the EIS analysis.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

8.3.1 (5193)
Comment - EIS001443 / 0018
Communities along State Route 127 constitute the most isolated populations in Inyo County. Assistance with roadway incidents must come from the Inyo County Sheriff Unit at Shoshone, Park Service Rangers dispatched out of Cow Creek near Furnace Creek, or California Highway Patrol also coming out of Death Valley or out of Pahrump, Nevada. Most of the route lies one to three hours from any public assistance. To deal with major

roadway incidents, County Sheriff units are sent from Lone Pine, which is three hours away from the closest segment of SR127.

Currently, the State Route 127 towns of Tecopa, Shoshone, and Death Valley Junction are served by a single Volunteer Fire Protection District that is without adequate funding. In case of a serious toxic or radiological release in Inyo County, specialist response teams must be brought in from either San Bernardino or Bakersfield, a process which takes a minimum of three to four hours, assuming that the response team is not occupied elsewhere. The closest medical facility of any note is in Pahrump, which is a minimum of thirty minutes from the closest segments of the road and several hours away from the furthest. The closest fully equipped hospital is in Las Vegas, which is at least two hours away from the closest sections of SR127.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes C and E include the use of California State Route 127) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternate preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Regional Servicing Contractor would be required to provide detailed written procedures for how it would respond to an incident and arrange for repair/replacement of equipment or recovery, as appropriate. In accordance with ANSI N14-27 (DIRS 156289-ANSI 1987), the carrier is expected to provide appropriate resources for dealing with the consequences of an accident, isolating and cleaning up contamination, and maintaining working contact with the responsible governmental authority until the latter has declared the incident to be satisfactorily resolved and closed. Section M.3 of the EIS contains more detail on the proposed role of the Regional Servicing Contractor.

Sections M.5 and M.6 of the EIS contain additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. Under Section 180(c), DOE will fund eligible jurisdiction planning activities to determine current capabilities and needs and fund training for emergency response activities. Should spent nuclear fuel and high-level radioactive waste be transported on SR 127, Inyo County and the communities along the route would be eligible for technical assistance and funds provided by Section 180(c).

In addition, there is a Federal Radiological Program outlined in the Federal Radiological Emergency Response Plan and the Federal Radiological Monitoring and Assessment Plan. These plans outline the policies, procedures, roles, and responsibilities of Federal, tribal, state, and local agencies in planning for and responding to emergencies involving releases or suspected releases of radiological materials from government and commercial facilities or operations. Under Section 180(c), DOE will fund eligible jurisdiction planning activities to determine current capabilities and needs and fund training for emergency response activities.

8.3.1 (5194)
Comment - EIS001443 / 0019
State Route 127 serves much of the tourist traffic flowing into Death Valley National Park from Las Vegas and Southern California, with recent estimates showing park usage on the order of 1.4 million visitors/year. Considerable increases in traffic volume are expected to accompany the growth of California and of both Pahrump and Las Vegas, Nevada (the Nation’s fastest-growing medium-size and large cities, respectively). Also, there are approximately 1000 acres of land in the vicinity of the town of Death Valley Junction (intersection of SR127 and SR190) that may be released to the Timbisha-Shoshone tribe for their use. If developed to mixed residential and commercial uses, this territory could host an unknown number of additional residents and contribute significantly to traffic on Route 127. Per information received from Caltrans, the route is not scheduled for major improvements through 2015.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation’s identification of Routes A through F (routes C and E include the use of California 127) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred routes, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation’s *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternate preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-43 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-43 and J-44 presents the results of the sensitivity evaluations, including the impacts nationally and in Nevada, based on the mostly legal-weight truck scenario.

The commenter mentions that State funding for upgrades to California State Route 127 are not anticipated until 2015. The transportation analyses (with the exception of that for the branch rail line) consider shipments on existing highway infrastructure that would not require upgrading. Where upgrading was required for safe transport or maintenance to keep roads and railroads safe, the necessary funding would be made available to responsible jurisdictions.

8.3.1 (5393)
Comment - EIS001887 / 0101
Page 2-47; Section 2.1.3.3.1 - Nevada Legal-Weight Truck Scenario

The Draft EIS completely ignores the costs and impacts associated with the type of vehicle inspection and escort operations that would be required upon entry into Nevada. Prior to transporting waste through Nevada, safety compliance of vehicles, loads, and drivers must be assured by appropriate State agencies. Legal-weight trucks would need to be inspected at port of entry facilities where vehicle and driver compliance verification with state and federal laws and regulations would be performed, shipping papers reviewed, and escorts assigned to accompany trucks. To capture commercial vehicles entering the state on I-15, ports of entry need to be constructed at or near Mesquite and Jean/Sloan.[20]

Costs to build ports of entry include land acquisition, construction, equipment and training, personnel, utilities, and other on-going or related expenses. Details of these costs are contained in the Nevada Highway Patrol study Base Case Scenario-High Level Transportation (see Attachment R). Other activities could also be conducted at the port of entry. These activities could include vehicle inspection, issuing NDOT [Nevada Department of Transportation] oversize load permits, and other related permit activities.

The ports of entry should have one inspection bay and pit that is segregated and protected from the other bays to provide maximum protection to employees and others using the facility during an inspection of vehicles transporting radioactive shipments.

The Nevada Highway Patrol estimates initial (start-up) costs for required ports of entry for inspection of legal-weight truck shipments at over $43 million, with subsequent annual costs for operating the ports of entry at over $6 million (see Attachment R).

[20] Should NDOT designate alternative routes, port of entry locations would need to be reviewed.

Response
Section 6.2.3 of the EIS provides the impacts of national transportation of spent nuclear fuel and high-level radioactive waste including impacts to workers, including inspectors. The EIS does not address costs of operations normally the responsibilities of shippers, carriers, or states. States would normally require fees of shippers or carriers to cover state-required operations specifically for spent nuclear fuel and high-level radioactive waste.

Sections M.5 and M.6 of the EIS contain additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction.

In response to comments on the Draft EIS, DOE added Appendix M to the EIS to provide additional information on transportation regulations and the operational aspects of spent nuclear fuel and high-level radioactive waste transportation (see Sections M.2 and M.3). This information includes more details on Inspections (Section M.3.2.2.2), shipping papers (Section M.2.3), and driver training (Section M.2.6).

8.3.1 (5719)
Comment - EIS001887 / 0332
Page 6-39 to 6-40; Section 6.3.1.2.1 - Impacts from Incident-Free Transportation

The Draft EIS fails to consider unique local conditions along potential highway routes in Nevada which could result in significantly higher collective doses and significantly higher doses to maximally exposed individuals. The Draft EIS analyses using the RADTRAN and RISKIND models do not reflect unique local conditions.

Individuals in Nevada who reside, work, or are institutionally confined at certain locations within 6 to 40 meters (20 to 130 feet) of a nuclear waste highway route, or within 6 to 50 meters (20 to 160 feet) of a nuclear waste rail route, could potentially receive yearly radiation doses equal to a significant percentage of, or even in excess of, average annual background doses (360 millirem/year). Such exposures could occur under circumstances where: (1) residences, workplaces, or certain institutions (especially schools, prisons, or long-term health care or retirement facilities) are located near route features or segments which would require nuclear waste trucks or trains to stop and start again, or travel at very slow speed; (2) the number of shipments is high enough (one to several casks per day) that opportunities for exposures occur frequently at the same locations, and (3) the individuals residing, working, or confined at near-route locations are regularly present to be exposed to a significant portion (if not all) of the shipments which occur annually.

All three circumstances exist along some of the truck routes identified in the Draft EIS. Route segments of special concern include US 95 from Las Vegas to Lathrop Wells; the so called NDOT [Nevada Department of Transportation] B Route, US 93A, US 93, US 6, and US 95 from West Wendover to Lathrop Wells (especially where vehicle stops and/ or left turns are required in West Wendover, McGill, Ely, Tonopah, Goldfield, and Beatty); and SR160 from I-15 to US95 (especially where vehicle stops are required in Arden and Pahrump).

For example, there are locations along the NDOT B Route in West Wendover, Ely, Tonopah, Beatty and Goldfield where exposure times at a distance of 6 – 10 meters could average 2 minutes per LWT [legal-weight truck] shipment. Under the proposed action, mostly truck scenario, the maximally exposed individual at these locations in Nevada could potentially receive annual doses ranging from 150 mrem to 260 mrem, equivalent to 42% to 62% of the average annual background radiation dose.

The Draft EIS fails to fully evaluate the impacts of routine exposures to individuals stuck in traffic jams (also referred to as gridlock incidents). The Draft EIS assumption that this would be a one time occurrence for the affected individual is an undocumented speculation. Given the regularity of commuting patterns, the opposite assumption may be more likely. Gridlock is likely to occur on a regular basis on I-15, I-215, and US95 in Las Vegas. Gridlock involving a large number of vehicles could also occur frequently in a rural area, for example, as a result of highway construction.

The Draft EIS fails to address the types of questions frequently asked by members of the public. How many people could be exposed to 40 mrem in a worst case gridlock incident (e.g., cask jammed up against school bus, city bus, tour bus, etc.)? Would the same 40 mrem exposure over 4 hours pose greater health risks to pregnant woman and unborn children, young children, or persons already exposed to higher than average levels of radiation? Should a health effects analysis address possible psychological consequences, or trauma-related illnesses, which might result from a gridlock incident?

Response

As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternate preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario. The various impacts are generally small for all cases, but for routes A and B the impacts are about a factor of two larger than the route used for the EIS analysis.

The U.S. Department of Transportation routing requirements, along with regulatory requirements to limit radiation dose external to a shipping cask, help to ensure that radiation dose to persons who live along routes would be low. The analysis in Chapter 6 of the EIS for the mostly legal-weight truck scenario estimates the dose to persons who would drive alongside the trucks as they travel on the highways, who would be stopped in locales where truck shipments stop, and who live along the routes that would be used. In response to public comments, DOE forecasted growth in populations along routes in order to improve its estimates of potential impacts that could occur in the future when shipments would occur. However, the estimated dose to an individual living along a route would not change with changes in population - only the integrated dose to the whole population would change. The dose for an individual who lived along a route would be an average of about 0.008 millirem per year. This is more than 30,000 times less than average annual background radiation in the United States and less than one-one thousandth of the dose from a chest X-ray.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

Nonetheless, based on public comments, the Final EIS includes representative impacts in communities along transportation routes. This analysis accounts for factors such as the locations of intersections, commercial establishments and residences, and traffic signals. Impacts to individual communities could be different if the actual routes from generator sites to Yucca Mountain were different from those analyzed, but the impacts of incident-free transportation would be so low for individuals who live and work along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured. The total impacts of transportation would be similar for different routes that might be used.

DOE used information contained in a report prepared for the City of North Las Vegas (DIRS 155112- Berger Group 2000). The information in this report provided DOE with an estimate of the cost of advancing completion of the Las Vegas Beltway for use by heavy-haul trucks, an estimate of the populations that might live along the Beltway, and a basis for estimating the dose to a maximally exposed individual in a Nevada community from transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. DOE also used information in *The Statewide Radioactive Materials Transportation Plan*, Phase II, to identify potential alternative highway routes for shipments of spent nuclear fuel and high-level radioactive waste that the State of Nevada has considered in the past (DIRS 103072-Ardila Coulson 1989).

To alleviate potential gridlock situations for the transportation of spent nuclear fuel and high-level radioactive waste, DOE would have contingencies in place to address inclement weather, local or regional disturbances, and construction-related activities. In addition, as with transuranic waste shipments to the Waste Isolation Pilot Project site in New Mexico, DOE would use a satellite communications and tracking system. This system can provide drivers with advance warning of poor weather, congested traffic, construction zones, and other potential hazards.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty
- Much of the uncertainty is irreducible, and
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.3.1 (5799)
Comment - EIS001622 / 0012
Routing and Emergency Response Concerns in California

California transportation agencies have expressed concern over the possibility that DOE may decide to route through California a major portion of the Yucca Mountain shipments using roads not designed for heavy truck traffic. This concern was heightened recently when DOE decided to reroute through southern California, including California State Route 127 (SR-127), thousands of low-level radioactive waste shipments from eastern states to the Nevada Test Site in order to avoid nuclear waste shipments through Las Vegas and over Hoover Dam.

California is concerned about the inherent risk and potential detrimental impact to highway and local roads and the surrounding areas as result of this additional heavy truck traffic. Alternative routing, such as the proposed for low-level wastes shipments to the Nevada Test Site, will take shipments off the interstate highway system and place them instead on state routes and local roads that are not designed or maintained to the same standards as the interstate highway system. As an example, although SR-127 is not approved for Highway Route Controlled Quantity (HRCQ) shipments, such as spent fuel shipments, SR-127 is mentioned on page 2-73 of the DEIS as part of a potential high route within California that includes I-40 from Needles to Barstow, I-15 from Barstow to Baker, and SR-127 from Baker to the Nevada State line.

SR-127 is a two-lane, asphalt highway, approximately 85 miles long, located in relatively isolated portions of eastern San Bernardino and Inyo Countries, California. The highway is subjected to intense desert heat, as Death Valley often reaches the highest temperature in the U.S. with long periods of no rainfall. Both conditions make the roadway susceptible to disrepair. Additional heavy traffic, such as from the transport of thousands of low-level radioactive waste shipments to Nevada as well as the transport of a major portion of 70,000 tons of Yucca Mountain spent fuel shipments, would hasten the deterioration process. Excessive numbers of shipments by heavy trucks on SR-127 would require complete reconstruction of some sections of the roadway.

Further, SR-127 is not an engineered route. Most of SR 127 originated as a wagon trail that was paved over a period of time to accommodate tourists to Death Valley resulting in large sections of roadway that are not built on proper base materials. During certain times of the year, this route is the primary access road for thousands of tourists to the Death Valley National Park. It has tight horizontal and vertical curves where visibility is limited, sustained grades, and dozens of washes crossing both under and over the pavement. The road does not include turnouts or wide shoulders and is subject to periodic flash flooding.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state routing or tribal agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes C and E include the use of California 127) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider the conditions of State Route 127 that were identified by the commenter, such as high accident rates in specific areas (for example, unbanked, unsigned high-speed turns; blind rises; limited visibility; and sustained grades in excess of modern standards), during the process of selecting and designating alternate preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

The low-level waste shipments through California referred to by the commenter did not begin until the summer of 1999, after the EIS was published. Prior to that time, the low-level waste shipments traveled over Hoover Dam and through the Las Vegas Valley on the way to the Nevada Test Site low-level waste disposal areas. Routing low-level waste shipments around Las Vegas and Hoover Dam was a voluntary action by the carrier, although DOE and stakeholders influenced it. This action does not necessarily set precedence for spent nuclear fuel and high-level radioactive waste shipments to Yucca Mountain, which must follow much more stringent routing requirements than low-level waste shipments.

The commenter mentions that major improvements to State Route 127 could be necessary to upgrade and maintain the highway. As discussed in Sections 2.3.3.2 and J.3.1.2 of the EIS, the transportation analyses (with the exception of the branch rail line) considered shipments on existing highways that would not require upgrading (with the exception of heavy-haul truck routes). Where upgrading is required for safe transport or maintenance to keep roads and railroads safe, funding would be available to responsible jurisdictions.

8.3.1 (6026)
Comment - EIS001273 / 0001
As a Trustee of the Death Valley Unified School District, I am concerned about 2 aspects of the transportation of nuclear wastes (high & low-level) to the proposed Yucca Mtn. Repository:

1.) In Southeastern Inyo County the highway to be used is Calif. #127. It is winding and full of curves, is classed as a Class #3 roadway by Cal. Trans, and federal funding for improvements are not scheduled til 2012. In essence, 127 is a dangerous route for nuclear transport.

2.) As of this spring there will be no emergency response infrastructure in Southeastern Inyo County through which #127 passes. Haz-mat teams are 85 & 100 miles distant. Should a school bus collide with a transport, no rescue of children could be made immediately. In fact the Calif. Highway Patrol would have to close down #127 at both ends in case of a spill.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes C and E include the use of California 127) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider the conditions of State Route 127 that were identified by the commenter, such as high accident rates in specific areas (for example, unbanked, unsigned high-speed turns; blind rises; limited visibility; and sustained grades in excess of modern standards), during the process of selecting and designating alternate preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

The comment mentions potential highway conditions that could be detrimental to the safety of transporting spent nuclear fuel and high-level radioactive waste on State Route 127. The transportation analyses (with the exception of a branch rail line) considered shipments on existing highways that would not require upgrading. If upgrading was required for safe transport or maintenance was required to keep roads and railroads safe, the necessary funding would be made available to responsible jurisdictions.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Regional Servicing Contractor would be required to provide detailed written procedures for how it would respond to an incident and arrange for repair/replacement of equipment or recovery, as appropriate. In accordance with ANSI N14-27 (DIRS 156289-ANSI 1987), the carrier is expected to provide appropriate resources for dealing with the consequences of an accident, isolating and cleaning up contamination, and maintaining working contact with the responsible governmental authority until the latter has declared the incident to be satisfactorily resolved and closed. Section M.3 of the EIS contains more detail on the proposed role of the Regional Servicing Contractor.

Sections M.5 and M.6 of the EIS contain additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction.

8.3.1 (7063)
Comment - EIS001337 / 0021
Because of the potential for U.S. Highway 6 and State Route 318 to be unavailable due to inclement weather, accidents, or construction, Lincoln County and the City of Caliente noted during scoping that the DEIS must consider impacts of transporting radioactive waste along U.S. Highway 93 through Lincoln County. The DEIS does not consider transportation along U.S. Highway 93 in Lincoln County.

Response
The analysis in Section 6.2.1 of the EIS used highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of Highway Route Controlled Quantities of Radioactive Materials, require the shipments of radioactive material to be made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway or a route selected by a state or tribal routing agency. The regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation identification of the Routes A through F as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3). None of these routes, including the preferred highways and other routes identified by the Nevada Department of Transportation, includes transportation on U.S. Highway 93 in Lincoln County or through the City of Caliente. As a consequence, the potential impacts of transporting spent nuclear fuel and high-level radioactive waste through Lincoln County and Caliente are not evaluated in the EIS.

Section M.3.2.1.4 of the EIS discusses the protocols and procedures to be followed under adverse weather or road conditions and describes how safe parking areas are to be determined. The procedures are in two parts. One part relates to pretrip planning that would use available data relating to expected conditions. Shipments would not be dispatched on a route where expected conditions would not comply with the requirements in the procedures. For en route problems, it is expected that those with the shipment are best able to discuss and report expected and encountered conditions. The transportation contractors are to develop detailed procedures for use by the drivers and crews in making determinations regarding adverse weather and road conditions. The procedure states that DOE would coordinate diversion to a safe area if delay was required. On this basis, it can be concluded that, only under extremely unlikely conditions, allowed pursuant to 49 CFR 397.101(c) when, "…emergency conditions make continued use of the preferred route unsafe or impossible," would a shipment travel on U.S. 93 through Lincoln County and Caliente.

Comment - EIS001961 / 0001
I am concerned about [an aspect] of the transportation of nuclear wastes (high and low-level) to the proposed Yucca Mountain Repository: 1) In Southeastern Inyo County the highway to be used is California Route 127. It is winding and full of curves, is classed as a class 3 roadway by CalTrans, and federal funding for improvements [is] not scheduled until 2012. In essence, 127 is a dangerous route for nuclear transport.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

Route 127 is currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternative preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider the conditions of State Route 127 that were identified by the commenter, such as high accident rates in specific areas (for example, unbanked, unsigned high-speed turns; blind rises; limited visibility; and sustained grades in excess of modern standards), during the process of selecting and designating alternate preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

Sections M.5 and M.6 of the EIS contain additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction.

The commenter mentions that State Route 127 is a winding highway, full of curves, and a dangerous route for nuclear transport. The legal-weight truck shipments postulated in the EIS would require no special highway design considerations, alignment, curvature, or other infrastructure requirements that are not already provided for the safe transportation of any cargo using 18-wheel tractor-trailer combination trucks. The transportation analyses (with the exception of that for the branch rail line) consider shipments on existing highway infrastructure that would not require upgrading. Where upgrading was required to keep roads and railroads safe for this type of transportation, the necessary funding would be made available to responsible jurisdictions.

8.3.1 (9611)
Comment - EIS001888 / 0283
Analysis of State Routes

In 1986, the State of Nevada began a process to analyze and identify potential SNF [spent nuclear fuel] the routes through the state.

Clark County agrees with some of the findings in the State report. However, Clark County's economic growth in the past decade has rendered some of the State of Nevada routes outdated. The recently approved Enterprise Land use plan charts a course for rapid and extensive economic growth in the southwestern part of urban Clark County. Due to this expansion, the State of Nevada routes C through F now pass through urban Clark County and should be regarded as non-preferred routes by Clark County. Among the routes considered by the State of Nevada, only the B route is acceptable to Clark County.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribeto designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada designate one of these other routes as analternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternate preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

8.3.1 (10139)
Comment - EIS001865 / 0014
Section 2.3.3.2, "Potential Highway Routes for Heavy-Haul Trucks and Associated Intermodal Transfer Station Locations Considered but Eliminated from Further Detailed Study": The County concurs that federal highway U.S. 127 should not be considered for heavy-haul trucks. The County also believes that regular truck haul under the "mostly legal-weight truck shipping" should not be considered for this narrow, winding highway that has poor

alignment and steep grades that make the road generally unsuitable for commercial hauling of high-level radioactive material. Considerable recreational travel occurs on this road due to its providing primary access to Death Valley National Park from the south. Slow moving recreational vehicles are well-known locally as a traffic hazard on this route. This section of highway is remote and emergency response units are limited in number and sufficiently distant from some road portions adding to the complexity of spill containment and cleanup should an accident occur. Furthermore, the County suggests that U.S. 95 is a route of major concern due to some of the same characteristics as U.S. 127. The use of U.S. 95 will require additional assessment on the part of the County of San Bernardino and Caltrans (California Department of Transportation).

Response

As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes C and E include the use of California 127) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

Neither State Route 127 nor U.S. 95 is currently designated as preferred highways and thus could not be used for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. However, should the State of Nevada or California designate one of these highways as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider the conditions of State Route 127 and U.S. 95, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternate preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

The commenter mentions that State Highway 127 is a narrow, winding highway that has poor alignment and steep grades that make the road generally unsuitable for commercial hauling of high-level radioactive material. The legal-weight truck shipments postulated in the EIS would require no special infrastructure that is not already provided for the safe transportation of any cargo using 18-wheel tractor-trailer combination trucks. The transportation analyses (with the exception of that for the branch rail line) consider shipments on existing highway infrastructure that would not require upgrading. Where upgrading was required for safe transport or maintenance or for heavy-haul truck transportation to keep roads and railroads safe, the necessary funding would be made available to responsible jurisdictions.

DOE does not intend to designate routes based solely on the EIS. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and would be conducted in accordance with U.S. Department of Transportation routing guidelines. The preferred routes would be submitted to the Nuclear Regulatory Commission for approval.

8.3.1 (10906)
Comment - EIS000353 / 0006
Irregardless of what routes are chosen, you'll be coming through that populated section of White Pine and Lincoln counties.

Now, you know, there's a lot of talk about alternate routes. It only takes a quick look at a Nevada map to realize there's not many alternative routes. Our mountains run north and south, and there's a road down in the valley. So when you say, haven't designated an alternative route, they're going to be hard-pressed to come up with too many alternate routes.

Some meetings we attend, NRC [Nuclear Regulatory Commission], or the Department of Transportation, because Yucca Mountain is yet to be a repository, yet there's thousands of shipments of low-level wastes. And they're using the same roads that they're going to utilize on the high-level.

The major source of concern to the people living in White Pine County, and particularly in the Ely vicinity, is the transportation of this material. With the apparent objections of the gaming industry, as expressed by the politicians, and as that gentlemen stated earlier, it is very unlikely any of the identified routes, rail or highway, will go through Clark County.

Response
As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (A and B pass through White Pine County) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternate preferred routes.

For completeness, Section J.3.1.3 of the EIS evaluates all six of the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. The data needed to characterize the Nevada Department of Transportation routes to support the impact calculations is equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario. The various impacts are generally small for all cases, but for routes A and B the impacts are about a factor of two larger than the route used for the EIS analysis.

The low-level waste shipments through White Pine referred to by the commenter did not begin until the summer of 1999, after the Draft EIS was published. Prior to that time, the low-level waste shipments traveled over Hoover Dam and through the Las Vegas Valley on the way to the Nevada Test Site low-level waste disposal areas. Routing low-level waste shipments around Las Vegas and Hoover Dam was a voluntary action by the carrier, although DOE and stakeholders influenced it. This action does not necessarily set precedence for spent nuclear fuel and high-level radioactive waste shipments to Yucca Mountain, which must follow much more stringent routing requirements than low-level waste shipments.

Section 8.4 of the EIS provides the results of cumulative impact analyses conducted to ensure that the environmental impacts of the Proposed Action and other potential actions that involve the same regions or resources are provided to decisionmakers. The information is used to minimize or avoid adverse consequences and to develop an appropriate mitigation strategy and enable DOE to monitor its effectiveness. The health and safety impacts of low-level waste shipments to Nevada Test Site disposal areas are included in Table 8-60 of the EIS where cumulative impacts are tabulated (see "Nevada Test Site expanded use" entry in the table). Note that the table does not identify impacts to specific populations (that is, for specific routes) for any of the categories listed in the table. However, the collective incident-free radiation doses to the public and workers from transporting low-level waste to Test Site disposal areas (150 person-rem in Table 8-58 for entire trips, including inside and outside Nevada) are small in relation to the cumulative radiation doses in Nevada for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain (approximately 2,000 to 4,000 person-rem in Table J-48). Therefore, the cumulative incident-free radiation dose impacts in Nevada of transporting low-level waste, spent nuclear fuel, and high-level radioactive waste are not significantly different than the impacts of shipping spent nuclear fuel and high-level radioactive waste alone. It is unlikely that any additional mitigation or monitoring would be required beyond that for spent nuclear fuel and high-level radioactive waste transportation.

8.3.1 (11092)
Comment - EIS000374 / 0003
The southeast County has recently seen several highway accidents involving non-nuclear hazardous waste. One leaking incident with a leaking toxic waste truck resulted in the responders being exposed to toxic levels of waste, followed by hospitalization and ongoing medical treatment. The time delay in getting toxic waste into the region was the reason for the severity of the incident.

In another area, a hazardous waste truck failed to negotiate a turn near a rest stop, rolled over, and crushed a picnic facility. Our confidence in truck transportation for dangerous materials on remote, narrow, two-lane roads is not high. Unfortunately, the DEIS is silent on this issue.

Road conditions. State Highway 127 itself not an engineered route. Most of it originated as a historic wagon trail that was paved over a period of time. Inyo County's recent survey of this route, from its junction in the south with Interstate 15 in Baker to its junction with US Highway 95 in the north, revealed many unbanked, unsigned, high-speed turns, numerous blind rises where visibility is limited, sustained grades in excess of modern standards, and dozens of washes that cross both under and over the pavement. The route passes through four towns, two of which include sharp 90° turns in the middle of town.

In the event of an incident, there are few alternative routes useful to diverting commercial and passenger traffic around accident or cleanup sites. For long sections of Highway 127, there's no alternative route whatsoever.

There are approximately 1,000 acres of land in the vicinity of Death Valley Junction that are proposed for release to the Timbisha-Shoshone tribe for their use. If developed to mixed residential and commercial uses, this territory could host an unknown number of additional residents and contribute significantly to traffic on Route 127.

During the period of emplacement, it is reasonably foreseeable for development densities on private lands located in Inyo County to approach those of the Pahrump Valley. This also will result in an unknown number of additional residents and contribute significantly to route traffic on 127.

The EIS's treatment of the State Route 127 corridor is also of concern. The status of the corridor with respect to Yucca Mountain shipments is not addressed in any meaningful fashion by the EIS. We don't see any mitigation in the EIS to compensate for the hazard which the waste would impose upon responders, travelers, and residents of this region. Conditions on possible primary and secondary routes in California are not evaluated, and no attempt is made to develop and weigh alternatives for getting nuclear waste originating in California into Yucca Mountain.

As it stands, the isolation and current configuration of the southeast county's roadways cannot reasonably and safely support the demands of the 25-year nuclear waste transport campaign. The EIS provides insufficient information to allow us to assess repository operations on county residents or determine our risk in the larger context of the national transportation effort.

Unless State Route 127 is officially dismissed from consideration for transport of high-level waste and spent nuclear fuel, the Draft Environmental Impact Statement, at a minimum, needs to be amended to evaluate the risks associated with the route, proposed measures to offset those risks, and identify the expected source of funding for those mitigation measures.

Response

As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

These same regulations allow a state or tribe to designate alternate routes in accordance with U.S. Department of Transportation guidelines. This is the basis for the Nevada Department of Transportation's identification of Routes A through F (routes C and E include the use of California 127) as potential alternative highway routes for legal-weight truck shipments to Yucca Mountain (see Section J.3.1.3 of the EIS).

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the U.S. Department of Transportation's Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials or an equivalent routing analysis that adequately considers overall risk to the public. Consultation with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider the conditions of State Route 127 that were identified by the commenter, such as high accident rates in specific areas (for example, unbanked, unsigned high-speed turns; blind rises; limited visibility; and sustained grades in excess of modern standards), during the process of selecting and designating alternate preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

The transportation analyses (with the exception of that for the Nevada branch rail line) considered shipments on existing highway infrastructure that would not require upgrading. Where upgrading was required for safe transport or maintenance to keep roads and railroads safe, the necessary funding would be made available to responsible jurisdictions.

Section 9.3 of the EIS describes management actions to mitigate the potential for environmental impacts from transportation of spent nuclear fuel and high-level radioactive waste to the repository. California State Route 127 is currently not a preferred route so DOE has not determined how these risks would be mitigated. As mentioned above, DOE would not designate preferred highway routes based on the information in the EIS alone. Additional environmental and engineering studies would be conducted before such a decision was made. DOE anticipates that potential mitigation measures, which might include infrastructure upgrades, would be considered as a part of these additional studies.

8.3.1 (11168)
Comment - EIS000370 / 0001
The [Inyo] county's primary concern with the EIS is the superficial analysis of the transportation campaign necessary to move some 70,000 or more tons of radioactive waste into Yucca Mountain. In terms of short-term risks to humans, the hazards associated with transportation pose the greatest threat to populations across the nation. The transportation campaign is an integral part of the Yucca Mountain project. It is inseparable from the operation of the proposed repository. Consideration, in detail, of transportation impacts cannot reasonably be deferred to future analysis any more than other off-site impacts. Without detailed information on likely primary and secondary routes in California and the staging of shipments, it is impossible for Inyo County to evaluate the impacts of the shipping campaign on our area.

At present, State Route 127 is being utilized for shipment of low-level nuclear waste to the Nevada Test Site, and may be used for shipment of transuranic waste from the test site to the Waste Isolation Pilot Plant in Carlsbad, New Mexico. This makes State Route 127 a likely candidate for eventual shipments of high-level waste.

Response
DOE believes that the EIS adequately analyzes transportation-related impacts that could result from, and that would be associated with, the Proposed Action. DOE also believes that the EIS provides the information necessary to make certain decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was approved. See the introduction to Chapter 8 of this Comment-Response Document for additional information.

DOE used state-specific accident data in the analyses, which included consideration of specific conditions and hazards along representative highway and rail routes. However, DOE does not believe it necessary to consider population and other route characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related public health impacts.

In response to comments, additional information on the potential state-specific routes and local and regional impacts is provided in Section J.4 of the EIS. In addition, Section J.3.1.3 presents a sensitivity analysis that compares estimated impacts for national transportation and transportation in Nevada over highway routes identified by the State as potential alternate preferred routes. One of the potential alternate routes would use California Route 127. It would be necessary for the State of Nevada to coordinate with the State of California before this route could be designated as an alternate preferred route. The Final EIS includes impacts representative of those to individuals who live in small communities along transportation routes. This analysis accounts for factors such as the locations of commercial establishments and residences.

Sections 6.2 and 6.3 of the EIS address the potential impacts of transporting spent nuclear fuel and high-level radioactive waste from facilities where it is generated to the proposed repository. Appendix J discusses the methods and data DOE used for these analyses. Based on the results of the impact analyses presented in Chapter 6 and Appendix J, as well as the results published in other studies and environmental impact analyses cited in the EIS, DOE is confident spent nuclear fuel and high-level radioactive waste it could transport spent nuclear fuel and high-level radioactive waste safely to Yucca Mountain. DOE also believes, as the EIS reports, that the potential impacts of this transportation would be so low for individuals who lived and worked along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured. The analysis presented in the EIS factored in the characteristics of spent nuclear fuel and high-level radioactive waste, the integrity of shipping casks that would be used in transport, and the regulatory and programmatic controls that would be imposed on shipping operations (see Appendix M). The EIS analytical results are supported by technical and scientific studies that have been compiled through decades of research and development by DOE and other Federal agencies, including the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as by the international community, including the International Atomic Energy Agency.

At this point in time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, states and tribes could designate

alternate preferred highway routes, and highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highways, beltways, or bypasses, and state or tribal designated alternates) that reduce time in transit. DOE identified rail lines based on current rail practices, since there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials. Analyses in the EIS (Sections J.2 and J.3) demonstrate that the total transportation impacts would be essentially the same regardless of the routes used. These analyses indicate that because all shipments would comply with regulatory limits, the impacts would be proportional principally to the number of shipment miles. Hypothetical accidents that would result in releases of radioactive materials from the casks would be extremely unlikely regardless of the routes because applicable transportation requirements prescribe that the casks must be able to withstand virtually all types of accidents without releasing their contents.
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes DOE would use would be identified approximately 5 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction.

8.3.1 (11538)
Comment - EIS010022 / 0001
We have heard the horror stories about spills in the horrendous traffic of Las Vegas. I have noticed a clear avenue of escape from this traffic.

At or near milepost CL 100 on US 95 a nearly empty stretch of land extends east and a bit south toward I-15. A road across this area would bypass Las Vegas.

Much of the waste will come from the east. CA-127 and NV-373 will bypass Las Vegas and is about empty space.

So build a bit of road and save a bunch of hassle from Las Vegas. I could also use such a road on the way to Mesquite and Utah.

Response
In this Final EIS, DOE has identified rail as its preferred mode for transporting spent nuclear fuel and high-level radioactive waste to the proposed repository at Yucca Mountain, both nationally and within Nevada for shipments that arrive in Nevada by rail. At this time DOE has not identified a preference for a specific rail corridor within Nevada. DOE would identify a preferred corridor only if the Yucca Mountain site was approved, and then only after consultation with affected stakeholders, particularly the State of Nevada.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, states and tribes could designate alternate preferred highway routes, and highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit.

8.3.1 (11748)
Comment - EIS002299 / 0005
There will be significant transportation impacts in California from the proposed Yucca Mountain repository. California has four operating commercial nuclear power plants, three commercial plants being decommissioned, and is a major generator of spent nuclear fuel. Spent fuel is now being temporarily stored at these reactor sites and at five research reactor locations throughout the State. Under DOE's plans, spent nuclear fuel from two of California reactors is scheduled for transport during the first year that shipments occur.

In addition, DOE could route through California a major portion of the Yucca Mountain shipments. Nevada officials estimate that 74,000 truck shipments (three-fourths of the total shipments to the repository) of spent fuel and high-level waste could be transported through California to Yucca Mountain under DOE's "mostly truck" scenario, an average of five truck shipments daily for 39 years. Under a mixed truck/rail scenario, an estimated 26,000 truck shipments and 9,800 rail shipments could be transported through California to the Yucca Mountain site. Our concern about DOE's possibly routing through California a major portion of these shipments was heightened recently when DOE announced their decision to reroute through Southern California, including SR-127, thousands of low-level radioactive waste shipments from eastern states to the Nevada Test Site, in response to Nevada and Arizona's requests to avoid shipments through Las Vegas and over Hoover Dam.

California's Concerns: The Draft EIS failed to identify shipments routes, modes, number and characteristics of shipments, and only superficially discussed transportation impacts. The logistics and risks associated with these shipments should be addressed in the Draft EIS. Transportation is the single area of the repository project, which will impact the most people and should be discussed thoroughly in the EIS.

DOE's possible routing through California, especially along SR-127, of a large portion of these shipments to Yucca Mountain is a major concern. SR-127 road conditions, flash flooding, seasonal peaks in tourism, scarcity and long response time for emergency response to a shipment accident, and impacts on the road infrastructure from increased heavy truck traffic are of serious concern.

Response

In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-34 of the EIS for the representative California routes). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-74 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would enter Nevada from California on Interstate-15 in the mostly legal-weight truck scenario. The table also lists the estimated number of rail shipment through California in the mostly rail scenario for each of the candidate Nevada rail corridors and heavy-haul truck routes.

If the Yucca Mountain site was approved, under the mostly legal-weight truck scenario, the total number of truck shipments through California was estimated to be 6,867 over 24 years, which is less than 1truck shipment per day. There would be no rail shipments.

The estimated numbers of shipments entering Nevada from California under the mostly rail scenario are less than the mostly legal-weight truck scenario. According to Table J-74, the number of rail shipments would range from 512 to 1,464 depending on the mode (rail or heavy-haul truck) and corresponding corridor/route selected in Nevada. This is slightly more than 1 rail shipment per week over 24 years. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

As described in Section J.1.1.2, the analysis in the EIS used representative highway routes that conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, which were developed to promote public safety and reduce radiological risk for transport of highway route controlled quantities of radioactive materials, require that shipments of radioactive material are made on preferred routes to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or a route selected by a state or tribal routing agency. As a consequence, when choosing representative routes in Nevada, DOE was limited to Interstate-15, the bypasses around Las Vegas (assumed complete at the time of transport) and U.S. 95 to the Yucca Mountain site.

The Nevada Department of Transportation-identified routes are currently not designated as preferred highways and thus could not be used at the present time for shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Should the State of Nevada or California designate one of these other routes as an alternate preferred route, it could do so only in accordance with U.S. Department of Transportation guidelines. The regulations require the State to select routes in accordance with the Department of Transportation's *Guidelines for Selecting Preferred Highway Routes for Highway Route Controlled Quantity Shipments of Radioactive Materials* or an equivalent routing analysis that adequately considers overall risk to the public. Consultations with affected states, tribes, and local jurisdictions would be necessary. The affected routing authorities would consider public risk and other conditions along the other routes, including emergency response capability, highway design and condition, population density, traffic conditions, etc., during the process of selecting and designating alternate preferred routes.

Section J.3.1.3 of the EIS evaluates the Nevada Department of Transportation routes as sensitivity analyses to provide comparisons with the currently allowed preferred routes. Table J-46 includes descriptions of the other routes evaluated in the EIS, including Case 2, which uses State Route 127. The data needed to characterize these routes to support the impact calculations, including State Route 127, are equivalent to the data collected for the base case routes. Tables J-47 and J-48 presents the results of the sensitivity evaluations, including the impacts nationally and within Nevada, based on the mostly legal-weight truck scenario.

Sections M.5 and M.6 of the EIS contain additional information on emergency response and the implementation of Section 180(c) of the NWPA. Section 180(c) requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction.

8.3.1 (12376)
Comment - EIS000142 / 0008
As noted in White Pine County's comments on the scope of the EIS, the Final EIS must consider the extent to which local emergency first response capabilities serve to mitigate or exacerbate risks. The extent to which environmental conditions in the County (i.e., climate and wildlife) bear upon transportation risks should be considered. Measures to mitigate transportation risks, at least to a level commensurate with the Base Case, should be identified and evaluated within the Final EIS.

Response
In addition to the routes that meet the current definition of a preferred route in accordance with U.S. Department of Transportation regulations (see 49 CFR 397.101), six other highway routing options within Nevada were analyzed in the EIS in Section J.3.1.3. The six other routes were based on those identified by the Nevada Department of Transportation and were evaluated as sensitivity cases to the base case routes (that is, routes that are consistent with current U.S. Department of Transportation regulations for highway route controlled quantities of radioactive material). The data needed to characterize the Nevada Department of Transportation alternative routes to support the impact calculations is equivalent to the data collected for the base case routes. It should be noted that only if the State of Nevada designates an alternative preferred route, such as Nevada Department of Transportation Alternatives A or B, would spent nuclear fuel or high-level radioactive waste be transported through White Pine County and that would only be by legal-weight truck.

Section 9.3 of the EIS addresses management actions to mitigate potential adverse environmental impacts of the transportation of spent nuclear fuel and high-level radioactive waste to the site from 77 locations around the nation. The section describes actions that could be taken based on the description of the affected environment given in Chapter 3 and the potential impacts described in Chapter 6. Section 116(c) of the NWPA states that "the Secretary shall provide financial and technical assistance to [an affected unit of local government or the State of Nevada] to mitigate the impact on such [an affected unit of local government or the State of Nevada] of the development of [a] repository and the characterization of [the Yucca Mountain] site." Such assistance can be given to mitigate likely "economic, social, public health and safety, and environmental impacts." Any decision to provide assistance under Section 116 would be based in part on an evaluation of a report submitted by an affected unit of local government or the State of Nevada to document likely economic, social, public health or safety, and environmental impacts. If the proposed repository were to become operational, DOE would enter into discussions with potentially affected units of local government and consider appropriate support and mitigation measures.

If the Yucca Mountain site was approved and after a decision was made regarding transportation modes and routes, local jurisdictions would be better able to identify the likely economic, social, public health and safety, and environmental impacts that would be the basis for a request for economic assistance under Section 116(c) of the

NWPA. Because several years would elapse between approval of the repository and start of a transportation campaign, affected units of local government and tribal governments would have sufficient time to request and receive funding.

8.3.1 (12467)
Comment - EIS001887 / 0095
Page 2-44; Section 2.1.3.3 - Nevada Transportation

The State of Nevada finds the analysis of Nevada transportation impacts associated with the Proposed Action contained in the Draft EIS to be legally and substantively deficient. The Draft EIS fails to address the interconnectedness of national and Nevada transportation issues and impacts. Instead, the Draft EIS treats Nevada transportation as if it were entirely isolated from the national transportation system and the characteristics, decisions, and other factors that condition and drive the national spent fuel and HLW [high-level radioactive waste] shipping campaign. For example, the issue of rail access to Yucca Mountain will have a major impact on the type and number of shipments that occur across the country. Likewise, the viability of, and decision to go forward with, an intermodal transfer facility in Nevada will be a major determinant of modal mix for shipments nationwide. Conversely, decisions made by utilities and contract shippers regarding transportation casks, routing considerations, weather, and many other factors will determine routes that are impacted within Nevada. Acknowledgment of such interconnectedness is not addressed in the Draft EIS.

The Draft EIS contains an inadequate and superficial treatment of Nevada transportation issues and impacts. The Draft EIS fails to evaluate alternative highway routes in a manner that permits the identification of preferred alternatives, and the level of information and analysis is different for various routes. The Draft EIS completely ignores at least one of the most likely highway shipping routes through the State (the NDOT [Nevada Department of Transportation] 'B' route). Moreover, the analysis of potential rail spur alternatives is uneven, exclusive of potentially attractive alternatives, lacks specificity, and insufficient for selecting preferred alternatives. Also, the analysis of rail construction impacts and the impacts/necessities of operating a rail line within Nevada are grossly understated. The evaluation of potential intermodal transfer facility locations is based on inadequate, extraordinarily incomplete and uneven information and fails to identify a preferred location, which is essential for adequately assessing impacts of other aspects of the transportation system, both in Nevada and nationally. The assessment of the costs and impacts of heavy-haul transportation on Nevada highways is incomplete and understates the difficulties inherent in an unprecedented activity of such scale and duration, difficulties and costs that will likely make intermodal transport within Nevada infeasible. Finally, the assessment of potential socioeconomic impacts associated with spent fuel and HLW transportation in Nevada is incomplete, inadequate, and fails to address the range of significant impacts to communities along the identified rail spur and to the State as a whole.

Response
The routing presented in Sections 6.2.3 and 6.2.4 of the EIS for truck and rail transportation is representative of the routing that could be used to transport spent nuclear fuel and high-level radioactive waste to Yucca Mountain. The impacts are not expected to vary significantly due to differences in rail or truck routes used. In addition, Section J.3.1.3 presents an analysis of the sensitivity of impacts to changes in Nevada routing. Specifically, the Nevada Department of Transportation 'B' route is presented as Case 5 in Table J-46. With regard to the insufficient presentation of impacts for the rail corridors, Section J.3.1 discusses the selection of the five candidate rail corridors and presents a list of studies that illustrate the process for screening potential rail alignments. Specifically, the *Nevada Potential Repository Preliminary Transportation Strategy Study 1* (DIRS 104795-CRWMS M&O 1995) and the *Nevada Potential Repository Preliminary Transportation Strategy Study 2* (DIRS 101214-CRWMS M&O 1996) are listed, among others, and provide information on the rail corridor alignments including detailed maps.

Section J.2 of the EIS discusses implementing alternatives for heavy-haul truck transportation routes and facilities. The interactions and dependencies between Intermodal modes and protocols are assessed and included in the impact analysis. The level of information acquired and assessed was as even as possible since the assessments were based on existing information. Potential heavy-haul truck route upgrades are addressed in Section J.3.1.2 and detailed cost estimates are given in *Cost Estimate for the Heavy-Haul Truck Transport Design* (DIRS 154675-Ahmer 1998). Total estimate for Nevada transportation is listed in Table 2-5; it would be about $800 million for a new branch rail line. Highway upgrades would be less depending on the condition and local of the roads.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

DOE does believe, however, that the EIS adequately analyzes the potential environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

8.3.1 (13181)
Comment - EIS010243 / 0028
Clark County is within the region of influence of Yucca Mountain Program (YMP) for transportation because Congress identified the interstate highway system as the default route for the transportation of HLW [high-level radioactive waste]. The most direct route from power generating sites to Yucca Mountain is the interstate highway system through Clark County. Therefore most of the truck trips from shipping sites will pass through Clark County.

The shortest routes from the waste generating sites to Yucca Mountain pass through Clark County en route to Yucca Mountain. Congress anticipated efforts to avoid transportation of waste through particular areas. That is why they designated the Interstate highway system as the default transportation route for the movement of HLW to a repository in the NWPAA. Therefore, any effort to avoid shipping any of these waste streams through Clark County will be met with requests from other similarly affected areas. The result of these requests will be an uneconomical routing process that will be both circuitous and expensive. Clark County assumes that the interstate highway system through Clark County will be the primary route used to transport waste to Yucca Mountain.

Because the majority of the truck-transported HLW will pass through the county en route to Yucca Mountain, the transportation impacts will be concentrated in Clark County. The Nuclear Regulatory Commission identified Clark County as part of the maximally affected region in the nation in an Environmental Impact Statement.

The DEIS assumed that DOE would be able to ship HLW using Clark County's planned northern and western beltways. However, these "beltways" are unlike beltways in other communities in several important respects. First, Clark County's beltway system is entirely paid for with local tax dollars and is not part of the Federal Highway System. As a result, Clark County's beltway is ineligible as a HLW route under Appendix A of HM 164. Another concern is that the beltway is being constructed as a frontage road rather than as a typical beltway facility. This is another reason Clark County's beltway system is ineligible as a transportation route. This means the primary route used for the truck transportation of HLW is likely to be Interstate 15 and US Highway 95 through Las Vegas. The SDEIS did not consider our comments in this area. However, the assumption that DOE cannot use the Clark County beltway system was used in this assessment.

Response
DOE has identified rail as its preferred mode of transportation both nationally and within Nevada to transport spent nuclear fuel and high-level radioactive waste to the Yucca Mountain site that arrive in Nevada by rail (see the introduction to Chapter 2 of the EIS). Nevertheless, DOE continues to analyze the impacts of legal-weight truck shipments. The U.S. Department of Transportation requires highway shipments to use routes that would be the safest, would reduce time in transit, and would avoid populated areas as far as is possible, consistent with the other requirements. The U.S. Department of Transportation provides procedures for states and tribes to designate routes that could be used. These procedures require a state to consider overall public safety in designating routes that would be alternates to routes specified by Department of Transportation regulations.

The U.S. Department of Transportation requirements and the planned completion of the Las Vegas Beltway led DOE to assume, for purposes of analysis in the EIS, that legal-weight truck shipments would not enter the Spaghetti Bowl interchange of Interstate-15 and U.S. 95. Nevertheless, to assess how impacts would be different from those of using the Las Vegas Beltway, DOE analyzed the impacts for legal-weight trucks to travel through the Spaghetti Bowl interchange (see Section J.3.1.3 of the EIS for an analysis of the impacts of using different routes in Nevada).

8.3.2 CALIENTE/CHALK MOUNTAIN

8.3.2 (136)
Comment - 25 comments summarized
Commenters objected to DOE's position that the Caliente Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route are nonpreferred alternatives based simply on U.S. Air Force opposition to routes passing through the Nellis Air Force Range because they would compromise critical and sensitive national security activities. Commenters said that the Air Force's position was not adequately explained in the EIS; that the specific reasons for Air Force opposition should be described; and that mitigation measures should then be developed and identified in the EIS. Commenters said that the Chalk Mountain routes are environmentally preferable because military security at Nellis would protect spent nuclear fuel and high-level radioactive waste shipments from terrorist attacks. Others said that environmental impacts associated with the Chalk Mountain routes would be less than other alternatives because the lengths of these routes are the shortest of all alternatives under consideration, and they would avoid many communities in Nevada. Moreover, some said that shipping the spent nuclear fuel and high-level radioactive waste through Nellis would force the Federal Government to bear some of the risks associated with such transport; if the people of Nevada are being asked to have spent nuclear fuel and high-level radioactive waste shipped through their communities, the Federal Government should show leadership by routing through the extensive less-populated Federal and military lands in Nevada. Others commenters objected to the deference given to the Air Force's position but not to other entities that have special status under the NWPA and who also strongly oppose certain routes (for example, routes through Lincoln and Nye Counties and through the Las Vegas Valley). These commenters wanted to know why the Air Force was given special status, whether the Air Force was a Cooperating Agency in the preparation of the EIS, and whether the Department of Defense has refused to allow DOE access to lands under the control of the Air Force.

Others, however, supported the Air Force's position. Some said that if these routes are not preferred by DOE, and not acceptable to the Air Force, then they should be eliminated from the EIS as viable alternatives, and included as considered but eliminated from further detailed studies.

Response
Public comments during the EIS scoping period requested that DOE evaluate routes through the Nellis Air Force Range (now called the Nevada Test and Training Range) to Yucca Mountain. In response, DOE added an implementing alternative for the transportation of spent nuclear fuel and high-level radioactive waste by rail or by heavy-haul truck to the Yucca Mountain site across the Nellis Air Force Range (the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route analyzed in the Draft EIS).

During preparation of the Draft EIS, DOE consulted with various organizations and agencies, including the Air Force (see Appendix C of the EIS). In a letter dated March 1999, F. Whitten Peters, Acting Secretary of the Air Force, commented that the Air Force believes that there is no route through the Nellis Air Force Range that could avoid adversely affecting classified national security activities, leading to the imposition of flight restrictions and affecting the ability for testing and training. As a consequence, DOE listed the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route in the Draft EIS as "nonpreferred alternatives."

In comments on the Draft EIS, the Air Force restated its position that routes across the Nevada Test and Training Range would not be consistent with its national security uses. The Air Force concluded that use of such a corridor or route could adversely affect critical and sensitive national security activities. The U.S. Air Force has stated that it knows of no route across the Nevada Test and Training Range that would avoid militarily sensitive areas and thus not affect the heavy volume of testing and training that occurs daily. The Nevada Test and Training Range is the nation's premier range for training of operational flying units and development and operational testing of weapons systems. The transportation of spent nuclear fuel and high-level radioactive waste would lead to the imposition of flight restrictions that would severely degrade the ability to test existing and evolving weapons systems, as well as train U.S. and allied aircrews. Therefore, the Air Force believes that such a route would be inconsistent with the national security uses of the Range.

In response, DOE reevaluated whether it should eliminate the Caliente-Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route from further evaluation. DOE met with the Air Force (see Appendix C of the EIS), considered the information the Air Force provided, and concluded that the Caliente-Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route implementing alternatives should remain identified as "nonpreferred alternatives" in this Final EIS.

The Air Force was not a cooperating agency in the preparation of the EIS and was not afforded "special status" as suggested by some commenters. Rather, DOE, in designating the corridor/route as "nonpreferred alternatives," recognized the implications of this corridor/route on national security uses of the Nevada Test and Training Range. At this time, DOE is not aware of any modifications to the corridor or route that would mitigate the concerns of the Air Force. DOE has been able to obtain sufficient information on the corridor and route to estimate environmental impacts that could occur from the construction and operation of a branch rail line or heavy-haul truck route.

DOE has not identified a particular rail corridor or heavy-haul truck route as "environmentally preferable." If the Yucca Mountain site was recommended and approved and a mode of transportation (rail or heavy-haul truck in Nevada) was selected in a Record of Decision, DOE would then identify an environmentally preferable corridor or route in a subsequent Record of Decision. In making such a determination, the Department would consider a variety of environmental factors, including many raised by the commenters. The potential environmental impacts from the construction and operation of the Caliente-Chalk Mountain Corridor or the Caliente/Chalk Mountain heavy-haul truck route are discussed in Sections 6.3.2.2.3 and 6.3.3.2.2 of the EIS, respectively.

8.3.2 (5044)
Comment - EIS001520 / 0012
The draft EIS identifies the Caliente/Chalk Mountain route (possible rail or heavy-haul route) as a non-preferred alternative. However, the draft EIS presents no environmental logic for this designation. Instead, the draft EIS states that the designation is based on opposition from the U.S. Air Force, which is concerned about potential interference with Nellis Air Force Range testing and training activities. Since this route is about half the overall distance of the more circuitous Caliente route and therefore should be less harmful to the environment, and since this route avoids the population centers surrounding Las Vegas, it would seem to be a candidate for designation as a preferred alternative from an environmental perspective. The Board recommends that the final EIS provide a more thorough explanation of the basis for deciding whether to exclude the Caliente/Chalk Mountain route from consideration.

Response
Public comments during the EIS scoping period requested that DOE evaluate routes through the Nellis Air Force Range to Yucca Mountain. In response, DOE added an implementing alternative for the transportation of spent nuclear fuel and high-level radioactive waste by rail or by heavy-haul truck to the Yucca Mountain site across the

Nellis Air Force Range (the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route analyzed in the Draft EIS).

During preparation of the Draft EIS, DOE consulted with various organizations and agencies, including the Air Force (see Appendix C of the EIS). In a letter dated March 1999, F. Whitten Peters, Acting Secretary of the Air Force, commented that the Air Force believes that there is no route through the Nellis Air Force Range that could avoid adversely affecting classified national security activities, leading to the imposition of flight restrictions and affecting the ability for testing and training. As a consequence, DOE listed the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route in the Draft EIS as “nonpreferred alternatives.”

In comments on the Draft EIS, the Air Force restated its position that routes across the Nevada Test and Training Range would not be consistent with its national security uses. The Air Force concluded that use of such a corridor or route could adversely affect critical and sensitive national security activities.

In response, DOE reevaluated whether the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route should be eliminated from further evaluation. DOE met with the Air Force (see Appendix C of the EIS), considered the information they provided, and concluded that the Caliente-Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route implementing alternatives should remain identified as “nonpreferred alternatives” in this Final EIS.

The Air Force was not a cooperating agency in the preparation of the EIS and was not afforded “special status” as suggested by some commenters. Rather, DOE in designating the corridor/route as “nonpreferred alternatives,” recognized the implications of this corridor/route on national security uses of the Nevada Test and Training Range. At this time, DOE is not aware of any modifications to the corridor/route that would mitigate the concerns of the Air Force. DOE has been able to obtain sufficient information regarding the corridor/route to estimate the potential environmental impacts that could occur from the construction and operation of a branch rail line or heavy-haul truck route.

DOE has not identified a particular rail corridor or heavy-haul truck route as “environmentally preferable.” If the site was approved and a mode of transportation (rail or heavy-haul truck in Nevada) was selected in a Record of Decision, DOE would then identify an environmentally preferable corridor/route in a subsequent Record of Decision to select a rail corridor or heavy-haul truck route. In making such a determination, a variety of environmental factors, including many raised by the commenters, would be considered. The potential environmental impacts from the construction and operation of the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route are included in Sections 6.3.2.2.3 and 6.3.3.2.2 of the EIS.

8.3.3 ALTERNATIVE ROUTES AND MODES

8.3.3 (23)
Comment - 20 comments summarized
Commenters suggested alternatives not considered in the EIS for using different mixes (for example, 50:50, 60:40) and special rail, highway, monorail, and air transportation modes to ship spent nuclear fuel and high-level radioactive waste.

Commenters suggesting the use of air transportation stated that impacts of transporting spent nuclear fuel and high-level radioactive waste using aircraft would be less than for rail or truck shipments. A commenter suggested that DOE should build a new national high-speed rail transportation system to ship spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Commenters also suggested that trucks should not be used and that rail lines and highways for shipping spent nuclear fuel and high-level radioactive waste should be constructed to circumvent towns and cities; another recommended a monorail system should be constructed to transport the materials. One commenter suggested DOE should evaluate the impacts of using dedicated trains for rail shipments. A commenter suggested the EIS should consider additional regional transportation corridors through the Nellis Air Force Range and in the vicinity of Goldfield, Nevada.

A commenter suggested the EIS should evaluate a third transportation scenario based on the current capabilities of waste generator sites. The suggested scenario would assume all generator sites not served by railroads would ship by legal-weight trucks.

Response

DOE evaluated the potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste from 72 commercial and 5 DOE sites to the proposed repository at Yucca Mountain. If there was a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. However, at this time, many years before shipments to a repository could begin, it is impossible to predict with a reasonable degree of accuracy the exact number of shipments that would be made by either truck or rail. Indeed, the commenters' suggestions about the possibility of mixing modes and routes demonstrated the wide range of possible transportation options. For this reason, in the EIS, DOE evaluated two scenarios for moving the materials to Nevada: (1) transport using mostly legal-weight trucks and (2) transport using mostly rail. DOE analyzed these scenarios to ensure that it considered the range of potential environmental impacts associated with the transportation of spent nuclear fuel and high-level radioactive waste.

DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste, or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada.

Nevertheless, in response to comments, DOE has analyzed the effects of different mixes of rail and truck shipments. The results of this analysis confirm DOE's estimate that the mostly rail and mostly legal-weight truck scenarios represent a reasonable range (lower and upper bound) of potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

As stated in Section 6.2 of the EIS, DOE analyzed two feasible scenarios – mostly rail and mostly legal-weight truck – for potential impacts of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Prior transportation analyses provide substantial evidence that truck, rail, and barge modes of transportation that could be used would result in small environmental impacts (see DOE environmental impact statements listed in Table 1-1). Different mixes of modes from the two analyzed in the EIS (for example, a 50:50 or 60:40 truck-to-rail mix or a mix in which shipments from 32 commercial sites would use legal-weight trucks and shipments from 45 commercial and DOE sites would use rail) would result in impacts that would be somewhere between those for the mostly legal-weight truck scenario and the mostly rail scenario (Section J.1.2.1.4 discusses how impacts would change for variations in the mix of transportation modes for shipments to Yucca Mountain). Thus, as mentioned above, DOE chose to analyze the mostly rail and mostly legal-weight truck scenarios as a means of displaying the range of impacts that could result from different mixes of modes.

The weight of spent nuclear fuel and heavily shielded shipping casks would make transportation by air very expensive. In addition, use of air transportation would not eliminate use of land transportation. Shipments would still have to travel from generator sites to nearby airports and from an airport in Nevada to Yucca Mountain by a land transportation mode. Finally, regulatory requirements in 10 CFR Part 71 regarding air transportation of plutonium in excess of 20 curies could preclude air transportation of spent nuclear fuel that could contain as much as 20,000 curies of plutonium per MTHM or 40,000 curies of plutonium per truck cask. Regulations in 10 CFR Part 71 address requirements prescribed by Congress regarding air transportation of plutonium.

Section J.2.3 of the EIS presents an assessment of impacts of using dedicated trains to transport spent nuclear fuel and high-level radioactive waste. Based on current information from the U.S. Department of Transportation and the Association of American Railroads, it is DOE's opinion that there is no clear advantage for using either dedicated trains or general freight service.

Section J.3.1.2 of the EIS lists studies of potential rail alignments from which DOE identified the five candidate rail corridors. In addition, that section discusses the screening approach for the five corridors and why DOE chose to analyze them. DOE assumed transportation of spent nuclear fuel and high-level radioactive waste would use existing highways and railroads except in Nevada, where a branch rail line would be needed for trains to travel from an existing railroad to a Yucca Mountain Repository. Other routes and corridors through Nevada, including Nellis Air Force Range, were considered in the selection of the routes analyzed (see Section J.3.1 and cited references of the EIS). Section J.3.1 provides the results of impact sensitivity studies performed for the various routes.

DOE did not consider alternatives such as those discussed in the comments, including special rail lines to circumvent cities, a new national rail line dedicated for shipment of spent nuclear fuel and high-level radioactive waste, or a monorail, because the potential impacts identified from rail and truck transportation using existing infrastructure would be small, cost of the suggested alternatives would be high, and new construction for these alternatives would increase impacts.

DOE could decide to use a dedicated train that carried only the material to be shipped to Yucca Mountain, or could elect to move the spent nuclear fuel and high-level radioactive waste in general freight. If the material was shipped as general freight, the position of the spent nuclear fuel or high-level radioactive waste car in the train would be regulated by 49 CFR 174.85. This regulation requires that railcars placarded "radioactive" must be separated from a locomotive, occupied caboose, or carload of undeveloped film by at least one nonplacarded car, and it may not be placed next to other placarded railcars of other hazard classes. Section J.2.3 of the EIS presents an assessment of impacts of using dedicated trains to transport spent nuclear fuel and high-level radioactive waste. Based on current information from the U.S. Department of Transportation and the Association of American Railroads, it is DOE's opinion that there is no clear advantage for using either dedicated trains or general freight service.

8.3.3 (24)
Comment - 9 comments summarized
DOE received both positive and negative comments on the potential for using barges to transport spent nuclear fuel and high-level radioactive waste. Included was a comment that argued large-scale use of barges would, or might, be preferred by states to land-only, cross-country transportation from generator sites to Yucca Mountain using railroads or trucks. This comment stated that barge transportation would reduce the risk of accidents and ground spillage of radioactive materials. The comment further stated that if barge transportation is the lowest risk mode of transport, it should be considered a feasible transport alternative. One commenter suggested that DOE should consider a shipping scenario in which barge transportation is maximized. Commenters addressed use of barges to transport spent nuclear fuel from nuclear powerplants along the East Coast (Atlantic Ocean) and Gulf of Mexico through the Panama Canal to a West Coast port such as San Diego, California. These commenters suggested shipments arriving in San Diego would be transferred to trucks or rail cars for delivery to Yucca Mountain.

Response
Transportation modes and scenarios analyzed in the EIS are based on DOE's assessment of what would be feasible and practical for delivering spent nuclear fuel from generator sites in the continental United States to a repository at Yucca Mountain, which is in the Nevada desert approximately 640 kilometers (400 miles) from the nearest seaport. In addition, prior analyses of transportation modes (rail, truck, and barge) provide substantial evidence that all modes of transportation that could be used would result in low impacts. These analyses include those presented in this EIS, the *Final Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel* (DIRS 101812-DOE 1996, all), and a report issued by the Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000, all).

Nevertheless, in response to public comments and as discussed in Section 2.3.3 of the EIS, DOE evaluated the potential for including a large-scale barge scenario. The purported advantage of large-scale use of barges was that it would reduce the amount of cross-country overland travel. However, DOE eliminated this barge scenario from further consideration in the EIS because it would be overly complex, requiring greater logistical complexity than either rail or legal-weight truck transportation; a much greater number of large rail casks than rail transportation; much greater cost than either rail or legal-weight truck transportation; long transportation distances potentially requiring the transit of the Panama Canal outside U.S. territorial waters; transportation on intercoastal and coastal waterways of the coastal states and on major rivers through and bordering states; extended transportation times;

intermodal transfer operations at ports and land transportation from a western port to Yucca Mountain. Section J.2.2 discusses the large-scale barge scenario.

Even though the large-scale barge scenario was eliminated from further consideration, the EIS does address the use of barges to transport spent nuclear fuel to nearby railheads from 17 commercial generator sites not served by a railroad. DOE considers this use of barge the maximum that would be operationally feasible and practical.

The shipping casks used to transport spent nuclear fuel and high-level radioactive waste would be massive and tough, with design features that complied with strict regulatory requirements that ensure the casks perform their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000, all). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

In addition, because spent nuclear fuel and high-level radioactive waste is in solid form, casks do not “leak” radioactive material as that term is commonly used, and this material cannot be “spilled.” Instead, a release of radioactive material would involve a release of spent nuclear fuel particles, gasses, volatile elements, and crud into the air.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts. In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. To ensure that the EIS analyses reflect the latest reasonably available information, DOE has either incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relied on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data.

8.3.3 (178)
Comment - 4 comments summarized
Commenters stated that even if DOE is unable to construct a branch rail line or use heavy-haul trucks to transport spent nuclear fuel and high-level radioactive waste in Nevada, it might still prefer to get casks to Nevada by rail. For this reason, commenters suggested the EIS should analyze transporting legal-weight truck casks from generator sites by rail to an intermodal transfer station in Nevada and then loading the casks onto legal-weight trucks for transport to Yucca Mountain.

Response
In response to public comments, DOE considered a truck cask-on-railcar scenario in which legal-weight truck casks would be shipped by rail from generator sites to Nevada and then loaded onto legal-weight trucks for transport to Yucca Mountain. The purported advantage of this scenario is that DOE could use rail transportation nationally but would not have to construct and operate a branch rail line or use heavy-haul trucks in Nevada. As discussed in Section 2.3.3 of the EIS, DOE determined that while this scenario would be feasible, it would not be practical and the scenario was eliminated from further consideration. The number of shipping casks and railcar shipments would be greater by a factor of 5 than for the mostly rail scenario and the additional cost would be more than $1 billion. In addition, the truck casks-on-railcar scenario would lead to the highest estimates of occupational health and public health and safety impacts (mostly coming from rail-traffic related fatalities.

Nevertheless, DOE assessed the sensitivity of transportation impacts to assumptions related to transportation scenarios (see Section J.2.1 of the EIS). Under this scenario, because all shipments (except shipments of naval spent nuclear fuel) would use legal-weight truck casks, which would house less fuel assemblies that rail casks, the number of railcar shipments would be about 53,000 over the 24 years of the Proposed Action. This is the same as the number of legal-weight truck plus naval spent nuclear fuel shipments in the mostly legal-weight truck scenario.

DOE estimated impacts of this variation of the mostly rail transportation scenario by scaling from the impacts estimated for the mostly rail scenario. The analysis used the ratio of the number of railcars that would be shipped to the number of railcar shipments estimated for the mostly rail scenario and assumed each shipment would include an escort car and five railcars carrying legal-weight truck casks. Compared to the mostly rail scenario, radiological impacts from truck casks on railcars would increase by approximately a factor of 5 and the nonradiological impacts would increase by approximately a factor of 3. The estimated number of public incident-free latent cancer fatalities would be approximately 3, and the estimated number of traffic fatalities would be 8. The total of these estimates, 11, is about 1.5 times the DOE revised estimate of 7 fatalities (2.5 latent cancer fatalities plus 4.5 traffic fatalities) for the legal-weight truck scenario.

8.3.3 (5690)
Comment - EIS001887 / 0303
Also in the Summary document (p. S-53) and later in Section 6, DOE fails to address the potential shipping alternative of repackaging spent fuel and HLW [high-level radioactive waste] at a potential inter-modal transfer site. Under the DOE heavy-haul scenario, HLW and SNF [spent nuclear fuel] coming to an intermodal facility by rail must be shipped to the repository via heavy-haul trucks and cannot be repackaged or reconfigured for legal-weight truck transport. It is possible that, given the length, geography, and impacts associated with heavy-haul transportation on the scale required to implement the Proposed Action, such shipments may prove to be impossible. In such an event, intermodal alternatives to heavy-haul should be evaluated.

Response
In response to public comments, DOE considered a truck Cask-on-railcar scenario in which legal-weight truck casts would be shipped by rail from generator sites to Nevada and then loaded onto legal-weight trucks for transportation to Yucca Mountain. The purported advantage of this scenario is that DOE could use rail transportation nationally but would not have to construct and operate a branch rail line or use heavy-haul trucks in Nevada. As discussed in Section 2.3.3 of the EIS, DOE determined that while this scenario would be feasible, it would not be practical and the scenario was eliminated from further consideration. The number of shipping casks and railcar shipments would be greater by a factor of 5 than for the mostly rail scenario and the additional cost to the Program would be more than $1 billion. In addition, the truck Casks-on-railcar scenario would lead to the highest estimates of occupational health and public health and safety impacts (mostly coming from rail-traffic related fatalities).

Nonetheless, DOE assessed the sensitivity of transportation impacts to assumptions related to transportation scenarios (see Section J.2.1 of the EIS). Under this scenario, because all shipments (except shipments of naval spent nuclear fuel) would use legal-weight truck casks, which would house less fuel assemblies that rail casks, the number of railcar shipments would be about 53,000 over the 24 years of the Proposed Action. This is the same as the number of legal-weight truck plus naval spent nuclear fuel shipments in the mostly legal-weight truck scenario.

8.3.3 (7822)
Comment - EIS001653 / 0019
Pg. 2-43 1st Par. Can the Navy ship by truck? If not, why not?

Response
Section 2.1.3.2.2 of the EIS states that "The Navy prepared an EIS (USN 1996, all) and issued two Records of Decision (62 *FR* 1095, January 8, 1997; 62 *FR* 23770, May 1, 1997) on its spent nuclear fuel." This EIS, *Final Environmental Impact Statement for a Container System for the Management of Naval Spent Nuclear Fuel* (DIRS 101941-USN 1996), evaluated a range of alternatives that would provide a system of containers for management of naval spent nuclear fuel following examination at the Idaho National Engineering and Environmental Laboratory. Section 3.0 of the Navy EIS describes and compares the alternatives evaluated, which includes most types of spent nuclear fuel container systems either in use or proposed for use.

Section 3.7 of the Navy EIS, Alternatives Eliminated from Detailed Analysis, contains the results of the evaluation performed for alternate methods of transporting naval spent nuclear fuel. Section 3.7 states:

"The use of trucks as the principal means for transporting naval spent nuclear fuel was also eliminated from detailed analysis in this EIS for other reasons. Rail transport permits the shipment of a greater number of spent fuel assemblies in each shipment than truck transport, resulting in fewer shipments. Those container systems which can be physically accommodated by truck would require many more shipments, with resultant increased environmental impacts. Preliminary estimates show that at least five times the number of shipments would be required for transport by truck as compared to rail. Since each container must be designed to the same regulatory requirements (10 CFR Part 71), each container would be expected to produce about the same radiological dose rate on the exterior surface of the container. However, considering the population distribution and proximity of people along and on the truck route, each truck shipment results in about five times greater radiation exposure than a rail shipment. Thus the five times greater number of shipments required for truck rather than rail transportation would be expected to result in about twenty-five times greater radiological dose to the public and workers. Transportation accident rates in general commerce are higher per truck mile than per rail mile (DIRS 101920-Saricks and Kvitek 1994). While the accident rate is not large for either rail or truck, the number of accidents could be about five times larger for truck shipments than for rail due to the greater number of shipments.

"In view of the above, the Naval Nuclear Propulsion Program has eliminated from consideration a shift to legal-weight truck transportation as a reasonable alternative to be evaluated in detail in this EIS for naval spent nuclear fuel. The ultimate decision on transportation options (legal-weight truck, some combination of legal-weight truck and rail or rail/heavy-haul truck) would be made by DOE on the basis of analyses to be performed in the repository EIS" (DIRS 101941-USN 1996).

The Navy has experience in the use of heavy-haul truck transportation for shipments of spent nuclear fuel in containers of similar or greater height and weight compared to those intended for use in the shipments to the repository. Although naval spent nuclear fuel is transported to the Idaho National Engineering and Environmental Laboratory by rail, naval spent nuclear fuel in shipping containers is moved for short distances at the point of origin at two naval prototype sites (Windsor and West Milton) by heavy-haul truck to a nearby rail terminal, where the containers are loaded onto railcars for the remainder of the journey to the Idaho National Engineering and Environmental Laboratory.

Heavy-haul truck movement of the naval spent nuclear fuel canisters inside transportation casks over local roadways in Nevada is feasible because the loaded containers, with an intermodal skid, would weigh about 140 metric tons (150 tons) and measure less than 3 meters (10 feet) in diameter and 7.6 meters (25 feet) in length. The length and width do not present unusual difficulties, but the weight would require a trailer with 13 to 15 axles and would require attention to bridge weight limits. Heavy-haul trucks with the capacity to handle such loads are typically capable of sustained highway speeds of 40 to 56 kilometers (25 to 35 miles) per hour.

8.3.3 (11299)
Comment - EIS001814 / 0028
DEIS Page 2-72
DOE eliminated the development of a new road for heavy-haul trucks from further detailed evaluation because the construction of a new branch rail line would be only slightly more expensive and transportation by rail would be safer (no intermodal transfers) and more efficient (TRW 1996, page 6-7).

The analysis cited is based on the constraints for grade and curvature used for heavy-haul vehicles designed for highway use. DOE did not consider the feasibility of adapting trucks designed for heavy-haul in mining activities to the transport of spent fuel casks. These vehicles have the advantage of being able to handle extremely heavy loads (up to 400,000 tons) without the constraints on grade and degree of curvature required for vehicles designed for highway transport. Allowing significantly increased grades, sharper curves, and different surfacing materials (e.g. gravel) could significantly reduce the cost of constructing dedicated heavy-haul roads.

Response
While the use of off-road heavy-haul transporters would allow a new road alignment within the proposed rail corridors to be designed at steeper road grades and tighter curvatures, the cost savings associated with the reduction

in earthwork is more than offset by the costs associated with constructing intermodal transfer stations and purchasing, operating, and maintaining a fleet of one-of-a-kind trucks.

The heavy-haul truck cost estimate in *Nevada Transportation Engineering File Table of Contents/Summary* (DIRS 154675-Ahmer 1998), which includes the "Cost Estimate for Heavy Haul Truck Transport Design" (5/98), shows, for example, that the estimated annual cost of operating and maintaining a truck fleet is $12 million on average for the Caliente heavy-haul truck route. The annual rail operating and maintenance costs for the Caliente Corridor are approximately $3 million on average, by comparison. Use of off-road trucks over a newly constructed road combines the high initial construction costs associated with rail with the high operating and maintenance costs associated with heavy-haul truck transportation.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.3.3 (11810)
Comment - EIS001622 / 0066
The massive scale of radioactive waste shipments to the proposed repository will be unprecedented. Total annual shipments of these wastes are projected to increase within the next decade from the current 15 to 25 rail shipments per year to between 400 to 600 rail shipments per year (Federal Railroad Administration, June 1998). The State of Nevada's preliminary estimates of potential legal-weight truck shipments to Yucca Mountain through California and Nevada show that an estimated 74,000 truck shipments, about three-fourths of the total, could traverse southern California under DOE's mostly truck scenario. This could be an average of five truck shipments through California every day for 39 years. Under a mixed truck and rail scenario, California could receive an average of two truck shipments per day and 4-5 rail shipments per week for 39 years. The State of Nevada estimates that under a "best case" scenario that assumes the use of larger rail shipping containers, there would be more than 26,000 truck shipments and 9,800 rail shipments through California. This represents a large increase in both scale and complexity of operations compared to past shipments.

Likely routes in California would impact Sacramento, the Los Angeles area, San Luis Obispo, Santa Barbara, San Bernardino, Fresno, Bakersfield, Barstow, and smaller cities and communities. Under a consolidated southern routing strategy, Nevada has stated that the likely east-west highway corridors would be I-44 from Missouri to Oklahoma, I-40 from Tennessee to California, and I-15 from California to Nevada. The most likely east-west rail corridor would be the Santa Fe-Burlington Northern line from Kansas City to San Bernardino, connecting with the Union Pacific from San Bernardino to Nevada.

Response
In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-32 of the EIS for the representative California routes). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-74 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would enter Nevada through southern California on Interstate-15 in the mostly legal-weight truck scenario. The table also lists the estimated number of rail shipment through California in the mostly rail scenario for each of the candidate Nevada rail corridors and heavy-haul truck routes. The shipment numbers are for the proposed action, which has a total emplacement of 70,000 MTHM, and does not include the values for the Inventory Modules 1 and 2, which address increased inventories, currently not allowed by the NWPA. The shipment numbers included by the commenter are for the currently unallowable Module 2 inventory. See Table J-1 for estimated numbers of shipments for the various inventory and national transportation analysis combinations.

If the Yucca Mountain site was approved, the total number of truck shipments through California was estimated to be 6,867 over 24 years, which amounts to less than one truck shipment per day. For Inventory Modules 1 and 2, if it were assumed that the number of shipments through California increases in proportion to the increase in the total number of shipments, the number of shipments though California would be about 14,000 shipments over 38 years, which is approximately 1 shipment per day.

The estimated numbers of shipments entering Nevada from California under the mostly rail scenario are less than the mostly legal-weight truck scenario. According to Table J-74, there would be no truck shipments through

California and, the number of rail shipments would range from 512 to 1,464, depending on the mode (rail or heavy-haul truck) and corresponding corridor/route selected in Nevada. At most, 1,464 rail shipments would be made on the Jean heavy-haul truck route over 24 years. This equates to about 1 rail shipment every 6 days. However, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use. Before such shipments began, states and tribes could designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified.

Nonetheless, the representative highway routes identified for the EIS analysis conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, developed for transportation of Highway Route Controlled Quantities of Radioactive Materials, require such shipments to be on preferred routes selected to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or an alternate route designated by a state or tribal routing agency. Alternate routes could be designated by states or tribes under Department of Transportation regulations (49 CFR 397.103) that require consideration of the overall risk to the public and prior consultation with local jurisdictions and other states and tribes. Federal regulations do not restrict the routing of rail shipments. However, for the analysis, as discussed in Section J.1.1.3 of the EIS, DOE assumed routes for rail shipments that would provide expeditious travel and the minimum number of interchanges between railroads.

It is not possible at this time to determine the validity of the so-called “consolidated southern routing strategy.” At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. Section M.3 of the EIS contains more detail on the proposed role of the Regional Servicing Contractor. As discussed in Section M.3.2.1.2, the Regional Servicing Contractors would submit route plans to DOE for approval prior to their submittal to the Nuclear Regulatory Commission for approval. The route plans would most likely include more than one potential routing option for shipments from each waste generator site. These plans would be developed based on consultations with shippers, Federal, state, tribal, and local authorities, and application of U.S. Department of Transportation and Nuclear Regulatory Commission regulations. Among these, there could be southern and northern highway options. However, the actual route taken by a specific shipment would consider additional criteria as part of the shipment dispatching process, such as potential adverse weather conditions and construction delays. Therefore, it is not possible to predict whether the Regional Servicing Contractors would dispatch a higher volume of shipments to the southern east-west routes than more northerly east-west routes. Although one would expect the southern highway corridors to be less susceptible to adverse weather conditions than a more northern corridor, especially in winter months, the southern corridor would involve longer distances and longer transit times from the waste generator sites in the north-central and northeastern United States. The Regional Servicing Contractors would be tasked to develop procedures for dispatching the shipments as well as procedures for use by drivers and crews in making determinations on adverse weather and road condition operations. Section M.3.2.1.4 provides a discussion of the protocols and procedures that would be implemented by a Regional Servicing Contractor and its subcontractors under adverse weather or road conditions.

8.4 Transportation Casks

8.4 (25)
Comment - 53 comments summarized
Many commenters stated that full-scale field testing of shipping casks should be required and undertaken by the Department. Full-scale tests should reflect expected conditions during transport and not conditions limited by regulations of the Nuclear Regulatory Commission. Examples of conditions of transport include testing with spent nuclear fuel rods, diesel and gasoline fires in excess of 30 minutes and high temperatures, high-speed traffic accidents, train accidents and derailments, accidents in mountainous terrain, immersion in water, and sabotage with penetrating weapons. Some commenters stated that computer simulations should not be relied on, particularly since such modeling is inadequate for testing of nuclear weapons. If computer modeling is used, commenters said that modeling in excess of that required by the regulations should be conducted to determine failure thresholds.

Commenters questioned the reliability of testing on existing casks (use of quarter-scale models or only computer modeling), noting that only a very few casks are in use in the United States and that the recently licensed GA4/9 cask has not yet been manufactured. The EIS should clarify whether new or existing casks or preliminary cask designs were considered in the analysis.

Response
The NWPA requires that DOE use casks certified by the Nuclear Regulatory Commission when transporting spent nuclear fuel and high-level radioactive waste to a repository. The Commission certifies that a cask meets the requirements of 10 CFR Part 71, which prescribes radiological performance standards for casks subjected to specific test conditions. These test conditions represent the kinds of forces that a cask would encounter in a severe transportation accident. A cask's ability to survive the tests prescribed by 10 CFR Part 71 can be demonstrated in several ways. These options include component, scale-model, and full-scale tests to demonstrate or confirm the performance of the casks. As part of its detailed technical review, the Commission decides what level of physical testing or analysis is appropriate and necessary for each cask design. If the applicant for a certificate fails to demonstrate compliance with the regulations, the Nuclear Regulatory Commission would not issue a certificate. Therefore, if full-scale testing was necessary, it would be done before the Commission issued a certificate of compliance. For a more complete discussion of cask testing, see Section M.4, of the EIS. DOE has the option of evaluating the need for a full-scale cask test demonstration in the future.

At this time, the Nuclear Regulatory Commission does not require that shipping casks demonstrate their ability to withstand sabotage events as part of the certification process. The Nuclear Regulatory Commission has developed a set of rules specifically aimed at protecting the public from harm that could result from sabotage of spent nuclear fuel casks. Known as physical protection and safeguards regulations (10 CFR 73.37), these security rules are distinguished from other regulations that deal with issues of safety affecting the environment and public health. The objectives of the physical protection and safeguards regulation are to minimize the possibility of sabotage and facilitate recovery of spent nuclear fuel shipments that could come under control of unauthorized persons. The cask safety features that provide containment, shielding, and thermal protection also provide protection against sabotage. The casks would be massive. The spent nuclear fuel in a cask would typically be only about 10 percent of the gross weight; the remaining 90 percent would be shielding and structure.

It is not possible to predict whether sabotage events would occur, and if they did the nature of such events, nevertheless, DOE examined various accidents, including an aircraft crash into a transportation cask. The consequences of both the maximum reasonably foreseeable accident and the aircraft crash are presented in the EIS for the mostly truck and mostly rail transportation scenarios and can provide an approximation of the types of consequences that could occur from a sabotage event. In addition, DOE analyzed the potential consequences of sabotage against a truck or rail cask (see Section 6.2.4.2.3 of the EIS). The results of this analysis indicate that the risk of the maximally exposed individual incurring a fatal cancer would increase from approximately 23 percent (the current risk of incurring a fatal cancer from all other causes) to about 29 percent. The same event could cause 48 latent cancer fatalities in an assumed population of a large urban area.

Because of the terrorist attack of September 11, 2001, the Department and other agencies are reexamining the protections built into their physical security and safeguards systems for transportation shipments. As dictated by results of this reexamination, DOE would modify its methods and systems as appropriate.

For the EIS, the analysis assumed that the radiation emitted from casks would be within regulatory limits. To determine the number of shipments to be used in the analyses, DOE used the CALVIN computer program. The CALVIN program estimated the number of shipments by using a collection of different kinds of rail and truck shipping casks, including currently existing or designed casks, and matching these to the characteristics of the fuel to be shipped by each generator and the cask handling capabilities of the generator's site. (See Table J-3 of the EIS.)

Comment - 37 comments summarized
Commenters expressed concerns that the shipping casks analyzed in the EIS were not yet designed, tested or fabricated, and therefore the environmental analyses were incomplete or erroneous. Design criteria and materials requirements are unknown, and manufacturing equipment is unavailable or has not been developed. Other commenters addressed the inability to preclude human error in the manufacturing process, and the lack of known

and experienced cask manufacturers and experienced workers. Others questioned whether it would be possible to manufacture casks that would be “flawless” (not leak) and could withstand extreme temperature changes. The elimination of the multi-purpose Canister program would expose workers to radiation during the transfer at the reactors, during shipping, and at the repository. Still others said that all manufacturing standards and requirements must be met; that manufacturing oversight is required; and that DOE should make a financial commitment for further research. Commenters provided examples of the problems with existing storage/transportation casks, and casks that have not been certified, requesting that DOE test and publish data on any proposed casks and seek public comment. Some commenters believe that shipping casks can safely transport spent nuclear fuel given the past safety record of the industry.

Response

The shipping casks DOE would use to transport these spent nuclear fuel and high-level radioactive waste would be massive and tough, with design features that complied with strict regulatory requirements that ensure the casks would perform their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

Because shipping casks are passive devices, human actions are not necessary to maintain the safety functions of a cask once it has been properly loaded and prepared for shipment. Human factors could affect cask safety in the design, fabrication, maintenance, and preparation for use. Effective practices promoted by a safety culture, strong regulatory oversight, quality assurance, and industry and regulatory standards provide a high degree of assurance that shipping casks meet the performance requirements of the regulations of the Nuclear Regulatory Commission and U.S. Department of Transportation. In addition, through continued commitment of resources to research and development, and development of consensus codes and standards, the Federal Government and private industry have contributed to ongoing improvement of cask safety.

At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which shipping casks would be used. However, many casks are currently being built in the United States for the dual purposes of storage and transportation. As a consequence, fabricators are experienced in cask construction; other fabricators are familiar with construction of nuclear systems and components. DOE is confident that skilled workers and their companies are capable of doing the quality work expected for construction of these casks. As part of the certification of a cask design, the Nuclear Regulatory Commission requires a quality assurance plan that covers all processes and procedures for manufacturing the casks. This quality assurance plan is made part of the contract for the manufacture of casks. The cask owner and the Nuclear Regulatory Commission conduct inspections and audits of the manufacturer’s operations and implementation of their quality assurance plan and procedures to ensure that casks are built to meet certification requirements.

Transportation activities conducted by DOE would use casks certified by the Nuclear Regulatory Commission. The regulations, which must be met prior to certification, include radiological performance standards that ensure public health and safety. These standards are established and well known. Although DOE would use casks designed by others, the designs and applicable quality assurance activities would have to be certified by the Nuclear Regulatory Commission.

Although human error cannot be totally avoided, modern cask design practices, design certification, and compliance with approved quality assurance programs for all aspects of DOE’s transportation activities would limit the occurrence of human factor-based errors and mitigate their effects, should they occur. For example, in cask manufacturing the Nuclear Regulatory Commission regulations require a comprehensive quality assurance program in which measures must be established to ensure that special processes, including welding, heat treating, and nondestructive testing, are controlled and accomplished by qualified personnel using qualified procedures in accordance with applicable codes, standards, specifications, criteria, and other special requirements (see 10 CFR Part 71 Subparts D and H).

Transportation accident data (truck and train accident rates) provided by states and other government agencies for use in the analyses incorporates human error. These rates include human error as causes of the accidents as well as equipment failures that could be caused by human errors in manufacturing. Hence, human error was incorporated into the estimates of impacts of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Additional detail on human error and accident rates is provided in Section J.1.4.2.2 of the EIS.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment Response Document for more information.

8.4 (159)
Comment - 3 comments summarized
Several commenters expressed concerns about gas generation and pressure buildup in spent fuel casks and the potential for venting and hydrogen explosion. One commenter expressed concern about undetected defects in shipping casks.

Response
As discussed in Section 2.1.3.4 of the EIS, the casks that DOE would use to ship spent nuclear fuel and high-level radioactive waste would be certified by the Nuclear Regulatory Commission. Commission regulations at 10 CFR 71.43 do not allow casks to be vented during transportation. In addition, during transportation the containment cavities of the casks, which would hold the spent nuclear fuel, would not contain significant quantities of water or any other material that could be a significant source of explosive or pressurizing gas from radiolytic decomposition or chemical reaction. Nuclear Regulatory Commission and U.S. Department of Transportation regulations, and DOE Orders, as appropriate, would be in effect for all shipments. These regulations and Orders, which include quality assurance programs, would provide the level of safety oversight and monitoring necessary to ensure every cask was properly prepared for shipment.

Casks are robust structures composed of well Characterized materials that are assembled to form relatively simple and massive structures that are within the scope of current technology. Manufacture of the cask is accomplished using many standardized processes and the resulting cask's quality is ensured through application of the Nuclear Regulatory Commission's comprehensive quality assurance program, which covers fabrication of casks and requires that measures be established to ensure that special processes, including welding, heat treating, and nondestructive testing, are controlled and accomplished by qualified personnel using qualified procedures in accordance with applicable codes, standards, specifications, criteria, and other special requirements (see 10 CFR Part 71, Subparts D and H). The quality assurance program picks up systematic errors in the product and shuts down production and use of the casks if a problem is found. The Commission's oversight is independent of DOE's schedule and funding and can be expected to ensure that quality casks would be produced.

8.4 (199)
Comment - 6 comments summarized
Commenters said that the EIS should address additional variations in shipping casks, packaging options, materials and designs for waste packages, and multipurpose canisters. The EIS should also address the various shipping casks to be used and the spent nuclear fuel and high-level radioactive waste contents that will be shipped in each. Commenters suggested the EIS should assume that transport-only casks would be used and that only 68-metric-ton (75-ton), and not 113-metric-ton (125-ton) multipurpose casks, would be used. One commenter wanted the description of the packaging options to indicate that as-low-as-reasonably-achievable principles would allow some radiation to be emitted from packages.

Response
Because all casks must meet the same Nuclear Regulatory Commission and U.S. Department of Transportation safety performance standards for routine radiological exposures and behavior in severe accidents, the principal differences in casks for purposes of risk assessment are their weight, heat load capacity, and carrying capacity. These cask characteristics directly affect the number of shipments and type of transport vehicle.

Section 2.1.1.1 of the EIS discusses the range of packaging scenarios DOE is currently considering for packaging spent nuclear fuel and high-level radioactive waste for shipment and disposal. Section 5.2.2 discusses the design of disposal containers and waste packages being considered. Table J-3 lists and briefly describes 24 different types of shipping casks, including dual-purpose casks, and their projected contents assumed for the purpose of analyzing the potential impacts of shipping commercial spent nuclear fuel. Although other assumptions regarding cask sizes and contents are possible, DOE concluded that the assumptions used in the EIS are appropriate for estimating impacts of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Section J.1.2.1.2 discusses the assumptions used in the EIS analysis for numbers of canisters of DOE spent nuclear fuel and high-level radioactive waste that would be transported in shipping casks.

Because the design and performance of shipping casks are strictly regulated and must be certified before use, DOE believes that the design details of casks that would not be used for many years are not needed to provide a reasonable estimate of the potential impacts in transporting spent nuclear fuel and high-level radioactive waste. Section 2.1.1.1 of the EIS explains the basis for DOE's selection of three packaging options.

DOE did not include a multipurpose canister option for legal-weight truck shipments because the quantity of spent nuclear fuel transported in a legal-weight truck cask is much less than the quantity that would be loaded into a disposal container. In addition, commercial storage casks that use multipurpose canisters for storage and transportation have capacities much greater than legal-weight truck casks. Designs of disposal containers, waste packages, dual-purpose and multipurpose canisters, other components, and operations of a geologic repository would implement the principle of reducing exposure to workers to levels that are as low as reasonably achievable.

8.4 (226)
Comment - 13 comments summarized
Commenters had general concerns about the shipment of spent nuclear fuel and high-level radioactive waste in casks. Commenters stated that casks are not safe and examples were cited of casks that had been broken in transit and of casks that had leaked. Others stated the casks had been inadequately tested and that every foreseeable risk should be eliminated so that there would be no danger of exposure to radioactive materials. Another commenter stated that spent nuclear fuel and high-level radioactive waste shipments are strictly regulated by the U.S. Department of Transportation and the Nuclear Regulatory Commission. This commenter noted that there have been nearly 3,000 shipments of spent nuclear fuel over the past 30 years, over which time there has never been a release of nuclear material due to a transportation accident. Another commenter believed that just because a cask had Nuclear Regulatory Commission certification, that was not a guarantee of good quality and cited examples from the nuclear powerplant located in the commenter's community. One commenter stated that the assumptions made in the Draft EIS related to cask permeability and potential for breach were very conservative and might have not been well thought through.

Response
In response to public comments, DOE has added Appendix M to the EIS, which presents information on cask safety (see Section M.4). DOE would be required to follow Nuclear Regulatory Commission and U.S. Department of Transportation regulations and use Commission Certified casks when transporting spent nuclear fuel and high-level radioactive waste to a repository. DOE is confident that by implementing these regulations and using Commission Certified casks, transportation would be carried out in a safe manner. Of the thousands of shipments completed over the last 30 years, none has resulted in an injury through release of radioactive material.

Shipping casks are robust structures composed of well-characterized materials that are assembled to form relatively simple and massive structures that are within the scope of current technology. Manufacture of the cask would be accomplished using many standardized processes and the resulting cask's quality would be assured through application of the Nuclear Regulatory Commission comprehensive quality assurance program. The program covers fabrication of casks and requires that measures be established to ensure that special processes, including welding, heat treating, and nondestructive testing, are controlled and accomplished by qualified personnel using qualified procedures in accordance with applicable codes, standards, specifications, criteria, and other special requirements (see 10 CFR Part 71, Subparts D and H).

Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel and high-level radioactive wastefully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

In addition, because spent nuclear fuel and high-level radioactive waste is in solid form, casks do not "leak" radioactive material as that term is commonly used. Instead, a release of radioactive material would involve a release of spent nuclear fuel particles, volatile elements, crud, and fission product gasses into the air.

8.4 (640)
Comment - EIS000141 / 0004
The DEIS also fails to consider unique local conditions along the potential truck route that could cause unacceptable safety and security risks for truck shipments using General Atomics GA-4/9 casks. Primarily a rural two-land highway with numerous steep grades and sharp curves, the route traverses high mountain passes subject to severe winter storms. Long segments (up to 60 miles) have no safe parking areas, few refueling facilities, and limited local emergency response capabilities. The Draft report assumes that almost all truck shipments will be made in the new GA-4/9 casks. The weight of the loaded GA-4/9 cask requires that it be used in conjunction with a specially designed trailer, a lower weight, cab-over-engine tractor, and a single fuel tank. DOE has failed to demonstrate that the GA-4/9 system is appropriately designed for a decades-long, nationwide shipping campaign to Yucca Mountain.

Response
The casks that DOE would use would be designed, manufactured, and operated in accordance with Nuclear Regulatory Commission requirements. These requirements apply to any cask and for any road or rail conditions, including those described in the comment. DOE is not limited to the GA4/9 casks for truck shipments. It could use any Commission-certified cask. The GA4/9 is attractive because of its advanced design and high capacity. The tractor-trailer designed for use with the cask was tested on a specially designed track. The transporter performed adequately in the test, which simulated about 400,000 kilometers (250,000 miles) of highway travel. Planning for shipments would consider route hazards, weather, logistics, and emergency response. For more information see Appendix M of the EIS.

8.4 (840)
Comment - EIS000173 / 0006
There is a problem of preventing criticality in a shipping cask, such as occurred in Japan last month due to an error made at a nuclear powerplant that injured many people, some critically.

Response
Preventing criticality in a shipping cask, as well as in any other system, structure, or component that handles spent nuclear fuel is a fundamental objective. The recent criticality accident that occurred in Japan did not involve spent nuclear fuel handling. The accident occurred at a processing facility. It was studied in depth by the Japanese government and international experts. The causes of the accident were multiple, but stemmed from inadequate training of operators and failure to follow approved procedures. DOE would ensure adequate training of its Federal and contractor staff. The Department would monitor all spent nuclear fuel handling activities at its facilities and ensure compliance with all safety requirements. The Nuclear Regulatory Commission standards for radioactive material shipping casks are found in 10 CFR Part 71. This ruling places limits on the amount of fissile material that can be loaded in a cask and stipulates that loaded casks remain subcritical even under conditions most favorable to

criticality. The criticality control systems for the cask are designed to maintain subcriticality for the most reactive contents permitted in a cask.

8.4 (1061)
Comment - EIS000289 / 0007
I can tell you that Radioactive Waste Management Associates in New York have presented me with facts about your casks that you have not. They are only built to withstand impact speeds of up to 30 miles per hour; and you admit to the fact they can only withstand temperatures of 1,400°, but diesel fuel burns at around 1,800°. And there was a famous fire that resulted from a truck accident in a tunnel that attained this temperature.

Response
The U.S. Nuclear Regulatory Commission requirements for transportation casks are described in 10 CFR Part 71. The requirements establish radiological performance standards for containment, shielding, and subcriticality that must be satisfied for cask designs when subjected to certain tests that represent the forces expected from normal and accident conditions of transportation. Included in the accident tests are a 9-meter (30-foot) free fall onto an essentially unyielding surface and exposure to a fully engulfing hydrocarbon fuel/air fire with an average temperature of 870°C (1,475°F). The 9-meter freefall does result in about a 48-kilometer (30-mile)-per-hour terminal velocity. However, hitting an unyielding target is significantly more severe than a 48-kilometer-per-hour traffic accident between vehicles, or between a vehicle and an ordinary stationary object. Similarly, an average temperature specification for a fire test adequately describes the range temperatures of visible flames of a hydrocarbon-air fire, which may range from 316°C to 1,112°C (600°F to 2,200°F). Although these accident conditions are called tests, analysis of the cask design is often sufficient to demonstrate compliance with regulatory performance requirements. Appendix M of the EIS provides additional information on cask testing and safety.

8.4 (1144)
Comment - EIS000087 / 0001
The truck drivers that transport this stuff have a limited amount of time they can be in front of these containers. Why? Because the containers leak. They do not provide containment.

If they were perfect, the truck driver would be able to be with his truck an unlimited amount of time each day. Therefore, we have a leaky container.

Response
Although the casks emit low-level radiation, they do not leak or release radioactive material, as implied in the comment. Spent nuclear fuel does emit gamma radiation and neutrons, which are largely absorbed by the massive cask. The shielding provided by the cask and distance reduces radiation levels near the cask to levels permitted by the Nuclear Regulatory Commission and the U.S. Department of Transportation. In accordance with those agency regulations, the dose rate around the cask can be no higher than 10 millirem per hour at 2 meters (6.6 feet) from the edge of the transport vehicle. The total dose received by all persons near the cask including crew and members of the public were estimated and are shown in Chapter 6 and Appendix J of the EIS. The maximum dose rate in the crew area permitted by regulation is 2 millirem per hour. Total annual radiation exposure to truck crews are limited by regulation.

8.4 (1575)
Comment - EIS000516 / 0003
Many activities were taken into account such as fire, puncture, accidents. But my question is, how hot of a fire? What kinds of lengths of heat burning would cause the casks to puncture? What will happen when the cask is immersed when combined with other possible factors such as falling off of a highway area into a river? What will happen when that's combined with high speeds with possibility of a fire?

Response
The Nuclear Regulatory Commission requirements establish radiological performance standards for containment, shielding, and sub Criticality that must be satisfied for cask designs when subjected to certain tests that represent the forces expected from normal and accident conditions of transportation (10 CFR Part 71). The regulatory tests for accident conditions are conducted sequentially. The sequence of tests is intended to represent the events expected in an accident (for example, impact, puncture, and fire). Although these accident conditions are called tests, analysis

of the cask design is often sufficient to demonstrate compliance with regulatory performance requirements. Appendix M of the EIS provides additional information on cask testing and safety.

8.4 (2458)

Comment - EIS000679 / 0004

Point number three: We suggested in the past they develop a variety of rail casks instead of the original. DOE was to make every reactor in the country use one big cask that half of them couldn't handle, this kind of the papa bear, mama bear, baby bear approach to cask design. Again they actually seemed to have listened to what they said, but there's so little detail in the Draft EIS that we can't tell what their small, medium, and large rail casks are all about.

Response

Because the specific casks that would be used for truck and rail shipments of spent nuclear fuel and high-level radioactive waste have not been designated, the EIS addresses the performance of generic cask designs in estimating transportation impacts. The important factors needed for this impact assessment are cask performance under normal and accident transportation conditions and cask capacity. Any cask DOE used would have to be certified by the Nuclear Regulatory Commission.

8.4 (2757)

Comment - EIS000859 / 0002

What if the canisters holding this material begin to leak? I know that an environmental impact study is being conducted; however, this study is assuming that these canisters are 100% safe. How can we know they are safe since we've never really used these casks for centuries at a time? I also know that the study is sponsored or directed by the same Department of Energy that is making the proposal. A study cannot prove that they are safe for a long period of time.

In the canister study, the tests conducted for a thirty foot free-fall seem hardly adequate. Trains and trucks often travel on bridges and overpasses, hills and mountains that are hundreds of feet high. What then? This nuclear waste will be coming from everywhere in the country, in some cases over 3000 miles. The risk is by far too great.

Response

Section 2.1.3.4 of the EIS discusses shipping cask manufacturing, maintenance, and disposal. For transportation, the reusable cask, not the spent nuclear fuel canister, provides containment. These casks are designed for service lives of 25 years or longer. During their service lives casks are continually monitored and maintained to ensure their performance level is adequate to protect public health and safety. Although the likelihood and consequences of releases of radioactive material from spent nuclear fuel casks are small, such risks and impacts are addressed in Section 6.2.4.2. The 9.1-meter (30-foot) freefall might seem inadequate when compared to the heights of some bridges and overpasses that a cask could encounter. However, hitting an unyielding surface is significantly more severe than hitting water, sand, hard soil, and even rock surfaces that could be encountered by a cask if such a drop occurred. Events were addressed in the EIS in determining that the risk of transporting spent nuclear fuel is low. Additional information about cask testing and safety is provided in Appendix M of the EIS.

8.4 (2787)

Comment - EIS000880 / 0004

How will DOE bound the number of shipments required to move waste from reactors to Yucca Mountain? Does the EIS assume that new, large rail and truck casks will be available and are these new casks realistic given the costs involved and the fact that DOE is now prohibited from engaging in cask design and production activities?

Response

As discussed in Sections 6.2.1 and 6.2.3 of the EIS, DOE considered a mostly truck and mostly rail scenario for the EIS. DOE factored casks now under development by private sector vendors into its analyses. As discussed in Section J.1.2.1, combining these modal assumptions with the amount of spent nuclear fuel to be shipped and the capacities of the truck and rail casks provides a good estimate of the numbers of shipments expected for the two scenarios. DOE believes that the mostly rail case, in which more than 95 percent of the spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. Although DOE is no longer developing spent nuclear fuel casks, the private sector is. DOE plans to use these vendor developed, Nuclear Regulatory Commission Certified casks for its transportation activities.

8.4 (5205)

Comment - EIS001443 / 0029

It is recognized that the Nuclear Regulatory Commission has recently initiated a new program of cask testing which proposes to subject transportation cask prototypes to an expanded range of physical tests. Since the nature and, of course, results these tests are at present unknown and cask options cannot be evaluated via the NEPA [National Environmental Policy Act] process at this time, the current Yucca Mountain DEIS cannot be used as a base document from which to tier off a NEPA evaluation of possible cask designs. Further discussion of cask designs at this time is therefore unwarranted.

Response

DOE believes that the comment refers to the Package Performance Study (PPS), which the Nuclear Regulatory Commission (NRC) began at the end of 1999. This study will be similar to the Modal Study conducted for the NRC by Lawrence Livermore National Laboratory. Both studies address the performance of NRC-approved casks for severe "real-world" accidents. Accident events and situations considered in the PPS might result in tests and analyses of tests that are different from regulatory test conditions. This would be consistent with the scope of the PPS and would not suggest major changes to the current NRC transportation regulations in 10 CFR Part 71. Information on these studies is on the Sandia National Laboratories Internet site (*http://www.ttd.sandia.gov/nrc/modal.htm*).

The Nuclear Regulatory Commission revises its regulations periodically. The most recent revision in 1996 reflected changes in the international transportation regulations developed by the International Atomic Energy Agency that serve as a model for most national regulations. However, the changes to the Commission regulations are not of the magnitude suggested in the comment and will not affect the applicability of the EIS to meet National Environmental Policy Act requirements.

Information on cask safety and testing is provided in Section M.4 of the EIS. It is DOE's opinion that sufficient information on cask safety and testing is provided in the EIS to support current decisionmaking.

8.4 (5478)

Comment - EIS001660 / 0016

The DOE will change the design of the casks which would transport the HLW [high-level radioactive waste] and SNF [spent nuclear fuel] to the proposed repository at Yucca Mountain. The DEIS does not address whether the new design of the casks has been tested and analyzed. What is the integrity of die valves, seals, and shielding of the new designed cask? (Referenced information is at Attachment A - "Radiological Waste Management Associates" report.) Full scale cask testing is needed rather than computer simulations. [Following is text of reference.]

Use of "reference cask" containing a water jacket neutron shield

The Modal Study used as its reference cask one using a water neutron shield. This shield was assumed to evaporate in event of fire. The resulting dead air space was modeled to cut the heat transfer rate into the cask by over 70% (Modal 6-36). Given a 1475°F fire transferring heat at a rate of 17,000 BTU/hr-ft2, this had the effect of reducing the heat actually absorbed by the cask to 5,000 BTU/hr-ft2. This reduction was assumed when the melting times were calculated. However, newer casks no longer use water jackets, and the thermal insulation device assumed in the Modal Study is no longer present. Therefore, the heat transfer rate absorbed by the cask is expected to be much closer to the thermal output from the fire itself, since it cannot be assumed without testing that the polypropylene shield will behave like a water jacket. Since the time to reach lead melt is proportional to the rate of thermal input, the absence of the dead air insulator would have the effect of reducing the time required to melt the lead shielding from 1.09 hours to about 20 minutes. (Audin, 18) For the uranium and/or stainless steel shield, this means quicker increases in temperature than those postulated by the Modal Study, resulting in a reduction in the fire severity needed to cause a given accident condition.

"Lead cask bias" used to select most appropriate measurement parameter

The decision to use strain on the inner cask wall as the primary measure of cask response is based on lead's tendency to "slump" when subjected to high loading, resulting in high strains on inner cask wall. However, uranium and/or stainless steel are strong and rigid and thus will not slump. Rather, the force from impacts will be transferred to the joints and welds of the cask, likely resulting in a greater force being applied to them than those in a lead cask. The choice of strain as the sole measurement parameter for physical duress will likely lead to an underestimation of the damage caused to newer casks through rupture of welds and seals in the event of an accident. Therefore, new experiments must be performed to model this behavior.

Response
Section 6.2.4.2 of the EIS addresses transportation accident scenarios and the radiological impacts from accidents. DOE has revised the transportation analysis in the EIS to reflect new information. For example, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates*. Based on the analysis in the report, DOE has concluded that the models used for analysis in the Draft EIS relied on assumptions that caused an overestimation of accident impacts. The radiological performance standards require that a design, in order to be certified, must provide radiological protection according to specified criteria for normal and accident conditions. The performance criteria are applied to containment, shielding, and sub Criticality. The performance standards are the same for any cask design.

8.4 (5825)
Comment - EIS001728 / 0003
Safe shipment containers [are] necessary. We believe that the current containers are of adequate design and have adequate testing and are safe for the general public. It goes through my mind there's a container that was in Europe that was put on a flat-bed truck, put across the railroad tracks, a locomotive and four cars hit that container at 100 miles an hour. The container was usable after that accident. I hate to say that I don't know of any other shipping container out there that would withstand that type of abuse; that the containers must be properly marked and properly identified such as under the requirements of the Department of Transportation; route plans which take into account interstate highways, bypasses, heavily populated areas and other such critical factors.

Response
Safety is DOE's primary concern when shipping spent nuclear fuel and high-level radioactive waste and, as stated in Section 2.1.3.2 of the EIS, DOE would comply with applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission. The U.S. Department of Transportation and the Nuclear Regulatory Commission strictly regulate all aspects of spent nuclear fuel and high-level radioactive waste transportation including packaging; marking, labeling, and placarding; shipping papers; routing; prior notification; and training. More details on transportation regulations are in Section M.2. In addition, Section M.5 discusses cask safety and testing, including crash tests.

8.4 (6215)
Comment - EIS001017 / 0001
After the accident at Three Mile Island, public awareness of the dangers associated with things radioactive was heightened. In 1980, in order to allay public fears surrounding the transportation of radioactive waste, the Energy Department produced public relations films that purported to demonstrate the safety of casks used to transport the waste. The films show five full scale tests and conclude that the casks survived all the tests without releasing any radioactivity. Footage for the film was lifted from tests conducted and filmed at Sandia National Laboratories to check predictions on computers, not cask safety. The conclusions stated in the promotional film are contradictory to the results of the actual tests.

In 1992, a reporter from a Las Vegas TV station interviewed the scientists who conducted the tests. The project manager told the reporter that during the actual fire test a breach occurred in the cask and some of the lead from the cask squirted out through the hole into the fire. The lead was part of the radiation shield.

In the terrorist test, the reporter learned that when scientists shot a cask with a cannon or rocket, the projectile made a hole in the cask one inch in diameter and ripped through the fuel rods inside. The project manager said that the hole itself would have let out "some very small fraction of the contents of the cask." Yet the promotional film maintains that all the casks survived the tests without damage severe enough to jeopardize containment of their contents.

Critics say the tests conducted at Sandia are not really comparable with conditions encountered in the actual transport of casks. Marvin Resnikoff, in his book The Next Nuclear Gamble, cites a litany of misleading concepts and images and omitted facts.

The fuel used in the Sandia tests was fresh fuel. The amount of radiation given off by irradiated fuel rods is much greater than that given off by new fuel rods. The fuel rods had stainless steel cladding which is stronger than the brittle zircaloy currently used in reactor fuel. The casks used in the tests were obsolete and at least one was designed to a higher standard. The casks had lead radiation shielding. Most casks today use depleted uranium.

In the crash tests the cask was cushioned by the cab of the truck and other impact limiters. Many types of crashes would not afford such protection. Also many routine shipments do not incorporate as many impact limiters. Additionally, there are many crash scenarios which could exceed the cask certification requirements. Faulty valves or welds could fail in a fire or under the impact of a crash. Not all casks are secured by the type of tie downs used in the test. A cask secured with ordinary chains used in many routine shipments would have broken loose and hit the wall.

Pressure in the test casks was 26 pounds per square inch, lower than that of many casks. When filled with high-level waste the internal pressure can be from 300-355 psi [pounds per square inch] (Mark Dowie, Mother Jones, 7/82).

The narrator in the public relations video stated that no radiation would have been released in any of the tests, but in fact two of the Sandia tests resulted in leaks of water. If the pressure and temperature in the casks had been higher, as it would be from spent nuclear fuel, the amount of radiation released would have been greater, making it more dangerous for emergency crews. In the Sandia fire test, faulty welds caused the cask to crack at 100 minutes and the lead shield began to vaporize. The test was stopped. In the promotional film there is no mention of the crack. The narrator simply states that after 90 minutes the cask showed no damage. The Nuclear Regulatory Commission claims that the probability of exceeding the 1/2-hour fire in an accident has been studied and found to be small. However many accident scenarios such as a fire in a remote location or the piling up of many cars could result in fires lasting longer than 30 minutes. The Sandia fire tests were conducted at 1475°. Since the fire test was developed, combustible materials are routinely shipped which burn at temperatures up to 4,000°.

In the drop test a crack formed along a weld, forming a pathway for a leak. This was not mentioned in the promotional film.

Response

This comment covers several issues related to the interpretation by DOE of a film of tests performed at Sandia National Laboratories in the 1970s, as well as specific statements about the tests. Some of the latter statements offer interpretations of the tests that lack factual basis. Both types of comments are addressed in this response. For specific information on those tests, please consult the following documents:

- *Full-Scale Tests of Spent-Nuclear-Fuel Shipping Systems* (DIRS 157157-Yoshimura and Huerta 1976)
- *Crash Testing of Nuclear Fuel Shipping Containers* (DIRS 157098-Jefferson and Yoshimura 1978)
- *Analysis, Scale Modeling, and Full Scale Tests of a Truck Spent-Nuclear-Fuel Shipping System in High Velocity Impacts Against a Rigid Barrier* (DIRS 157096-Huerta 1978)
- *A Study and Full-Scale Test of a High-Velocity Grade Crossing Simulated Accident of a Locomotive and a Nuclear-Spent-Fuel Shipping Cask* (DIRS 157097-Huerta and Yoshimura 1983)
- *Analysis, Scale Modeling, and Full-Scale Test of a Railcar and Spent-Nuclear-Fuel Shipping Cask in a High-Velocity Impact Against a Rigid Barrier* (DIRS 157099-Huerta 1981)
- "Modeling of Pool Fire Environments Using Experimental Results of a Two-Hour Test of a Rail/Cask System" (DIRS 157110-Hamann et al. 1980)

DOE sponsored the testing performed at Sandia National Laboratories. The documentation for the tests (reports and films) is available to any member of the public. While the purpose of the tests was to confirm analytical models, the performance of the casks in conditions simulating severe accidents showed that the casks were very durable. They were not significantly damaged and continued to provide containment and shielding as required by Nuclear Regulatory Commission regulations. To suggest that the tests showed that shipping spent nuclear fuel in the casks would be "safe" was not an unreasonable interpretation of the test data.

In paragraph 2, the reply given to the reporter was correct. A crack in the outer skin of the cask resulted from expansion of the lead shielding after an intense fire, three times the duration of the Nuclear Regulatory Commission test fire. The crack released a small amount of lead before the fire was extinguished. The crack was a result of a manufacturing flaw that neglected to allow an expansion path for molten lead (which expands on melting) to flow into a volume provided for that purpose. The crack did not compromise the inner wall of the cask, which forms the containment boundary for the fuel.

The "terrorist test" referred to in the third paragraph was not part of the accident test series referred to earlier. The test was done in 1982. That test was not part of the film referred to earlier as the commenter suggests and the conclusion regarding the accident tests as quoted was correct.

The quote from Resnikoff in the fourth paragraph is correct. The Sandia National Laboratories tests did not mimic transportation conditions. Actual transportation conditions and accidents are much more benign than the accident environments provided in the tests.

The fifth paragraph deals with the fuel used. The facts are correct. The fuel was included to mimic the weight of spent nuclear fuel; it had no other role in the test. The higher temperature the cask might have achieved with real fuel would have had no effect on the results. The casks were lead shielded, as many are today and many would be for the shipping campaign to a repository. While the casks were no longer usable, they were designed to meet the same Nuclear Regulatory Commission standards in use today.

Most casks are equipped with impact limiters. Those in the Sandia National Laboratories tests were typical of the technology at the time. It is true that the truck cab did absorb some energy as it would in the real life high-severity accident situation modeled in the test. A recent report suggests that the assertion that "many crash scenarios could exceed cask certification requirements" is not correct (DIRS 152476-Sprung et al. 2000). Tiedowns in the Sandia National Laboratories tests met U.S. Department of Transportation requirements, but if the casks in both tests had no tiedowns, the results would have been the same. Little energy is absorbed in breaking the tiedowns. The role of tiedowns is keeping the cargo on the vehicle during incident-free transportation.

Paragraph seven of this comment suggests that the pressure in the casks in the Sandia National Laboratories test was lower than the 210,000 to 250,000 kilograms per square meter (300 to 355 pounds per square inch) said to be typical of high-level radioactive waste casks. During the 1970s, it was common practice to have water-filled casks to provide a cooling medium for the thermally hot, short cooled fuel for which the casks were designed. Because no heat rejection was needed for the surrogate fuel and the internal pressure was sufficient to force water from any leaks that might occur in the cask's seals, there was no need for high pressure (though the pressure level suggested as typical for high-level radioactive waste casks seem to be higher than one might expect during the normal conditions of transportation).

Documentation of the Sandia tests indicates a small quantity of cooling waster escaped from the cask as stated in paragraph eight. The documentation indicates that the loss was not beyond that allowed by Nuclear Regulatory Commission regulations after the hypothetical accident test. The Sandia fire burned at temperatures exceeding 854°C (1,600°F); the 766°C (1,475°F) value is used for analysis and, together with other test conditions specified in the regulation, provides generally equivalent thermal input. The fire required for Commission certification must be fully engulfing (no view of the cask through the flames) for 30 minutes. The Commission assertion that this is not common is based on studies of fires that show that fires in accidents can be hotter and of longer duration, but they do not burn in one location and not with constant intensity as required in the test. As a result, the thermal input to the cask is seldom as high as achieved in the test.

The Sandia tests did not include a drop test as mentioned in the last paragraph of the comment, but if a crack appeared after a test for certification, it would likely result in a redesign of the package if it compromised containment. That is one of the functions of certification testing and analysis.

DOE has added Appendix M to the EIS to provide additional information on cask safety and testing.

8.4 (6556)
Comment - EIS001328 / 0012
NCSL [National Conference of State Legislatures] calls upon the federal government to: Proceed to develop dual-purpose (transportation and storage) and universal casks (transportation, storage and disposal) to reduce the handling of spent fuel and, thus reduce the risk of mishaps and lessen worker exposure.

Response
DOE would not develop transportation casks, but plans to contract with the private sector to provide waste acceptance and transportation services, including equipment. All cask designs must contribute to overall efficiency and operability of the entire transportation systems and meet Nuclear Regulatory Commission regulations. Information on the process for acquisition of waste acceptance and transportation services, including casks, through the Regional Servicing Contractors is provided in Appendix M of the EIS.

DOE did not include a multi-purpose canister option for legal-weight truck shipments because the quantity of spent nuclear fuel transported in a legal-weight truck cask is much less than the quantity that would be loaded into a disposal container. In addition, commercial storage casks that use multi-purpose canisters for storage and transportation have capacities much greater than legal-weight truck casks. Designs of disposal containers, dual-purpose and multipurpose canisters, other components, and operations of a nuclear waste repository will implement the principle of reducing exposure to workers to levels that are as low as reasonably achievable (ALARA).

8.4 (6559)
Comment - EIS001328 / 0011
NCSL [National Conference of State Legislatures] calls upon the federal government to: Consult with all affected parties regarding cask compliance with radiation emissions standards. Because cask integrity and safety is of paramount concern in a transportation system, all affected parties must be involved in a consultation process including, but not limited to, states, local governments, Indian tribes, carriers, labor, the Nuclear Regulatory Commission, the Department of Transportation, the Occupational Safety and Health Administration, the Federal Emergency Management Agency and the Environmental Protection Agency.

Response
The Nuclear Regulatory Commission has established and enforces the regulatory requirements for cask designs. All shipments would be made in Commission Certified casks. There would be various opportunities for states, tribes, and stakeholders to work and consult with DOE as the project moved forward to developing the transportation program. For more information, see Appendix M of the EIS.

8.4 (6925)
Comment - EIS001335 / 0003
The DEIS states that the cask design has been tested through simulation to withstand worse case scenario disasters, which includes withstanding a 30-minute all-engulfing fire at 800° Celsius and a 40 inch fall onto a 6-inch diameter steel rod. It is not hard for me to imagine a derailment on a section of multiple main track involving a coal train and a freight train moving in opposite directions at 50 mph less than 15 feet apart. The cask car containing the nuclear waste slams into the coal cars and is buried under 700 tons (10 cars) of coal, from 20 cars back the force of an additional 100 cars hurls two cars of propane, carrying 150,000 pounds of fuel each, into the pile of twisted metal and they ignite. Now you have an all-engulfing fire that won't burn for 30 minutes, but for 8 hours. The men and women and the two fire trucks of the Gibbon, NE Volunteer Rural Fire Department stand back and watch it burn, wondering how they will extinguish the pile of coal after the two tank cars burn themselves out. Hazardous material regulations should separate highly flammable cars from the cars containing nuclear waste lessening the potential for this type of incident but on February 8, 2000, a 120 Car freight left Lincoln, NE. and was 25 miles down the line when a failed equipment detector/car counter at Firth, NE. indicated two extra, unknown cars on the train. After all the paperwork was checked it was discovered that the unknown cars contained hazardous, flammable material.

I would like to emphasize that I am not being an alarmist, with the exception of the flaming tank cars in the derailment, these are all situations that I see on a daily basis. I'm sure if you wanted to check with the Federal Railroad Administration you could find more than one example of burning cars of hazardous material.

Response
In the EIS, train fires were assumed to burn for up to 11 hours, which exceeds the 8 hours cited by the commenter. As discussed in Section J.1.4.2.3 of the EIS, the rail accident data used in the transportation accident analyses were obtained from the Federal Railroad Administration and were for the period 1994 through 1996. These data include accidents involving hazardous materials fires. Information on cask safety and testing is provided in Section M.5.

As discussed in Appendixes J and M of the EIS, most real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask into a river, and similar extreme accident conditions, would not likely result in release of radioactive materials from the shipping casks. The performance standards for the casks prescribed by the Nuclear Regulatory Commission were selected to ensure that less than 1 percent of real-world accidents would result in loss of cask integrity and release of radioactivity from the cask. These standards ensure that the casks would be extremely robust.

8.4 (8016)
Comment - EIS000817 / 0067
P. 2-56 -- You say "one or more qualified companies that provide specialized metal structures, tanks, and other equipment would manufacture new shipping casks" -- just as "nonchalant" as that -- simple. -- I say, wait a minute. Have you looked at the track record of cask vendors? Do you know the problems? This is not just an easy thing. These are new designs -- untested, not time tested, and you expect it all to go like clockwork. Well, don't. The demand for casks is great and subcontractors are not used to nuclear QA. Did you ever hear of Sierra Nuclear and March Metalfab and that fiasco? Do you know of the faulty casks Pacific Nuclear sold DOE in Tru-pact agreements long ago? I mean who are we going to really trust to build these things?? And how do you really plan to verify shielding, structure, and heat transfer in these casks? How and when will O-rings be replaced? -- How are casks monitored en route? What if they "weep"? What is "minor cask maintenance," anyway? Has this been carefully thought out?

Response
Section 2.1.3.4 of the EIS addresses cask manufacturing, maintenance, and disposal. Although DOE does not know the specific companies who would build the casks used to transport spent nuclear fuel and high-level radioactive waste, casks have been successfully built and operated in the United States. As a consequence, many companies are experienced in cask construction and others are familiar with construction of nuclear systems and components. DOE is confident that skilled workers and their companies are capable of doing the quality work expected for construction of these casks.

Prior to issuing or renewing a certificate of compliance, the Nuclear Regulatory Commission must determine that a cask design complies with the requirements of 10 CFR Part 71, Packaging and Transportation of Radioactive Material. This regulation requires that an application for package approval be submitted to the Nuclear Regulatory Commission. This application is known as a "safety analysis report for packaging." The standard format and content guide for this application, Regulatory Guide 7.9, contains sections on structural evaluation, thermal evaluation, and shielding analysis. These analyses and evaluations are reviewed and approved by the Nuclear Regulatory Commission as part of the package approval process. The application must describe the maintenance program for the package, which would include the inspection of items such as O-rings.

Casks would be monitored using a satellite tracking system such as TRANSCOM. More details are provided in Section M.3.2.1.5 of the EIS.

The phenomenon of cask weeping can be described as follows: a cask that has been loaded or unloaded in a spent nuclear fuel storage pool becomes contaminated with radioactivity on its surface. Before shipment, the external surface of the cask is decontaminated to levels specified by regulations, but when the cask is inspected on arrival at its destination, contamination above the levels allowed by regulations is found. It is likely that when a cask is repeatedly placed into water-filled spent nuclear fuel storage pools, it becomes contaminated over time, with the contamination penetrating deeper into the pores of the cask body. The cleaning removes the surface contamination, but the contamination that is deep in the pores remains. During transportation of a loaded cask, the surface can become contaminated again as the deep contamination is driven out of the pores by the heat of the spent nuclear fuel.

The levels of contamination associated with the weeping phenomenon are not high enough to be factored into the risk assessment for transportation, and procedures would be used to effectively preclude this problem during shipments. For example, wrapping the cask in plastic before entry into spent nuclear fuel storage pools is an effective practice that is currently used. Therefore, weeping is not expected to be a significant contributor to risk during spent nuclear fuel transportation.

Minor cask maintenance consists of activities such as replacing seals, valves, and bolts that are identified during inspections. Additional information on cask testing and safety is provided in Appendix M of the EIS.

8.4 (8223)
Comment - EIS001021 / 0007
One thing the EIS definitely reinforces is that storage containers DO degrade, and there IS a measurable risk to the public from nuclear waste shipments to Yucca Mountain. The question is how fast does the damage occur and how much radiation exposure will there actually be?

Response
The degradation of storage containers is discussed in Sections K.2.1.1 and K.2.1.2 of the EIS. The results in Table K-1 show that storage canisters are breached within 500 to 5,400 years after the loss of institutional control.

The radiation dose from nuclear waste shipments is presented in Sections 6.2.3.1 and 6.2.3.2 of the EIS.

8.4 (8297)
Comment - EIS000817 / 0107
P. 4-88 Shipping Container -- depleted uranium and lead add to hazards in any accident and add to total waste at close of the repository. Why use these materials?

Response
Depleted uranium and lead are both used in spent nuclear fuel casks as gamma radiation shields. Depleted uranium is similar to natural uranium except that it has a lower concentration of the fissile isotope, U-235, than does natural uranium. Depleted uranium and lead are both very effective gamma absorbers. When used in a cask they would be fully encapsulated within the cask structure. The transport casks, which would contain the encased depleted uranium or lead gamma shields would be reusable. The spent nuclear fuel and high-level radioactive waste would be placed in waste packages, different from the transport casks, for deep geological disposal. At the end of their useful life, casks would be decommissioned and would be sent to appropriate waste management facilities. The depleted uranium and lead used for shielding in spent nuclear fuel casks would not be added to the repository waste inventory.

8.4 (8396)
Comment - EIS002014 / 0002
There is gong to be at least one accident during the transportation of the casks to Yucca Mountain. The tests you have performed on the casks are not good enough. You were only using simulated nuclear waste so you don't know exactly what will happen. What if it is thrown 40 feet? You never tested it on that far of a distance. I am also concerned that if one of the casks is broken, radioactive waste could seep down into the water table contaminating our drinking water.

Response
The potential for an accident involving transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain is discussed in Chapter 6 and Appendix J of the EIS. DOE recognizes that accidents would occur. The potential for a release of radioactive material is very small and is not expected to occur during the 24-year period of transportation. Of the thousands of shipments completed over the last 30 years, none has resulted in an identifiable injury through release of radioactive material. In addition, the radioactive material in the cask is in the form of gases or solids, not liquids. The mode of release would be a gas or particulate. The release would be

carried by the wind. Contamination of surface water would be by deposition of the particles, which would be relatively small amounts.

The Nuclear Regulatory Commission regulates the design, construction, use and maintenance of shipping containers or casks for shipments of spent nuclear and high-level radioactive waste. The casks must be designed to withstand a series of impact, puncture, and fire environments, thereby providing reasonable assurance that packages would withstand serious transportation accidents. Additional information on cask safety and testing is provided in Section M.4 of the EIS.

While no test has been done for a 12-meter (40-foot) drop of a spent nuclear fuel cask, all analytical tools that are shown to predict the results of a 9.1-meter (30-foot) drop and the results of tests at other speeds and orientations indicate that a 12-meter drop is not going to produce a leak path to the environment (see DIRS 152476-Spring et al. 2000).

Comment - EIS000817 / 0195
P. J-52....DOE sort of says NRC [Nuclear Regulatory Commission] will make sure everything is OK and prevent anything like this. Are you kidding? This has all happened! Do you know the history of Sierra Nuclear and the VSC-24 and Transtor casks? Nonconformance after nonconformance -- fines and violations, QA [quality assurance] problems over and over, undocumented weld repairs, charpy testing not done right, cracks in side welds found in a loaded canister, more casks fabricated than NRC exemption allowed before certification, unloading procedure not ready, weld cracks in seal lid welds, a coating that causes exploding hydrogen that lifted up the lid on a cask they were loading in Wisconsin, requirement of UT testing on loaded casks already on the pad at Palisades, Pt. Beach and ANO because of weld cracks. Stop work orders and stop loading orders from NRC numerous times, vent holes too small for unloading procedures in some Palisades casks -- (have to be drilled larger in unloading), shims welded in around shield lid and no initial plan as to how to get them out, no soil testing at the Palisades pad until after casks were loaded and on it there -- (the EIS for the plant on bedrock was used for the pad on sand dunes!). Concrete for outer shell not mixed correctly, rebars put in wrong at ANO, equipment not calibrated correctly -- etc., etc., etc., etc. A real fiasco! And then BNFL [British Nuclear Fuels, Ltd.] buys them out and promises to do better. Do they? No! -- we have the mess at Trojan with coatings washing off and clouding the water so you can't see to load. And the repeated hydrogen burns at Palisades even after we were promised they knew how to vent the hydrogen safely. Then we have Nuhoms with too thin walls than specified, and we have the TN casks at Prairie Island where the resin wasn't treated according to specifications as I understand it -- dry cask storage has problem after problem. But do I think Yucca Mountain is better? No! for these problems will be hidden underground instead of on pads where we can repair and test and monitor them. If those VSC-24 casks were underground, you'd have had to haul them all back up again several times by now! Where is a vendor we can trust? Where is a time tested (over long term) cask? Where is spent fuel that has been checked after unloading a cask? I sure can't recommend any.

Response
Sections 2.1.1.1 and 2.1.3.4 of the EIS discuss repository waste package scenarios and shipping cask manufacturing, maintenance, and disposal, respectively. Although DOE does not know the specific companies who would build the shipping casks or repository waste packages used for spent nuclear fuel and high-level radioactive waste, casks have been successfully built and operated in the U.S. As a consequence, many companies are experienced in cask construction and others are familiar with construction of nuclear systems and components. DOE is confident that skilled workers and their companies are capable of doing the quality work expected for construction of shipping casks and repository waste packages.

Long-term testing of repository waste packages would be part of the Performance Confirmation Program for the repository, which is a program of tests, experiments, and analyses that DOE would conduct to evaluate the accuracy and adequacy of the information used to determine that long-term repository performance objectives have been met. More details on this program are provided in Section 2.1.2.4 of the EIS.

DOE would start monitoring and maintenance activities of the repository and the waste packages after the first emplacement of waste packages. These activities would continue through repository closure, and would include monitoring and inspection of emplaced waste packages, investigations in support of predictions of long-term repository performance, and retrieval of waste packages if necessary. This would ensure that repository problems were identified and not hidden underground.

Spent nuclear fuel has been shipped to various locations around the U.S. for examination. Most of this spent nuclear fuel currently resides at the Idaho National Engineering and Environmental Laboratory.

Comment - EIS001888 / 0103

The quality of the report is flawed in fundamental ways. Sources cited by the report in Chapter 6 refer to reports that assumed the use of a Multi-Purpose Canister (MPC) system. The DOE has abandoned the MPC system as unworkable. Despite this, the DEIS uses references about the MPC design to support its conclusions even though they are not relevant for the proposed action described by the DEIS.

Response

None of the calculated environmental impacts of transportation accidents in Section 6.2.4.2 of the EIS, conclusions about the impacts, or decisions to be made from the EIS assumed the use of the multi-purpose canister system. For example, some information in the EIS was derived from previous evaluations of the system, such as *Health and Safety Impacts Analysis for the Multi-Purpose Canister System and Alternatives*. Section J.1.2.1.1 lists shipping cask configurations and their capacities. Note that some of the casks are designated dual-purpose. Information directly applicable to the cask configurations under consideration in the EIS (that is, accidents at commercial facilities during spent nuclear fuel loading operations for single-purpose casks) was taken directly from the study. The probability of a lift-handling accident involving a fuel assembly was estimated to be 0.0001 per handling operation (DIRS 104794-CRWMS M&O 1994), as reflected in Section 6.2.4.1. This estimate is applicable to fuel assembly handling by crane and is independent of the type of cask or canister into which the fuel assembly is being placed. Thus, the information extracted from the reference is relevant to the shipping cask configurations assumed in the EIS.

Adjustments were made to the information extracted from references in cases where bases for the studies were not consistent with the assumptions made in the EIS. For example, the reference listed above assumed a 30-year operational period for the repository. In the EIS, adjustments were made to account for the assumed 24 years of repository operation, where appropriate. There are many similar instances in which data as extracted from a reference and adjusted to account for different bases and assumptions. This is consistent with Council on Environmental Quality guidance and DOE policies and procedures. Each EIS reference has been reviewed in detail, a determination of its applicability has been made, and appropriate adjustments have been made where necessary. As a consequence, DOE believes there is an adequate technical basis for the conclusions presented in the EIS.

8.4 (9582)

Comment - EIS001888 / 0256

The greatest cause for concern is the absence of operational performance data for most of the complex packaging, handling and shipping equipment required to implement the Proposed Action and Modules 1 and 2. For example, the GA-9 transportation cask is one of the primary components of the waste handling system envisioned in the DEIS. However, that cask requires a special trailer to handle and transport. This trailer has not yet been constructed. As was noted in one of the reference documents supplied with the DEIS, only "preliminary sketches" exist. This problem is particularly acute for the heavy haul transportation proposal. No data are presented in the DEIS to support any conclusions about the safety of transporting a 125 ton cask twice daily at 25 mph on an urban bypass with posted speeds of 65 mph through Clark County. No past experience, transporting spent fuel is relevant to the proposed action because there is no operational performance data for the equipment used to handle the waste.

Response

Although the GA4/9 shipping cask is a new design, it has no design features that are new. The shipping cask consists primarily of a thick stainless steel cask body that provides the primary containment of the radioactive cargo. Closure lids are welded to the bottom of the cask body and bolted to flanges at the top. Double elastomeric O-ring seals are provided for the top lid. Aluminum honeycomb impact limiters are provided to absorb energy should an accident occur. Depleted uranium is provided for gamma shielding and a solid hydrogenous material is provided for shielding against neutron radiation. All of these features and materials have been provided in past shipping cask designs and DOE and Nuclear Regulatory Commission are confident that the computer modeling and testing that has been conducted on the GA4/9 cask design accurately predicts the behavior and performance of the shipping cask under severe accident conditions.

In terms of operational characteristics, the GA4/9 is not significantly different than other spent nuclear fuel shipping casks. The cask is shipped horizontally and loaded vertically, incorporates an internal basket for supporting the spent nuclear fuel cargo, and is closed using double O-rings seals and a bolted closure. Nevertheless, commercial and DOE facilities would develop site-specific cask handling procedures and conduct dry runs of cask handling operations prior to loading actual spent nuclear fuel assemblies into the shipping casks. Therefore, based on operating experience with similar spent nuclear fuel shipping casks and requirements to develop site-specific procedures and conduct dry runs, DOE believes that the lack of operating experience with actual GA4/9 shipping casks is not an issue with respect to the transportation impact analysis.

The commenter was concerned about the trailers that would be used to haul the spent nuclear fuel shipping casks. Although the GA4/9 trailer is specially designed for the shipping cask, it is similar to other trailers used to haul concentrated heavy loads. The trailer meets the requirements of American National Standards Institute (ANSI) N14.30-1992, “American National Standard for Nuclear Materials – Semi-Trailers Used in the Highway Transport of Weight Concentration Radioactive Loads Design, Fabrication, and Maintenance.” Modifications would be made to incorporate the devices necessary to secure the shipping cask to the trailer, but otherwise the trailer is little different than other trailers in use today for weight Concentrated loads.

On the other hand, the heavy-haul truck transportation systems are in conceptual stages of development. Preliminary design and engineering studies have been conducted [see “Road Upgrades for Heavy-Haul Truck Routes - Design Analysis” and “Yucca Mountain Potential Nuclear Waste Repository Supplemental Transportation Analysis” in CRWMS M&O (DIRS 155347-1999)] that identify potential upgrades for mitigating the potential impacts of the heavy-haul truck concept shown in Figure 2-33 of the EIS. DOE believes it has adequately demonstrated the feasibility of these alternatives and developed them sufficiently to support comparisons of alternatives and decisionmaking about transportation alternatives.

DOE agrees the mostly rail/heavy-haul truck mode in Nevada is unprecedented, with only the heavy-haul truck campaign in France as a close comparison. However, based on the analysis mentioned above, this mode of transportation is technically feasible and its costs are comparable to rail transportation. Furthermore, DOE believes adequate measures are available or can be developed to ensure the safety of heavy-haul truck shipments. Safety measures currently required for heavy-haul truck shipments include restricting travel to daylight hours and providing escorts in front of and behind the shipments to warn other drivers of the slow-moving vehicles. In addition, DOE proposes to upgrade candidate heavy-haul truck routes to enhance the safety of the heavy-haul truck shipments and other vehicles and drivers on the highway. With these and other safety measures in place, DOE believes the heavy-haul truck implementing alternatives can be conducted safely.

Comment - EIS001888 / 0262
Cask Fleet

No safety performance data exist to provide the basis for a credible transportation risk assessment. How many casks will be built? How long will a cask be used? When will they be built? Once a design is selected, how will it be tested? Will the tests be full-scale or models? How many spare parts will be fabricated? When? When will they be tested? How will changes to cask design be performed? How will the Regional Service Companies (RSCs) manage the spare parts and the cask fleets? None of these questions are addressed by the DEIS.

Response
In the United States, more than 2,700 shipments of spent nuclear fuel have been made over the past 3 decades with no releases of radioactive material due to a transportation accident. About 90 percent of those shipments used truck casks and the remaining 10 percent used rail casks. Although different casks might have been used over that period, they all met the Nuclear Regulatory Commission design standards. Thousands of shipments have been made internationally with casks that are certified to the same standards that confirm the U.S. experience. This safety record for spent nuclear fuel transport in the United States is excellent and is consistent with the overall highway and rail accident data. Risk assessment accident data for commercial transportation has been used in conjunction with

analysis of cask performance to estimate risks associated with spent nuclear fuel transportation. The approach is appropriate and widely accepted in the risk assessment community as the basis for credible risk assessment.

For the purposes of the Draft EIS, details relating to logistics of cask operations are not important. The transportation system would be operated in compliance with Nuclear Regulatory Commission requirements in regards to operation and maintenance of the cask. These requirements would ensure that casks used in operating the system would meet the safety standards on which the Draft EIS analysis was based.

In response to comments, DOE added Appendix M to the EIS. This appendix presents additional details on transportation planned operations and the Regional Servicing Contractors; on cask design, safety and testing; emergency planning and response; and on liability concerns.

Comment - EIS001888 / 0264
Fabrication Issues

In a film of cask tests made in 1977, a cask is shown engulfed in flame as part of the 30-minute fire test required for cask certification. Twenty minutes after the camera was turned off, having recorded an ostensibly successful test, the cask broke open due to a manufacturing defect. An under appreciated aspect of transporting SNF [spent nuclear fuel] is the high level of technical sophistication required to fabricate a waste cask. The challenge of fabricating casks on the massive scale required by the programs proposed by the DEIS is problematic at best and could be greatly complicated by short production schedules, sporadic program financing, and other considerations not mentioned in the DEIS.

The transportation cask is assumed to be the primary component ensuring the safety transportation of spent nuclear fuel. The slightest flaw in manufacturing casks could have a greater impact on safety than many other variables. Although it is not a traditional NEPA [National Environmental Policy Act] consideration, it is an important part of ensuring the safe transportation of waste and a discussion of cask fabrication issues should have been included.

Response
The commenter is correct in stating that the transportation cask is the primary component for assuring the public's safety. This is one of the primary tenets of the radioactive materials transportation regulations. The design of casks and process of certification that is outlined in regulation and carried out by the Nuclear Regulatory Commission is such that casks which do not meet the requirements do not get certified.

Casks do not, in general, show a high degree of technical sophistication, as suggested in the comment. They are a passive structure composed of well characterized materials that are assembled to form relatively simple and massive structures that are within the scope of current technology. Manufacture of the cask is accomplished using many standardized processes and the resulting cask's quality is assured through application of the Commission's comprehensive quality assurance program. The Commission's quality assurance program covers fabrication of casks and requires that measures be established to ensure that special processes, including welding, heat treating, and nondestructive testing, are controlled and accomplished by qualified personnel using qualified procedures in accordance with applicable codes, standards, specifications, criteria, and other special requirements (see 10 CFR Part 71, Subparts D and H). The quality assurance program picks up systematic errors in the product and shuts down production and use of the casks when a problem is found. The Nuclear Regulatory Commission oversight is independent of DOE's schedule and funding and would ensure that quality casks would be produced. The example quoted in this comment was related to a manufacturing defect in a cask that was: (1) too old to be covered by the Commission's quality assurance program; (2) not in any way a threat to containment of the spent nuclear fuel; and (3) so subtle that it was not detected until conditions existed that would be seen in fewer than 1 in 10,000 severe accidents (DIRS 152476-Sprung et al. 2000).

8.4 (10016)
Comment - EIS001932 / 0001
Many of the safety tests on the "packaged for shipment" casks are flawed. The NRC [Nuclear Regulatory Commission] regulations require casks to be able to withstand a fire of 1,475° F for 1/2 hour seems impressive, but it is inadequate for highway and rail conditions. Many hazardous [cargoes], as a result of an accident, burn at

temperatures in excess of 1,475° F and longer than 1/2 hr! Diesel fuel burns hotter, as does propane at 4,000° F, butane at 1,875° F. In fact, the average temperature of a highway accident fire is 1,850° F (with a range between 1,400° F and 2,400° F). In addition, I am concerned about the integrity of the pressure relief valves in case of fire. I also understand that the trucks will be carrying extra fuel to avoid fuel stops or [stopovers]. In the case of rail shipments, rail bed integrity on bridges or trestles over rivers seem particularly vulnerable. Either from terrorists or improper maintenance.

Response
Safety is DOE's primary concern when shipping spent nuclear fuel and high-level radioactive waste and, as stated in Section 2.1.3.2 of the EIS, DOE would comply with applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission. The standards being questioned by the commenter are established by the Nuclear Regulatory Commission, not DOE. DOE will continue to rely on the Nuclear Regulatory Commission to verify the adequacy of these standards. For example, the design of pressure relief valves would be reviewed and approved by the Nuclear Regulatory Commission during the package approval process.

Because of the weight of the truck casks analyzed in the EIS, it is likely that the trucks would carry less than typically carried.

Adequate rail lines, crossings, bridges, and tunnels exist to support spent nuclear fuel and high-level radioactive waste transportation, which requires no special transportation infrastructure that is not necessary for the safe transportation of commodities in the United States.

More details on cask safety and testing, including crash testing, are provided in Appendix M of the EIS.

Section 6.2.4.2 of the EIS addresses accidents including acts of sabotage. Sabotage of rail infrastructure would yield consequences similar to those estimated for transportation accidents.

8.4 (11360)
Comment - EIS002242 / 0002
Now, in the 1970's I was asked to conduct some experiments to evaluate whether or not our analytical tools were accurate in predicting what would happen to these shipping containers in severe accidents.

The other thing that I wanted to do was to try to develop some understanding of the environment of a severe accident, so that we would have a better handle on how to analyze these things. These tests were conducted with public involvement. On the first test we had 900 people show up for the test. Everybody loves to see smashing and crashing. The first test involved a 60-mile-an-hour impact of a truck mounted-shipping cask into a 20-foot cube of reinforced concrete. 960 tons of it.

The second test we took the same cask, since it suffered no damage, and impacted it on another truck at 84 miles an hour -- that's roughly twice the kinetic energy. Again no problem. We did a series of five full-scale tests during the time I was with Sandia Labs -- we did a total of about 1500 tests involving transportation of these materials.

The result was, of these tests -- since the public was involved, I would get up in front of people and say here is what we are going to do, here is what we expect after the tests. They were free to go up and look for themselves. And in every single case we predicted the damage accurately. If there was any inaccuracy, we overpredicted the damage.

Response
This commenter shares his personal experience in conducting the test program at Sandia National Laboratories in the mid-1970s. That experience suggests to the commenter that the capability to estimate the upper limit of the results of a wide variety of accident scenarios exist. DOE agrees with this comment and points to the work by Lawrence Livermore National Laboratory (DIRS 101828-Fischer at al. 1987) and, more recently by Sandia National Laboratories (Sprung et al. 2000), in demonstrating analytical capability related to cask response and estimation of risk to the public. Additional information on cask safety and testing is provided in Section M.4 of the EIS.

8.4 (11480)
Comment - EIS002247 / 0008
And I would like to know what casks are currently NRC [Nuclear Regulatory Commission] certified and whether or not they have the Transcom system in them, or in the trucks that are carrying them.

Response
The casks DOE is considering would have a valid Nuclear Regulatory Commission certificate of compliance when shipments began. Examples of truck casks certified by Commission include the General Atomics GA-4, the NAC International NLI-1/2, the NAC International NAC-LWT, and the Transnuclear TN-8 and TN-9.

The TRANSCOM system is a device attached to a vehicle that monitors vehicle movement by satellite tracking. DOE would use such a tracking system to monitor shipments when shipping began.

Appendix M of the EIS provides information on the transportation casks, regulations, and the operational protocols including shipment monitoring.

8.4 (11579)
Comment - EIS002235 / 0002
There are questions as to the crash test studies that were performed on the casks as to whether they are adequate to withstand the rigors of our Cajon Pass.

Response
As discussed in Sections 6.2.4 and J.1.4 of the EIS, neither the EIS nor the Nuclear Regulatory Commission's (NRC) transportation regulations (10 CFR Part 71) address specific hazards on specific highways or railways. However, both address the types of hazards that could be encountered over highways and railways. Casks certified by the NRC for transportation are designed to perform their radiological protection functions under normal and accident conditions of transportation. These radiological protection functions ensure public health and safety. Section J.1.4.2 considers the likelihood and consequence of accidents for transportation of spent nuclear fuel in estimating risk. The likelihood or probability of the occurrence of an accident with specific characteristics is based on historic statistical behavior. The consequence of an accident with specific characteristics is based on engineering factors and the fact that casks used by DOE would be NRC-certified. Because of these considerations (statistically based accident rates and cask performance), the risks estimated for the EIS are expected to cover transportation of spent nuclear fuel anywhere in the United States, even over highways and railways that might have more severe conditions or be prone to higher than average accident rates. The conditions that exist at El Cajon Pass (long steep grades) are covered by the analyses in the EIS.

8.4 (11929)
Comment - EIS000817 / 0200
P. 6-29. And, frankly, seeing how the NRC [Nuclear Regulatory Commission] handled the VSC-24 fiasco, I have not a great deal of confidence in what they predict for cask performances either. NRC staff is overworked and can't handle the gigantic amount of problems that vendors and utilities have dropped in their lap dealing with cask certification and use. Every reactor wants casks; every vendor wants certification -- there is a big push by the industry to get everything done as fast and as cheaply as possible.

Exemptions to regulations and codes are handed out all over the place. This leads to trouble! Safety analysis documents are not current with what is really being done with casks as the procedures and designs are constantly changed by each utility. The "generic" cask has become a chameleon and is "site specific" at each location in the end. Also, the lack of communication between vendor, utility, and NRC on problems and troubleshooting has led to repeated problems that were not necessary. They could have been prevented. Workers don't even know when to call a fire a fire apparently when it comes to hydrogen flames vented from a cask. And then, at Palisades, they vented it through a flammable plastic tube attached to the machine by duct tape and was way too close to the cask. So it burned again! Do you really expect public trust when such stupid things go on with dry cask storage? And of course the mess at Trojan with Transtor was predictable -- but they did it anyway knowing full well the coating wasn't completely baked on as it was supposed to be. And other casks have problems too -- you know it. So don't act as if casks will work as expected. They won't.

Response
The Nuclear Regulatory Commission (NRC) is an independent agency of the Federal Government. NRC responsibilities include regulation of the Nation's civilian use of radioactive materials to ensure the protection of public health and safety. The NRC and its licensees share the responsibility for protecting public health and safety (DIRS 153561-NRC 2000). When the licensee fails to carry out its responsibilities to public health and safety, the NRC takes appropriate enforcement action. In the example given by the commenter, the NRC did that. The NRC learned of the problem and took appropriate enforcement action.

The NRC was established 25 years ago by the Energy Reorganization Act of 1974. The NRC record for regulating civilian use of radioactive materials is outstanding. DOE would use only Commission-certified casks for activities conducted under the NWPA. The Department is confident that the NRC will perform its mission, and the Department will uphold its responsibility for protecting public health and safety. Appendix M of the EIS provides additional information on applicable regulations and cask testing and safety.

8.4 (11980)
Comment - EIS002101 / 0014
Then you bounce them across our highways all the way out to here. All that corrosion's falling off of the casks. 750°, thousands of times background radiation emitting off of these things.

Response
Section 6.2.4.2 of the EIS addresses transportation accident scenarios and the radiological impacts from accidents.

Because of the strength and construction of a certified cask, it is not expected that a transportation accident could result in the ejection of spent nuclear fuel though the release of spent nuclear fuel would be a source of corrosion and large doses. The former would be a containment concern, the latter a shielding concern, since the shielding surrounds the containment vessel. The type of failure suggested would require large forces and cask designs that used brittle structural materials for their containment systems. The structural materials used in cask containment systems are characterized as ductile materials. Such materials, should they fail, would tend to stretch beyond their design limits, or in severe cases, tear. Although accident forces could be large, casks are designed with large safety margins to limit such stretching to meet regulatory requirements even for large accident forces. They are designed to preclude tearing or breaching of the containment system. Neither the forces possible in transportation accidents, nor the cask materials used, are consistent with the suggested scenario.

8.4 (12573)
Comment - EIS001887 / 0324
Page 6-31 to 6-32; Section 6.2.4.2.1 - Impacts from Accidents - National Mostly Legal-Weight Truck Scenario

Impact Issues Specific to Use of GA 4/9 Casks

The Draft EIS mostly legal-weight truck national transportation scenario fails to consider unique circumstances of the transportation system being evaluated. Specifically, the Draft EIS assumes that all shipments will be made in the new General Atomics GA4/9 truck casks, but fails to explicitly address aspects of the design and performance of those casks which may increase the probability and consequences of highway accidents.

Nevada's 1995 scoping comments requested that DOE consider the following issues. In order to achieve a four-fold increase in cask capacity, the GA4/9 casks utilize a number of new design features and materials. Further, the weight of the loaded GA4/9 cask requires that it be used in conjunction with a specially designed trailer, a lower weight cab-over-engine tractor, and a single fuel tank, in order to comply with legal weight limits. To date, there is no operating experience with spent fuel shipments in actual GA 4/9 casks, although DOE contractors have conducted operational tests using mock-ups. To our knowledge, no GA 4/9 casks have yet been manufactured under the recently issued NRC [Nuclear Regulatory Commission] certificate. The validity of the Draft EIS LWT [legal-weight truck] transportation risk assessment therefore rests entirely upon speculative assumptions about the performance of casks which have never been used.

Nevada believes the Draft EIS must demonstrate that the GA4/9 cask, trailer, and tractor system is appropriately designed for use in a decades-long, nationwide shipping campaign to Yucca Mountain. DOE's risk assessment must evaluate issues such as: the power and handling characteristics of the tractor relative to long hauls in mountainous terrain under winter driving conditions; noise and vibration levels within the cab, and the potential impacts on driver fatigue and increased probability of human error; and the constrained fuel capacity of the tractor, requiring refueling every 300 to 400 miles, which could may additional safety and safeguards risks. The performance of GA4/9 cask's depleted uranium gamma shield in high-speed collisions with relatively unyielding structures, and the vulnerability to terrorist attack with armor piercing weapons and commercial shaped charges, must specifically be evaluated.

Response
As stated in Chapter 6 of the EIS, all shipping casks used to ship spent nuclear fuel and high-level radioactive waste to Yucca Mountain would be certified by the Nuclear Regulatory Commission. These casks would meet the design, performance, and testing requirements in 10 CFR Part 71.

The shipping cask performance data used to estimate the radiological risks of transporting spent nuclear fuel are from the Nuclear Regulatory Commission report *Reexamination of Spent Fuel Risk Estimates* (DIRS 152476-Sprung et al. 2000). These data represent the best available information on the performance of shipping casks during accidents, including shipping casks that use depleted uranium shielding. In addition, the report *Projected Source Terms for Potential Sabotage Events Related to Spent Fuel Shipments* (DIRS 104918-Luna, Neuhauser, and Vigil 1999) evaluated shipping casks that use depleted uranium shielding.

In terms of operational characteristics, the GA4/9 is not significantly different than other spent nuclear fuel shipping casks. The cask is shipped horizontally and loaded vertically, incorporates an internal basket for supporting the spent nuclear fuel cargo, and is closed using double O-ring seals and a bolted closure. Nevertheless, commercial and DOE facilities would develop site-specific cask handling procedures and conduct dry runs of cask handling operations prior to loading actual spent nuclear fuel assemblies into the shipping casks. Therefore, based on operating experience with similar spent nuclear fuel shipping casks and requirements to develop site-specific procedures and conduct dry runs, DOE believes that the lack of operating experience with actual GA4/9 shipping casks is not an issue with respect to the transportation impact analysis.

The commenter was concerned about the tractors and trailers that would be used to haul the spent nuclear fuel shipping casks. Although the GA4/9 trailer is specially designed for the shipping cask, it is similar to other trailers used to haul concentrated heavy loads. The trailer meets the requirements of ANSI Standard N14.30-1992, *American National Standard for Nuclear Materials – Semi-Trailers Used in the Highway Transport of Weight Concentration Radioactive Loads Design, Fabrication, and Maintenance*. The tractor is commercially available and is used today for long hauls and to traverse difficult terrain under adverse weather conditions. The operating characteristics of the tractors and trailers are not significantly different than other load Concentrated shipments. Therefore, the power and operating characteristics of the tractor-trailer are adequately addressed in the transportation impact analysis. In addition, noise and vibration levels in the truck cab would be no different than other similarly designed truck-tractor combination vehicles and would not contribute any more to human error than other truck-tractor systems.

The transportation impact analysis incorporates the constrained fuel capacity of the tractor, which does not appear to DOE to be a source of additional safety and safeguards concerns. In terms of safeguards concerns, the shipments would meet the Nuclear Regulatory Commission requirements in 10 CFR Part 73. Stops, including refueling stops, are addressed in the route plans submitted to the Nuclear Regulatory Commission for approval. Appropriate safeguards and security provisions are specified during the preshipment planning process and are implemented for each shipment. See Appendix M of the EIS for additional information.

A number of activities are conducted to provide assurance that the shipping casks and vehicles are not deteriorating over time. The shipping casks are visually inspected for damage, their sealing surfaces and seals are inspected and replaced or repaired, and a leak test is performed prior to each shipment in accordance with operating procedures at the commercial, DOE, and Yucca Mountain sites. In addition, the fabricated casks are tested, including weld and hydrostatic tests, before they are placed in service. The shipping casks are subject to periodic inspections in accordance with the Certificate of Compliance issued by the Nuclear Regulatory Commission. Furthermore, periodic inspection and maintenance requirements for the vehicle (including in-transit brake, tiedown, and undercarriage inspections conducted by state agencies) provide assurance that the tractors and trailers used to haul the shipping casks are in proper working order. Further information on cask testing, operational protocols, and test and inspection procedures is provided in Sections M.4 and M.5 of the EIS.

8.5 Intermodal Transfer Facilities and Heavy-Haul Trucks

8.5.1 INTERMODAL FACILITY OPERATIONS

8.5.1 (180)
Comment - 8 comments summarized
Commenters said that the range of environmental, social, and economic impacts from the construction and operation of an intermodal transfer station was not adequately addressed in the EIS.

For the Caliente intermodal transfer station, commenters were concerned about the radiological risks to residents of Caliente because of the proximity of the facility to the city. Some wanted to know if the spent nuclear fuel and high-level radioactive waste would be repackaged at the facility, thereby increasing the risks of radiation exposure. Others said that this site is not an appropriate place to build such a facility. Some said that people in Caliente have already been adversely affected by the possibility of having an intermodal transfer station so close to the city and that citizens have become polarized just from the planning and decisionmaking associated with the facility. Others said that such a facility could adversely affect the lifestyle of residents. Commenters were concerned that businesses would not locate in Caliente because of the threat of constructing an intermodal transfer station or would move out if such a facility were constructed.

For the Sloan/Jean intermodal transfer station, commenters said that air quality and health impacts associated with this facility were not addressed in the EIS.

For the Apex/Dry Lake intermodal transfer station, commenters were concerned about the proximity of this facility to Las Vegas.

Response
Section 6.3.3 of the EIS discusses the impacts of Nevada heavy-haul truck implementing alternatives, including the impacts associated with an intermodal transfer station. The discussion indicates that, because spent nuclear fuel and high level radioactive waste casks would not be opened at the intermodal transfer station, the potential for accidents that could threaten the integrity of the casks is remote. These casks would be designed and certified by the Nuclear Regulatory Commission to withstand a range of severe transportation accident conditions, including collision impacts, drops, fires, and immersion in water. These conditions are much more severe than any expected at an intermodal transfer station. Therefore, the radiological risks from accidents to workers at an intermodal transfer station would be low, and the risk to the public from accidents at the facility would be negligible.

Section 6.3.3.1 of the EIS covers the impacts, including socioeconomic impacts, that would be common to the five heavy-haul truck alternatives. For example, it states that the total increase in employment (direct and indirect) that would result from construction of the intermodal transfer station, "… would peak in 2008 and would include about 135 workers. It also states that, "Increases in real disposable income from constructing an intermodal transfer facility would peak in 2008 at between about $2.7 million and $3.1 million." Air quality impacts common to operation of an intermodal transfer station at the Caliente, Apex/Dry Lake, or Sloan/Jean site are listed in Table 6-83. Health and safety impacts common to the alternative locations for an intermodal transfer station are listed in Tables 6–85, 6-86, and 6-87. Specific impacts associated with the construction and operation of an intermodal transfer station for each heavy-haul truck route analyzed are discussed in EIS Section 6.3.3.2.1 to 6.3.3.2.5. Radiological impacts to the health and safety of workers and persons living along transportation routes in Nevada, including impacts to persons who lived in the vicinity of an intermodal transfer station, are included in the results presented in Tables 6-93, 6-107, 6-112, and 6-117. The possible cumulative impacts from the operation of an intermodal transfer station at Caliente for shipments from the Proposed Action and shipments of low-level radioactive waste are discussed in Section 8.4.2.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in

predicting future behavior based on perceptions had advanced sufficiently since the EIS scoping process to enable DOE to quantify the impacts of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate either to Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods by which such impacts could be predicted with any degree of certainty.
- Much of the uncertainty is irreducible.
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

If Yucca Mountain was recommended and approved as the site for a monitored geologic repository, DOE would strive to provide clear, accurate information to the public regarding the repository and transportation planning, including potential risks.

8.5.1 (328)
Comment - EIS000028 / 0003
As for transporting low-level nuclear waste, a good truck route currently exists from the rail at Yermo, California. That area is practically void of human population. Yermo is isolated and could serve as a rail/truck terminal.

Response
A heavy-haul truck route originating in Barstow or Yermo, California, using State Route 127 would be similar to a route originating in Baker, California. A route originating from Baker using State Route 127 was considered but eliminated from further detailed study (see Section 2.3.3.2 of the EIS). A route originating from Barstow or Yermo would be eliminated from detailed study for reasons similar to that of the Baker route.

8.5.1 (911)
Comment - EIS000139 / 0001
It appears that intermodal transportation is the most effective and efficient way of transporting both low-level and high-level radioactive materials. We definitely would like to see the DOE seriously consider and push, if possible, the intermodal option preferably out of Caliente, Nevada.

Response
DOE has noted the commenter's preference for intermodal transportation in Nevada. However, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. The choice of a rail corridor or intermodal transfer station location and heavy-haul truck route within Nevada would not be based solely on the potential environmental impacts identified in the EIS. DOE would consider factors such as engineering feasibility, safety, input from the State of Nevada and surrounding communities, and cost in its decisionmaking. Consultations also would consider mitigative measures necessary to preclude or reduce potential impacts.

8.5.1 (997)
Comment - EIS000235 / 0003
The Draft EIS does not describe the type of staff that will be required to operate an intermodal facility in Caliente. Such staff will presumably include persons with training in the proper handling of radioactive materials (i.e., radiation health physicist) and emergency first response. The availability of specialists in Caliente would provide a capability to manage risks associated with other hazardous materials being shipped through the community every

day by rail. The Final EIS should characterize the types of specialists who would be required at an intermodal facility and how their presence in Caliente would help to manage existing risks from shipments of hazardous materials through the community.

Response
A preliminary description of the staff at an intermodal station is given in the *Intermodal Transfer Station Preliminary Design* (DIRS 104849-CRWMS M&O 1997). Specific staff capabilities at an intermodal station that could supplement and/or support the surrounding communities emergency response capability, would be addressed during the development of the system under the Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management (see Section M.3 of the EIS for details). If a decision to proceed with an alternative that includes intermodal transfers was made, detailed designs of the intermodal facility would be developed as well as detailed staffing plans.

However, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. The choice of a rail corridor or intermodal transfer station location and heavy-haul truck route within Nevada would not be based solely on the potential environmental impacts identified in the EIS. DOE would consider factors such as engineering feasibility, safety, input from the State of Nevada and surrounding communities, and cost in its decisionmaking. Consultations would consider mitigative measures necessary to preclude or reduce potential impacts.

8.5.1 (2431)
Comment - EIS000683 / 0009
In the interest of doing this, we've asked that our local oversight committee give a special attention to identifying the impacts that would be associated with this intermodal facilities in Caliente.

Our officials came out and actually said that they supported having the facility as early as 1995, but the studies so far have not been done to show what the impacts of this would be.

There's no way of knowing what the cumulative impacts would be of this proposal with the possibility of low level nuclear waste shipments through Lincoln County which might use the same facility.

So it's a major concern of mine that though I understand that finally at the late day, a certain amount of money from the County's funding has been diverted to do a study of the risks of this new mobile facility.

The results of the study are not out yet. They will probably barely be out in time to have input to you guys by the end of the comment period, and it's fairly clear that the citizens will not have an opportunity to review these findings or to say whether or not the results are being used to adequately protect the citizens or simply to support a benefits package, which I certainly do not.

Response
DOE cannot comment on the study being conducted by local officials until the study is complete and made available. Actual data generated by the study would be considered as the project develops. The specific impacts associated with the construction and operation of an intermodal transfer station for each heavy-haul truck route analyzed are given in EIS Section 6.3.3.2. Radiological impacts to the health and safety of workers and persons living along transportation routes in Nevada, including impacts to persons who lived in the vicinity of an intermodal transfer station, are included in results presented in the section. The possible cumulative impacts from operation of an intermodal transfer station at Caliente for shipments from the Proposed Action and shipments of low-level radioactive waste are discussed in Section 8.4.2.

8.5.1 (3080)
Comment - EIS000735 / 0008
When the EIS considers intermodal transfer stations, no consideration is given to a potential location in Barstow or Yermo, California. This is a well established rail yard with a large capacity with easy access to route 15 north bound to Baker then northwest though Death Valley and into the southern entrance to the Test Site.

Response
A heavy-haul truck route originating in Barstow or Yermo, California, using Route 127 would be similar to a route originating in Baker, California. A route originating from Baker using Route 127 was considered but eliminated from further detailed study (see Section 2.3.3.2 of the EIS). A route originating from Barstow or Yermo would be eliminated from detailed study for reasons similar to that of the Baker route.

8.5.1 (5407)
Comment - EIS001887 / 0110
Page 2-51; Section 2.1.3.3.3.1 - Intermodal Transfer Stations

This section describes the possible locations, configurations, and operations at an intermodal facility. It points out the increased handling and logistics introduced into any multi-modal transportation campaign to the Yucca Mountain site. It refers to transfer cranes and movement of casks from rail cars to heavy-haul trucks. This added transfer of the casks introduces increased risks to any transportation campaign. This movement, which would not be necessary in a rail-only shipping campaign, increases the possibility of an accident or damage to the shipping casks or the containers inside.

This scenario also contemplates heavy-haul truck transport primarily through congested metropolitan highway systems where impacts of such transport have not been adequately assessed.

The issue of general freight versus dedicated trains is expanded upon in this section. Intermodal transfer station operations would depend on whether the railcars that carried spent nuclear fuel and high-level radioactive waste arrived on dedicated or general freight trains. DOE states that there will be operational differences for the intermodal transfer station between the dedicated train and general freight options. The Draft EIS, however, does not contain sufficient information on these differences to allow an evaluation of the difference in impacts between the two options. The difference between staging requirements for the heavy-haul vehicles for the two options should be described. If general freight is used, the Draft EIS states that the "General freight trains would switch from the main Union Pacific track to an existing or newly constructed passing track." The Draft EIS does not state where the existing or newly constructed passing track would be located. If it is located at the intermodal transfer station, this would significantly alter the design of the station. If a new passing track is constructed at a location independent of the station, this would create potential impacts that have not been evaluated. Even if an "existing passing track" is used, this would probably require the Union Pacific to construct a new passing track for other railroad traffic.

Any delivery by dedicated trains would move directly into the intermodal facility for cask inspection and transfer to trucks. Shipments via general freight would be "set out," as is typical for railroad operations, on a siding at the intermodal facility. Then a "local" or rail yard locomotive would make the final move into the facility. Again, this clearly introduces another move that involves coupling and uncoupling cars, adding another element of potential human error or mechanical failure.

Response
Section 6.3.3 of the EIS discusses the impacts of Nevada heavy-haul truck implementing alternatives, including the impacts associated with an intermodal transfer station. The discussion indicates that, because spent nuclear fuel and high-level radioactive waste casks would not be opened at the intermodal transfer station, the potential for accidents that might threaten the integrity of the casks is remote. These casks would be designed and certified by the Nuclear Regulatory Commission to withstand a range of severe transportation accident conditions, including collision impacts, drops, fires, and immersion in water. These conditions are much more severe than any expected at the intermodal transfer station. Therefore, the radiological risks from accidents to workers at the intermodal transfer would be low, and the risk to the public from accidents at the intermodal transfer facility would be negligible.

The impacts of heavy-haul truck transportation for routes that would pass through the Las Vegas metropolitan area are evaluated in Section 6.3.3.2 of the EIS.

An intermodal transfer concept of operation for both dedicated and general freight train operation has been included in the *Intermodal Transfer Station Preliminary Design* (DIRS 104849-CRWMS M&O 1997). The conceptual design of an intermodal transfer station would have staging for eight heavy-haul vehicles. DOE anticipates that the staging provided for in the conceptual design would have sufficient staging for heavy-haul vehicles for dedicated or general freight trains. The intermodal transfer station design evaluated in the EIS would accommodate both dedicated and general freight shipments (DIRS 104849-CRWMS M&O 1997). DOE anticipates that operation of an intermodal station would be consistent with current Union Pacific operating practices and would not require construction of an additional passing track at sites in which one exists.

8.5.1 (7073)
Comment - EIS001337 / 0026
Lincoln County and the City of Caliente recommended that alternatives for accomplishing operation of the intermodal facility should be evaluated for their contribution to risk management and local economic benefits. It was suggested that DOE and DOE/contractor approaches should be considered against private development and operation. The County and City requested that options for shared use of the facility by other government (i.e. defense) and private industries should be assessed for their contribution to regional economic development. Alternatives for management of throughput at the facility were suggested for evaluation for their relative contributions to risk management. Of particular concern to the County and City was the potential for buildup of loaded shipping containers at the intermodal transfer site. The County and City asked that the DEIS evaluate the exposure risks associated with alternative numbers of in-transit containers resident at the site. The DEIS does not consider any of the specific intermodal operational issues raised by Lincoln County and the City of Caliente during EIS scoping.

Response
At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. Section M.3 of the EIS contains more information on routing regulations and operational procedures and protocols DOE would use if the Yucca Mountain site received approval. Section M.3 also contains more detail on the proposed role of the Regional Servicing Contractor.

As discussed in Section 6.3, the EIS provides estimates of the number of shipments that would be received at an intermodal transfer station in a week. Actual rates of receipt, or throughput, would be determined once a mode and route for transportation has been selected. The throughput volumes were used to develop the preliminary intermodal transfer station design, as described in *Intermodal Transfer Station Preliminary Design* (DIRS 104849-CRWMS M&O 1997).

8.5.1 (7076)
Comment - EIS001337 / 0028
Lincoln County and the City of Caliente requested that the DEIS consider the disposition of the intermodal transfer facility following cessation of waste emplacement at Yucca Mountain. Several alternatives were offered by the County and City for consideration by DOE including: (1) abandon the facility at the end of emplacement; (2) maintain the facility during the period of monitored Retrievability (i.e. 50-100 years) in case waste needs to be removed from the site; and (3) sell or deed the facility to another governmental or private party following emplacement of waste. The County and City requested that consideration of these alternatives evaluate impacts upon local economies, impacts upon other public and private users, and barriers to effective relocation of waste from the site in the event removal is required. The DEIS does not consider the fate of an intermodal facility following cessation of waste emplacement at Yucca Mountain.

Response
If the Yucca Mountain site was recommended and approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor or selection of a site for an intermodal transfer station, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews. These additional evaluations would include an assessment of the impacts for alternate closure scenarios for the intermodal transfer station on local economies,

impacts upon other public and private users, and barriers to effective relocation of waste from the site in the event removal is required.

8.5.1 (7184)
Comment - EIS001337 / 0075
Page 2-51 Section 2.1.3.3.3.1. The description of intermodal transfer stations should be refined to address 1) the length of siding required to accommodate waste shipments as well as other materials destined for Yucca Mountain; 2) the number of locomotives required to perform operations in the; 3) whether the types of support facilities which would be required at the site include maintenance of rail equipment; 4) the number of tractors and trailers required; 5) when and where tractor and trailer inspection would occur; 6) what, if any, emergency first response capabilities would resident at the intermodal station.

Response
If the Yucca Mountain site was recommended and approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor or selection of a site for an intermodal transfer station, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

Preliminary designs were developed for the intermodal transfer station for the Draft EIS and the impacts of construction and operation of the intermodal transfer station evaluated and presented in Section 6.3.3 of the EIS. The preliminary design requirements indicated that the length of a siding or passing track would be dependent on use of dedicated train(s) or general freight. In the case of general freight, a 1,400-meter (4,593-foot) passing track or siding would be necessary to allow general freight trains to pull off the mainline and switch to allow the cask cars to be pushed into the railyard (DIRS 104849-CRWMS M&O 1997). The analysis assumed that one local locomotive would be necessary for operations at an intermodal station. An optional railcar maintenance building is shown in the conceptual design of the intermodal transfer station (see DIRS 104849-CRWMS M&O 1997). DOE has estimated that a heavy-haul vehicle configuration with two tractors per trailer would be necessary for transportation of large rail casks (see Section 2.1.3.3.3.2). Two fleet sizes have been assumed for estimating purposes: a 12-transporter fleet all routes from Caliente, and an 8-transporter fleet for the Apex/Dry Lake and Sloan/Jean routes (see DIRS 154675-Ahmer 1998). Locations and times of tractor and trailer inspections for all routes have been included in *Road Upgrades for Heavy Haul Truck Routes* (DIRS 154448-CRWMS M&O 1998). Determination of the need and scope for resident emergency first-response capabilities at the intermodal transfer station would be determined during subsequent environmental and engineering analyses.

8.5.1 (8097)
Comment - EIS001873 / 0003
The Meadow Valley Wash, a perennial stream which flows to Lake Mead via Moapa Valley, is known for heavy flooding which has destroyed the UP rail line more than once. The DEIS states that the Caliente intermodal site is in a 500 year floodplain. However, I believe it has been inundated within the memory of local people. DOE admits that a flood and surface water analysis of the area has not been performed. This is an example of why, in my view, this EIS is insufficient to support a decision to select this or any other transportation mode or route.

Response
As discussed in Section 6.3 of the EIS, the selection of a specific location for an intermodal transfer station would require additional field surveys, environmental and engineering analyses, State and local government consultation, and appropriate National Environmental Policy Act reviews. Sections 3.2.2.2.3.1, L.3.2.6, and L.4.2.2 contain the most recent information on the proximity of the Caliente intermodal transfer station site to floodplains. If DOE selected the Caliente site, it would conduct a more detailed floodplain assessment for public review.

8.5.1 (8359)
Comment - EIS001873 / 0043
P. 3-127. Caliente intermodal site appears to be about 200 meters from the stream.

Response
Section L.3.2.6 of the EIS contains information on flooding and the presence of wetlands at the Caliente intermodal transfer station site. The selection of a specific location of an intermodal transfer station would require additional field surveys, environmental and engineering analyses, State and local government consultation, and appropriate National Environmental Policy Act reviews.

8.5.1 (8381)
Comment - EIS001873 / 0065
P. 6-57. The negative socioeconomic impacts from transportation including accidents are missing here and throughout the DEIS as I have said.

DOE should specifically address the issue of how security requirements around the intermodal sites would affect the residents of Caliente. For example, would access be denied to areas near the facility that are presently available for public use?

Response
Section 6.3.3.1 of the EIS covers the impacts, including socioeconomic impacts, that would be common to the 5 heavy-haul truck implementing alternatives. For example, it states that the total increase in employment (direct and indirect) that would result from construction of the intermodal transfer station, "… would peak in 2008 and would include about 135 workers. It also states that, "Increases in real disposable income from constructing an intermodal transfer facility would peak in 2008 at between about $2.7 million and $3.1 million." Air quality impacts common to operation of an intermodal transfer station located at the Caliente, Apex/Dry Lake, or Sloan/Jean sites are presented in the section. Health and safety impacts common to the alternative locations for an intermodal transfer station are given in tables in the section. The specific impacts associated with the construction and operation of an intermodal transfer station for each heavy-haul truck route analyzed are given in Section 6.3.3.2. Radiological impacts to the health and safety of workers and persons living along transportation routes in Nevada, including impacts to persons who lived in the vicinity of an intermodal transfer station, are included in results presented in the section. The possible cumulative impacts from operation of an intermodal transfer station at Caliente for shipments from the Proposed Action and shipments of low-level radioactive waste are discussed in Section 8.4.2.

DOE has completed a conceptual design of a generic intermodal transfer station. It covers an area of approximately 0.2 square kilometer (50 acres). Security would be achieved by enclosing the entire intermodal transfer station with a security fence, with gated entries at road and rail entrance/exit points, and continuous security monitoring. Access to this facility would be restricted requiring approval from DOE.

Section 2.1.3.3.3.1 of the EIS provides descriptions of the several proposed intermodal transfer stations associated with the heavy-haul truck implementing alternatives. The section addresses size, operations, access, and security of the stations. Sections 6.3.3.1 and 6.3.3.2 discuss the impacts of construction and operation of the facilities at the several proposed sites, including land use, access, and security.

8.5.1 (8666)
Comment - EIS001837 / 0026
The San Bernardino County Association of Governments has been receiving intermodal funding for about a year now. The first time PARD heard the term intermodal was in connection with nuclear waste shipments at the DOE annual conference in Salt Lake City in 1998. [What are] the connections between intermodal funding for the Needles depot (El Garces Harvey House?) and the DOE? Were DOE funds routed through the State Department of Transportation and on to SANBAG and the City of Needles for the preparation of an intermodal nuclear waste transfer station where waste from the Palo Verde Nuclear reactor would be boarded on trains?

Response
Funding of intermodal transportation studies are not a part of environmental impact studies and are not addressed in this EIS.

8.5.1 (8842)
Comment - EIS000869 / 0015
Paragraph six [in Section S.4.1.12] addresses the development of an emergency services team to respond to an accident at the repository but does not address transfer station or transport situations which would involve more members of the public. There are no public HazMat [hazardous materials] teams available qualified to intervene in a nuclear situation. This again appears to be a situation where the DOE is more concerned with its own employees than with the American population.

Response
DOE would, as required by Section 180(c) of the NWPA provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions spent nuclear fuel or high-level radioactive waste would be transported. Therefore, there would be personnel along all the routes qualified to respond to an incident during transportation. Personnel at transfer stations would be trained in responding to an emergency at the station.

In addition, as discussed in Section M.5 of the EIS, if requested by a state or tribal authority, DOE would provide assistance from its Regional Coordinating Offices located across the United States to reduce the consequences of accidents related to the transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. The assistance would involve providing equipment, logistical and medical resources, and qualified personnel as necessary. States and tribes can request and obtain assistance from other Federal agencies including the Federal Emergency Management Agency, Environmental Protection Administration, Nuclear Regulatory Commission, Department of Transportation, and Department of Defense.

Section 6.3.3 of the EIS discusses the impacts of Nevada heavy-haul truck implementing alternatives, including the impacts associated with an intermodal transfer station. The discussion indicates that, because spent nuclear fuel and high-level radioactive waste casks would not be opened at the intermodal transfer station, the potential for accidents that might threaten the integrity of the casks is remote. These casks would be designed and certified by the Nuclear Regulatory Commission to withstand a range of severe transportation accident conditions, including collision impacts, drops, fires, and immersion in water. These conditions are much more severe than any expected at the intermodal transfer station. Therefore, the radiological risks from accidents to workers at the intermodal transfer facility would be low, and the risk to the public from accidents at the intermodal transfer facility would be negligible.

The specific impacts associated with the construction and operation of an intermodal transfer station for each heavy-haul truck route analyzed are given in EIS Section 6.3.3.2. Radiological impacts to the health and safety of workers and persons living along transportation routes in Nevada, including impacts to persons who lived in the vicinity of an intermodal transfer station, are included in results presented in the section. The possible cumulative impacts from operation of an intermodal transfer station at Caliente for shipments from the Proposed Action and shipments of low-level radioactive waste are discussed in Section 8.4.2.

8.5.1 (9560)
Comment - EIS001888 / 0233
The DEIS does not provide a thorough description of intermodal handling operations. What are the risks of cask handling at intermodal sites? Does cask-handling equipment exist? Has it been tested? Who will test it? When? When will a decision about intermodal site selection be made?

Response
The *Intermodal Transfer Station Preliminary Design* (DIRS 104849-CRWMS M&O 1997) contains an operating plan for the proposed station. Sections J.3.3.1, J.3.4.3, and J.3.5.3 of the EIS discuss the risks associated with cask handling at an intermodal transfer station. Commercial nuclear powerplants with dry cask storage use cask-handling equipment similar to the equipment DOE would use at an intermodal station. The equipment design would accommodate a number of cask types. The design effort would occur during detailed design activities for an

intermodal transfer station, and would comply with “Special Lifting Devices for shipping Containers Weighing 10,000 Pounds (4500 kg) or More” (American National Standards Institute standard ANSI.N14.6), against which DOE would test the equipment. In addition, inspections of the equipment by the intermodal transfer station contractor would comply with this standard.

Section 6.3.3 of the EIS discusses the impacts of Nevada heavy-haul truck implementing alternatives, including the impacts associated with an intermodal transfer station. The discussion indicates that, because spent nuclear fuel and high level radioactive waste casks would not be opened at the intermodal transfer station, the potential for accidents that might threaten the integrity of the casks is remote. These casks would be designed and certified by the Nuclear Regulatory Commission to withstand a range of severe transportation accident conditions, including collision impacts, drops, fires, and immersion in water. These conditions are much more severe than any expected at the intermodal transfer station. Therefore, the radiological risks from accidents to workers at the intermodal transfer would be low, and the risk to the public from accidents at the intermodal transfer facility would be negligible.

DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was recommended and approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor or identification of a specific location for an intermodal transfer station, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

8.5.1 (9600)
Comment - EIS001888 / 0275
Intermodal Handling Risks

One of the challenges for risk analysts is to completely describe the risks of the activity being analyzed. In this case, the DEIS fails to adequately address the risks of transferring a waste Cask from a rail car to a heavy haul transporter. One of the problems with intermodal transportation is that it increases the number of times the waste package is handled. In past campaigns, most accidents occur due to handling. The DEIS should have examined the safety of intermodal handling based on some proposed handling process. No handling process is described in the DEIS.

Both of the intermodal handling facilities proposed in the DEIS are located in urban Clark County. In the case of the Apex facility, the facility is located near a veterans hospital, the jet fuel storage tanks for an air force base, and burgeoning residential areas. The other proposed intermodal facility, in southern western Clark County, is adjacent to two major hotels. Most of those hotel rooms would look out onto the intermodal-handling yard. All of the approximately 24,000 vehicles that use Interstate 15 to travel to or through Las Vegas would pass over the Union Pacific rail line that would carry the spent fuel to the intermodal facility. In order for the DEIS to be sufficient a Risk Management Plan required for SARA Title III facilities should be prepared as part of the final EIS.

Response
Section 6.3.3 of the EIS discusses the impacts of Nevada heavy-haul truck implementing alternatives, including the impacts associated with an intermodal transfer station. The discussion indicates that, because spent nuclear fuel and high level radioactive waste casks would not be opened at the intermodal transfer station, the potential for accidents that might threaten the integrity of the casks is remote. These casks would be designed and certified by the Nuclear

Regulatory Commission to withstand a range of severe transportation accident conditions, including collision impacts, drops, fires, and immersion in water. These conditions are much more severe than any expected at the intermodal transfer station. Therefore, the radiological risks from accidents to workers at the intermodal transfer would be low, and the risk to the public from accidents at the intermodal transfer facility would be negligible.

The transportation analysis within Nevada is in the conceptual stage. If the decision to utilize an intermodal transfer station was made, the preliminary design phase would address safety analysis, based on a more detailed concept of operations. As part of the design process, a risk identification and management plan would be developed and implemented.

8.5.1 (9604)
Comment - EIS001888 / 0278
In order for the intermodal handling and heavy haul sections of the DEIS to be regarded as complete analyses, it is necessary for the following additional reports or supplements to the DEIS: An analysis of the risks at each proposed intermodal facility. This plan should be prepared in accordance with the Risk Management Plans mandated by the Clean Air Act Amendments of 1996. A revised DEIS that provides a specific analysis of the risks of intermodal handling at each of the proposed facilities should be prepared. The handling procedures at each facility must be described.

Response
Section 6.3.3 of the EIS discusses the impacts of Nevada heavy-haul truck implementing alternatives, including the impacts associated with an intermodal transfer station. The discussion indicates that, because spent nuclear fuel and high level radioactive waste casks would not be opened at the intermodal transfer station, the potential for accidents that might threaten the integrity of the casks is remote. These casks would be designed and certified by the Nuclear Regulatory Commission to withstand a range of severe transportation accident conditions, including collision impacts, drops, fires, and immersion in water. These conditions are much more severe than any expected at the intermodal transfer station. Therefore, the radiological risks from accidents to workers at the intermodal transfer would be low, and the risk to the public from accidents at the intermodal transfer facility would be negligible.

The transportation analysis within Nevada is in the conceptual stage. If the decision to utilize an intermodal transfer station was made, the preliminary design phase would address safety analysis, based on a more detailed concept of operations. As part of the design process, a risk identification and management plan would be developed and implemented.

8.5.1 (10594)
Comment - EIS002122 / 0008
There's no description of the security or adequate description of the security requirements around the possible intermodal transfer sites. For those of us in the county who live near the City of Caliente, would our freedom of motion be limited? Would we be able to climb on the hills overlooking the possible site? How far away is it? How large would the buffer area be, especially considering the fact that a terrorist could from above lob some sort of projectile into the area where these casks would be left over the weekend because of the transportation requirements.

Response
A facility such as this would require a Site Safeguards and Security Plan that is site specific. At this time, DOE has not chosen the heavy-haul truck mode of transportation. Should heavy-haul truck be chosen as the mode, addition decisions would be required on the specific route and the specific location of the intermodal transfer station.

DOE has completed a conceptual design of a generic intermodal transfer station. It covers an area of approximately 0.2 square kilometer (50 acres). Security would be achieved by enclosing the entire intermodal transfer station with a security fence, with gated entries at road and rail entrance/exit points, and continuous security monitoring. Access to this facility would be restricted requiring approval from DOE.

Section 2.1.3.3.3.1 of the EIS provides descriptions of the several proposed intermodal transfer stations associated with the heavy-haul truck implementing alternatives. The section addresses size, operations, access, and security of the stations. Sections 6.3.3.1 and 6.3.3.2 discuss the impacts of construction and operation of the facilities at the several proposed sites, including land use, access, and security.

8.5.2 HIGHWAY UPGRADES

8.5.2 (5411)
Comment - EIS001887 / 0114
Page 2-54; Section 2.1.3.3.3.2 - Highway Routes for Heavy-Haul Shipments

The Draft EIS assumes that most borrow material for construction could come from existing Nevada Department of Transportation borrow areas, if the State agreed. Most road design projects attempt to balance cut and fill requirements during construction of the roads. Therefore, it is not reasonable to assume that borrow material will be available in existing borrow areas for the extensive fill requirements necessary to construct truck climbing lanes and other road improvements. Obtaining fill material from other areas could result in significant impacts not discussed within the Draft EIS.

The last sentence in the second paragraph of the first bullet says, "This parking area would be near the U.S. 6 and U.S. 95 interchange at Tonopah." The point where U.S. 6 and U.S. 95 meet in Tonopah is an intersection in town. It is hardly a place to park this type of truck. This is a busy intersection, not a freeway-type interchange.

Response
DOE developed a *Cost Estimate for Heavy Haul Truck Transport Design* (DIRS 154675-Ahmer 1998). This study identifies the estimated embankment material and aggregate material needed to upgrade roads for use by heavy-haul trucks. For example, the cost estimate for the Caliente Route identifies the need for approximately 1.5 million cubic meters (2 million cubic yards) of embankment material, and approximately 190,000 cubic meters (250,000 cubic yards) of aggregate base material. If this material was not available in the Nevada Department of Transportation's current borrow areas, the material would have to be purchased from commercial borrow material suppliers, unless the Project can negotiate borrow area development with the Bureau of Land Management or private landowners in local areas. Details of the borrow requirements and sources would be developed in the detail design, should heavy-haul trucks be selected as the transportation mode in Nevada. The analysis in Section 6.3.3 of the EIS includes estimates of impacts to land areas from which borrow materials would be taken for upgrading roads.

The analysis of the road upgrades (DIRS 154448-CRWMS M&O 1998) includes a potential location for an overnight truck stopping area approximately 48 kilometers (30 miles) east of Tonopah along U.S. 6. A specific location for such a stop has not been identified. DOE does not propose to construct a safe parking area at the U.S. 6 and U.S. 95 interchange in Tonopah.

8.5.2 (5716)
Comment - EIS001887 / 0330
Page 6-35; Section 6.3 - Nevada Transportation

Land Use and Ownership: The Draft EIS makes note of land use and ownership impacts to landowners due to the creation and use of a branch rail line or heavy-haul facility. It does not account for impacts to the Nevada Department of Transportation (NDOT) as a landowner. Negative impacts include corridor degradation, loss of pavement structure, and operational disruptions (queues, etc.). DOE has also failed to assess what will happen to facilities, shipments, and operations when the time comes to rebuild or resurface the roadways sustaining this shipping campaign. These roadways will have to be refurbished, since axle loads of the kind proposed for spent fuel and HLW [high-level radioactive waste] shipments were never anticipated and would accumulate and reduce the service life of affected roadways. The Draft EIS does not consider the fact that during a 24 year shipping campaign, roadways will deteriorate and must be rebuilt. In section 6.3.3.1, the Draft EIS states that resurfacing would occur every eight years. What 'ESAL' calculations are driving this number? What happens to shipments when highway construction closes down roadways for months at a time? In addition, it would appear that field inspections of 'choke points' and areas of operational concern have not been effectively carried out. Areas such as Hancock Summit, for example, may not be able to legally allow a heavy-haul vehicle configuration to pass through the summit and roadway cut. The turning radius may be too small to allow the vehicle to traverse the roadway.

Response
Impacts such as loss of pavement structure and operational disruptions have been addressed in analysis presented in the EIS (see EIS Sections 6.3.1 and 6.3.3.1). As described in *Road Upgrades for Heavy Haul Routes*

(DIRS 154448-CRWMS M&O 1998), use of the conceptual heavy-haul transport vehicle, which is also described in Section 2.1.3.3.3.2, and roadway geometry were taken into account. In addition, for this analysis field surveys of routes were made to determine if roadway geometry would support use of the transport vehicle. A road upgrade design would mitigate areas of operational concern and "choke points" through lane widening, intersection widening, and/or a truck alternate route (DIRS 154448-CRWMS M&O 1998; DIRS 154824-Ridilla et al. 1997). In addition, because transport and escort vehicles would compromise only a small percentage of the average daily traffic along routes, impacts such as corridor degradation would be small.

Traffic control measures would be used in order to accommodate heavy-haul truck shipments during times of road maintenance of routes.

The potential road upgrades that were evaluated in the EIS analysis for each candidate heavy-haul truck route can be found in Section J.3.1.2 of the EIS. These upgrades were based on projected annual average daily traffic for 2010 to 2033. These annual average daily traffic estimates were used to calculate estimated Equivalent Single Axle Loads for 2010 through 2033 combined with estimates for the 17-axle heavy-haul vehicle configuration assumed for the analysis. These combined Equivalent Single Axle Loads were used to calculate the necessary pavement thickness of initial road upgrades with assumed subsequent pavement overlays every 8 years and a road serviceability life of 20 years (see DIRS 154448-CRWMS M&O 1998).

8.5.2 (7069)
Comment - EIS001337 / 0024
Lincoln County and the City of Caliente noted that the DEIS should evaluate alternatives for establishing and maintaining a highway system capable of withstanding repeated heavy-haul loads. They further suggested that where new road construction is required, improved yet unpaved surfaces should be evaluated against pavement. The County and City encouraged DOE to evaluate risk management benefits associated with options for construction of dedicated travel lanes in areas of excessive grades or poor sight distance. The DEIS does not consider paved versus unpaved roadway improvement alternatives. Evaluation of the risk management benefits potentially associated with construction of dedicated travel lanes was not addressed within the DEIS.

The County and City recommended several operational alternatives for consideration within the DEIS including escorted versus unescorted shipments; time of day travel restrictions versus unrestricted transport; and use of local versus nonlocal trucking firms. The first two were recommended for consideration for their contribution to risk management. DOE was encouraged to evaluate the third option set to determine regional economic benefits. The DEIS does not consider specific heavy-haul operational alternatives offered by Lincoln County and the City of Caliente during scoping.

Response
DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

An EIS reference (DIRS 154675-Ahmer 1998) includes a "Cost Estimate for Heavy Haul Truck Transport Design." It includes a detailed cost estimate for the design, construction, and management of upgrades for public roads for each of the five candidate heavy-haul truck routes. DOE based the estimated costs presented in Section 6.3.3.2 of the EIS on those estimates, which include lane widening, truck lane and turnout construction, pavement upgrades, intersection upgrades, and shoulder upgrades. Cost estimates developed for highway upgrades associated with heavy-haul truck scenarios include costs for annual maintenance of the roads. Table J-89 summarizes road upgrades for a proposed Caliente Route.

Before DOE used a heavy-haul truck transportation implementing alternative it would work with the State of Nevada to conduct engineering and environmental studies that would support detailed design and construction of upgrades to highways. The studies would include traffic analysis to identify the specific turnout requirements for each road section based on the estimated increase in annual average daily traffic over the life of the project. Turnouts preliminarily identified by the analysis [see *Road Upgrades for Heavy Haul Routes* (DIRS 154448-CRWMS M&O 1998)] were included in estimating the cost for road upgrades. Although the installation of additional lanes for the proposed routes is not necessary to maintain level of service for the roads that are not heavily used, turnout locations and the number of turnouts could be adjusted to maximize their effectiveness.

DOE would follow State of Nevada requirements for heavy-haul truck shipments. Such requirements include time-of-day travel restrictions and escorts. DOE has developed a draft Request for Proposal for Regional Servicing Contractors for waste acceptance and transportation. The contractor(s) would be responsible for shipping arrangements and transportation services in the servicing region(s). DOE plans for transportation operations are discussed in Section M.3 of the EIS.

8.5.2 (7186)
Comment - EIS001337 / 0125
Page 2-54 Highway Routes for Heavy-Haul Shipments - It is unacceptable to Lincoln County that the DOE is only considering adding up to 4 feet to the existing shoulders. Some of the existing shoulders are only 2-3 feet wide which means at a maximum the shoulder would be only 7 feet wide. With the heavy-haul truck and cask being up to 10 1/2 feet wide, DOE should insure that the shoulders are at least 12 feet wide so that the vehicle could be safely and completely removed from the main part of the road. This section also discusses the routes from each of the intermodal transfer stations to Yucca Mountain. Having to modify intersections in the vicinity of Hiko, SR 375 and U.S. 6 to accommodate the 220 foot long heavy-haul trucks should be relatively easy, however, if any of the intersections at I-15, the new beltway, U.S. 93 or U.S. 95 are inadequate to handle the transporter, both in terms of weight or geometry, this could be a show stopper. DOE needs to evaluate these [intersections] carefully before considering them to be feasible routes.

Also, DOE needs to consult with the Nevada Department of Transportation to determine if NDOT [Nevada Department of Transportation] would issue a heavy-haul permit on these routes.

Furthermore, turnouts located every 20 miles is not acceptable and would adversely impact commerce, tourism and general transportation in Lincoln County and create potentially unsafe passing conditions. This issue would be mitigated via construction of dual lanes in each direction on any highway in Lincoln County used for heavy-haul transport.

Response
DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Section J.3.1.2 of the EIS provides tables that list potential upgrades for roads in Nevada to handle heavy-haul trucks. This information is summarized from reference (DIRS 154448-CRWMS M&O 1998). The road widening proposed for the two lane roads includes widening two-lane roads to two 4.3-meter (14-foot)-wide lanes with a 0.6-meter (2-foot) shoulder on each side. Existing road widths along the candidate routes for heavy-haul trucks include two 3.7-meter (12-foot) lanes and shoulder widths ranging from 0.3 to 0.6 meter (1 to 2 feet). The existing 3.7-meter-wide lanes support maximum legal vehicle widths of 2.6 meters (8.5 feet). The proposed 4.3-meter lanes would be sufficient for a 3-meter (10-foot)-wide heavy haul transporter. The 0.6-meter shoulder width provides additional road width for the transporter in transit and would help reduce pavement “breakout” along the edge of the road. Truck turnouts would be used to remove a transporter from travel lanes, if needed. For details, see *Road Upgrades for Heavy Haul Routes* (DIRS 154448-CRWMS M&O 1998).

Interstate System intersections were evaluated in the analysis discussed above. Costs associated with upgrading those intersections to support heavy-haul truck transport were included in costs assumed for analysis in the EIS [for additional information, see *Cost Estimate for Heavy Haul Truck Transport Design* (DIRS 154675-Ahmer 1998)].

As described in the analysis *Road Upgrades for Heavy Haul Routes* (DIRS 154448-CRWMS M&O 1998), informal discussions were held with the Nevada Department of Transportation to identify preliminary road upgrade requirements. Permits for heavy-haul trucks have not been discussed with the Nevada Department of Transportation. However, the State routinely issues travel permits to operators of heavy-haul trucks.

Before DOE used a heavy-haul truck transportation implementing alternative, it would work with the State of Nevada to conduct engineering and environmental studies that would support detailed design and construction of upgrades to highways. The studies would include traffic analysis to identify the specific turnout requirements for each road section based on the estimated increase in annual average daily traffic over the life of the project. Turnouts preliminarily identified by the analysis [see *Road Upgrades for Heavy Haul Routes* (DIRS 154448-CRWMS M&O 1998)] were included in estimating the cost for road upgrades. Although the installation of additional lanes for the proposed routes is not necessary to maintain level of service for the roads that are not heavily used, turnout locations and the number of turnouts could be adjusted to maximize their effectiveness.

8.5.2 (11312)
Comment - EIS001814 / 0041
DEIS Page 6-11
The potential impacts from upgrading Nevada highways for heavy-haul truck use would be small because modifications to roads would occur in previously disturbed rights-of-way.

The amount of upgrade required varies significantly between the various heavy-haul route options. Portions of the Caliente Chalk Mountain route will require significant upgrades, resulting in much more impact than some of the other route segments. Realigning roads to avoid significant grades and to improve curvatures will impact areas outside of current rights-of-way. The impact of the heavy-haul alternative on critical habitat for wildlife will be similar to that discussed above for the rail line alternative.

Response
The road upgrades proposed for candidate routes for heavy-haul trucks include (1) increasing the pavement thickness to meet the requirements of the heavy-haul truck axle loads, (2) increasing the lane width and shoulder width to accommodate the width of the 10-ft wide transporters, and (3) installing truck lanes and turnouts adjacent to the existing pavement to allow additional lanes for passing vehicles. All proposed upgrades would occur in existing highway rights-of-way. The upgrades would not change road alignment or hill grade. The routes were evaluated for heavy-haul truck maneuverability, and no unacceptable conditions were identified. Therefore, no critical habitat disturbance has been identified. However, before DOE used a heavy-haul truck transportation implementing alternative, it would work with the State of Nevada to conduct engineering and environmental studies that would support detailed design and construction of upgrades to highways.

8.5.2 (11981)
Comment - EIS000688 / 0003
The second should wait till tomorrow as you commute back to Las Vegas. Try to envision making the trip on that narrow curvy round between here and Alamo in a truck that’s 270 feet long, has forty wheels, two engines and two drivers and weighs almost 300,000 pounds, and then go back to Washington, D.C. and tell someone they need to rethink their transportation plan.

Response
At this time, the heavy-haul truck implementing alternatives for transporting spent nuclear fuel and high-level radioactive waste to the proposed repository are conceptual. Section 2.1.3.3.3.2 of the EIS shows a concept for such a heavy-haul truck. Proposed road upgrades to allow use of such trucks, such as improvements to pavement and construction of turnouts and truck passing lanes, would mitigate impacts on congested roads, traffic flow, and highway infrastructure. However, before DOE used a heavy-haul truck transportation implementing alternative it would work with the State of Nevada to conduct engineering and environmental studies that would support detailed design and construction of upgrades to highways.

DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.5.3 HEAVY-HAUL TRUCK OPERATIONS

8.5.3 (190)
Comment - 33 comments summarized
Commenters stated that the Draft EIS did not adequately demonstrate either the feasibility of implementing a heavy-haul truck scenario or evaluate the impacts if such a scenario was implemented. Commenters stated that the implementation of such an approach is totally unprecedented in the United States and were concerned that, since heavy-haul trucks are slow moving oversized vehicles, their presence on the roads would cause more accidents and result in the effective loss of use of the major arterial roads. Commenters stated that DOE would need to consult with the Nevada Department of Transportation before considering heavy-haul truck transport of spent nuclear fuel and high-level radioactive waste as a viable option. Commenters questioned whether the postulated routes would even be feasible for heavy-haul trucks and if additional highway lanes would have to be constructed to accommodate the size of the vehicles. They stated that detailed surveys of roads, bridges, and overpasses would be needed to ensure that heavy loads could be handled. Another commenter was concerned about the potential cost of having to build bypasses to either go around or through towns because the trucks would be so large they would not be able to make a right-angle turn.

Commenters stated that the heavy-haul truck analysis was deficient. Commenters stated that conclusions regarding changes in level of service in congested areas such as Las Vegas were not supported by the analysis and that no evidence was presented to support the speed assumptions [that is, 32 to 48 kilometers (20 to 30 miles) per hour] made for the heavy-haul truck scenario. If the actual speeds were less, traffic impacts would be exacerbated. Other commenters noted that the impacts to normal traffic flows on heavy-haul truck routes were grossly underestimated considering convoy length and frequency and slower travel speeds. Because disruptions on congested highways often continue after the removal of the cause, the duration of the traffic flow disruption would be longer than the time the vehicle would travel on the highways. Commenters also stated that because of the turning radius requirements for heavy-haul trucks, certain intersections and road segments might have to be shut down to allow passage of heavy-haul trucks. Commenters stated that the Draft EIS did not consider in-transit refueling requirements, safety, security, and the perceived risk of overnight parking for heavy-haul trucks.

Other commenters stated that the EIS did not include analysis of accident rates for this type of vehicle or of accident rates for other vehicles caused by the heavy-haul vehicle. Commenters were concerned that the cost to upgrade candidate heavy-haul truck routes in problem areas such as through Hancock Summit, Tonopah, and Goldfield could be 3 to 10 times greater than Draft EIS estimates. Another commenter said that the Nevada highway system as it now exists could not sustain the accumulation of axle loads this type of shipping campaign would produce and that infrastructure improvements, including lane construction and widening, would be required in both directions for almost the entire length of the heavy-haul truck routes evaluated in the Draft EIS.

Commenters were concerned that the use of heavy-haul trucks would increase traffic congestion in major metropolitan areas such as Las Vegas or in smaller communities along the route. Others were concerned that highway travel times could increase because of the use of these vehicles and questioned what the impact would be on local commerce and air quality. Some commenters stated that Interstate System highways could not be used and that the roads might have to be closed to all other traffic.

Response
DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. If the Yucca Mountain site was approved, DOE would issue at some future date a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. A similar process would occur if DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional

field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

At this time, the heavy-haul truck alternatives for transporting spent nuclear fuel and high-level radioactive waste to the proposed repository are in the conceptual stages of development, although preliminary design and engineering studies have been conducted for the heavy-haul truck options (see DIRS 154448-CRWMS M&O 1998; DIRS 154824-Ridilla et al. 1997). These studies identify potential upgrades for mitigating the potential impacts of the heavy-haul truck concept shown in Figure 2-29 of the EIS.

Based on the analysis mentioned above, heavy-haul truck transportation is technically feasible and its costs would be comparable to those for rail transportation. Sections of the Caliente route such as Hancock Summit and affected communities have been evaluated and are feasible options if the recommended road upgrades were completed. The basis for the cost of upgrading the Caliente heavy-haul truck roads are a result of engineering analysis, limited discussions with the Nevada Department of Transportation, input from heavy-haul trucking companies, and actual cost estimates from highway contractors in Nevada. This information is presented in *Cost Estimate for Heavy-Haul Truck Transport Design* (DIRS 154675-Ahmer 1998). This reference includes detailed cost estimates for the design, construction, and management of the initial road upgrades for public roads for each of the five heavy-haul truck routes. DOE believes this is an adequate technical basis to support the EIS cost estimates for the Caliente and other heavy-haul truck routes.

DOE has received input from heavy-haul truck companies on the estimated speed of the heavy-haul vehicle identified in the EIS. The speed depends on the highway grade. At 0-percent grade, the estimated speed is 68 kilometers (42 miles) per hour and at 4-percent grade, 24 kilometers (15 miles) per hour. Thus, an average speed of 32 to 48 kilometers (20 to 30 miles) per hour for an entire trip does not seem unreasonable. The State of Nevada restricts heavy-haul truck transport to daylight hours only. Thus, intermediate overnight stops would be necessary for the longest of the heavy-haul truck routes. Sections 6.3.3.2.1 through 6.3.3.2.3 of the EIS identify the heavy-haul truck routes that would require an overnight stop. The trucks would carry sufficient fuel to travel the entire one-way distance before refueling.

DOE calculated heavy-haul truck impacts using the Primary road rates in *State-Level Accident Rates of Surface Freight Transportation: A Reexamination* (DIRS 103455-Saricks and Tompkins 1999). Although the document does not explicitly address heavy-haul truck accident rates, DOE believes it provides the latest reasonably available data, as relevant to heavy-haul truck as it is to legal-weight truck transport. The accident rates used in the analysis are conservative because of the special precautions taken with heavy-haul truck shipments to prevent accidents, such as restricting travel to daylight hours and providing escort vehicles in front and behind the trucks. The heavy-haul trucks could affect the accident rates for other vehicles. However, the additional precautions described above in addition to the planned road improvements would mitigate these effects.

Section 6.3.3.1 of the EIS states that most of the highways that heavy-haul truck shipments would use are classified as having freely flowing traffic without delays and that the addition of 11round trips each week should not affect the level of service. The EIS also states that the slow-moving heavy-haul trucks could present a traffic obstruction that increased congestion, delayed other vehicles, and caused short queues to form between turnout areas, even after the shipment passed. However, given the low frequency of heavy-haul truck shipments, congestion would occur predominantly on relatively short segments of the heavy-haul truck routes and mitigation measures could be implemented to alleviate congestion concerns.

DOE would meet all Federal requirements for safety and security of the heavy-haul trucks and comply with the conditions of the Nevada Department of Transportation permits, including restrictions that lead to the need for overnight parking areas. The heavy-haul trucks would be escorted at all times, providing safety and security for the vehicles in transit, including warning other drivers on the highway of the slow-moving, oversized vehicles. Restricting the heavy-haul trucks to travel only during daylight hours is a safety-related requirement that would ensure the shipment was visible to other drivers. DOE anticipates that security systems and personnel would be provided at the overnight parking sites. Preliminary sites for the overnight parking areas are identified in Sections 6.3.3.2.1 to 6.3.3.2.3 of the EIS for each heavy-haul truck implementing alternative that would require overnight parking. As discussed in Section 6.3.3.1, workers at an overnight parking area would receive only small radiation doses because the vehicles would not be unloaded. Table 2-10 lists air quality impacts for all heavy-haul truck implementing alternatives. Section 6.3.3.1 discusses the derivation of the air quality impacts of heavy-haul truck transportation.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since the scoping process for the EIS to enable DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty.

- Much of the uncertainty is irreducible.

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

If Yucca Mountain was approved as the site for the geologic repository, DOE would continue to provide clear, accurate information to the public regarding the potential risks of a repository at the site and of transporting spent nuclear fuel and high-level radioactive waste to the site.

8.5.3 (776)
Comment - EIS000096 / 0005
Third, the document grossly underestimates HHT [heavy-haul truck] routine radiation doses to members of the public along the route, particularly in Tonopah and Goldfield. Stop-times and reduced speeds due to intersections, sharp curves, school zones, and other local conditions could result in significant cumulative exposures within 150 yards of the highway.

Response
In responding to public comments regarding individuals in Nevada who live close to candidate transportation routes, DOE used information from a recent report prepared for the City of North Las Vegas (DIRS 155112- Berger Group 2000). This report presents suggested assumptions for a hypothetical maximally exposed individual who lived 15 meters (49 feet) from a roadway used by heavy-haul trucks and who would be present and stay at that location, when, over the 24 years, each shipment stopped for 1 minute. DOE believes that such an exposure scenario is highly unlikely and therefore unrealistic. Nonetheless, DOE estimated the maximum cumulative radiation dose to this hypothetical individual would be about 520 millirem over 24 years of the Proposed Action (see Section J.1.3.2.2.1 of the EIS). This dose would lead to an estimated increase in risk of cancer of 1 in 4,000 over the individual's lifetime. In addition, the analysis in the EIS considered other potential maximally exposed individuals who could live along routes in Nevada. These included:

- A person in Alamo living in a residence approximately 5 meters (15 feet) from U.S. 93 where heavy-haul trucks could pass who could receive a dose of 25 millirem over 24 years;

- A person who could be in the courthouse or fire station in Goldfield, Nevada approximately 5 meters (15 feet) from U.S. 95 where heavy-haul trucks could pass, who could receive a dose of 56 millirem over 24 years;

For perspective, cancer from all other causes is fatal to about 1 in 4 persons.

8.5.3 (1173)

Comment - EIS000229 / 0006

The HHT [heavy-haul truck] routes identified in the DEIS do not meet U.S. Nuclear Regulatory Commission (NRC) safeguards criteria. A curious deficiency in the DEIS HHT routing analysis is DOE's apparent ignorance of the NRC safeguards route approval process and criteria. Advance route approvals are part of a safeguards system designed to "[m}inimize the possibilities for radiological sabotage of spent fuel shipments, especially within heavily populated areas..." [10CFR73.37(a)(1)(i)] In 1980, NRC issued a regulatory guidance document [NUREG-0561, Rev.1] which identified five types of route characteristics that receive special consideration when Commission staff review requests for route approval: (1) routes through highly populated areas; (2) routes which would place the shipment or the escort vehicle in a significantly tactically disadvantageous position (for example, tunnels which would prevent the escort vehicle from maintaining continuous surveillance of the shipment vehicle); (3) routes with marginal safety design features (for example, two-lane routes, absence of guard rails, etc.); (4) routes with limited rest and refueling locations; and (5) routes where responses by local law enforcement agencies, when requested, would not be swift or timely. None of the HHT routes identified in the DEIS meet the safeguards routing criteria established by the NRC.

Response

The five candidate heavy-haul truck routes in the EIS represent reasonable alternatives using existing public highways in Nevada. DOE is required by the National Environmental Policy Act implementing regulations to evaluate a range of reasonable alternatives in addition to its preferred alternative.

The Nuclear Regulatory Commission (NRC) issued guidance to provide added protection of spent nuclear fuel shipments against sabotage and diversion (DIRS 154766-NRC 1980). This document contains route selection criteria used by the Commission. Within the section of the document titled "Route Selection Criteria," a brief explanation is given as to the use of these criteria:

> The following are descriptions of criteria frequently used by the NRC staff to determine the preferability and acceptability of spent fuel shipment planned routes and alternative routes. These criteria apply generally to road, rail and sea modes. In the case of road shipments, in particular, Interstate System highways typically best satisfy these criteria.
>
> Likelihood of swift local law enforcement agency (LLEA) response. Routes that permit more timely responses by the LLEA when assistance is requested are preferred.
>
> Avoidance of tactically disadvantageous positions. Routes are preferred which avoid passage through areas including features or terrain which would place the shipment or shipment escorts in significantly tactically disadvantageous positions (for example, passage through long tunnels or over bridges spanning heavily populated areas).
>
> Availability of appropriate rest and refueling stops. Road shipment routes should feature sufficient locations for rest and refueling stops to allow flexibility in adjusting schedules to accommodate unexpected situations.
>
> Availability of good transportation safety design features. Road and rail routes featuring advanced safety design features (for example, divided highways, guard rails, limited access highways for road shipments; high grade track for rail shipments) are preferred over those including portions that are in disrepair or obsolescent (DIRS 154766-NRC 1980).

These criteria do not include "routes through highly populated areas" as a route characteristic that should receive special consideration when Commission staff members review requests for route approval, as stated by the commenter.

In addition, no route would meet the highest standards of these criteria over its entire length. However, the five candidate routes for heavy-haul trucks that are analyzed in the EIS would meet the overall standards of these criteria if the proposed road upgrades to permit use by the trucks were completed.

As stated in Section 2.3.3.2 of the EIS, "The Department identified highway routes for heavy-haul trucks, and associated intermodal transfer station locations to provide reasonable access to existing mainline railroads, to minimize transport length from an existing mainline rail interchange point, and to maximize the use of roads identified by the Nevada Department of Transportation for the highest allowable axle load limits."

8.5.3 (1267)
Comment - EIS002043 / 0005
In the section that discusses heavy-haul highway routes (Pg. 2-54), the DEIS identifies that shoulder widening and the construction of turnout and truck lanes would occur as needed along the side of the existing pavement and shoulders would be widened from 1 to 4 feet. The shoulders should be widened sufficiently for the transporter to be pulled off the main part of the road and away from the fast moving traffic.

Also, DOE only proposed to provide turnouts every 5 to 20 miles. Along U.S. 95 turnouts at 5 miles would be insufficient and would create additional risk to travelers. People are accustomed to traveling along this route at a high rate of speed. If travelers were forced to follow a long slow moving convoy carrying nuclear waste, drivers would make risky vehicle passes for the purpose of decreasing travel time. DOE should plan to construct two lanes each way if heavy-haul transporters are used.

Response
The road widening proposed for the two lane roads includes widening two-lane roads to two 4.3-meter (14-foot)-wide lanes with a 0.6-meter (2-foot) shoulder on each side. Existing road widths along the candidate routes for heavy-haul trucks include two 3.7-meter (12-foot) lanes and shoulder widths ranging from 0.3 to 0.6 meter (1 to 2-feet). The existing 3.7-meter wide lanes support maximum legal vehicle widths of 2.6 meters (8.5 feet). The proposed 4.3-meter lanes would be sufficient for a 3-meter (10-foot)-wide heavy haul transporter. The 0.6-meter shoulder width provides additional road width for the transporter in transit and would help reduce pavement "breakout" along the edge of the road. Truck turnouts would be used to remove a transporter from travel lanes, if needed. For details, see *Road Upgrades for Heavy Haul Routes* (DIRS 154448-CRWMS M&O 1998).

The analysis of potential road upgrades presented in *Road Upgrades for Heavy Haul Truck Routes – Design Analysis* (DIRS 154448-CRWMS M&O 1998) identifies that the average rate of speed for the heavy-haul vehicles at low grades similar to those on U.S. 95 is between 56 kilometers (35 miles) per hour and 68 kilometers (42 miles) per hour. At that speed, the transporters would pass turnouts that were spaced 8 kilometers (5 miles) apart approximately every 7 to 8 minutes. Therefore, based on this short travel time between turnouts, the few shipments of this type each day, and the limited amount of traffic of other vehicles along the candidate highways, DOE believes the spacing of turnouts would be sufficient to allow queued vehicles to pass and would not adversely affect highway safety. In areas of steeper upgrades, DOE assumed truck lanes would be constructed.

Although proposed road upgrades to allow use of such trucks would mitigate impacts on congested roads, traffic flow, and highway infrastructure, before DOE used a heavy-haul truck transportation implementing alternative it would work with the State of Nevada to conduct engineering and environmental studies that would support detailed design and construction of upgrades to highways.

Section 2.1.3.3.3.2 of the EIS discusses operations of heavy-haul trucks. Section 3.2.2.2.1.1 describes existing traffic on candidate heavy-haul truck routes. Section 6.3.3.1 discusses heavy-haul truck impacts, stating "even with the highway upgrades, heavy-haul trucks would cause delays for other vehicles because of their size and slower travel speeds." Section 6.3.3.1 presents estimates of traffic fatalities associated with heavy-haul truck operations for the five candidate routes.

8.5.3 (4419)
Comment - EIS001472 / 0007
The draft EIS also does not consider the potential of heavy haul truck transportation, and yet we know from the PFS [Private Fuel Storage] facility discussion that's proposed that that's one of the alternatives that will be considered. Recognizing the impact of the PFS facility at Yucca Mountain, those considerations are also to be taken into account.

Response
Similar to the proposed Private Fuel Storage project, DOE has considered the potential of heavy-haul truck transportation in Nevada in Section 6.3.3 of the EIS. Section 6.2 includes the impacts of using heavy-haul trucks to transport rail casks containing spent nuclear fuel from 24 commercial sites that are not served by a railroad to nearby railheads. In addition, the EIS considers the cumulative impacts from the proposed Private Fuel Storage project in Section 8.4.

8.5.3 (5286)
Comment - EIS000968 / 0007
What are the operational characteristics of the proposed heavy-haul system? If heavy-haul trucks are used, how will they effect traffic? It could only move 25-35 miles per hour, on our highways the speed limits are 65 or 75 mph, how many accidents will this cause? Will it warrant additional lane construction? What about where the roads are only two-lanes? How often and by whom will these trucks be inspected? Does the inspection require special tools/equipment? If it breaks down who fixes it and are there special parts needed? Where do they come from? Is there additional radioactive exposure while it sits? Who measures it and with what equipment?

The last several questions also apply to legal weight trucks.

Response
At this time, the heavy-haul truck implementing alternatives for transporting spent nuclear fuel and high-level radioactive waste to the proposed repository are conceptual. Section 2.1.3.3.3.2 of the EIS shows a concept for such a heavy-haul truck. Proposed road upgrades to allow use of such trucks, such as improvements to pavement and construction of turnouts and truck passing lanes, would mitigate impacts on congested roads, traffic flow, and highway infrastructure. However, before DOE used a heavy-haul truck transportation implementing alternative it would work with the State of Nevada to conduct engineering and environmental studies that would support detailed design and construction of upgrades to highways.

Section 2.1.3.3.3.2 of the EIS discusses operations of heavy-haul trucks. Section 3.2.2.2.1.1 describes existing traffic on candidate heavy-haul truck routes. Section 6.3.3.1 discusses heavy-haul truck impacts, stating "even with the highway upgrades, heavy-haul trucks would cause delays for other vehicles because of their size and slower travel speeds." Section 6.3.3.1 presents estimates of traffic fatalities associated with heavy-haul truck operations for the five candidate routes.

DOE would comply with Commercial Vehicle Safety Alliance standards for all truck (heavy-haul and legal-weight) inspections. Federal regulations (49 CFR 397.17) cover hazardous materials transportation inspection of tires. These inspections are required before departure and at regular intervals. Motor carriers are required to conduct load inspections during transport within the first 40 kilometers (25 miles) and after 3 hours or 240 kilometers (150 miles) of transport (49 CFR 392.9). Drivers usually perform these inspections.

Heavy-haul truck transport would require maintenance personnel to assist in the event of breakdowns. At this time, DOE has not determined how, where, or if, maintenance personnel would be positioned along routes.

There could be additional radioactive exposure to transport crews in the event of a vehicle break down. Maintenance personnel would be exposed, with the amount of exposure depending on the length of time required to fix the vehicle. However, the amount of radioactive exposure would be small – within allowable limits set by DOE. Radiological exposure of vehicle crew members and DOE or DOE contractor personnel working near a transportation cask would be subject to controls of a radiological health and safety protection program, which DOE would establish. Radiological exposures would be managed to remain within DOE radiological exposure guidelines.

8.5.3 (5303)
Comment - EIS001887 / 0040
The Draft EIS fails to demonstrate the feasibility of the unprecedented large-scale, long duration heavy-haul transport of SNF [spent nuclear fuel] and HLW [high-level radioactive waste] on public highways. It misrepresents the operational complexity of such shipments; grossly underestimates the amount and cost of infrastructure

improvement required along Nevada highways; and contains an incomplete and inadequate analysis of potential heavy-haul truck (HHT) routes.

Nevada believes that the use of heavy-haul trucks for thousands of shipments of spent nuclear fuel from any of the proposed intermodal transfer facility sites to Yucca Mountain is infeasible and dangerous. The costs associated with highway construction and improvements would be prohibitive, if the necessary infrastructure modifications could be made at all. The disruption to traffic flows and the accident risks posed by these massive, slow-moving, multiple unit vehicles and their escorts would pose unacceptable and unmitigable problems for Nevada's highways. In addition, the frequency of heavy-haul trips required to deliver waste and return the empty vehicle to the intermodal facility would place an unprecedented and unacceptable burden on Nevada's highway transportation infrastructure.

The Draft EIS should have evaluated heavy-haul transport in Nevada against the other alternatives for delivering spent fuel and HLW to Yucca Mountain, and DOE should have determined that such shipments are costly and impractical at best, dangerous and irresponsible at worst. Simply examining the heavy-haul option as a stand-alone alternative, as the Draft EIS does, is inadequate.

Response
In developing its concept for heavy-haul truck transportation in Nevada of large rail shipping casks containing spent nuclear fuel, DOE solicited and obtained information from several companies that routinely use heavy-haul trucks to transport large and heavy equipment. DOE's conceptual operating plans for heavy-haul truck operations involving up to 11 trips per week are based on this input and the experience of these companies in transporting similar size and weight loads both in one-of-a-kind and multiple shipments. Based on this information, DOE believes that use of heavy-haul trucks to transport spent nuclear fuel contained in large rail casks over highways in Nevada would be feasible and could be accomplished without causing large impacts to Nevada transportation infrastructure or the flow of traffic on Nevada highways. In fact, DOE believes that improvements to highway infrastructure that could be made to make routine use of heavy-haul trucks possible could benefit transportation in the State.

In addition to obtaining information from others, DOE employed qualified engineers to conduct mile-by-mile analysis of existing highways in Nevada that would be used for each of the five candidate routes for heavy-haul trucks. This analysis included an evaluation of each candidate route for Nevada Department of Transportation restrictions on axle loading. Using this information, the concept design of a heavy-haul truck, and information obtained from the Nevada Department of Transportation, DOE developed a conceptual design-level engineering analysis that identified potential road upgrades. With the upgrades that this analysis estimated could be needed, the five candidate routes for heavy-haul trucks evaluated in the EIS would be placed in the highest category of allowable axle loading published by Nevada Department of Transportation. DOE used the engineering and operations information developed in these studies to develop cost estimates for the highway upgrades, highway maintenance, and shipments using heavy-haul trucks. These cost estimates, which DOE believes are reasonable and realistic, are the basis for estimating socioeconomic impacts discussed in Section 6.3.3 of the EIS.

Section 6.3.3 of the EIS identifies potential traffic impacts and health and safety risks of transporting spent nuclear fuel in Nevada using heavy-haul trucks. The analysis in this section observes that even with highway upgrades, DOE anticipates that use of heavy-haul trucks would cause some delay in the free flow of highway traffic. Tables 2-10 and 2-11 provide side-by-side presentations of estimated impacts in Nevada of using a branch rail line in each of five candidate rail corridors and of using heavy-haul trucks on each of five candidate routes to transport spent nuclear fuel.

8.5.3 (5406)
Comment - EIS001887 / 0109
Page 2-50; Section 2.1.3.3.3 - Nevada Heavy-Haul Truck Scenario

Heavy-haul vehicles of the type and quantity described in the heavy-haul truck scenario present significant concerns and impacts not addressed in the Draft EIS. Training for inspectors to properly inspect these unique vehicles must be scheduled and performed in a timely manner to insure the safety of all concerned. Vehicle inspection areas must be established at the intermodal transfer station and include appropriate equipment, manpower, and environmentally safe employee working areas.

Escorts for these heavy-haul vehicles will not only provide the usual escort responsibilities, but will also include responsibilities to control and clear large expanses of roadway and conduct preventative sweeps ahead of the load, keeping other traffic moving in an orderly fashion, and interacting with security teams.

Impacts from non-fatal (injury/property) accidents are not addressed in the Draft EIS. However, it is likely that most accidents involving heavy-haul truck (and legal-weight truck) shipments would cause injury or property damage, rather than fatalities.(21) These accidents will have a substantially larger impact than portrayed in the Draft EIS, especially with traffic congestion, reduced travel lane expectancy, and the necessity to reroute traffic due to highway blockage.(22)

The projected speed of 20 to 30 miles per hour for heavy-haul vehicles is highly optimistic, especially during peak or congested traffic periods. The Nevada Highway Patrol estimates that a more realistic speed would be 12 to 18 miles per hour, which will significantly increase traffic congestion and disruption along affected highways.

(21) Section 6.2.4.2.1

(22) See Attachment S for comparing fatal and injury crash rates for large trucks.

Response

Inspections for heavy-haul truck shipments would be completed at the intermodal transfer station and at the Yucca Mountain site prior to and after transport in accordance with Commercial Vehicle Safety Alliance standards, U.S. Department of Transportation regulations, Nuclear Regulatory Commission regulations and applicable state and local codes and standards. During transport, heavy-haul vehicles would make periodic stops for inspections at Commission-approved areas (approved in accordance with Commission safeguards and security regulations in 10 CFR Part 73) and in accordance with U.S. Department of Transportation regulations (see 49 CFR 397.17 and 392.9). Personnel completing inspections would receive training specific to their job function prior to transportation. Escorts used in heavy-haul truck transportation would maintain allowable distances from the heavy-haul vehicles in accordance with Nevada Administrative Codes (see NAC 484.545) and permitting requirements. Escorts used in transport could be used for security in accordance with Nuclear Regulatory Commission regulations (see 10 CFR 73.37). The EIS assumes the use of escorts discussed here. It therefore includes analysis of impacts to the health and safety of this group of workers and of the socioeconomic impacts of the escort jobs.

Potential impacts from operation of the heavy-haul vehicles, including impacts on traffic congestion, are presented in Section 6.3.3 of the EIS. These impacts include estimates of traffic fatalities that could occur for the heavy-haul truck implementing alternatives. Traffic fatality estimates are also presented for commuting workers. Fatalities were used as the measure of the total impact because non-radiation-related traffic fatalities can be combined with radiation-related latent cancer fatalities to yield an estimate of the total number of fatalities for the Proposed Action and the No-Action Alternative. In contrast, combining non-radiation-related measures of impact such as traffic related injuries, illnesses, and other environmental impacts with radiation-related latent cancer fatalities would not yield an easily understandable estimate of total impacts. For the same reason, genetic effects, nonfatal cancers, and other radiation effects were not included in the estimates of the total impact.

The EIS analysis assumed that heavy-haul transport vehicles would utilize two tractors with a reference design of 650 horsepower each. With this reference design, transporter travel times were calculated based on input from commercial operators of overweight and overdimensional vehicles similar to the vehicles in consideration. The estimated speeds of the transported were calculated based on road grade. Estimated heavy-haul transport vehicle speeds ranged from 68 kilometers (42 miles) per hour at a zero-percent grade to 10 kilometers (6 miles) per hour at a 6-percent inclined grade (see DIRS 154448-CRWMS M&O 1998). For the highways in Nevada that would be used, DOE assumed truck lanes would be constructed in areas with road sections longer than 61 meters (200 feet) having grades greater than 4 percent. It also assumed turnout lanes would be constructed on each side of the road at intervals of 8 to 32 kilometers (5 to 20 miles) depending on a route's average daily traffic (see CRWMS M&O 1998). These truck lanes and turnouts would alleviate traffic congestion behind slower moving transport vehicles.

8.5.3 (5730)
Comment - EIS001887 / 0338
Page 6-96; Section 6.3.3.1 - Impacts Common to Nevada Heavy-Haul Truck Implementing Alternative

Incident-Free Transportation

The Draft EIS does not adequately evaluate the radiological impacts of routine HHT [heavy-haul truck] transportation. The Draft EIS appears to significantly underestimate HHT routine radiation exposures to the general public, especially in Tonopah, Goldfield, Beatty, and other locations where residences and businesses are located within 25 to 200 feet of the U.S. 95 road shoulder. The RADTRAN model is not sufficiently sensitive to local conditions and probable HHT operating characteristics. DOE must recalculate the annual and cumulative collective dose and maximum individual dose, assuming a range of HHT speeds and stop-times. The analysis must consider the actual location of all occupied buildings within ¼ mile of the route. The analysis must accurately reflect the actual population within ¼ mile of the route during daylight hours on week days, including children in schools and nonresidents in hotels and commercial establishments. Nevada believes that numerous individuals could receive annual doses from HHT operations equal to ten to thirty percent or more of annual background radiation exposures.

Response
Section 6.3.3 of the EIS presents estimates of radiological impacts for each of the five alternative routes in Nevada. Section J.3.1.2 describes calculation parameters used for each of the Nevada routes including distances through rural, suburban, and urban areas along the routes and the populations along each route. Tables of times, speed, and distances used in estimating parameters for the analysis of impacts are provided in *Road Upgrades for Heavy Haul Truck Routes* (DIRS 154448-CRWMS M&O 1998). Estimated speeds through towns and around sharp corners for heavy-haul trucks range from 8 to 24 kilometers (5 to 15 miles) per hour. The analysis used route-specific data such as length and population within 800 meters (about 2,600 feet) of the route provided by a Geographic Information System analysis. To estimate the risks, DOE used accepted methods and data that it has used in other recent environmental documents.

In addition, in responding to public comments regarding individuals in Nevada who live close to candidate transportation routes, DOE used information from a recent report prepared for the City of North Las Vegas (DIRS 155112-Berger Group 2000). This report presents suggested assumptions for a hypothetical maximally exposed individual who lived 15 meters (49 feet) from a roadway used by heavy-haul trucks and who would be present and stay at that location, when, over the 24 years, each shipment stopped for 1 minute. DOE believes that such an exposure scenario is highly unlikely and therefore unrealistic. Nonetheless, DOE estimated the maximum cumulative radiation dose to this hypothetical individual would be about 520 millirem over 24 years of the Proposed Action (see Section J.1.3.2.2.1 of the EIS). This dose would lead to an estimated increase in risk of cancer of 1 in 4,000 over the individual's lifetime. The analysis in the EIS considered other potential maximally exposed individuals who could live along routes in Nevada. These included:

- A person in Alamo living in a residence approximately 5 meters (15 feet) from U.S. 93 where heavy-haul trucks could pass who could receive a dose of 25 millirem over 24 years;

- A person who could be in the courthouse or fire station in Goldfield, Nevada approximately 5 meters (15 feet) from U.S. 95 where heavy-haul trucks could pass, who could receive a dose of 56 millirem over 24 years;

- A person who would live at the edge of a 60-meter wide (196 feet) right-of-way for a branch rail line where all rail shipments would pass, who could receive a dose of 2 millirem over 24 years; and

- A person who would live in southern Nevada approximately 11 meters (35 feet) from a roadway used by legal-weight trucks who could receive a dose of 20 millirem over 24 years.

For perspective, cancer from all other causes is fatal to about 1 in 4 persons.

DOE believes that the risks of transporting spent nuclear fuel and high-level radioactive waste in Nevada to Yucca Mountain would be very small for the Proposed Action and for the Inventory Modules.

Should the heavy-haul truck scenario be selected, additional engineering and environmental studies could be conducted as a basis for detailed design and appropriate National Environmental Policy Act reviews. These studies would be used in selecting final roadways, upgrades, and associated facilities for heavy-haul trucks. Consultation with responsible agencies and interested stakeholders would provide for input to these studies and become part of the National Environmental Policy Act reviews.

8.5.3 (7048)
Comment - EIS001847 / 0006
The DEIS fails to address the fact that the number of shipments and the amount of radioactive material that will be shipped is unprecedented in world history. About 90% of the volume would be spent fuel from nuclear power plants, and virtually none of this type of material has ever been shipped before.

Response
Of the thousands of spent nuclear fuel shipments completed over the last 30 years, none has resulted in an identifiable injury from the release of radioactive material. Future shipments will be conducted under the same regulations that have contributed to the safe transportation of more than 2,700 shipments conducted in this country over the last 30 years. For additional information on the regulations, procedures, and equipment that would be followed and used to ensure this safety record continues with shipments to a repository, see Appendix M to the EIS.

8.5.3 (7187)
Comment - EIS001337 / 0076
Page 2-51 Section 2.1.3.3.3.2. This section [should] provide an indication of maximum and minimum speeds that heavy-haul trucks will travel. The length of time to complete trip for each route should be discussed.

Response
The maximum and minimum speeds, and route travel times are included in *Road Upgrades for Heavy Haul Routes* (DIRS 154448-CRWMS M&O 1998). A review of information in this report indicates that the travel speeds would range from about 16 kilometers (10 miles) per hour on steep grades and through towns to about 65 kilometers (40 miles) per hour on open highways. Each table lists the mileage by road condition type, the speed over the section, and the time to travel the section. This information includes inspection stops and intersections to be navigated on each route and were used for estimating road upgrades and operating plans. Section 6.3.3.2 of the EIS presents estimated travel times for heavy-haul trucks for each of the five candidate routes for heavy-haul trucks in Nevada.

8.5.3 (7653)
Comment - EIS001912 / 0097
Heavy haul truck options. There is no indication of roadway wear and the cost to upgrade and maintain this type of facility. Will DOE commit to roadway and other improvements needed? Is the Nevada Department of Transportation a cooperating agency on this DEIS? Has DOE discussed the infrastructure improvements needed for a heavy haul route?

Response
Section J.3.1.2 of the EIS lists potential upgrades for the five candidate heavy-haul truck implementing alternatives in Nevada. This information is summarized from *Road Upgrades for Heavy Haul Routes* (DIRS 154448-CRWMS M&O 1998). Estimates of costs to upgrade and maintain the highways that would be used over 24 years for the Proposed Action are detailed in *Cost Estimate for Heavy Haul Truck Transport Design* (DIRS 154675-Ahmer 1998). Section 2.1.5 , Table 2-5, lists the estimated project lifetime cost of up to $800 million for transportation in Nevada. This project cost includes costs of upgrading and maintaining highways for heavy-haul trucks. The Nevada Department of Transportation was not a cooperating agency for the EIS. Personnel from DOE and the Nevada Department of Transportation have informally discussed highway upgrades needed to support use of heavy-haul trucks to transport spent nuclear fuel to Yucca Mountain.

8.5.3 (7941)
Comment - EIS001903 / 0008
P. 6-5, text box. "Nine-axle tractor-trailer truck (steering axle and three drive axles on the tractor and three axles on the trailer)…." 1+3+3 is 7, not 9.

Response
The error has been noted and a correction to reflect a seven-axle tractor-trailer has been included in the Final EIS.

8.5.3 (8405)
Comment - EIS001873 / 0071
P. 6-115. I fail to see what objective could be accomplished by heavy-haul from Caliente to Las Vegas.

Response
Section 2.1.3.3.3 of the EIS describes five transportation implementing alternatives that would use heavy-haul trucks to transport spent nuclear fuel and high-level radioactive waste in Nevada. The Caliente/Las Vegas heavy-haul truck route is one of these, which include routes that would be longer and shorter. Section 6.3.3.2.3 describes the potential impacts of upgrading and maintaining highways, constructing an intermodal transfer station, and making shipments using heavy-haul trucks on the route. DOE included this route in the EIS because it is one of three feasible routes that could be used for shipments of spent nuclear fuel contained in rail casks and that would be transferred from railcars to heavy-haul trucks at an intermodal transportation station in Caliente, Nevada. DOE believes the Caliente-Las Vegas route could meet the requirements of the U.S. Department of Transportation requirements for shipments that would originate at a Caliente intermodal transfer station.

8.5.3 (9425)
Comment - EIS001888 / 0116
In addition, the DEIS did not analyze the effects that construction of the heavy haul infrastructure improvements or a rail line would have on the Regional Transportation Plan of Clark County.

Response
Sections 6.3.2 and 6.3.3 of the EIS discusses the potential impacts from Nevada rail and heavy-haul truck implementing alternatives (respectively), including the potential impacts of construction and infrastructure improvements. For the three candidate heavy-haul truck routes through the Las Vegas Valley, DOE assumed the use of the Las Vegas Beltway. For these implementing alternatives, the applicable segment(s) of the Beltway would be completed in time for the beginning of shipments approximately 10 years earlier than the current Clark County estimate for completion in 2020. The assumption used is that this would reduce traffic congestion in the Las Vegas Valley, and would thereby promote the objectives of the Regional Transportation Plan of Clark County. In fact, DOE believes that improvements to highway infrastructure that could be made to make routine use of heavy-haul trucks possible could benefit transportation in the County. In addition, should DOE select one of the three candidate heavy-haul truck implementing alternatives that would use highways in Clark County, additional engineering and environmental studies could be conducted as a basis for detailed design and appropriate National Environmental Policy Act reviews. These studies would be used in selecting final roadways, upgrades, and associated facilities for heavy-haul trucks. DOE would consult with the County regarding the specific impacts to the transportation system that would be caused by the associated highway improvements and use of heavy-haul trucks.

DOE assumed construction and use of a branch rail line in Clark County, in either the Jean or the Valley Modified Corridor, would not disrupt highway traffic. Construction of grade separations over existing highways would have the largest, although temporary, impact on traffic flow. However, grade separations that would be needed are well outside the Las Vegas Valley area.

DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.5.3 (10804)
Comment - EIS002043 / 0006
The EIS needs to address what corrective measures will be taken to make the right bend just south of the center of the Town of Goldfield safe for other drivers. In addition, there is insufficient room for the heavy-haul transporter to

pull over to the side of the highway in the more populated business district of Goldfield. If the transport vehicle had a breakdown in Goldfield, there would be no place to pull the vehicle to the side and out of the way of the travel lane. This situation could be mitigated by constructing a roadway that by-passes the center of Goldfield. The EIS should include a by-pass route and address methods for mitigating any potential adverse socioeconomic impacts of a by-pass.

Response
Section 6.3.3.2.1 of the EIS discusses the potential impacts of implementing the Caliente heavy-haul truck implementing alternative. The analysis of this candidate route is based on information contained in *Road Upgrades for Heavy Haul Truck Routes – Design Analysis* (DIRS 154448-CRWMS M&O 1998). The report estimates the needs for highway upgrades including improvements to the Goldfield curve discussed by the commenter. Based on the analysis, a heavy-haul truck such as the one illustrated in Section 2.1.3.3.3.2 could negotiate the curve although in the course of making the turn the vehicle would have to encroach into the opposing lane. The Department's analysis suggests the curve could be widened (both shoulders) so that transit by the heavy-haul vehicles would not require stopping opposing traffic. DOE considered the alternative of constructing a by-pass around Goldfield. However, after preliminary engineering analysis and consideration of vehicle turning capabilities for up to a 140-metric-ton (150-ton) payload DOE concluded a bypass would not be necessary. Nonetheless, although proposed road upgrades to allow use of heavy-haul trucks would mitigate impacts on congested roads, traffic flow, and highway infrastructure, before DOE used a heavy-haul truck transportation implementing alternative it would work with the State of Nevada to conduct engineering and environmental studies that would support detailed design and construction of upgrades to highways.

8.5.3 (11007)
Comment - EIS001896 / 0005
Section 2.1.3.3.3.2

The heavy-haul trucks would travel north on I-15 from the Sloan interchange. The trucks would then exit on the beltway and travel northwest to Yucca Mountain. This route could affect potential annexation areas.

Response
Section 2.1.3.3.3 of the EIS describes the Nevada heavy-haul truck implementing alternatives including the Sloan/Jean route for heavy-haul trucks and intermodal transfer station. Section 6.3.3 discusses the potential impacts, including land use of the Nevada heavy-haul truck transportation implementing alternatives. A Sloan/Jean route would originate from an intermodal transfer station located along the mainline Union Pacific track near Jean. Another possibility would be for the route to originate at an area along the Railroad's mainline near the town of Sloan. Both areas are currently public lands managed by the Bureau of Land Management. The Department is not aware of any plans for annexation in these areas. Should a heavy-haul truck implementing alternative be selected and prior to a specific route and intermodal station location being chosen, further engineering and National Environmental Policy Act analysis could be required. Such analyses would address the potential for land-use impacts. Should DOE select one of the Sloan/Jean heavy-haul truck implementing alternative, additional engineering and environmental studies could be conducted as a basis for detailed design and appropriate National Environmental Policy Act reviews. These studies would be used in selecting final roadways, upgrades, and associated facilities for heavy-haul trucks. DOE would consult with the County and other cognizant agencies regarding specific impacts that would be caused by the associated highway improvements, construction and use of an intermodal transfer station, and use of heavy-haul trucks.

8.5.3 (11017)
Comment - EIS001896 / 0015
Section 3.2.2.2.11

The implementation of the Sloan/Jean heavy-haul route would impact already congested roads. Level of service E&F are currently experienced on Sloan/Jean route.

Response
As noted in Section 6.3.3.1 of the EIS, DOE acknowledges this potential impact. The EIS states that operations of heavy-haul trucks on routes through the Las Vegas valley would cause delays for other vehicles due to the size and

speed of the heavy-haul vehicles and the associated escorts. However, the Department assumes requirements for heavy-haul truck operations that would be contained in permits issued by the Nevada Department of Transportation would include time-of-day and day-of-the-week restrictions to reduce impacts of heavy-haul trucks on traffic congestion.

8.5.3 (11292)
Comment - EIS001814 / 0021
DEIS Page 2-50
Under this scenario, rail shipments to Nevada would go to an intermodal transfer station where the shipping cask would transfer from the railcar to a heavy-haul truck. The heavy-haul truck would travel on existing roads to the repository.

DOE has not demonstrated that heavy-haul truck is a feasible option to transport railroad casks to the proposed repository. States are required to enforce weight and size limitations on Interstate System and on routes providing reasonable access to and from the interstate. The penalty for failure to do so is the withholding of a State's National Highway System apportionment. States may issue permits for overweight and/or oversize vehicles if the load meets the definition of a nondivisible load as defined at 23 CFR Part 658:

Nondivisible load or vehicle.
(1) As used in this part, nondivisible means any load or vehicle exceeding applicable length or weight limits which, if separated into smaller loads or vehicles, would:

(i) Compromise the intended use of the vehicle, i.e., make it unable to perform the function for which it was intended;

(ii) Destroy the value of the load or vehicle, i.e., make it unusable for its intended purpose; or

(iii) Require more than 8 workhours to dismantle using appropriate equipment. The applicant for a nondivisible load permit has the burden of proof as to the number of workhours required to dismantle the load.

(2) A State may treat emergency response vehicles and casks designed and used for the transport of spent nuclear materials as nondivisible vehicles or loads.

The decision as to whether or not to treat casks for the transport of spent nuclear materials is left to the discretion of the states. The Federal Highway Administration (FHWA) adopted a single definition of nondivisible loads to apply to both oversize and overweight loads, since "Congress has authorized the States, in identical terms, to issue overweight and oversize permits 'for those vehicles and loads which cannot be easily dismantled or divided [(23 U.S.C. 127(a); section 4006(a) of the ISTEA, 49, U.S.C. app. 2311(j)(1)].'" (58 *FR* 11455)

Casks designed and used for the transport of spent nuclear materials were added to the definition of nondivisible loads in the preamble to the final rule. FHWA stated, "Spent Nuclear Fuel: The Pennsylvania DOT [Department of Transportation] pointed out that the FHWA informed the American Association of State Highway and Transportation Officials (AASHTO) several years ago that the FHWA regarded overweight casks used to move spent nuclear fuel as nondivisible. This determination was not reflected in the SNPRM (Supplemental Notice of Proposed Rule Making). The casks used to transport spent nuclear materials, especially nuclear fuel, are extraordinarily strong and heavy, both to prevent a release in case the transporter vehicle was involved in an accident and to block radiation that would penetrate lighter materials. Some of these containment devices can make a vehicle overweight even before the nuclear materials are loaded. These vehicles cannot be used for any other cargo or reduced to legal weights without frustrating their purpose. A new provision has therefore been added which essentially states that specially designed casks used to move spent nuclear fuel meet the definition of a nondivisible load." (59 *FR* 30409)

In the Supplemental Notice of Proposed Rule Making, FHWA stated: "Nonetheless, nondivisible load permits should be used sparingly. Loads which are inherently divisible, including bulk items such as liquids, grain, or cement, would not qualify as 'nondivisible.' Nor would shipments consisting of more than one of a unit item or assemble, which by itself may be nondivisible. In such cases, items can be removed until the load meets the legal limits. Nondivisible load permits are not 'loopholes' in Federal law, and the FHWA expects to see the number of nondivisible load permits stabilize or even decline in the next few years." (58 *FR* 11457)

FHWA further clarified the intent of the definition of nondivisible loads with an additional example. "A similar argument has been made, although not in this rulemaking, that tank vehicles weighing more than 80,000 pounds should be eligible for nondivisible-load overweight permits because a partially loaded tank of legal weight is susceptible to cargo surge that can make the vehicle unstable and even cause accidents in turns or emergency maneuvers. By this reasoning, a nondivisible-load overweight permit would be authorized to increase safety. Proponents of this position do not explain the reason tanker operators purchase vehicles that necessarily exceed applicable weight limits when fully loaded. It is certainly true that tank trucks must be operated with particular care; that is the reason the FHWA's commercial driver's license regulations require drivers of these vehicles to obtain a special endorsement. But the fact is that liquids, like two concrete panels, are easily divisible. If a safety element were added to the definition of nondivisible load, the concept of nondivisibility could lose all meaning if economic interests were to masquerade as safety issues." (59 *FR* 11457)

FHWA's intent when adopting the definition of nondivisible loads was to reduce the number of permits issued for overweight and oversize vehicles. Casks for transporting spent nuclear fuel were added to the definition of nondivisible since the design of the cask requires heavy materials for strength and shielding, resulting in some cases, for the need for overweight vehicles. This definition, however, clearly applies to casks that were designed for highway transport, not those designed for rail. In the Supplemental Notice of Proposed Rulemaking, FHWA stated that "shipments consisting of more than one of a unit item or assembly, which by itself may be nondivisible," are not considered nondivisible. DOE can transport the material in casks that meet the requirements for legal weight and size trucks, they are simply proposing to ship "more than one of a unit item or assembly" by putting many more fuel rod assemblies in a cask designed for rail than they could with legal weight truck casks.

In FHWA's example of tank vehicles, they also noted that "the concept of nondivisibility could lose all meaning if economic interests were to masquerade as safety issues." In this case, DOE is not even claiming a safety benefit for the use of rail casks, but rather just one of convenience. Since the use of rail casks is clearly optional, and the material could be shipped in legal weight casks, DOE's proposed use of rail casks transported on overweight and oversize vehicles clearly does not meet the definition of nondivisible load, and does not qualify for an overweight and oversize permit based upon nondivisibility of the load.

Response
Section 2.1.3.3.3 of the EIS describes the Nevada heavy-haul truck scenario and Sections 6.3.3.1 and 6.3.3.2 provide the results on the impacts analysis. Should heavy-haul truck mode be selected, detail engineering and environmental studies would be conducted to provide the basis for detailed design. During these studies, consultations with Federal, State, tribal and local authorities would be initiated to address regulatory, permitting and related issues. Heavy-haul truck permitting would be one topic for consultation with the Nevada Department of Transportation. Those detailed consultations have not yet occurred. However, the definition of "nondivisible loads" pertaining to transportation casks for the transportation of spent nuclear fuel and high-level radioactive waste has been addressed in the preamble to the *Federal Register* Notice that added the 23 CFR 658.5 definition. In general, this definition says that any cask that can be transported on the highways fits the definition of 23 CFR 658.5. This holds true even if the cask must be transported on a heavy-haul truck. This has been acknowledged by the Office of Freight Management and Operations in the Federal Highway Administration, U.S. Department of Transportation.

8.5.3 (11294)
Comment - EIS001814 / 0023
DEIS Page 2-53
The station would accept railcars as they arrived (24 hours a day, 7 days a week), but it would normally dispatch heavy-haul trucks during early morning daylight hours on weekdays, consistent with current Nevada heavy-haul shipment regulations.

The EIS does not contain sufficient information on the schedule of arriving shipments to the station and the schedule on dispatch of heavy-haul trucks from the station to allow an evaluation of the impacts. During winter time, the restriction on travel during daylight hours will significantly limit the time available for travel from the station to the proposed repository. In December, for example, there are only about 10 daylight hours available for travel. Depending on the location of the intermodal transfer station, dispatch of the heavy-haul trucks in the "early morning daylight hours" could result in heavy-haul trucks traveling through the Las Vegas urban area during rush hour.

The EIS does not provide any information on the impact of limiting travel to weekdays. Given the restriction on travel during daylight hours, this means that casks arriving at the station Friday through Monday morning cannot be dispatched until Monday morning. To comply with NRC [Nuclear Regulatory Commission] requirements, a significant number of heavy-haul trucks will have to be dispatched on Monday mornings. The EIS should provide information on this scheduling requirement, and include an evaluation of the impacts of having multiple heavy-haul trucks dispatched during a short time-frame on Monday mornings. Since travel is also prohibited on holidays, this problem will be even worse over three-day holiday weekends.

The number of casks arriving over a weekend could vary significantly depending on whether DOE decides to use general freight or dedicated trains. DOE should state in the EIS its preferred option for the type of service utilized so that an estimate of the number of railcars arriving over a weekend can be made to evaluate impacts of scheduling options. Conceivably, if DOE opts for dedicated train service, the dispatch of trains from shipping sites could be optimized to prevent an excessive number of casks arriving at the intermodal transfer site over weekends.

Response
DOE does not have detailed operational information regarding a concept of operations; however, conceptual level engineering analysis has been completed. For example, the document titled *Road Upgrades for Heavy Haul Truck Routes* (DIRS 154448-CRWMS M&O 1998), contains estimated travel times for the five heavy-haul truck routes identified in the Draft EIS. An assumption used in the EIS for the three routes originating from Caliente, Nevada would be a mid-route overnight parking area, because of the length of the routes, restricted nighttime travel, and allowance for operations contingencies. However, with the exception of the Caliente route, travel times for heavy-haul trucks are estimated to be less than 10 hours, including inspection stops.

For the Caliente/Las Vegas route, heavy-haul trucks leaving Caliente in the morning would arrive in the Las Vegas area at mid-day. Trucks using the Apex/Dry Lake route or Sloan/Jean route could avoid Las Vegas rush-hour traffic in the mornings and evenings. Both of these routes have estimated travel times of about 4 hours.

Regarding the use of dedicated versus general freight trains, Section J.2.3 of the EIS states, "DOE has not determined the commercial arrangements it would request from the railroads for shipment of spent nuclear fuel and high-level radioactive waste." Until this decision is made with sufficient shipment details, transportation logistics cannot be analyzed in detail with any accuracy. However, in its Draft Request For Proposal, *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management*, DOE stated, "The RSC [Regional Servicing Contractor] shall provide all transportation services to include heavy haul and intermodal transfer services that make maximum use of special rail service wherever reasonably possible" (DIRS 153487-DOE 1998).

8.5.3 (12195)
Comment - EIS000096 / 0008
The Draft EIS also ignores the potential impacts on Tonopah, Goldfield, and Beatty of legal-weight truck (LWT) shipments of SNF [spent nuclear fuel] and HLW [high-level radioactive waste]. US 6 from Ely to Tonopah and US 95 from Tonopah to Amargosa Valley are identified as potential state-designated preferred routes in Appendix J. According to the Draft EIS, there could be as many as 96,000 LWT shipments to the repository under the mostly truck scenario. The adverse impacts of these shipments would be similar to those of HHT [heavy-haul truck] shipments. The larger number of LWT shipments, averaging 5 to 10 trucks or more per day, could result in higher routine radiation exposures and heightened levels of risk.

Response
DOE believes that the risks of transporting spent nuclear fuel and high-level radioactive waste in Nevada to Yucca Mountain would be very small for the Proposed Action and for the Inventory Modules. Section J.3.1.3 of the EIS presents estimated impacts for the Proposed Action and for the approximately 53,000 shipments under the mostly legal-weight truck scenario if shipments used the routes described in a 1989 Nevada Department of Transportation report (DIRS 103072-Ardila Coulson 1989, all). The route identified as "Wendover via U.S. 95", which is

described in the section and includes U.S. 95 through Tonopah, Goldfield, and Beatty, is one of the routes evaluated as a sensitivity analysis. For this route, DOE estimated the total dose over 24 years to the population along the sections of Interstate-80, U.S. 93, U.S. 6, and U.S. 95 that make up the total route in the State would be about 900 person-rem. A dose of 900 person-rem to the affected population would be estimated to result in a 45-percent chance of 1 latent cancer fatality in the population over the 24 years of operations. The information was compiled to illustrate the sensitivity of impacts nationally and in Nevada to the potential use of different routes in Nevada. The analysis used State-specific data for rates of accidents on primary highways in Nevada for the segments of trips analyzed in these cases. The analysis also used route-specific data such as length and population within 800 meters (about 2,600 feet) of the route provided by a Geographic Information System analysis. To estimate the risks, DOE used accepted methods and data that it has used in other recent environmental documents.

8.5.3 (12548)
Comment - EIS001157 / 0009
A heavy-haul route through North Las Vegas and the Las Vegas Valley is not recommended. The costs of using such routes in terms of congestion and decreased air quality were not adequately addressed in the study.

Response
At this time, the heavy-haul truck implementing alternatives for transporting spent nuclear fuel and high-level radioactive waste to the proposed repository are conceptual. Section 2.1.3.3.3.2 of the EIS shows a concept for such a heavy-haul truck. Proposed road upgrades to allow use of such trucks, such as improvements to pavement and construction of turnouts and truck passing lanes, would mitigate impacts on congested roads, traffic flow, and highway infrastructure. In addition, Section 6.3.3 discusses impacts of implementing and using each of the proposed heavy-haul truck transportation implementing alternatives including potential impacts on the air quality in the Las Vegas air basin. However, before DOE used a heavy-haul truck transportation implementing alternative it would work with the State of Nevada to conduct engineering and environmental studies that would support detailed design and construction of upgrades to highways.

DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.6 Rail Transport

8.6.1 DEDICATED TRAINS

8.6.1 (223)
Comment - 13 comments summarized
A number of commenters provided views on the type of train service that should be used for the transportation of spent nuclear fuel and high-level radioactive waste. There was a consensus among the commenters that dedicated trains should be used rather than general freight service; commenters listed the advantages of dedicated trains. The commenters stated that the Draft EIS does not make a decision between dedicated trains and general freight service. Several commenters indicated that DOE should state in the EIS whether the EIS is intended to support the decision between dedicated and general freight trains. One commenter suggested DOE should include the use of general freight and dedicated trains as separate alternatives in the description of the Proposed Action in the EIS.

Response
As indicated in the EIS, DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

DOE could decide to use a dedicated train that carried only the material being shipped to Yucca Mountain, or could elect to move the spent nuclear fuel and high-level radioactive waste in general freight. If the material was shipped as general freight, the position of the spent nuclear fuel or high-level radioactive waste car in the train would be regulated by 49 CFR 174.85. This regulation requires that railcars placarded "radioactive" must be separated from a locomotive, occupied caboose, or carload of undeveloped film by at least one nonplacarded car, and it may not be placed next to other placarded railcars of other hazard classes. Section J.2.3 of the EIS presents an assessment of impacts of using dedicated trains to transport spent nuclear fuel and high-level radioactive waste. Based on current information from the U.S. Department of Transportation and the Association of American Railroads, it is the Department's opinion that there is no clear advantage for using either dedicated trains or general freight service.

DOE has not determined the commercial arrangements it would request from the railroads, including the use of dedicated or general freight trains, nor is the EIS intended to develop the scheduling and cost information necessary to make this determination. DOE recognizes the different attributes of dedicated trains and general freight service. DOE believes that general freight service, and dedicated train service are both capable of meeting the performance objectives of 10 CFR 73.37(a)(1) based on successful completion of past shipments of spent nuclear fuel by rail.

8.6.1 (402)
Comment - EIS000088 / 0002
Remember those trucks that delivers those nuclear waste from throughout the world and they go over there to that Nevada Test Site.

When they dump their load, they come on down here to California and go pick up your food. How much radiation is on that truck?

Response
The spent nuclear fuel that would be transported to a repository by truck would be contained in sealed casks. This would prevent the flatbed trailers used to transport the casks from becoming contaminated. In addition, the trucks would be checked for contamination prior to being allowed to leave the repository facility. It is not likely that these particular trucks would be used for any other purpose.

8.6.1 (4464)
Comment - EIS001232 / 0008
Is the proposed rail line to be a single use line or will it have other potential uses?

Will the rail roads handle these shipments as dedicated cargo or will they be shuffled from rail line to rail line and possibly lost?

Will there be buffer zones along the tracks?

Response
Decisions on whether or not to build a branch rail line, management of such a line, and other potential uses would be addressed after a decision on the suitability of the repository site. As discussed in Section 2.1.3 of the EIS, the conceptual design used in preparing the EIS assumed a single set of tracks and rail sidings. Sidings would be an average of 20 miles apart and approximately 0.5 kilometer (0.3 mile) long (see DIRS 154822-CRWMS M&O 1998). Should the mostly rail alternative be selected, additional, more detailed studies and designs would be conducted for the particular corridor and alignment identified. The need for additional sets of tracks and rail sidings would be evaluated during this design stage. Additional National Environmental Policy Act reviews, as required, would be conducted at that time.

A qualitative comparison of attributes of general rail-freight to dedicated train service in Table J-25 and in Section J.2.3 of the EIS, which is based in part on results of a recent U.S. Department of Transportation study, does not indicate a clear advantage for the use of either type of rail service. Thus, impacts discussed in the EIS are estimated based on typical railroad operations. In these operations, railroads transport freight cars, including cars carrying hazardous materials, along with other freight in trains that average 67 cars in length. DOE believes the analysis presented in the EIS supports use of either general-rail freight or dedicated-train service.

DOE's Draft Request for Proposals for Regional Servicing Contractors (see Appendix M of the EIS), states that contractors could be directed to use dedicated train service where it can be demonstrated to enhance operations efficiency and cost-effectiveness.

The branch rail line would be built following applicable Federal Railroad Administration, American Association of Railroads, and State of Nevada requirements.

8.6.2 BRANCH RAIL LINE CONSTRUCTION

8.6.2 (137)
Comment - 3 comments summarized
Commenters expressed concern with the estimated time to complete preconstruction activities associated with branch rail line construction, including environmental reviews and approvals, acquisition of rights-of-way, resolution of Native American tribal rights issues, and any associated legal issues. In addition, commenters expressed concern with the estimated time to complete branch rail line construction activities due to difficult terrain, environmental sensitivity, and unidentified Native American tribal cultural resources. Commenters believed that the estimated time for construction is optimistic and underestimates the difficulty of construction. A commenter noted that the EIS failed to provide a detailed description of rail construction activities and impacts.

Response
To ensure that the EIS analyses reflect the latest reasonably available information, DOE has incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the EIS now includes additional and more detailed mapping of minority populations, and additional mapping and information that describes the proximity of tribal lands and cultural and ceremonial areas to candidate rail corridors in Nevada.

The cost estimates and schedules for the construction of branch rail lines were prepared after surveying the candidate corridors, investigating the topography, and reviewing potential environmentally and culturally sensitive areas. The conceptual design for rail implementing alternatives, the "Rail Alignments Analysis," attempted to minimize impacts to areas of known environmental concern or archaeological significance (including Native American cultural resources) by choosing corridor alignments that minimized or eliminated crossing of known sensitive areas (DIRS 131242-CRWMS M&O 1997). These corridor alignments include variations that could mitigate environmental or engineering issues. The analysis was then used in the development of a detailed cost estimate for rail construction, the *Nevada Transportation Study Construction Cost Estimate* (DIRS 154822-CRWMS M&O 1998). The construction cost estimates considered the cut and fill operations necessary to traverse the terrain associated with each route. Through the use of the estimated worker-hours for construction activities contained in this study rail construction schedules were developed (DIRS 155356-CRWMS M&O 1999) for conservative estimates of the duration of rail construction. Rail construction was estimated to take from 3 years and 4 months to 3 years and 10 months on a normal construction schedule.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. If the Yucca Mountain site was approved, DOE would issue at some future date a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. A similar process would occur in the event DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

Because DOE cannot anticipate the length of any agency delays or legal challenges, including issues related to Native American tribal treaty lands, contingencies were not placed in estimated activity durations for preconstruction activities.

8.6.2 (186)
Comment - 18 comments summarized
Commenters stated that the EIS did not provide sufficient information on branch rail line system specifications, construction activities, and operations to allow the complete assessment of impacts and risks as required under National Environmental Policy Act. Other commenters asked what the costs would be to construct the five rail routes and which of the five could be constructed at the least cost. Commenters stated that the EIS did not contain sufficient information on branch rail line system specifications, including rail weight, tie materials, grade crossing separations, road crossings and crossing signals, overpasses, administration and maintenance facilities (including any remote water supply and sanitation specifications), seismic standards, flood standards, train control signal systems, platform dimensions, ditch dimensions, bench dimensions, and ballast and sub-ballast requirements. Other commenters questioned what the fencing specifications would be, including location and type, because this would affect the ability of wildlife to cross the tracks. Commenters stated that the EIS did not contain sufficient information on branch rail line construction activities, including defining what the buffer zone would be during construction to protect human health and safety, defining cut and fill requirements, and identifying sources for ballast and sub-ballast material. Commenters stated that the quarrying of ballast and sub-ballast materials, the reclamation of ballast and sub-ballast source areas, the installation of water wells and their locations, and construction and safety oversight by State and Federal agencies were not addressed in the EIS. Finally, commenters stated that the EIS did not contain sufficient information on rail branch line operations, including safety oversight of rail line operations by Federal and State agencies, to allow the complete assessment of impacts and risks. Another commenter is interested in whether union labor would be required to construct the branch rail line.

Response
If the Yucca Mountain site was approved, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. However, follow-on implementing decisions, such as the selection of a specific rail alignment in a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

If the site was approved, transportation system specifications would be developed during detailed design activities. Specifications for items such as administration and maintenance facility and any associated remote water supply and sanitation needs, train control signal systems, and road crossing signals would be developed during these activities. Detailed field studies and geotechnical work would be required for development of specifications for seismic, flood, platform dimensions, ditch dimensions, bench dimensions, ballast requirements, and sub-ballast requirements. Specifications for grade crossing separations, road crossings, fencing locations, and fencing type would be developed in conjunction with government agency consultations, environmental analyses, and any necessary National Environmental Policy Act reviews, which would be conducted at the time of detailed design activities.

Based on standard engineering practices, DOE developed assumptions for the branch rail line conceptual designs analyzed in the EIS (DIRS 131242-CRWMS M&O 1997). In addition, conceptual engineering designs were developed for each of the rail corridors. These conceptual designs are referenced in the EIS and are available to the public. They incorporate assumptions based on regulatory requirements, established engineering practices, and existing railroad design. The documents contain sufficient design information to allow estimation of the environmental impacts of constructing and operating a branch rail line, but were not intended to provide specifications and detailed design descriptions, such as the information requested by the commenters, for constructing, maintaining, and operating a branch rail line. Additional information on operational protocols is provided in Section M.3 of the EIS.

DOE assumed for the purpose of the EIS that operations of trains on a branch rail line and the maintenance of the line would be conducted in compliance with applicable regulations and standards for railroads and that the safety of operations would meet or exceed that of mainline railroads in the United States.

The conceptual design assumed a rail weight of 115 pounds per yard of rail, which is equivalent to that used by railroads for mainline track and grade crossings at all major public crossings. The conceptual design also assumed that seismic and flood specifications for railbed structure would use national standards contained in the American Railway Engineering Association *Manual for Railway Engineering* (DIRS 106860-AREA 1997, all) (see EIS Section 3.2.2.1.3.1 for a description of the avoidance of wetlands and riparian lands). For cost estimation, specifications for fencing type, ballast requirements, sub-ballast requirements, tie material, train control signal systems, and road crossing signals have been assumed in *Nevada Transportation Study Cost Estimate* (DIRS 154448-CRWMS M&O 1998). DOE used these specifications in the analysis of Nevada transportation activities in Section 6.3.

The life-cycle cost estimates for each rail corridor alternative in Nevada are presented in the EIS Summary, Section 6.3.2.1. The conceptual designs and cost estimates for all five rail corridor alternatives were developed at similar levels of detail and have similar uncertainties, so valid comparisons can be made. DOE anticipates that the cost estimates would change, albeit not substantially, as a result of detailed engineering and design studies.

If there was a decision to proceed with the development of a repository at Yucca Mountain, DOE would determine the type of contractual relationships that would be implemented to construct the branch rail line, if that implementing alternative was selected. As a consequence, DOE is uncertain at this time whether union labor would be used to construct the branch rail line and cannot determine the implications on rural resident employment opportunities. Decisions such as this are administrative in nature and would be unlikely to have environmental impacts.

Though field studies and geotechnical work are needed to determine true cut and fill quantities, quantities have been estimated as a part of the cost estimating process. These quantities have been used in the analysis of branch rail line construction in Section 6.3 of the EIS. As a part of the cost estimate, DOE has assumed that ballast material would be obtained from existing quarries and shipped to the branch rail line by rail (DIRS 154822-CRWMS M&O 1998). DOE would comply with Federal Railroad Administration regulations (see Section 2.1.3.3.2.2), including inspections during construction and operation in accordance with 49 CFR Parts 212 and 213, which require safety inspections by the Administration and allow joint State participation in inspections.

8.6.2 (804)
Comment - EIS000201 / 0002
Build a railroad. Get it off our highways. If you're going to transport it, do the railroad, build it.

I realize that we are not an isolated place in our nation. There are highways like this all through this nation. Little towns, large cities that it will have to be transported to get it to Yucca Mountain.

Again, build the railroad, period. Who cares how much it cost?

Response
DOE has noted the commenter's preference for rail transportation within Nevada. DOE has identified in the EIS the Nevada rail scenario as the preferred transportation alternative in the State.

8.6.2 (3165)
Comment - EIS001195 / 0003
We would expect DOE to work closely with Cortez Gold Mines in designing a reasonable route [Carlin Corridor] through our properties that minimizes impacts to not only our existing facilities and operations but, also to future potential orebodies and associated facilities. We would also expect an assurance that DOE would relocate the rail track at no expense to Cortez Gold Mines should future operational needs require. This is important, as portions of the identified corridor cross some of our mining claims that have not yet been explored for mineral potential. One solution that may be considered by DOE is to cooperatively fund deep condemnation drilling in selected areas.

Response
DOE appreciates the involvement of the Cortez Gold Mines and anticipates working with the Cortez Gold Mines in the event that the Carlin Corridor was selected. The EIS addresses the potential for a land-use and ownership impacts with the Cortez Gold Mine Projects (see Sections 8.1.2.3 and 8.4.2 of the EIS), and DOE would work with

the Cortez Gold Mines to minimize these impacts. Because detailed design work for a rail branch line would be completed at a later time, it is premature to determine DOE's involvement in funding for deep condemnation drilling or relocation of rail track should Cortez Gold Mines future operational needs require such actions.

8.6.2 (6496)
Comment - EIS001241 / 0009
If the alternate rail route alignment of the Carlin route in Crescent Valley would be used, would my land and home be inside or outside the corridor? If inside: exactly how much, and when would I be compensated? If my land and home are immediately outside the corridor, would I be compensated in any way or "merely" exposed to disruption, disturbance, discomfort, inconvenience, and health hazards without compensation?

Response
DOE has developed a conceptual rail design that identifies candidate corridors (DIRS 155022-CRWMS M&O 1997). If a rail implementing alternative was chosen for transport within Nevada, environmental and engineering field studies would be conducted during the rail design phase. These field studies would be used in selecting a final alignment that minimizes, to the extent possible, impacts to stakeholders along the final rail alignment. DOE has included in its cost estimate for rail construction (DIRS 154822-CRWMS M&O 1998) costs for obtaining right-of-way for each candidate rail corridor. Because a final alignment for any candidate rail corridor would be determined at a later date, it is premature for DOE to specify any dollar amount that would be used to compensate any private stakeholder for land within a final rail alignment right-of-way. DOE does not anticipate compensating stakeholders with land adjacent to any final rail alignment.

8.6.2 (9601)
Comment - EIS001888 / 0274
Infrastructure Improvements

The DEIS does not assign specific roles and responsibilities for significant actions. For example, what agency will construct road improvements and facilities, what agency will maintain them, when will these be constructed, when will the NEPA [National Environmental Policy Act] analysis be done. The sparse information contained in the DEIS makes it impossible to negotiate mitigation or even understand the proposed action. The DEIS must specify when construction on infrastructure improvement will begin, what agency will construct and maintain them, and provide a schedule for the required National Environmental Policy Act documentation for the projects.

Response
Roads under consideration for heavy-haul truck transport are under the jurisdiction of the Nevada Department of Transportation (State and Federal highways) and Clark County (the Las Vegas Beltway). DOE anticipates that the Nevada Department of Transportation would perform road upgrade construction activities under its jurisdiction and Clark County would perform road upgrade construction activities under its jurisdiction. Road maintenance would be conducted under the jurisdiction of the Nevada Department of Transportation. Any National Environmental Policy Act activities associated with road upgrades would be conducted in conjunction with road upgrade design activities, *Road Upgrades for Heavy Haul Truck Routes – Design Analysis* (DIRS 154448-CRWMS M&O 1998). DOE's procurement strategy continues to rely on private industry and would seek competitive proposals for the construction of facilities (an intermodal transfer station) associated with transportation. Any National Environmental Policy Act activities associated with construction of an intermodal transfer station would be conducted in conjunction with intermodal transfer station design activities. It is uncertain at this time when DOE would make any transportation-related decision that would indicate when potential road upgrade or intermodal transfer station construction would occur.

8.6.2 (11896)
Comment - EIS001878 / 0087
The DEIS also leaves many unanswered questions, such as:

Would there be one or more sets of tracks, and would there be sidings?

Who would own the tracks, trains, rights-of-way, and support facilities, and who would operate them?

Would all of the tracks and access roads be fenced, or only portions, with what types of fences, maintained and paid for by whom, and owned by whom? How wide would the fenced corridors be? Would consultation regarding fences be limited only to other federal agencies, to the exclusion of agricultural producers, local governments, and public safety officials?

How would the access roads be constructed and surfaced, and who would be allowed to use them?

If roadbed and access roads would be constructed using balanced cut and fill techniques, where would the DOE obtain the fill necessary to elevate many miles of roadbed above anticipated flood levels in Nevada's valleys and playas?

Would blasting be utilized?

Response
As discussed in Section 2.1.3 of the EIS, the conceptual design used in preparing the EIS assumed a single set of tracks and rail sidings (DIRS 131242-CRWMS M&O 1997). Sidings would be an average of 32 kilometers (20 miles) apart and approximately 0.5 kilometer (0.3 mile) long (DIRS 154822-CRWMS M&O 1998). Should the mostly rail alternative be selected, additional, more detailed studies and designs would be conducted for the particular corridor and alignment identified. The need for additional sets of tracks and rail sidings would be evaluated during this subsequent design stage. National Environmental Policy Act reviews, as required, would be conducted at that time.

In keeping with DOE's policy to utilize private industry to the extent possible, DOE would seek competitive bids for the operation and maintenance of a rail branch line. The contractor would be responsible for operation of the rail branch line and for maintenance of appurtenances within the right-of-way, including any fencing that DOE installed. Analysis of fencing location would be evaluated in subsequent engineering and environmental analyses and public and government agency consultations (see Section 2.1.3.3.2.1). Stakeholders would be able to provide comments during these National Environmental Policy Act reviews. DOE would negotiate land withdrawal or right-of-way with the Bureau of Land Management and other responsible agencies for all public land used and purchase required private land. DOE would own all tracks and support facilities, and the operations and maintenance contractor would own or lease all operating and maintenance equipment, including locomotives.

The rail branch line would use balanced cut and fill techniques to the extent possible, however spoil and borrow areas could be needed to establish a stable platform for the rail track (see Section 2.1.3.3.2.1). These borrow and fill areas would be identified during geotechnical surveys that would be conducted during subsequent design stages and evaluated in appropriate National Environmental Policy Act reviews. Rail branch line maintenance roads would be built adjacent to the branch rail line. Maintenance roads would be constructed using a gravel surface and balanced cut and fill techniques adjacent to the rail branch line. Temporary access roads would be used only by the construction contractor during construction and the maintenance roads used only by the operation and maintenance contractor for maintenance and inspection of the rail branch line. Track roadbeds would be evaluated to meet flood requirements established for the detailed design criteria. Blasting would be used as necessary.

8.6.3 OPERATIONS

8.6.3 (3364)
Comment - EIS001242 / 0013
What effects will earthquakes have on the rr [railroad] tracks? The trains, the site and the canisters.

Response
There was an earthquake with a Richter magnitude of 7.4 in El Asnam, Algeria in October 1980. At the time of the main shock a train was straddling the fault. The train was completely overturned. At another site nearby the railroad tracks were bent; it is suspected that this might have been caused by a secondary fault. If a train carrying a shipment of casks containing spent nuclear fuel or high-level radioactive waste was involved in a similar earthquake, the impact on the train would probably be comparable. However, it is not expected that any radioactive material would be released from the transportation casks. They are designed to survive a much more severe shock than that resulting from an overturned or derailed train.

8.7 Transportation Operational Policy and Procedures

8.7 (28)
Comment - 20 comments summarized
Commenters said that the EIS should examine the effects on the transportation of spent nuclear fuel and high-level radioactive waste from earthquakes, faulting, floods, range fires, areas of high winds, tornadoes, lightning strikes, and severe weather. Commenters wanted to know what is being done to protect trains and trucks during these events, and suggested that road safety and train-track safety be tested. Some wanted to know if spent nuclear fuel and high-level radioactive waste would be transported through northern Nevada during the winter when severe blizzards can strike. Commenters also wanted to know whether safe havens or alternative routes could be designated on short notice based on real-time data sources, and who would decide when a shipment should be halted. The responsibility for checking and interpreting road conditions, stopping a shipment, or allowing it to proceed was also questioned.

Response
At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. Section M.3 of the EIS provides a discussion of the protocols and procedures that would be implemented by a Regional Servicing Contractor and its subcontractors under adverse weather or road conditions. The procedures are in two parts.

One part of the procedure relates to preshipment planning, which would use available data related to expected conditions. Shipments would not be dispatched on a route where expected conditions would not comply with the requirements in the procedures. Weather forecasts would be obtained by the Regional Servicing Contractor as part of the preshipment planning, and forecasts for rain, snow, fog, high winds, and tornado warnings would be considered in the determination of the shipment schedule. In general, Regional Servicing Contractors would be responsible for the planning, implementation, and control of the shipments, including responding to changing conditions, as necessary. A contractor would acquire information of road or highway construction that could temporarily affect the planned route. Through consultations with the affected states along the planned route, the contractor would obtain road and highway conditions and information on anticipated construction, along with planning information on long-range highway construction.

The other part of the procedure relates to problems along the route and is for those persons actually involved in making the shipment who would be best able to discuss and report expected and encountered conditions. DOE Protocols, which would be implemented by the Regional Servicing Contractors, require that shipments would not travel when severe weather conditions along routes or adverse road conditions would make travel too hazardous to proceed. Driver and crew communications with the control center would provide advanced warning of potential adverse conditions along the route. If unanticipated severe weather or adverse road conditions were encountered, the driver and crew would contact the control center to coordinate routing to a safe parking or stopping area if it became necessary to delay the shipment until conditions improved. Section M.3.2.1.3 of the EIS provides detailed information on the selection of safe parking areas to be used in the event a shipment had to be delayed.

Rail carriers would use train control and monitoring systems to identify the location of their trains within the rail system and to make informed decisions based on this information to avoid or minimize potential weather-related or track Condition risks. Under 49 CFR 174.20, the carrier can impose local restriction on transportation when local conditions make travel hazardous.

The transportation regulations of the Nuclear Regulatory Commission include shipping cask design requirements for normal and accident conditions of transport (10 CFR Part 71). The regulations do not specifically address natural disasters such as earthquakes, floods, or tornadoes. However, if a shipment to Yucca Mountain was involved in any of these natural disasters, the impact on the cask would be within the bounds of the hypothetical accident defined in 10 CFR Part 71. The shipping casks used to transport spent nuclear fuel and high-level radioactive waste would be massive and tough with design features that complied with strict regulatory requirements that would ensure the casks performed their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of*

Spent Fuel Shipment Risk Estimates (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

8.7 (140)
Comment - 5 comments summarized
Commenters stated that truck safety had been left up to private industry and yet, with these standards, accidents still occurred. Commenters expressed concern about the plan and the protocol that would be used to recover a heavy cask that was displaced from the conveyance vehicle. Commenters questioned how a cask would be recovered if there was a train or truck wreck and the cask dropped to the ground, fell down the side of a mountain, a flash flood overturned a shipment, a cask fell into a gorge, or a cask rolled into a river or lake. Commenters asked, if there was a crash from a collision that involved fire, would the cask remain intact and would there be a chance of a serious nuclear release. Other commenters wondered how a massive cask would be lifted and stated that to lift a 91-metric ton (100-ton) or larger cask would require a portable crane that might not available.

Response
DOE agrees that accidents could occur during transportation of spent nuclear fuel and high-level radioactive waste to a repository. However, the shipping casks that would be used to transport these materials would be massive and tough with design features that complied with strict regulatory requirements that ensured the casks performed their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

Recovering 23-metric-ton (25-ton) truck casks or rail casks weighing up to 136 metric tons (150 tons) loaded with spent nuclear fuel or high-level radioactive waste would use methods commonly used to recover heavy trucks or railcars and locomotives following accidents. The capability to lift such weights exists and would be deployed as required. Railroads use emergency response contractors with the capability to lift derailed locomotives that could weigh as much as 150 tons. Difficult recoveries of equipment as heavy as spent nuclear fuel casks have been accomplished in areas such as those identified by the commenters. DOE anticipates that if such a recovery was necessary, it would be accomplished using methods and equipment similar to those used in prior difficult recoveries.

The Operational Protocols that the transportation contractors would have to follow are included in Section M.3 of the EIS. These protocols require the transportation contractors to be responsible for providing DOE with specific written procedures that clearly define detailed actions to be taken in the event of an abnormal event. These procedures would address repair or replacement of equipment, or recovery, as appropriate. These requirements would apply to transport by both truck and rail. Section M.5 addresses emergency response.

8.7 (141)
Comment - 31 comments summarized
Commenters asked questions about the potential for individual radiation exposure, including radiation doses to people living along the transportation routes as a result of normal cask radiation emissions. Of concern was monitoring of public and worker exposure and compensation for effects of radiation on public health.

Response
Transportation workers' exposure would be the responsibility of their employers.

Exposure to the public under incident-free conditions is discussed in Sections 6.2.3.1 and J.1.3.2.1 of the EIS. An analysis was done to determine the amount of radiation exposure to the maximally exposed individual, a hypothetical person who would receive the highest dose.

The U.S. Department of Transportation routing requirements, along with regulatory requirements to limit radiation dose external to a shipping cask, help to ensure that radiation dose to persons living along routes would be low. The analysis in Chapter 6 of the EIS for the mostly legal-weight truck scenario estimates the doses to persons who would drive alongside the trucks as they traveled on the highways, who would be stopped in locales where truck shipments stopped, and who lived along the routes that would be used. In response to public comments, DOE forecasted growth in populations along routes to improve its estimates of impacts that could occur during shipments. However, the estimated dose to an individual living along a route would not change with changes in population: only the integrated dose to the whole population would change. The dose for a maximally exposed individual who lived along a route would be an average of about 0.25 millirem per year. This is about 400 times less than the maximum dose permitted for members of the public in 10 CFR Part 20 (100 millirem).

Based on public comments, the Final EIS includes estimated public health impacts along transportation routes. This analysis accounted for factors such as the locations of intersections, commercial establishments and residences, and traffic signals. The impacts of incident-free transportation would be so low for individuals who lived and worked along the routes that these individual impacts would not be discernible even if the doses could be measured. The total impacts of transportation would be similar for different routes that might be used.

Although DOE has characterized the environment along the candidate transportation routes and corridors in Nevada, it has not performed a baseline health assessment. DOE believes it has estimated the potential environmental impacts, including health impacts, in sufficient detail to allow decisionmakers to determine the relative merits of each transportation scenario. However, DOE would assess the environmental and engineering conditions along the selected corridor in the appropriate National Environmental Policy Act document.

The Price-Anderson Act establishes a system of financial protection (compensation for damages, loss, or injury suffered) for the public in a nuclear accident, regardless of who causes the damage. See Section M.8 of the EIS for a discussion of the Price-Anderson Act. Responsibility for cleanup of released materials would be shared between DOE, the owners of the materials, and carriers under regulation of the Motor Carrier Act of 1980.

8.7 (142)
Comment - 27 comments summarized
A number of commenters expressed concern about the safety of shipments by rail. Commenters expressed concern with both mainline and branch rail line shipments to the repository. Commenters expressed concern with adherence to Federal and state regulations (and allowing Nevada oversight on branch line operations). Other commenters suggested specific operational restrictions to ensure safety. Commenters also expressed concern that privatization of rail operations would jeopardize the relationships and agreements that have been developed between DOE and states, tribes, and other responsible jurisdictions, including planning, operations (when, where, and how), training, technical assistance, and funding. A specific concern was having a low bidder planning and transporting spent nuclear fuel and high-level radioactive waste. Other commenters were concerned with the degraded conditions of railroads, including the inadequacies of rail crossings and increased collisions. Several commenters expressed concern with the rail maintenance programs and the need to switch from reactive maintenance to preventive maintenance programs to improve safety. Several commenters expressed concern with the placement of cars carrying spent nuclear fuel and high-level waste in a train indicating that cars near the front seem to be less affected by rail breaks and displacements than cars near the end of a train. Part of this concern was related to the signal systems on rail lines and data that indicate that rail malfunctions have occurred without a corresponding signal. All in all, the commenters' focus was on a recommendation that trains carrying spent nuclear fuel and high-level radioactive waste need to be operated in a different, more controlled mode than regular freight trains and that ownership and operational management of any new branch rail line should be evaluated against the contribution to risk management and regional economic benefit.

Response
In response to these and other public comments, DOE has added information on proposed transportation activities to the EIS (see Appendix M). Information added includes the regulations that govern spent nuclear fuel and high-level radioactive waste transportation, the proposed process that DOE would use to acquire commercial transportation services, and the expected operational details and protocols DOE would follow if the Yucca Mountain site was approved.

Transportation of hazardous materials in the United States is a very highly regulated activity, and transportation to a repository would be conducted under the umbrella of these regulations with oversight, as applicable, of various local, Native American tribal, state, and Federal agencies. This would ensure that all shipments would be made safely (see Section M.2 of the EIS).

At this time, DOE plans to use private industry, including railroads, to the maximum extent possible, to accomplish its transportation mission. Such an arrangement, however, would not jeopardize the relationships and agreements that have been developed between DOE and its stakeholders. DOE would retain responsibility for policy decisions, stakeholder relations, final route selection, and implementing Section 180(c) of the NWPA. DOE would award contracts for acceptance of spent nuclear fuel and high-level radioactive waste and transportation services to bidders whose proposals DOE considered to be most advantageous to DOE, with cost being only one of a variety of selection factors. One of the qualifications that must be met by a successful bidder would be to have performed a major transportation and logistics coordination project involving railroad, truck, or intermodal carriage of radioactive, toxic, or other types of hazardous materials within the past 10 years. DOE would require the transportation contractor to provide for maximum use of dedicated train service and advanced rail equipment features where this type of service or equipment can be demonstrated to enhance operating efficiency, dependability, and cost-effectiveness or lessen the potential of adverse railroad equipment incidents. See Section M.3.1 of the EIS for more information on the acquisition of contractor services.

Oversight of branch rail line operations in Nevada, if there was a decision to build such a line, would depend on several factors not known at this time. Maintenance of rail lines is prescribed by Federal Railway Administration regulations and the maintenance is checked by the Administration. The U.S. Department of Transportation has issued regulations designating the placement of cars carrying spent nuclear fuel in the makeup of a train (49 CFR 174.85 and 49 CFR 174.700).

8.7 (143)
Comment - 7 comments summarized
Commenters wanted to know what specific guidelines govern the movement of spent nuclear fuel and high-level radioactive waste. They stated that the designation of the rail routing should be determined in advance, that the U.S. Department of Transportation does not regulate the routing of rail shipments or radioactive materials, and that some entity must assume authority for routing and that designee should be identified in the EIS. Other commenters stated that the shipment of spent nuclear fuel would be regulated by the Nuclear Regulatory Commission and the U.S. Department of Transportation and that routing would be strictly controlled with input from states and Native American tribal groups.

Another commenter stated that the Public Utilities Commission regulates the safe transportation of radioactive and other hazardous materials on the state's highways and railways and that it has adopted the U. S. Department of Transportation safety regulations. A representative from the Public Utilities Commission of Ohio stated that it was the Commission's intention to involve local communities when routes were designated in communities under its jurisdiction. Another commenter stated that the U.S. Department of Transportation and the Nuclear Regulatory Commission, as overseers of spent nuclear fuel and high-level radioactive waste storage and transportation, are both demanding organizations that would not allow activities to occur if they did not meet the prescribed requirements.

Response
In response to public comments, DOE has added to the EIS information on the regulations that govern the transportation of spent nuclear fuel and high-level radioactive waste (see Appendix M). The Nuclear Regulatory Commission and the U.S. Department of Transportation share primary responsibility for establishing and enforcing requirements for the safe transportation of radioactive materials, including spent nuclear fuel and high-level

radioactive waste, and DOE would comply with these regulations when transporting spent nuclear fuel and high-level radioactive waste to the proposed repository.

U.S. Department of Transportation regulations set the standards for packaging, transporting, and handling radioactive materials, including labeling, shipping papers, placarding, loading, and unloading requirements (49 CFR Part 173). These regulations specify training needed for personnel who perform handling and transport of hazardous materials, which includes spent nuclear fuel and high-level radioactive waste.

The NWPA requires that DOE use casks certified by the Nuclear Regulatory Commission when transporting spent nuclear fuel and high-level radioactive waste to a repository. The Commission certifies that a cask meets the requirements of 10 CFR Part 71, which prescribes radiological performance standards for casks subjected to specific test conditions. These test conditions represent the kinds of forces that a cask would encounter in a severe transportation accident. In addition, the Commission establishes safeguards and security regulations to minimize the possibility of theft, diversion, or attack on shipments (10 CFR Part 73).

The representative highway routes identified for the EIS analysis conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, developed for transport of Highway Route Controlled Quantities of Radioactive Materials, require such shipments to be on preferred routes selected to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or an alternate route designated by a state or tribal routing agency. Alternate routes could be designated by states or tribes under Department of Transportation regulations (49 CFR 397.103) that require consideration of the overall risk to the public and prior consultation with local jurisdictions and other states and tribes. Federal regulations do not restrict the routing of rail shipments. However, for the analysis, as discussed in Section J.1.1.3 of the EIS, DOE assumed routes for rail shipments that would provide expeditious travel and the minimum number of interchanges between railroads. See Section M.3.2.1.2 for more information on route selection. As required by regulations in 10 CFR Part 73, routes must be submitted in advance to the Nuclear Regulatory Commission for approval.

8.7 (144)
Comment - 15 comments summarized
Commenters stated that the Draft EIS did not address the provision for state notification regarding routes and mode of transportation and that states and tribes needed to be informed if spent nuclear fuel and high-level radioactive waste were to be shipped through their state or community. One commenter stated objection to secret unescorted shipments and stated that local and state authorities had the need to know where spent nuclear fuel would be traveling. Other commenters stated their opposition to shipments pending reliable safeguards being in place to protect their communities. Other commenters expressed concern that notification was necessary so the right people could be available including local response agencies, workers, inspectors, and maintenance workers, and also stated that signage should be posted on the transportation vehicles to clearly notify the public of the hazardous cargo. Other commenters stated that they would expect DOE to voluntarily comply with their state's prenotification requirements to assure the residents of their states that spent nuclear fuel and high-level radioactive waste shipments could cross their states safely.

Response
DOE would comply with Nuclear Regulatory Commission regulations requiring notification to the governor or the governor's designee by mail or messenger [10 CFR 73.37(f)]. Governors would notify state and local safety officials, as appropriate, of the pending shipments. Tribes would receive notification if the Commission amended the regulation to allow such notice. In response to comments, additional information on the notification process is included in Section M.3.2.2.1 of the EIS.

Nuclear Regulatory Commission physical security regulations apply only to shipments of spent nuclear fuel; notification is not required for shipments of high-level radioactive waste. However, DOE intends to follow the same procedures for these shipments and for all unclassified shipments of DOE-owned spent nuclear fuel and other material, that could be shipped to Yucca Mountain. Notification procedures already in place would apply to shipments of naval spent nuclear fuel. The Nuclear Regulatory Commission has promulgated regulations for guards and escorts for spent nuclear fuel shipments that DOE would follow.

All vehicles (trucks and railcars) carrying spent nuclear fuel or high-level radioactive waste would be placarded in accordance with U.S. Department of Transportation regulations in 49 CFR Part 172, Subpart F. More information on these marking requirements is provided in Section M.2.2 of the EIS.

8.7 (147)

Comment - 13 comments summarized

Several commenters expressed concern about privatization of the transportation system. A common theme was that DOE cannot privatize or delegate to a contractor any key transportation responsibilities because of conflicts between transportation safety and the profit motivation of the private industry. One commenter stated concerns that many critical policy decisions would be improperly delegated to a contractor, such as the responsibility for selecting modes, routes, and casks, as well as the development of institutional plans and the preparation of an EIS addressing transportation. Several commenters referred to DOE's draft "Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management." Commenters were concerned that privatization could interfere with emergency response and DOE's interactions with tribes and local and state governments.

Response

Section 137(a)(2) of the NWPA requires the Secretary of Energy to utilize private industry to the fullest extent possible in each aspect of transportation of spent nuclear fuel under the Act. At present, DOE plans to implement this requirement by contracting with private industry to provide equipment such as casks and transport vehicles, to provide training of utility personnel in the use of the equipment, and to provide the transportation of the loaded and unloaded casks between the generator sites and Yucca Mountain. The exact form of the contracts with private industry continues to be studied. In response to public comments, DOE added Appendix M to the EIS, which discusses planned operational policies, procedures, and protocols for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Section M.3.1 contains more information on the acquisition of contractor services.

DOE's draft request for proposal for Regional Servicing Contractors requires that all bidders must meet certain qualification criteria and technical requirements. Each bidder must have performed a major transportation and logistics coordination project involving railroad, truck and/or intermodal carriage of radioactive, toxic, or other hazardous materials within the past 10 years as well as have a Nuclear Regulatory Commission-approved Quality Assurance Program. Bidders would be evaluated on their past performance and the degree to which their technical approach addresses the safety, operational, and logistical requirements of the program. Cost would be the last factor to be evaluated. Most important, DOE would continually assess the performance of each of the transportation contractors in relation to the contract.

DOE would retain responsibility for approval of routes to be proposed to the Nuclear Regulatory Commission in consultation with states, tribes, and local authorities (see Section M. 3.2.1.2 of the EIS). DOE would implement and administer programs that implemented Section 180(c) of the NWPA for routine transportation and emergency response planning and training. DOE would be responsible for working with the states and tribes to ensure their input was factored into the development of a national transportation program. DOE would work with the states and tribes to develop communication, training, and security plans (see Section M.6). If additional National Environmental Policy Act reviews for transportation activities were necessary, DOE would be the responsible agency.

8.7 (153)

Comment - 40 comments summarized

Commenters stated that DOE should improve its coordination and consultation with local and state communities, planning organizations, and other national organizations (for example the National Conference of State Legislatures), and develop a comprehensive transportation plan for the Final EIS. As written, the EIS is inadequate without such planning information because it did not consider the true complexities and management of a large-scale transportation program. If such comprehensive planning were included, DOE would have reached different conclusions than those presented in the Draft EIS.

The Waste Isolation Pilot Plant transportation program, which was developed cooperatively with affected states, was touted as the model that should be followed by DOE for the Yucca Mountain transportation program. In the context of transportation planning, commenters identified many issues that should be addressed, including the following:

- Federal/state/local cooperative agreements and DOE support, including (1) financial support for highway and rail improvements, maintenance, and rehabilitation; (2) financial support and training, equipment, materials, personnel, and coordination years before the first shipments to ensure the preparedness of involved agencies; (3) training and planning and preparedness sessions for state and local jurisdictions near shipment routes; (4) route coordination with state and local jurisdictions, and route identification for each generator site to the repository years before anticipated shipments; (5) review of accident and terrorism responses and responsibilities of all involved; (6) coordination and the supply of equipment for responses, tracking, record keeping and communications; (7) a prior commitment for needs assessment by state and local agencies for safety improvements, signing, signals, emergency crews, equipment, training, overall route improvements (rehabilitation, reconstruction and improvements); and (8) formation of a working committee of state and local jurisdictions years prior to the first shipment to facilitate coordination, cooperation, communications, and training.

- Local community criteria and relevant resolutions (for example, those of Nye County),

- Local community emergency-response capabilities, route planning, and selection to minimize shipments through highly populated areas or avoid Native American tribal lands,

- Provisions for contract carriers, shipment methods, accident prevention, cask testing, financial and technical assistance, potential for terrorism and sabotage, timetables for shipments, mitigation measures including highway maintenance and improvements, contingency planning, operation of the transportation system (for example, how many casks would be built, their lifetimes), organizational structure and management practices, field operations and provisions for these services by the Regional Servicing Contractor, and safe parking areas.

Commenters urged DOE to consult with communities in making future decisions regarding the mode of transport and rail corridors.

Response

DOE agrees that detailed, comprehensive planning would be required prior to the start of shipments to a repository. The level of planning suggested by many of the commenters, however, would be useful only when carried out closer to the time any rail or truck transportation would be scheduled to begin. Otherwise, the information upon which such planning was based would be likely to change before shipments could begin. Operational protocols for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain are presented in the draft Request for Proposal, *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153487-DOE 1998). They are summarized in Section M.3 of the EIS. The *Waste Isolation Pilot Plant Transportation Safety Program Implementation Guide* (DIRS 156384-WGA 1995) protocols were used as a model for Yucca Mountain-related protocols. The Department expects to interact with affected stakeholders on routing and related local issues if the repository site is approved.

The number of highway and rail shipments required to transport all of the spent nuclear fuel and high-level radioactive waste to Yucca Mountain, under any of the scenarios analyzed, would be a very small fraction of the total number of highway and rail shipments throughout the country on a daily, monthly, or yearly basis. Therefore, the impact of the repository shipments on the transportation infrastructure would be small. If the repository was approved, DOE would discuss transport details with stakeholders, including financial support, before the start of shipments. If the heavy-haul truck implementing alternative was used extensively in Nevada, DOE would provide funds for highway upgrades and maintenance, as appropriate. If rail was the selected mode in Nevada, DOE would construct a branch rail line.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions the Department would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) (63 *FR* 23753, April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

First responses to accidents would be the responsibility of the jurisdiction where the accident occurred. DOE and the transportation contractors would be available to provide assistance as requested. DOE would comply with the requirements of the Nuclear Regulatory Commission to ensure that shipments were properly safeguarded and met security requirements (see Section M.7 of the EIS).

As discussed in Section 1.5 and Appendix C of the EIS, throughout the scoping process and development of the EIS, DOE has encouraged broad participation in this National Environmental Policy Act process. DOE held 15 public scoping meetings, held Draft EIS public hearings in 21 locations across the United States held hearings on the Supplement to the Draft EIS in three locations in Nevada, and consulted and interacted with various government agencies, other organizations, and stakeholders across the country.

8.7 (184)
Comment - 19 comments summarized
Commenters expressed concern about measures to be taken to ensure safe transportation of spent nuclear fuel and high-level radioactive waste. The concerns include condition of the highways and railroads; inspection of old, deteriorating roads and bridges; and consideration of weather and temperature and their effects on roads, rails, and bridges. Commenters stated that actions should be taken to prevent derailments. Commenters stated that during transport, railroads and highways should be cleared, drivers and crews should have comprehensive training, drivers with records of violations should be excluded, there should be controls at crossings, and there should be buffer cars and security guards. Commenters expressed concern about the designation and acceptance of responsibility for accident response and cleanup, radiation monitoring of trains and trucks, and contamination control. Some commenters made suggestions for restrictions on the shipments, restrictions on routing, restrictions on time of day, restrictions around population centers, and the use of dedicated or special trains. Other commenters stated that careful plans should be developed and implemented (including risk minimization strategies) to ensure that proper measures are taken to ensure safe transportation of spent nuclear fuel and high-level radioactive waste.

Response
In response to these and other public comments, DOE has added information on proposed transportation activities to the EIS. Appendix M includes additional information on the regulations that govern spent nuclear fuel and high-level radioactive waste transportation, the proposed process that DOE would use to acquire commercial transportation services, and the expected operational details and protocols DOE would follow if the Yucca Mountain site was approved (see Sections M.2 and M.3).

DOE is required to follow Nuclear Regulatory Commission, U.S. Department of Transportation, and applicable state, Native American tribal, and local regulations and use Commission Certified casks when transporting spent nuclear fuel and high-level radioactive waste to a repository. DOE is confident that by implementing these regulations and using Commission Certified casks, this transportation can be carried out in a safe manner. Of the thousands of shipments completed over the last 30 years, none has resulted in an injury through release of radioactive material.

U.S. Department of Transportation regulations require carriers of spent nuclear fuel and other materials with a high level of radioactivity to use preferred routes that reduce time in transit. A preferred route for highway shipments is an Interstate System highway or alternate route selected by a state or tribe. Rail routes for shipping radioactive materials are determined by the shipper and the railroad companies based on safety, available trackage, schedule efficiency, and cost-effectiveness. See Section M.3.3.1.2 of the EIS for additional information on route selection.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors that would perform waste acceptance and transportation operations. The contractor providing transportation services would be required to prepare a transportation plan that would discuss the various steps it would take to ensure the shipments were conducted in a safe and efficient manner. Among other things, the plan would provide for the use of dedicated train service where this type of service could be demonstrated to enhance operating efficiency, dependability, and cost-effectiveness, or lessen the potential of adverse railroad equipment incidents (see Section M.3.1 of the EIS).

DOE could decide to use a dedicated train that carried only the material being shipped to Yucca Mountain, or could elect to move the spent nuclear fuel and high-level radioactive waste in general freight. If the material was shipped as general freight, the position of the spent nuclear fuel or high-level radioactive waste car in the train would be regulated by 49 CFR 174.85. This regulation requires that railcars placarded "radioactive" must be separated from a locomotive, occupied caboose, or carload of undeveloped film by at least one nonplacarded car, and it cannot be placed next to other placarded railcars of other hazard classes. Section J.2.3 of the EIS presents an assessment of impacts of using dedicated trains to transport spent nuclear fuel and high-level radioactive waste. Based on current information from the U.S. Department of Transportation and the Association of American Railroads, it is DOE's opinion that there is no clear advantage for using either dedicated trains or general freight service.

Drivers would be required to meet the qualifications specified in U.S. Department of Transportation regulations (49 CFR Part 391). They would also be required to complete the training called for in 49 CFR 177.816 (see Section M.3.2.1.7 of the EIS).

The radiation levels on the surface of casks carrying spent nuclear fuel and high-level radioactive waste to a repository would be measured prior to the shipment to ensure levels were within regulatory limits. Additional measurements could be made en route any time the shipment underwent an inspection.

As with any traffic accident, local, tribal, and state public safety officials would be the first to respond to accidents involving radioactive materials. Additional assistance could be requested from Federal agencies. Damages from the accident caused by the release of radioactive materials would be handled under the provisions of the Price-Anderson Act. Any damages caused by a non-nuclear accident (an accident not involving the release of radioactive materials or authorized precautionary evacuation) would be covered by the carrier's private insurance and handled through state tort law as with any other transportation accident.

8.7 (197)
Comment - 14 comments summarized
Commenters expressed a concern for safe transportation of spent nuclear fuel and high-level radioactive waste under routine conditions. They indicated a need for ensuring that the transportation contractor conducted business properly (for example, followed procedures, routinely inspected equipment, used safety Conscious drivers) and only permitted transport on the safest rails or roads. Other commenters questioned driver behavior and questioned whether relief drivers would be used. One commenter asked if staffing points for refueling would be identified ahead of time and publicized. Another commenter expressed specific concern with travel through rural areas, in particular if the vehicle was unescorted, since rural driving could be more hazardous and there would be no one available to call for help. A few commenters stated that the community, or at least the state or tribal government, should be informed when Yucca Mountain-bound shipments were traveling through their community. One commenter suggested independent inspections (mechanical and radiological) at the point of origin, mid-transport, and prior to acceptance at the Yucca Mountain site. One commenter stated their county would require additional services to monitor DOE. Commenters questioned who would supervise the suitability of the vehicle used in transport and expressed concern with the protocols to be followed in the event of a spill or leak.

Response
In response to comments, the transportation regulations and operational protocols the shipping contractors would be required to follow have been included in Sections M.2 and M.3 of the EIS. The Nuclear Regulatory Commission and the U.S. Department of Transportation regulate the transportation of spent nuclear fuel and high-level radioactive waste. As a result of strict compliance with their regulations, thousands of shipments have been completed over the last 30 years, none of which has resulted in an injury through release of radioactive material.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors that would perform waste acceptance and transportation operations. DOE would ensure that its contractors providing transportation services for the repository abided by all applicable regulations at the time of transport.

DOE's draft Request for Proposal for Regional Servicing Contractors requires the contractors selected to provide transportation services must demonstrate that they have had successful experience transporting hazardous materials. Carriers would be required to develop and maintain a driver and crew training program that meets the requirements of 49 CFR 172.600 and 177.825. For more detailed information, see Appendix M of the EIS. Driver scheduling would ensure that the hours of service regulations in 49 CFR Part 395 could be met. The transportation contractor would be required to prepare a transportation plan that would include proposed routes and other information such as safe emergency parking areas and other planned stops. DOE would make the plan available to states and tribes for comment before the shipments took place. The carrier would be able to communicate to its dispatch center and others through various means of communication, including a satellite-based tracking system. This would enable the carrier to communicate problems even in remote areas (see Section M.3.1).

Inspections of highway shipments, including the vehicle, load, and driver, at point of origin and elsewhere as required, would be conducted in accordance with the procedures developed by the Commercial Vehicle Safety Alliance. Rail shipments would be inspected according to Federal Railroad Administration policy (see Section M.3.2.1.5 of the EIS).

Under Nuclear Regulatory Commission regulations, information regarding the time and date of shipments of spent nuclear fuel is restricted. States would receive advance notification of impending shipments in accordance with Nuclear Regulatory Commission regulation 10 CFR 73.37. Tribes would receive notification if the Commission amended the regulation to allow such notice (see Section M.2.5 of the EIS).

In the event of a transportation accident, first responders would follow their local procedures. Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) (63 *FR* 23753, April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. If there was a decision to proceed with the development of a repository at Yucca Mountain, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

Comment - 11 comments summarized
Several commenters requested that DOE provide ways to monitor shipments so that officials, states, and tribes as well as individuals, would know the locations of the shipments and supporting equipment at all times. Other commenters asked if trucks and rail cars would be marked and tracked and stated that the public has a right to know when and where shipments would take place. Concerns were expressed about a missing cask, or other problem such as O-ring failures, human error, vehicular accidents, or sabotage. Commenters wanted to know who would take the responsibility for these events. One commenter summarized the capabilities of the TRANSCOM system but questioned how DOE could measure health and safety impacts and emergency management mitigation needs if it is not clear how DOE plans to communicate with local entities. Several commenters expressed the concern that letting the public know when and where shipments will take place would increase the risk of terrorism.

Response
In response to public comments, DOE provided additional information on the planned operational aspects of transportation in the EIS (see Section M.3). DOE and the transportation contractors would use the latest version of the TRANSCOM system, or a similar satellite-based tracking system, to provide continuous real-time position

tracking for all shipments. In addition, DOE continues to improve its tracking system based on lessons learned during actual shipments. As a result, DOE does not expect that a cask could be "missing" as suggested in a comment. The currently operational TRANSCOM system allows messages to be sent from the drivers and crew directly to the control center. Any unusual or unexpected situations encountered or any problems with the cask or other equipment would be immediately communicated to the control center. DOE intends to make satellite tracking information available to the states and tribes, subject to Nuclear Regulatory Commission determination that use of satellite tracking technology would be allowed by safeguards and security regulations in 10 CFR Part 73. Thus, there would be information on which to base requests for aid to local law enforcement or emergency response personnel as needed (see Section M.3.2.1.5).

Casks would be prepared for shipment under quality assurance procedures approved by the Nuclear Regulatory Commission. The casks and transporter would be inspected prior to shipment. Truck shipments would not be allowed to leave the waste generator site unless found to be defect-free, as required by the Commercial Vehicle Safety Alliance inspection procedures. Rail shipments would be subjected to railroad hazardous materials inspections prior to being accepted by a railroad for transportation. Inspections would occur along the route and at the repository destination. More information on inspection activities is provided in Section M.3.2.2.2 of the EIS.

Trucks and railcars carrying spent nuclear fuel and high-level radioactive waste would be placarded in accordance with U.S. Department of Transportation regulations. Placarding and labeling requirements for shipments are discussed in Section M.2.2 of the EIS.

The Nuclear Regulatory Commission would publish the routes the shipments would take. However, regulations at 10 CFR Part 73 require shipment schedules to be held as confidential safeguards information. DOE would comply with Nuclear Regulatory Commission regulations requiring notification to the governor or the governor's designee by mail or messenger [10 CFR 73.37(f)]. Governors would notify state and local safety officials, as appropriate, of the pending shipments. Tribes would receive notification if the Commission amended the regulation to allow such notice. In response to comments, additional information on the notification process is included in Section M.2.5 of the EIS.

Comment - EIS000116 / 0004
As you look at the maps back here and as this audience looks at those maps on the walls, you've -- you've told us that virtually any public state highway coming into Nye County could be a potential route for a truck borne transportation of high-level waste, that there's a number of routes that are proposed for rail routes.

So we have to be prepared and integrate into our planning for the next eight to ten years all possibilities for all those routes and all those modes.

You haven't given us precise information on quantities, scheduling, and certainly as you heard here tonight, the public understanding of the risks associated with this document are poorly understand -- understood.

Response
DOE evaluated the potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste from 5 DOE and 72 commercial sites to the proposed repository at Yucca Mountain. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, states or tribes may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. If the Yucca Mountain site was approved, DOE would identify for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In response to public comments, DOE has included, state maps of representative highway routes and rail lines it used for analysis in Appendix J of the EIS (see Figure J-53 for the Nevada map). Section J.4 includes potential health and safety impact estimates associated with shipments for each state through which shipments could pass.

In response to comments on the Draft EIS, DOE prepared Appendix M to provide additional information on transportation regulations and the operational aspects of spent nuclear fuel and high-level radioactive waste transportation (see Sections M.2 and M.3 of the EIS). This information includes more details on how DOE would select transportation routes if the Yucca Mountain site received approval. The routes selected would comply with the applicable regulations in place at the time of shipment.

Comment - EIS000461 / 0007
You got all this nonsense about money. Why are you worried about how much money you are spending on this issue? You don't seem to care. You go around spending money like drunken sailors until it comes to a point now we're worried about health and children. And now all of a sudden, it's a money issue. It doesn't make any sense.

Response
Much of the money used to characterize Yucca Mountain comes from the Nuclear Waste Fund, and DOE cannot spend money from this Fund for purposes not authorized by law. With regard to adequate funding, Congress annually determines the appropriate funding for the DOE Office of Radioactive Waste Management, based on appropriate requests from the Secretary of Energy and the President. DOE believes that Congress, having directed the Government to begin this project, would continue to fund it adequately to protect the public health and safety and the environment.

8.7 (2066)
Comment - EIS000599 / 0002
There is insufficient transportation analysis in it. This is one of the most glaring omissions in the statement itself. There is not a clear picture of where the transportation routes are going to be, how the waste is to be transported. How is the public to make a decision on the impacts when we're unclear how it is going to be transported?

The mode of transportation and the stopping points along the routes are unknown as well. So routine exposure on route cannot be properly evaluated either.

There is also, to my knowledge, still the possibility that the transportation may be privatized. If that is the case, then all bets are off. That is another unknown or are we yet to swallow? So that is a question also. Is privatization off the books, or is it still a possibility?

Response
Based on the results of the impact analyses presented in Chapter 6 and Appendix J of the EIS, as well as the results published in numerous other studies and environmental impact analyses cited in the EIS, DOE is confident that spent nuclear fuel and high-level radioactive waste can be and would be safely transported to Yucca Mountain. DOE believes, as the EIS reports, that the potential impacts of this transportation would be so low for individuals who live and work along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured. The analysis presented in the EIS factored in the characteristics of spent nuclear fuel and high-level radioactive waste, the integrity of shipping casks that would be used in transport, and the regulatory and programmatic controls that would be imposed on shipping operations (see Section M.2). The EIS analytical results are supported by numerous technical and scientific studies which have been compiled through decades of research and development by DOE and other Federal agencies of the United States, including the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as by the international community, including the International Atomic Energy Agency.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site is approved. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. The reader is referred to the introduction to Chapter 8 of the CRD for additional information.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, state or Native American tribal governments may designate alternate preferred highway routes, and highways and rail lines may be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12). In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Section J.4). Section J.4 includes potential health and safety impacts associated with shipments for each state through which shipments could pass.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Department has issued a draft Request for Proposals requiring the Regional Servicing Contractor to prepare a transportation plan that describes the Contractor's operational strategy and delineates the steps it would implement to ensure compliance with all regulatory and other DOE requirements. Section M.3.1 of the EIS contains more detail on the proposed role of the Regional Servicing Contractor.

8.7 (2203)
Comment - EIS000615 / 0001
The U.S. Navy has an EIS concerning welfare of sites in Smoky Valley where the proposed train route is. I want to know if the Navy or the DOE has interacted and taken this into consideration and worked together.

And did the DOE interact and work with the BLM [Bureau of Land Management] and U.S. Forest Service on lands in Lander County that they would go through.

Response
Land use and ownership in the Carlin Corridor are discussed in Section 6.3.2.2.2 of the EIS. DOE is aware of the Fallon Range Training Complex Requirements Naval Air Station EIS, but chose not to hold formal consultation meetings with the Navy or other Federal agencies on it. The reason is that the size and number of electronic warfare sites is small in the Smoky Valley area, and would not be affected by the rail corridor (DIRS 148199-USN 1998).

The documents cited in Section 3.2 of the EIS are source documents used by DOE for land-use considerations and they include possible future actions within the transportation corridor. The more notable land-use features and potential influences that exist on lands within the corridors are presented in Section 6.3.2. For example, the land features within the Carlin Corridor are presented in Section 6.3.2.2.2. Commenters are referred to the corridor-specific sections of Section 6.3.2.2, where DOE identifies potential conflicts with existing or future land uses and land-use plans that could be affected by a given corridor.

As stated in Chapter 6 and Section 11.2.2 (subsection on Compliance with Floodplain/Wetlands Environmental Review Requirements), more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews would be prepared if a decision is made to select a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes. These would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. They also would include field surveys (as applicable) and more detailed assessments and analyses of wetlands and other waters; floodplains; sensitive species; effects of habitat fragmentation, interruption of movements, mortality, and harassment on wildlife, horses, and burrows; loss of hunter-generated revenue, spread of noxious weeds, and soils.

8.7 (2311)
Comment - EIS001888 / 0531
[Clark County summary of comments it has received from the public.]

Carriers should respond to all driver advisories and notification of delays and adjust routes accordingly. All vehicles should be inspected quarterly and display appropriate safety inspection stickers.

Response
DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. Section M.3.2.1.4 of the EIS provides a discussion of the protocols and procedures that would be implemented by a Regional Servicing Contractor and its subcontractors under adverse weather or road conditions. The procedures are in two parts.

One part of the procedure relates to preshipment planning, which would use available data relating to expected conditions. Shipments would not be dispatched on a route where expected conditions would not comply with the requirements in the procedures. Weather forecasts would be obtained by the Regional Servicing Contractor as part of the preshipment planning, and forecasts for rain, snow, fog, high winds, and tornado warnings would be considered in the determination of the shipment schedule. In general, Regional Servicing Contractors would be responsible for the planning, implementation, and control of the shipments, including responding to changing conditions, as necessary. A contractor would acquire information of road or highway construction that could temporarily affect the planned route. Through consultation with the affected states along the planned route, the contractor would obtain road and highway conditions and information on anticipated construction. Planning information on long-range highway construction provided by state highway departments would be given to the contractor.

The other part of the procedure relates to en route problems and is for those persons actually involved in making the shipment who would be best able to discuss and report expected and encountered conditions. DOE Protocols, which would be implemented by the Regional Servicing Contractors, require that shipments would not travel when severe weather conditions along routes or adverse road conditions would make travel too hazardous to proceed. Driver and crew communications with the control center would provide advanced warning of potential adverse conditions along the route. If unanticipated severe weather or adverse road conditions were encountered, the driver and crew would contact the control center to coordinate routing to a safe parking or stopping area if it became necessary to delay the shipment until conditions improved. Section M.3.2.1.3 of the EIS provides detailed information on the selection of safe parking areas to be used in the event a shipment had to be delayed.

Casks would be prepared for shipment under quality assurance procedures approved by the Nuclear Regulatory Commission and the casks and transporter would be inspected prior to shipment. Truck shipments would not be allowed to leave the waste generator site unless found to be defect free as required by the Commercial Vehicle Safety Alliance inspection procedures. Rail shipments would be subjected to railroad hazardous materials inspections prior to being accepted by a railroad for transportation. Inspections would occur en route and at the repository destination. More information on inspection activities is provided in Section M.3.2.2.2 of the EIS.

8.7 (2874)
Comment - EIS001100 / 0003
Every stop along the way and every time the waste is handled would cause some contamination. An expert from a firm that deals with cleaning up disasters said at a public meeting in St. Louis that homes within a 1/4 mile of the tracks would receive a dose of radiation comparable to leaving an x-ray machine on night and day for thirty years.

Response
The spent nuclear fuel or high-level radioactive waste would be handled only twice; once while loading the material into the transportation cask at the generator site and once while unloading the material at the repository from the transportation cask and transferring it to the disposal package. In both cases, the operation takes place in a building

designed for this with the objective of protecting the public and the environment from contamination. The transportation cask is designed to protect the public and the environment from contamination and radiation while the material is being shipped.

The U.S. Department of Transportation routing requirements, along with regulatory requirements to limit radiation dose external to a shipping cask, help to ensure that radiation dose to persons who live along routes would be low. Exposure to the public under incident-free conditions is discussed in Sections 6.2.3.1 and J.1.3.2.1 of the EIS. An analysis was done to determine the amount of radiation exposure to the "maximally exposed individual (MEI)." The MEI is a hypothetical person who would receive the highest dose. The EIS estimates the dose to persons who would drive alongside the trucks as they travel on the highways, who would be stopped in locales where truck shipments stop, and who live along the routes that would be used. In response to public comments, DOE forecasted growth in populations along routes in order to improve its estimates of potential impacts that could occur in the future when shipments would occur. However, the estimated dose to an individual living along a route would not change with changes in population - only the integrated dose to the whole population would change. The dose for an individual who lived along a route would be an average of about 0.008 millirem per year. This is more than 30,000 times less than average annual background radiation in the United States and less than one-one thousandth of the dose from a chest X-ray.

8.7 (3323)
Comment - EIS001002 / 0003
Neither science nor industry has figured out how to clean up an oil spill; imagine radioactive spills! To avoid accidents, will you close down the highways every other day as another shipment passes by? That is a lot of logistical planning and citizen inconvenience. If you are worried about terrorists, will you be able to announce the routes and slowdowns or closures in advance? Will I and other drivers want to share the highways with a nuclear convoy? Or will I get used to the risks and drive anyway? As I understand from my reading, designs for transports, routes and contingency plans have not been prepared yet.

Response
Spent nuclear fuel and high-level radioactive waste are not easily dispersed; they do not readily dissolve in water; they are not liquids or gases that can be easily spilled or leaked, and radiation from them does not make other materials radioactive. Spent nuclear fuel and high-level radioactive waste are solids. They are hard, tough, and dense ceramics, metals, or glasses contained within tough metal barriers. The shipping casks used to transport these spent nuclear fuel and high-level radioactive waste are massive and tough with design features that comply with strict regulatory requirements that ensure the casks perform their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

There are no plans to routinely close highways during shipments to a repository. Shipments of spent nuclear fuel have been made safely in this country for many years without having to resort to highway closures. Shipments would be subject to safeguards regulations of the Nuclear Regulatory Commission (10 CFR 73.37) that are designed to minimize the already small potential for sabotage attacks. Additional information on the physical protection of spent nuclear fuel and high-level radioactive waste during transportation can be found in Section M.7 of the EIS. DOE would comply with Nuclear Regulatory Commission regulations requiring notification to the governor or the governor's designee by mail or messenger [10 CFR 73.37(f)]. Governors would notify state and local safety officials, as appropriate, of the pending shipments. Tribes would receive notification also if the Commission amended the regulation to allow such notice. Additional information on the notification process is included in Section M.2.5.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, states and tribes may designate alternate preferred highway routes, and highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). Rail lines were identified based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials (see Figure 6-12).

8.7 (3427)
Comment - EIS001160 / 0125
The DEIS should describe time of day, day of week and seasonal characteristics of shipping campaigns. Would there be an effort for shipments to occur during low season traffic times?

Response
At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations (see Section M.3 of the EIS). The contractor providing transportation services would be required to prepare a transportation plan that would discuss the various steps it would take to ensure the shipments are conducted in a safe and efficient manner. DOE's draft Request for Proposal requires the contractors selected to provide transportation services must demonstrate that they have had successful experience transporting hazardous materials. The transportation contractor would be required to prepare a transportation plan that would include proposed routes and other information such as safe, en route emergency parking areas and other planned stops.

DOE expects that shipping rates would be approximately uniform throughout the year for both rail and highway shipments. The issue of restricting hours of operations is covered in the protocols, which require the Regional Servicing Contractors to consider preferred time of day travel through urban areas in their route planning. Many local governmental organizations have time-of day-restrictions for certain types of traffic (for example, no heavy-haul truck traffic on certain highways during rush hours). DOE shipments only observe applicable restrictions. In addition, DOE transportation contractors are required to closely monitor road and weather conditions to be certain that conditions are acceptable for safe vehicle operation.

8.7 (3430)
Comment - EIS001160 / 0128
Would shipments be scheduled to occur during low traffic or high traffic hours, being moved at night or during the day?

Response
DOE expects that shipping rates would be approximately uniform throughout the year for both rail and highway shipments. The issue of restricting hours of operations is covered in the protocols, which require the Regional Servicing Contractors to consider preferred time of day travel through urban areas in their route planning. Many local governmental organizations have time-of-day restrictions for certain types of traffic (for example, no heavy-haul truck traffic on certain highways during rush hours). DOE shipments observe applicable restrictions. In addition, DOE transportation contractors are required to closely monitor road and weather conditions to be certain that conditions are acceptable for safe vehicle operation (see Section M.3.2 of the EIS).

8.7 (3796)
Comment - EIS001272 / 0006
The majority of high-level radioactive waste generated in the North Eastern part of the United States will be transported through the city of Cleveland, OH, and its suburbs. This puts many people, including my family, friends, co-workers, and neighbors at risk when an accident occurs. I have never had a voice in choosing the method of generating electricity, and I had no choice in which electric company would provide power to my home. I would never have chosen a company that built nuclear power plants for my provider, had I been given the choice. I hope

that I may have a voice in deciding if this highly toxic and dangerous waste should journey across the country and across my backyard, putting every person along the route at risk, EVERY DAY FOR 24 YEARS.

Response

In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-41 of the EIS for the representative Ohio routes). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-81 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would either originate or pass through Ohio. The table also lists the estimated number of rail shipment through Ohio in the mostly rail scenario for each of the candidate Nevada rail corridors and heavy-haul truck routes.

If the Yucca Mountain site was approved, under the mostly legal-weight truck scenario, the estimated total number of truck shipments through Ohio would be 17,258 over 24 years, approximately 2 truck shipments per day (total number of shipments would be 52,786). There would be no rail shipments over the 24-year period.

The estimated numbers of shipments passing through Ohio under the mostly rail scenario are less than the mostly legal-weight truck scenario. According to Table J-81, the number of rail shipments through Ohio would be approximately 2,381. This is less than 1 shipment per day over 24 years. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low.

DOE believes that its public involvement process during the development of the EIS is consistent with Council on Environmental Quality and DOE regulations on implementing the National Environmental Policy Act, and DOE guidance on public participation during the preparation of EISs.

The procedures used by DOE for the development of this EIS provided for public input at hearings and by written submissions. The Nuclear Regulatory Commission during its review of the license application for Yucca Mountain will provide similar opportunities for public input. Therefore, the public does have a voice in the decision of how to solve the nuclear waste problem in the United States.

8.7 (4231)

Comment - EIS001160 / 0046

Can the experience of transport of low-level and transuranic nuclear waste and impacts (i.e. Waste Isolation Pilot Plant (WIPP) and shipments to Nevada Test Site) be used as a model for the Yucca Mountain repository? To what extent was WIPP Program Implementation Guide for transportation considered as a model for Yucca Mountain regarding mitigation within the DEIS? Was the experiences of these other shipping campaigns used as examples to assess community impacts and transport accident rates within the DEIS?

Response

In response to public comments, DOE has added Appendix M to the EIS to provide further information on topics concerning transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. These topics include liability for transportation accidents, emergency management, cask safety and testing, and transportation services acquisition and protocols.

DOE is utilizing Waste Isolation Pilot Plant experience for planning its transportation program. The operational protocols to be used by the transportation contractors are similar to those in the *Pilot Plant Program Implementation Guide* (DIRS 156384-WGA 1995; see Section M.3 of the EIS). DOE would use vehicle inspection criteria and procedures, developed by the Commercial Vehicle Safety Alliance, for all truck shipments to a repository. These are the same procedures that are being used successfully on the Waste Isolation Pilot Plant shipments. They place requirements on these shipments that go beyond those required for shipments of other hazardous materials. In addition, the experience gained from the emergency planning associated with Waste Isolation Pilot Plant shipments would be factored into the planning for repository shipments and the implementation of Section 180(c) of the NWPA (see Section M.5).

The Yucca Mountain EIS uses procedures comparable to those used by the Waste Isolation Pilot Plant for the assessment of community impacts.

8.7 (4244)
Comment - EIS001160 / 0058
The DEIS does not appear to address where and how relief drivers will be stationed or where and how these drivers will stop and park their trucks for meals, vehicle maintenance, fuel, etc. In addition, the DEIS does not address the qualifications of drivers and their respective knowledge in handling vehicle breakdowns or equipment failures as a means to mitigate risk. These issues need to be addressed in the FEIS.

The DEIS does not address restrictions in hours of operations for truck shipments as a possible measure to mitigate exposure risk in communities. For example, shipments could be restricted from passing schools at the beginning and end of each school day.

The DEIS does not consider the availability of specialized equipment which may be needed to transfer shipping casks from one vehicle to another while in transient. Delays in availability of such equipment may exacerbate exposure risks. This information must be considered in the FEIS.

Response
At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The contractor providing transportation services would be required to prepare a transportation plan that would discuss the various steps it would take to ensure the shipments are conducted in a safe and efficient manner. DOE's draft Request for Proposal requires the contractors selected to provide transportation services must demonstrate that they have had successful experience transporting hazardous materials. Carriers would be required to develop and maintain a driver and crew training program that meets the requirements of 49 CFR 172.600 and 177.825 (see Section M.3.2.1.7 of the EIS). Driver scheduling would ensure that the hours of service regulations found in 49 CFR Part 395 could be met. The transportation contractor would be required to prepare a transportation plan that would include proposed routes and other information such as safe, en route emergency parking areas and other planned stops. DOE would make the plan available to states and tribes for comment before the shipments take place. The carrier would be able to communicate to its dispatch center and others through various means of communication, including the satellite-based tracking system. This would enable the carrier to communicate problems even in remote areas (see Section M.3.2.1.5).

The issue of restricting hours of operations is covered in the protocols, which require the Regional Servicing Contractors to consider preferred time of day travel through urban areas in their route planning.

The Regional Servicing Contractor would be required to provide detailed written procedures for how it would respond to an incident and arrange for repair/replacement of equipment or recovery, as appropriate. In accordance with ANSI N14-27 (DIRS 156289-ANSI 1987), the carrier is expected to provide appropriate resources for dealing with the consequences of an accident, isolating and cleaning up contamination, and maintaining working contact with the responsible governmental authority until the latter has declared the incident to be satisfactorily resolved and closed. Section M.3 of the EIS contains more detail on the proposed role of the Regional Servicing Contractor.

8.7 (4310)
Comment - EIS001160 / 0120
Page 11-10: Department of Transportation Hazardous Materials Packaging and Transportation Regulations 49 CFR: 4th paragraph. These regulations "attempt" to reduce potential hazards. At present, the Department of Transportation does not regulate the routing of rail shipments of radioactive materials. The EIS does not address the environmental impact of an accident using specific rail routes for radioactive materials.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use. Before such shipments began, states and tribes may designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified.

Nonetheless, the representative highway routes identified for the EIS analysis conform to U.S. Department of Transportation regulations (49 CFR 397.101). These regulations, developed for transport of Highway Route Controlled Quantities of Radioactive Materials, require such shipments to be on preferred routes selected to reduce the time in transit. A preferred route is an Interstate System highway, bypass, or beltway, or an alternate route designated by a state or tribal routing agency. Alternate routes could be designated by states or tribes under Department of Transportation regulations (49 CFR 397.103) that require consideration of the overall risk to the public and prior consultation with local jurisdictions and other states and tribes (see Figure 6-11). Federal regulations do not restrict the routing of rail shipments. However, for the analysis, as discussed in Section J.1.1.3 of the EIS, DOE assumed routes for rail shipments that would provide expeditious travel and the minimum number of interchanges between railroads (see Figure 6-12).

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site is approved. The introduction to Chapter 8 of this Comment-Response Document contains additional information.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

8.7 (4430)
Comment - EIS001042 / 0005
Training to handle and monitoring of safety concerns involving the railroads and truck fleets that would be used are inadequate to the task. Will the U.S. DOE hire and train a specialty truck fleet just for this job? Or will the contract(s) go, as is usually the case with government contracts, to the lowest bidder?

Response
Section 137(a)(2) of the NWPA requires the Secretary of Energy to utilize by contract private industry to the fullest extent possible in each aspect of transportation of spent nuclear fuel under the Act. At this time, DOE plans to use private industry, including railroads, to the maximum extent possible, to accomplish its transportation mission. Such an arrangement, however, would not jeopardize the relationships and agreements that have been developed between DOE and stakeholders. DOE would retain responsibility for policy decisions, stakeholder relations, final route selection, and implementing Section 180(c) of the NWPA. One of the qualifications that must be met by a successful bidder would be to have performed a major transportation and logistics coordination project involving railroad, truck, or intermodal carrier of radioactive, toxic, or other types of hazardous materials within the past 10 years.

DOE has developed a possible private sector acquisition process. The acquisition process is described in Section M.3.1 of the EIS. A draft Request for Proposal for Acquisition of Waste Acceptance and Transportation Services has been published (DIRS 153487-DOE 1998). If Yucca Mountain was recommended as a repository site, the final request would be issued after the recommendation. There would be from two to four contractors selected to transport the spent nuclear fuel from the waste generator sites to Yucca Mountain. The current plan is to have a contractor for each of the four Nuclear Regulatory Commission regions in the contiguous United States; a single contractor could be assigned to no more than two of the regions. Each contractor would be responsible for providing all necessary casks, transport vehicles and other equipment, and transportation services. All bidders must meet certain qualification criteria and technical requirements. Each bidder must have performed a major transportation and logistics coordination project involving railroad, truck and/or intermodal carriage of radioactive, toxic, or other hazardous materials within the last 10 years. In addition, each bidder must have a Commission-approved quality assurance program. Bidders would be evaluated on their past performance and the degree to which their technical approach addresses the safety, operational, and logistical requirements of the program. Cost would be the last factor to be evaluated.

8.7 (5278)
Comment - EIS000968 / 0002
The DEIS does not adequately address the financial impact of the repository and the transportation thereto. How can the Local Emergency Planning Committee (LEPC) prepare for emergencies when there is no starting point on fiscal impacts? Specific questions that need to be answered are:

1. What will it cost to monitor the transportation program for the life of the project?

2. What is the estimated cost to prepare for and respond to the maximum reasonably foreseeable accident (MRFA)?

3. Does the Price-Anderson Act, the Stafford Act or a combination of both cover the costs if an evacuation is necessary as the result of an accident? This needs to include long term shelter and business losses.

4. What are the financial impacts on our healthcare system? Do they have the equipment/training necessary to deal with the everyday effects of exposure? In the MRFA do we have enough hospital beds or providers? How much will it cost to prepare?

5. Much of the DOE document discusses Grant funding for costs anticipated with the development of Yucca Mountain. However, Grants are discretionary and Nevada would be competing with every State effected by transportation, should not a fixed funding source be identified?

6. Affected areas have no mass Community Warning System other than the Emergency Alert System. What will it cost to create a useful warning system to notify the public in the event of an emergency?

7. Public safety training is not addressed. In large communities you may have experienced Hazardous Materials Response Teams, but in most rural areas the first responders will be volunteers. Ongoing training will need to be addressed for the life of the project.

Response
In response to comments, DOE has revised the EIS by adding Appendix M to provide additional information on DOE funding for improvements in emergency response training and capabilities along the routes (see Section M.5). State and Native American tribal governments have primary responsibility to respond to and to protect the public health and safety in their jurisdictions from accidents involving radioactive materials. However, Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress.

Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) of the NWPA (63 *FR* 23753, April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

Specific responses:

1. The EIS does not include an estimate of the cost to state, local, and tribal governments to monitor the transportation program for the life of the project. DOE and the transportation contractors would use the latest version of the TRANSCOM system (see Section M.3.2.1.5 of the EIS), or a similar satellite based tracking system, for providing continuous real-time position tracking for all shipments. In addition, DOE intends to make satellite tracking information available to the states and tribes, subject to Nuclear Regulatory Commission determination that use of satellite tracking technology would be allowed by safeguards and security regulations in 10 CFR Part 73. Thus, there would be information on which to base requests for aid to local law enforcement or emergency response personnel as needed.

2. In response to public comments, Section J.1.4.2 of the EIS discusses the costs of cleanup following a severe transportation accident. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 environmental assessments, and information submitted by the State of Nevada in its public comments on the Draft EIS. This information included estimates of cleanup costs as high as $9.4 billion. The studies included cost data compiled from case studies involving actual cleanup of radioactive contamination. In addition, the studies address consequences for releases of radioactive materials in communities. Although the studies project high costs for cleanup following severe accidents, the accidents evaluated are very unlikely and, as a consequence, the economic risks of transportation accidents would be very small.

3. The Price-Anderson Act establishes a system of financial protection (compensation for personal injury and property damage, including loss of use of property) for the public in a nuclear accident, regardless of who causes the damage. See Section M.8 of the EIS for a discussion of the Price-Anderson Act. The Price-Anderson Act would indemnify any person held liable for damage including cleanup of released radioactive materials.

4 and 6. In the unlikely event someone was contaminated as the result of an accident involving shipments to a repository, there are several means to deal with such incidences. The Department has several programs available to provide assistance to state, tribal, and local governments in response to radioactive material accidents. The Radiological Assistance Program, for example, provides trained personnel with equipment to evaluate, assess, advise, and assist in the mitigation and monitoring of potential immediate hazards associated with a transportation accident. As part of the program, DOE maintains eight Regional Coordinating Offices across the country that are staffed 24 hours a day, 365 days a year. The staff consists of nuclear engineers, health physicists, industrial hygienists, public affairs specialists, and other personnel who provide field monitoring, sampling, decontamination, communications, and other services, as requested. In addition, DOE's Radiation Emergency Assistance Center/Training Site (REAC/TS) focus on providing rapid medical attention to people involved in radiation accidents. REAC/TS maintains a 24-hour response center to provide direct support, including deployable equipment and personnel trained and experienced in the treatment of radiation exposure to assist Federal, state, tribal, and local organizations.

5 and 7. Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

8.7 (5425)
Comment - EIS000323 / 0001
First of all, the international experience with spent nuclear fuel shipments is absolutely irrelevant to what we're talking about in this EIS. I will not belabor the point except to say most of the long-distance experience in the

international area is with water transportation, not being proposed in the U.S. Most of the land-shipment experience is in England or in France, to a lesser extent in Germany, with relatively short land shipments. Until someone makes a compelling case that those shipments are relevant based on the comparability characteristics of the shipments that are being proposed for Yucca Mountain, I suggest we put that one to sleep.

Now, a more interesting question is, how relevant are the past shipments in the United States, given their characteristics? I would argue first that the naval fuel shipments are of no relevance whatsoever because of robust physical construction of naval reactor fuel which, after all, is designed for combat conditions and, secondly, because of the special protocols under which that fuel is shipped.

The real issue is, how relevant are the past shipments of the civilian industry in the United States to what's being proposed for Yucca Mountain? Turn to the database maintained by the Nuclear Regulatory Commission. The best data that we have comes from that source through the public information circular on irradiated fuel shipments. That database begins in 1979. It doesn't include a few of the DOE shipping campaigns like the across Country shipments from Surrey and Three Mile Island to Idaho, but it includes just about everything else including a lot of research reactor shipments. And when people give you this 3,000 shipments, you know, a lot of these shipments contained a piece of fuel rod, small research reactor assembly, and are in no way comparable to what the Department of Energy is proposing. So look, for example, at what the numbers are. Amount shipped between 1979 and 1995: a total of 1,335 metric tons uranium. That's an average of 79 metric tons uranium. Okay, that's equivalent to about eight casks that the DOE will ship in the future. Look at the total number of shipments in that period, 1,306. That's an average of 77 shipments per year. You know, they'll be shipping more than that per month, in some cases maybe that much by week under one of the scenarios that they're talking about in the Draft EIS. No, in the past, truck shipments, not a very good experiential base for people who are talking about a heavily rail scenario, although I will argue that in fact they'll be real lucky if they move 65 percent of the inventory by rail, and frankly I would consider that a real good target for them to be shooting for.

Now, the real issue is distance. Over the last 15 years, guess what the average rail shipment has been. Three hundred and fifty-six miles. In fact, 80 percent of the shipments have been less than 500 miles. And when you look at the truck shipments, you find the average shipment distance has been a little longer, 678 miles; but even there you find that 82 percent of the shipments are less than 900 miles. Now, the average distance for both rail and truck shipments is going to be about 2,200 miles when you average out all the sites in the U.S. And I would submit that that means greater likelihood of equipment failure, greater likelihood of human error and certainly greater likelihood of human error and certainly greater likelihood of bad luck in the way of accidents caused by other vehicles, bad weather, natural disasters and so forth.

Finally, what we haven't talked about, my third point, is if the industry wants to tell us a success story and say, "Base your transportation program on a success story," they have to look no further than the Waste Isolation Pilot Plant in New Mexico. Unfortunately, the DOE has chosen to ignore the lessons learned from the only good transportation campaign that they've planned. Why is that program accepted by the western states affected by it? Why is it endorsed by all the western governors? We haven't had a governor in Nevada saying anything good about DOE for, you know, many, many years; but they've all endorsed this program. The principles are this: one, the shipping casks were physically tested full scale. Whether they needed to be or not, the demonstration and the proof of the pudding was laid on the table where people could see that the containers actually met the NRC [Nuclear Regulatory Commission] performance standard. Some of these tests are boring, you know. You drop it in one orientation. You pick it up, you drop it again, you drop it again, you roast it and so forth. But, you know, as boring as that may sound, there's nothing in the world like showing people a video that shows honest testing and shows the package surviving. And when the earlier version failed, we found out there was a problem with the O-rings that would allow particles to escape from the package, and that was fixed. So sometimes you learn things. It's just like in the old Sandia tests where we found out that the tie downs that hold the cask to the trailer are just as important as the integrity of the cask. So number one, the WIPP program is accepted because of full-scale testing of the package.

Number two, routes have been out there for ten years. They came out in the Draft EIS. Some people didn't like them. Down in New Mexico the routes caused so much controversy that the State Legislature took the authority away from one agency and gave it to another, but in the end they came up with routes that were acceptable to the people of New Mexico. You can't do that unless you're starting with a discussion of the routes and you take input from all parties, and that's how you solve the problem. DOE seems not to have learned the second big lesson form WIPP.

The third big lesson of WIPP is those regulations that some of you guys in the industry think are great -- well, maybe they are, maybe they aren't. But a big advantage in terms of public credibility came about when the DOE guys on the WIPP program said, "You know what? We're willing to go beyond the minimum that the regulations require in two areas, accident prevention and emergency response."

So when somebody comes to you and says here's all this experience in Europe, you ask them to prove to you that the characteristics of the European shipments have some relevance to this. When someone says, oh, we've got this great experience in the U.S. remind them most of the shipments in the U.S. took place over 20 years ago. The great utility people like Howard Schieman (phonetically) form WEPCO and Paul Standish from Westinghouse -- they've all retired; they're not around anymore. One of the problems in the utility business will be they don't have a lot of people who've got hands-on experience with PWR and BWR fuel kind of shipments. But the characteristics of the shipments, I think, are more important than the people; and the characteristics don't tell you anything.

And finally, when somebody says they don't know how to please those people, those crazy people in Nevada who can't seem to find anything good the DOE does, you remind them that the State of Nevada endorsed the transportation and safety protocols that they developed for WIPP. And that's the yardstick that we hope their colleagues at the Office of Civilian Radioactive Waste management will eventually wake up and follow the example that has been set.

Response
DOE believes that all past spent nuclear fuel shipping experience, international and domestic, would be relevant to planning for shipments of spent nuclear fuel and high-level radioactive waste if the Yucca Mountain site was approved. In addition, the operational protocols to be used by the transportation contractors are similar to those in the *Pilot Plant Program Implementation Guide* (DIRS 156384-WGA 1995) (see Section M.3 of the EIS). DOE would use vehicle inspection criteria and procedures, developed by the Commercial Vehicle Safety Alliance, for all truck shipments to a repository. These are the same procedures that are being used successfully on the Waste Isolation Pilot Plant shipments. They place requirements on these shipments that go beyond those required for shipments of other hazardous materials. Furthermore, the experience gained from the emergency planning associated with Waste Isolation Pilot Plant shipments would be factored into the planning for repository shipments and the implementation of Section 180(c) of the NWPA.

In response to public comments, DOE has added Appendix M to the EIS to provide further information on topics concerning transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. These topics include liability for transportation accidents (Section M.8), emergency response (Section M.5), and transportation services acquisition and protocols. Appendix M discusses protocols for managing adverse weather and road conditions (Section M.3.2.1.4) and driver training (Section M.3.2.1.7).

DOE has added information on the safety and testing of transportation casks (see Section M.4 of the EIS). In addition, based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 presents consequences for accidents that could release radioactive materials.

The TRUPACT package used in the Waste Isolation Pilot Plant program is completely different from the spent nuclear fuel casks to be used for shipment to Yucca Mountain. It has relatively thin walls and a different type of seal. Full-scale testing was appropriate for this type of package. However, many types of spent nuclear fuel casks have been certified by the Nuclear Regulatory Commission without full-scale tests being performed on the designs. The Commission is currently conducting a Package Performance Study that might include full-scale testing of a typical spent nuclear fuel transport cask. DOE is monitoring this study closely and will comply with any revised regulations that result from the study.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway or rail lines would be used. For example, in the interim, state or Native American tribal governments might designate alternate preferred highway routes and new highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in the EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) (see Figure 6-11). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials (see Figure 6-12).

The final routes would be selected following the requirements and protocols outlined in the Draft Request for Proposals for Regional Servicing Contractors (DIRS 153487-DOE 1998; see Section 3.2.1.2 of the EIS). DOE and its shipping contractors would consult with the states and tribes along proposed routes in a procedure similar to that used for Waste Isolation Pilot Plant route selection. DOE would submit selected routes to the Nuclear Regulatory Commission for approval.

DOE believes that the mostly rail scenario, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada. In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.7 (5688)
Comment - EIS001887 / 0302
In the Draft EIS Summary document (p. S-21), DOE states that legal-weight vehicles would not require special state-issued permits to transport HLW [high-level radioactive waste] or SNF [spent nuclear fuel]. This statement is not correct. These vehicles would still need valid hazardous materials transport permits to enter and traverse Nevada with such loads.

Response
Section 6.2.1 of the EIS refers only to the special overweight permits that would be required if the weight of the truck were to exceed 80,000 lbs. This type of permit would not be required for shipments on legal-weight trucks, but they would be needed if a large rail cask were loaded on a heavy-haul truck.

All permits required by the State of Nevada, or any local jurisdiction traversed by the shipment, would be obtained by DOE in accordance with the applicable regulations. In Nevada, these permits would be those required by the Nevada Administrative Code and could include a Certificate of Registration or a Hazardous Material Triennial Permit. County or city hazardous material permits or certificates would be obtained as necessary.

8.7 (5755)
Comment - EIS001887 / 0359
Page 9-18; Section 9.3.3.2 - Groundwater

The Draft EIS does not discuss potential impacts to groundwater from an accident occurring during transport.

Response
The shipping casks used to transport spent nuclear fuel and high-level radioactive waste are massive and tough with design features that comply with strict regulatory requirements that ensure the casks perform their safety functions even when damaged and the casks would be designed to be watertight even after a severe accident. Furthermore, the high-level radioactive waste would be in a solid form that would not be easily dispersed (ceramics, metals, or glasses).

Numerous tests and extensive analyses, using the most advanced analytical methods available, have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Thus, it is extremely unlikely that an accident that resulted in a cask falling into any body of water would result in surface water contamination, let alone groundwater. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

As discussed in Section J.1.1.4, the EIS does not specifically analyze a transportation accident involving contamination of surface water or groundwater. While small particles generated by the impact forces and driven out of the cask by a severe fire (which would be extremely unlikely because there would be no fuel to sustain an engulfing fire of the type required in order to release radioactive material), might ultimately end up contaminating soils and surface waters outside the cask, this would not be the dominant pathway for radiological exposure and uptake after an accident.

8.7 (5817)

Comment - EIS001802 / 0002

We have heard a lot of talk about earthquakes in Nevada, but I've lived 18 years with the notion that there may be -- it's not may and it's not if, it's when the major earthquake will occur along the New Madrid fault.

I can't quote my specifics at this point, but the New Madrid fault, St. Louis is on the north end. It would extend all the way down to the Memphis area along the Mississippi River, the St. Louis area and the areas to the south all the way to Cape Girardeau consist of soils that are very unstable in the event of a major earthquake. Those of us who are privy to a lot of information can literally see buildings, all unreinforced masonry buildings in the City of St. Louis collapsing in the event of a major earthquake, not to mention the bridges across the river in St. Louis, Cape Girardeau, points north and points south.

The material that's been presented here this evening, in going through some of it, I see scenarios painted whereby over the next 24 years there would be three rail shipments per year through Missouri, for the next 40 years there would be two trucks a day which is 14 trucks per week going through St. Louis, and then as a slight-aside I hear mention of barge traffic which puts barge transport up and down the Mississippi possibly for these cartridges, and what I see -- and the probability of a major, I believe a magnitude of 6.8 or greater earthquake occurring on the New Madrid fault is extremely high for the next 15 years, and it's almost imperative that it will happen within the next 30, if I understand my previous training.

And then when I see a picture of two trucks a day moving through St. Louis through the rush hour traffic, not to mention the three trains a week and the barge traffic and you have painted some of your scenarios about how the casks were treated in the event of accidents, but I didn't read anything that would approximate a building falling on one of these trucks or railroad cars or having the bridge dislodged and it falling into the Mississippi River or a barge accident being in the Mississippi River. When I imagine a terrible earthquake compounded by a nuclear waste spill all happening at the same time in this region, it's more than I can bear, and if these cartridges have to be -- if it's -- in the end, if it's agreed they have to be transported across the country, I think you should take a closer look at routing all of this through the New Madrid fault area, this part of the country.

Response

The transportation regulations of the Nuclear Regulatory Commission include shipping cask design requirements for normal and accident conditions of transport (10 CFR Part 71). The regulations do not specifically address natural disasters such as earthquakes, floods, or tornadoes. However, if a shipment to Yucca Mountain were to be involved in any of these natural disasters, the impact on the cask would be within the bounds of the hypothetical accident defined in 10 CFR Part 71. The shipping casks used to transport these materials are massive and tough with design features that comply with strict regulatory requirements that ensure the casks perform their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents.

In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, states and tribes may designate alternate preferred highway routes, and highways and rail lines could be constructed or modified. Final routing decisions would be conducted in accordance with U.S. Department of Transportation routing guidelines. The routing evaluations would consider such parameters as emergency response capabilities; local terrain, road design, and climate characteristics as they affect accident rates; economic effects of accidents; sensitive environments exposed; and locations of special facilities such as hospitals and schools (see DIRS 103718-DOT 1998, *Identification of Factors for Selecting Modes and Routes for Shipping High-Level Radioactive Waste and Spent Nuclear Fuel*). The preferred routes would be submitted to the Nuclear Regulatory Commission for approval.

8.7 (5866)
Comment - EIS001557 / 0002
That being said the [Public Utilities] Commission’s [of Ohio] position can be simply stated in this matter. And that is; that if these shipments are to be made, it’s our desire that these shipments be made as safely as possible for the citizens of Ohio.

Response
DOE shares the Ohio Public Utilities Commission’s objective of making the shipments as safely as possible. As stated in Section 2.1.3.2 of the EIS, DOE would meet all requirements and regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission (NRC) in transporting spent nuclear fuel and high-level radioactive waste to the repository. DOE would meet these requirements and regulations in consultation with state and tribal authorities. To attain this objective, the waste would be shipped in casks certified by the NRC as meeting strict performance standards, the shipments would be escorted to minimize the possibility of terrorist attacks in accordance with NRC requirements, and the routes would be selected in accordance with applicable Department of Transportation regulations and in consultation with state, tribal, and local authorities.

In response to public comments, DOE has added Appendix M to the EIS to provide further information on topics concerning transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. These topics include the protocols to be used by the Regional Servicing Contractors (see Section M.3) and the training and technical support that DOE would provide under NWPA Section 180(c) (see Section M.6) and cask safety and testing (see Section M.4).

8.7 (5969)
Comment - EIS001879 / 0004
The Draft EIS does not take cognizance of several Nye County Commission resolutions regarding the transportation of nuclear waste in Nye County. The resolutions state that it is unacceptable to ship highly radioactive wastes on Nye County’s Main Street (US-95, between Tonopah and Mercury), or on Nevada Highway-160, the Main Street of the site county’s largest and most rapidly growing community, and its link to the state’s metropolitan center. Commission resolutions also state that shipment of high-level wastes should be by rail (cross country and in Nevada), and that the preferred rail route is one that avoids site county communities to the greatest possible extent.

The Draft EIS examines the shipment of highly radioactive wastes on 220-foot long heavy-haul tractor trailers, moving at average speeds of 20 miles per hour (or less) on two-lane rural public highways directly through Nye County communities. Resolutions by the Nye County Commission have made it clear that such shipment is unacceptable in Nye County.

Nye County Commission resolutions constitute local government plans, and should be recognized and treated as such in the analysis, identification, and evaluation of human health, environmental, and socioeconomic impacts.

Response
DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

Although some counties, towns, and cities have ordinances in place prohibiting the transportation of high-level nuclear waste, these ordinances, in order to be officially recognized by the Federal Highway Administration (FHA) a person, State, or political subdivision thereof, or Native American Tribe directly affected by a highway routing designation, must submit an application for preemption determination to the Administrator of the FHA, to determine if the route designation can be preempted as defined by 49 U.S.C. 5125 and 49 CFR Part 397, Subpart E. After review of the application, the FHA Administrator may grant a waiver of preemption, if the preemption standards of 49 CFR 397.203 are met. Highway routing designation includes any regulation, limitation, curfew, time of travel, restriction, lane restriction, routing ban, port-of-entry designation, or route weight restriction applicable to the highway transportation of hazardous materials (including class 7 radioactive waste) over a specific highway route or portion of a route.

DOE would adhere to all applicable ordinances that have been granted a waiver of preemption by the Administrator of the Federal Highway Administration when transporting high-level nuclear waste or spent nuclear fuel.

8.7 (6206)
Comment - EIS001291 / 0003
The Public Utilities Commission of Ohio requires every motor carrier of radioactive and hazardous materials to register with and obtain a Uniform Permit from the Commission.(iv) This program helps to ensure that every carrier meets basic, minimum safety requirements before transporting radioactive or other hazardous materials in this state.

In addition, the Commission employs rail inspectors who are certified by the Federal Rail Administration in specialties affecting rail safety, such as equipment, track, operating practices and hazardous materials. Under an agreement between the Commission and the FRA [Federal Rail Administration], the Commission rail inspectors will conduct inspections of rail track and equipment and forward any violations on the FRA for enforcement action.

The Commission has been designated by the Governor as the state routing agency for the highway transportation of radioactive materials and other hazardous materials, but we cannot prevent the transportation of these radioactive materials through this state. Any such effort would be viewed as interfering with interstate commerce and would be clearly unconstitutional. However, if the materials are shipped by highway, the Commission does have the authority to require that such transportation take place on routes which minimize the potential radiological risk to the public and the environment.

Please note that the Commission's authority under Federal law is limited to highway routing of radioactive materials; the Commission has no authority to designate routes for shipment by rail. If the Department of Energy chooses to move these shipments by rail, the Department will bear sole responsibility for selecting which rail lines will be used to transport these shipments. However, the Commission will use its knowledge of the rail lines in the State of Ohio to work with the Department of Energy to select the most appropriate rail lines for these shipments. Moreover, the Commission staff will conduct inspections to monitor the safety of the track, equipment and the radioactive materials.

Federal regulations require that certain "highway route controlled quantities" of radioactive materials be transported only on "preferred routes."(v) In the event that a state has not designated an alternative route, the "preferred routes" are considered to be interstate highway system routes; bypasses and beltways, if available, are required to be used around densely populated urban areas.(vi) The state routing agency, however, can designate routes to be used in addition to, or instead of, the interstate highway system as the "preferred routes."(vii) The Commission has not designated any such "alternative routes" at this time.

However, the Commission is examining the possibility of preferred routes for these shipments of radioactive wastes. The Commission has provided a grant of $98,000 to the Ohio State University to research the risk factors involved in routing radioactive materials on the state's highways. This research will provide the Commission with the data necessary to determine which routes would minimize potential radiological risk to the public and the environment.

Before the Commission will designate any such routes, the Commission will be guided by two principles. First, the Commission will only designate routes at the behest of, and where there is a full participation among, the local communities. The Commission strongly believes that recommendations for routing radioactive and other hazardous materials should come from the local communities affected by the transportation. The Commission should not impose routing requirements unless there is full participation among the local communities as to the proper route, and the proposed route minimizes potential radiological risk to the public and the environment.

Secondly, the Commission will not designate routes for radioactive and other hazardous materials which serve to export the risk to other communities or states. Decisions by Federal courts and agencies make it clear that routing designations which serve to export the risk to other communities are preempted by Federal law. Therefore, local communities which are potentially affected by any routing recommendation must be part of the process which proposes the routing recommendation. Likewise, any proposed routing recommendations must not serve to export the risk to our neighboring states.

At the appropriate time, when there is greater certainty as to the timing, volume and routes of the shipments, the Commission staff will be available to provide technical assistance to local communities which desire to prepare routing recommendations. Moreover, the Commission will provide grants through the Hazardous Materials Grant Program to local communities to fund the costs of the planning and study necessary for routing recommendations.

Finally, it is important to bear in mind one additional requirement under Federal law. Any radioactive materials routing designation made by the Commission on behalf of the State of Ohio may have an impact upon, and thus, under Federal law, will require the consent of, any state affected by such a designation. The shipments discussed in the Draft Environmental Impact Statement predominantly would be through shipments, shipments which neither begin in nor end in this state; therefore, any action by the Commission will require close coordination with our neighboring states of Pennsylvania, West Virginia, Kentucky, Michigan and Indiana.

(iv) Ohio Admin. Code Section 4901:2-6-14; Ohio Rev. Code Ann. Section 4905.80(B)(1).
(v) 49 C.F.R. Section 397.101(b).
(vi) 49 C.F.R. Section 397.101(b)(2).
(vii) 49 C.F.R. Section 397.103.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this point in time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, state or Native American tribal governments may designate alternate preferred highway routes, and highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate) that reduce time in transit. DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials.

DOE would welcome the opportunity to work with the Public Utilities Commission of Ohio to ensure the safety of shipments of nuclear waste in and through Ohio. The Commission's knowledge of local highway and rail conditions would be especially valuable in aiding DOE's selection of routes. DOE appreciates the Commission's recognition of the role of neighboring states.

As required by the NWPA, DOE would acquire Regional Servicing Contractors to support planning and operation of the transportation system (additional details of the responsibilities and process are provided in Section M.3 of the EIS). The Department has issued a draft Request for Proposals requiring the Regional Servicing Contractor to prepare a transportation plan that describes the Contractor's operational strategy and delineates the steps it would implement to ensure compliance with all regulatory and other DOE requirements. This includes identification of proposed routes and associated routing considerations, coordination and communication with all participating organizations and agencies, including other Regional Servicing Contractor(s), DOE, state, Native American tribal, and local governments, and interactions with appropriate Federal and state organizations. The route and mode determinations would be interactive. If, during the course of the mode or route determinations, one of the previously determined factors changed, the site-specific mode and route analysis would be reevaluated to ensure consistency. The Regional Servicing Contractor would consult with other Regional Servicing Contractor(s) as appropriate to ensure continuity and consistency of routes and to ensure trained emergency.

8.7 (6488)
Comment - EIS001774 / 0006
Who will monitor worker and public exposure? Who will implement and evaluate quality assurance and quality control in the NRC [Nuclear Regulatory Commission], DOE and DOT [U.S. Department of Transportation]? Who will run the incident reporting system? Where is the funding for state and local inspectors enforcement? Who pays for or provides for evacuation plans, training and radiological protection equipment? If there is no Price Anderson coverage on theft or sabotage if a truck or train goes off a planned route, who pays for that?

Response
Nuclear Regulatory Commission and DOE regulations require monitoring of radiation workers, records of their exposures, and maintenance of those records. Regional Servicing Contractors would monitor their workers to ensure that no individual's exposure exceeded regulatory limits. The Regional Servicing contract would contain a clause in accordance with DOE Acquisition Regulation 952.223-75 that would require individual occupational radiation exposure records generated in the performance of work under the contract to be subject to inspection by DOE and preservation by the contractor until DOE authorized disposal. The Nuclear Regulatory Commission limits radiation emitted from radioactive packages to protect the public. The Regional Servicing Contractors and responsible agencies would monitor waste casks containing spent nuclear fuel or high-level radioactive waste.

Although the EIS analyses are based on the latest reasonably available information and state-of-the-art analytical tools, not all aspects of incident-free transportation or accident conditions can be known with absolute certainty. In such instances, DOE has relied on conservative assumptions that tend to overestimate impacts. For instance, DOE assumed that the radiation dose external to each vehicle carrying a cask during routine transportation would be the maximum allowed by U.S. Department of Transportation regulations. Similarly, DOE assumed that an individual, the "maximally exposed individual," would be a resident living 30 meters (100 feet) from a point where all truck shipments would pass. Under these circumstances, the maximally exposed individual would receive a dose of about 6 millirem from exposure to all truck shipments (6 millirem represents an increased probability of contracting a fatal cancer of 3 in 1 million). Although it can be argued that individuals could live closer to these shipments, it is highly unlikely that an individual would be exposed to all shipments over the 24-year period of shipments to the repository, even though DOE incorporated this highly conservative assumption in the analysis. Given these very low exposures, DOE has no plans to monitor exposures to the public during transport.

The Nuclear Regulatory Commission has established Quality Assurance requirements that apply to the design, purchase, fabrication, handling, shipping, storing, cleaning, assembly, inspection, testing, operation, maintenance, repair, and modification of waste package components such as the casks that DOE would use to transport radioactive waste to a repository (10 CFR Part 71). The requirements mandate cask designers and fabricators to have an approved Quality Assurance program. The DOE Office of Civilian Radioactive Waste Management (OCRWM) and its contractors must comply with Nuclear Regulatory Commission requirements. DOE has a Quality Assurance program applicable to all its activities and contractors. The Nuclear Regulatory Commission and DOE can audit a contractor's activities at any time to determine compliance with the requirements. The U.S. Department of Transportation does not impose specific Quality Assurance requirements.

U.S. Department of Transportation regulations require a carrier to notify the Department by telephone at the earliest practicable moment after an incident involving certain hazardous materials (49 CFR 171.15). The carrier must report the incident in writing within 30 days. The Department of Transportation keeps a record of such incidents and publishes an annual report. (The latest report is available on the Internet at http://hazmat.dot.gov/ brindex98.htm.) In addition, DOE has a reporting system that includes reporting of unusual, off-normal, and emergency occurrences (Order 232.1A, Occurrence and Processing of Operations Information).

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. The schedule in the proposed policy and procedures for implementation of Section 180(c) of the NWPA (63 *FR* 23753, April 30, 1998) is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. The Department would provide an initial planning grant and a base grant for a need assessment and planning and coordination activities associated with interacting with local jurisdictions and neighboring jurisdictions. A percentage of these funds (25 percent in the first year, 10 percent thereafter) could be used for the purchase of equipment. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

With respect to compensation for losses associated with an accident involving spent nuclear fuel and high-level radioactive waste, the Price-Anderson Act (discussed in Section M.8 of the EIS) establishes a system of financial protection for persons liable for and for persons injured by a nuclear accident or incident. The Price-Anderson Act establishes a system of private insurance and Federal indemnification that generally ensures that up to $9.43 billion is available to compensate for damages suffered by the public, regardless of who causes the damages. Beyond that level, Congress will consider further action that it determines is necessary to provide full and prompt compensation to the public. Price-Anderson indemnifies all persons liable for the nuclear damage including state, local, and tribal governments, emergency response workers, health care personnel, victims, and any other citizens or members of the public.

Because of the public's interest in transportation, DOE has added to this EIS Appendix M and maps and tables that show the analyzed routes and estimated health and safety impacts for each state through which the shipments would pass. Appendix M provides general background information about transportation-related topics, such as transportation regulations (Section M.2), transportation operations (Section M.3), cask testing (Section M.4), and emergency response (Section M.5).

8.7 (6558)
Comment - EIS001328 / 0007
To assure a technically superior transportation system and to help attain public confidence in the safe transportation of nuclear waste, NCSL [National Conference of State Legislatures] urges Congress and DOE to: Apply special criteria to the shipment of spent fuel, including the development of guidelines for routing when shipping by rail, the use of special trains (unit or dedicated trains; moving at designated safe speeds) for rail shipments, safety inspections at origin and enroute, and full-scale testing of casks used for spent fuel transport.

Response
In response to these and other public comments, DOE has added information on proposed transportation activities to the EIS (see Appendix M). Appendix M includes additional information on the regulations that govern spent nuclear fuel and high-level radioactive waste transportation, the proposed process that DOE would use to acquire commercial transportation services, and the expected operational details and protocols DOE would follow if the Yucca Mountain site was approved (see Sections M.2 and M.3).

DOE intends to purchase services and equipment from Regional Service Contractors who would perform waste acceptance and transportation operations. Section M.3.1.6 of the EIS provides a discussion of the protocols and procedures that would be implemented by a Regional Servicing Contractor and its subcontractors.

DOE would require its Regional Servicing Contractors to follow specific guidelines in the recommendation of rail routes. These guidelines are in the operational protocols in Section M.3 of the EIS.

DOE could decide to use a dedicated train that carries only the material to be shipped to Yucca Mountain, or could elect to move the spent nuclear fuel and high-level radioactive waste in general freight. DOE continues to evaluate the safety, cost, and schedule aspects of dedicated trains, however a decision on their use has not been made at this time. If the material was shipped as general freight, the position of the spent nuclear fuel or high-level radioactive waste car in the train is regulated by 49 CFR 174.85.

Truck shipments would be inspected in accordance with the *Commercial Vehicle Safety Alliance Enhanced North American Standard Level I Inspection Procedures and Uniform Enhanced Out-of-Service Criteria* (DIRS 102209 CVSA 1999). Rail shipments would be inspected in accordance with the rules of the Federal Railroad Administration.

The NWPA requires DOE to use casks certified by the Nuclear Regulatory Commission when transporting spent nuclear fuel and high-level radioactive waste to a repository. The Commission’s certification regulations indicate that cask testing must represent the kinds of forces that a cask would encounter in a severe transportation accident. A cask’s ability to survive the tests prescribed by the regulations (10 CFR Part 71) can be demonstrated either through component analysis or through scale-model and full-scale testing to demonstrate and confirm the performance of the casks. The Nuclear Regulatory Commission would decide which level of physical testing or analysis was appropriate for each cask design submitted.

8.7 (6567)
Comment - EIS001632 / 0055
EPA [the Environmental Protection Agency] suggests that the final EIS provide a section which lays out the responsibilities of various federal, state, local and tribal agencies in regulating, approving and monitoring shipments of nuclear waste. This information should provide additional assurance to the public that a national network of controls is in place designed to ensure public safety.

Response
Because of the public’s interest in transportation, DOE has added to this EIS Appendix M and maps and tables that show the analyzed routes and estimated health and safety impacts for each state through which the shipments would pass. Appendix M provides general background information about transportation-related topics, such as transportation regulations (Section M.2), transportation operations (Section M.3), cask testing (Section M.4), and emergency response (Section M.5).

DOE has issued a draft Request for Proposals requiring the Regional Servicing Contractor to prepare a transportation plan that describes the Contractor's operational strategy and delineates the steps it would implement to ensure compliance with all regulatory and other DOE requirements. This includes identification of proposed routes and associated routing considerations, coordination and communication with all participating organizations and agencies, including other Regional Servicing Contractor(s), DOE, state, Native American tribal, and local governments, and interactions with appropriate Federal and state organizations. The route and mode determinations would be interactive. If, during the course of the mode or route determinations, one of the previously determined factors changed, the site-specific mode and route analysis would be reevaluated to ensure consistency.

Comment - EIS001160 / 0068
Page 1-8: The DEIS does not consider the potential for certain defense high-level radioactive wastes to have security requirements which limits pre-notification of emergency first responders about pending shipments. Measures to mitigate pre-notification restrictions should be addressed within the FEIS.

Response
DOE would comply with Nuclear Regulatory Commission regulations requiring notification to the governor or the governor's designee by mail or messenger [10 CFR 73.37(f)]. Governors would notify state and local safety officials, as appropriate, of the pending shipments. Tribes would receive notification if the Commission amended the regulation to allow such notice. In response to comments, additional information on the notification process is included in Section M.3.2.2.1 of the EIS.

The Nuclear Regulatory Commission regulations require notification to the governor or the governor's designee by mail or messenger [10 CFR 73.37(f)]. If the notification is by mail, it must be postmarked at least 7 days before transport of a shipment within or through the state. If the notification is delivered by messenger, it must reach the office of the governor or the governor's designee at least 4 days before transport of a shipment within or through the state. The Commission is considering amending the regulations to provide for notification of Native American tribes in addition to the governors. DOE intends to notify the tribes along the routes if the regulations are revised. In accordance with these regulations, DOE cannot notify local municipalities or other jurisdictions of upcoming shipments. The governor has the option to notify others in the state of the shipments provided the others agree to protect the schedule information.

8.7 (6905)
Comment - EIS001539 / 0007
Compliance with State Hazardous Materials Routing Regulations: Colorado law precludes the shipment of nuclear materials on much of I-70. The unavailability of I-70 makes Denver highways unattractive as shipping routes to Yucca Mountain.

DOE must comply with the State of Colorado's Rules and Regulations Concerning Nuclear Materials Transportation Route Designation (8CCR 1507-6). Among other requirements, these regulations preclude the shipment of nuclear materials on I-70 west of Denver, between the junction of U.S. 40 and the Colorado-Utah state line, and on I-70 east of I-25 to the junction with State Highway 2. As all shipments directed through Denver must either travel north or south before being directed west to Yucca Mountain, it will be much more effective to direct shipments to the north or south prior to entering the Denver metro area.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway route or rail lines DOE would use. In the interim, state or Native American tribal governments may designate alternate preferred highway routes, and highways and rail lines might be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route) that reduce time in transit (see Figure 6-11). DOE identified rail lines based on current rail practices,

as there are no comparable Federal regulations applicable to the selection of rail lines for shipment of radioactive materials (see Figure 6-12).

DOE recognizes that Colorado has designated preferred routes through the state for radioactive materials in accordance with these regulations. In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Figure J-35 for the representative Colorado routes). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass. Table J-75 lists the estimated number of legal-weight truck shipments of spent nuclear fuel and high-level radioactive waste that would either originate or pass through Colorado. The table also lists the estimated number of rail shipment through Colorado in the mostly rail scenario for each of the Nevada rail corridors and heavy-haul truck routes.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.7 (6971)
Comment - EIS001545 / 0001
But I guess a question that I have is that we have been transporting nuclear waste up to now? Correct? And we are still having hearings, yet we are still doing this. And to me, having these hearings, although they are probably beneficial in some respects, if you 're doing it already, I think we are in harm's way.

I guess I would feel that the idea of having hearings and input from the citizens should be – should come before any transportation of any nuclear waste occurs. I think we're sort of putting the cart before the horse. I don't really have anything other to say than that.

Response
In Section 2.1.2 of the EIS, the Department assumes that, for this EIS, receipt and emplacement of waste materials would begin in 2010. No material coming to the repository is expected to be shipped prior to that time so there should be opportunities for public involvement during the route selection and approval process. Almost 3000 shipments of spent nuclear fuel have been made safely in the United States over the past 30 years by many different organizations. Most of these shipments were not part of a significant Federal action requiring an Environmental Impact Statement, and, therefore, no hearings were required.

The hearings that were held on the Draft EIS for Yucca Mountain gave the public an opportunity to comment many years before the shipments are scheduled to begin. DOE has considered all comments received on the Draft EIS since August 13, 1999, as well as all comments received on the Supplement to the Draft EIS through October 19, 2001 in its development of this Final EIS. In response to comments, DOE has modified the EIS in a variety of ways, including clarifications or changes to the text, new or more recent information (such as 2000 Census data and population projections), and modified analyses (such as those for transportation impacts in which it modified the characteristics of the representative commercial spent nuclear fuel and accident source terms).

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Department has issued a draft Request for Proposals requiring the Regional Servicing Contractor to prepare a transportation plan that describes the Contractor's operational strategy and delineates the steps it would implement to ensure compliance with all regulatory and other DOE requirements. This includes identification of proposed routes and associated routing considerations, coordination and communication with all participating organizations and agencies, including other Regional Servicing Contractor(s), DOE, state, Native American tribal, and local governments, and interactions with appropriate Federal and state organizations. The route and mode determinations would be interactive. If, during the course of the mode or route determinations, one of the previously determined factors changed, the site-specific mode and route analysis would be reevaluated to ensure consistency.

8.7 (7014)
Comment - EIS001600 / 0001
To give a little background, or to get the arms around the question of what I was about to address, I bothered to state a dilemma in the past in the industry. That was when we were ocean bearing nuclear waste. Brookhaven National

Laboratory loaded a barge to be unloaded outside the appropriate boundaries of the United States in water. After it was launched, the law was changed.

Considerations became political, emotional and certainly financial. The barge could not land on the coast of the United States. As a result we had nuclear waste wandering up and down the shoreline of the United States for some period of time. I forget. I know what the specific period of time was, but it was lengthy, at least a year.

This is the kind of thing when I hear a presentation that talks about transportation and reviewing since 1943 all of the shipments that occurred, it becomes very hard to focus on point. It is one instance as opposed to a statistical accumulation of data or miles, et cetera, versus risk, but it seems to me to be the keynote of the issue. The issue was what happens when things don't work correctly.

Not that they blow up, not that some more emotional issue becomes involved, but the issue becomes what happens if there is change in the political climate, the law, and an accident causes some change to occur in the protocol, and we have shipments coming into Yucca for a period of time when Yucca cannot accept it.

And then during the discourse I heard that the NRC [Nuclear Regulatory Commission] set up this protocol to recall waste from the facility, assuming it got incorrectly -- something happened at the Yucca Valley site, to make it less tentative to remain there, they could recall it, but I haven't heard anything that addressed the question of what happens if something goes wrong at Yucca while shipments are being shipped and commitments of shipments to be made, have to be made. Once again, a fait accompli is involved.

I ask, was that evaluated? Since I had asked the question once before, I had made it very specific and I was told no, that the DOE has not evaluated that. I consider it a very important administrative overview, a decision at a very high level to look at outliers and statistics, not to accumulate data and talk about 1943, look for the embarrassment that was a minor embarrassment and not a focus of the nation at the time of the Brookhaven situation, but when it translates into much further exponential amplification of shipments and the risks, that it be raised in the priorities of balance.

Meaning that we don't change the statistic and pull an outlier in to evaluate. I would urge the DOE to make such an evaluation. The response to the question was, no, we didn't.

Response

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The contractor providing transportation services would be required to prepare a transportation plan that would discuss the various steps it would take to ensure the shipments are conducted in a safe and efficient manner. One of the functions of this contractor would be the coordination of shipments of waste to meet the requirements of both the waste generators and the repository. Based on comments received on the Draft EIS, Appendix M was added to the EIS that summarizes transportation operations. Section M.3 provides a discussion of the protocols and procedures that would be implemented by a Regional Servicing Contractor and its subcontractors.

If, for any reason, Yucca Mountain was unable to receive shipments of waste, the shipments would be stopped, either temporarily until the problem is remedied, or permanently if the problem cannot be fixed.

The Yucca Mountain Repository provides a design and management approach that isolates wastes from the public while allowing flexibility to preserve options for modifying emplacement and retrieving the waste. This design would maintain the ability to retrieve emplaced materials for at least 100 years and possibly more than 300 years after the end of waste emplacement in the event of a decision to retrieve the waste to protect the public health and safety or the environment or to recover resources from spent nuclear fuel. Because retrieval is not anticipated, DOE did not include it as part of the Proposed Action. However, the EIS evaluates retrieval as a contingency action and describes potential impacts if it were to occur (see Section 4.2).

8.7 (7061)
Comment - EIS001337 / 0018
Lincoln County and the City [Caliente] recommended that various options for rail spur be considered within the EIS. Operational alternatives affecting transportation safety which the County and City suggested for consideration included varying maintenance schedules and standards (i.e. for roadbed, track and trains); options for coordinating train movements with Air Force overflights; train speeds; options for provision of security against sabotage or acts of terrorism; alternative locations for train maintenance and crew change facilities; the potential for and implications of allowing shared-use of the rail spur by other government agencies (i.e. Air Force) and industrial users (i.e. mining and energy); and options for ownership and operational management of the rail spur. It was recommended that each of these options should be evaluated against their contribution to risk management and regional economic benefit. The DEIS does not consider operational alternatives affecting transportation safety including varying maintenance schedules and standards (i.e. for roadbed, track and trains); options for coordinating train movements with Air Force overflights; train speeds; alternatives for provision of security against sabotage or acts of terrorism; alternative locations for train maintenance and crew change facilities; the potential for and implications of allowing shared-use of the rail spur by other government agencies (i.e. Air Force) and industrial users (i.e. mining and energy); and options for ownership and operational management of the rail spur.

Response
Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use. Nor is possible to provide the detailed plans suggested by the commenter, however, these elements could be considered in the future.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations (see Section M.3.1 of the EIS). The contractor providing transportation services would be required to prepare a transportation plan that would discuss the various steps it would take to ensure the shipments are conducted in a safe and efficient manner. DOE's draft Request for Proposal requires the contractors selected to provide transportation services must demonstrate that they have had successful experience transporting hazardous materials. The transportation contractor would be required to prepare a transportation plan that would include protocols to implement the multitude of requirements promulgated in U.S. Department of Transportation and Nuclear Regulatory Commission regulations, including land use and ownership, maintenance, scheduling, risk management, security, safety, and communications, and require consultations with responsible agencies (see Section M.3).

DOE could decide to use a dedicated train that carries only the material to be shipped to Yucca Mountain, or could elect to move the spent nuclear fuel and high-level radioactive waste in general freight. DOE continues to evaluate the safety, cost, and schedule aspects of dedicated trains, however a decision on their use has not been made at this time. If the material was shipped as general freight, the position of the spent nuclear fuel or high-level radioactive waste car in the train is regulated by 49 CFR 174.85.

DOE identified the potential for shared use of a branch rail line in Section 8.4.2 of the EIS as a reasonably foreseeable future action. This section states "DOE would have to consider these impacts [of shared use] in any decision it made to allow shared use of the branch rail line." If the site is approved, then decisions regarding ownership and shared use would be made. Line ownership, however, would not affect potential environmental impacts.

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

Comment - EIS001337 / 0070

Page 2-43 Section 2.1.3.2.2, 2nd paragraph. The text here should indicate whether there will be any pre-notification of shipments given to state and local authorities and whether escorts will be used with each shipment.

Response

DOE would comply with Nuclear Regulatory Commission regulations requiring notification to the governor or the governor's designee by mail or messenger [10 CFR 73.37(f)]. Governors would notify state and local safety officials, as appropriate, of the pending shipments. Tribes would receive notification also if the Commission amended the regulation to allow such notice. In response to comments, additional information on the notification process is included in Section M.3.2.5 of the EIS.

DOE believes that a shipment of spent nuclear fuel or high-level radioactive waste is an unlikely target in part due to the physical security measures imposed by the Nuclear Regulatory Commission regulations. Under certain conditions, armed escorts either follow or ride in the truck cab or an escort railcar. Requirements for escorts can be found in 10 CFR 73.37. Other security measures include devices that shut down or immobilize the transport vehicle in case of a sabotage attempt. DOE monitors its spent nuclear fuel and high-level radioactive waste shipments through a satellite-based tracking system (see Section M.7 and M.3.2.1.5 of the EIS for additional information).

8.7 (7445)

Comment - EIS001969 / 0005

We agree with the DOE that a major accident involving a shipment of this material is of low probability with a level of general uncertainty, and therefore, is not quantified to be zero. Moving 70,OOO metric tons of high- level nuclear waste, including 50 metric tons of weapons grade materials, from sites that are almost entirely east of the Mississippi River, over a 100 year period, almost ensures that an accident will occur, sometime, somewhere. Testing has shown that conditions exist under which shipping casks can be penetrated or ruptured (page 6-33 of the EIS). It is not clear in the draft whether a head-on truck or train collisions and train derailments will produce such conditions but it is important that the final EIS address DOE's plans to contain or control such events and their impacts.

Response

The shipping casks used to transport these spent nuclear fuel and high-level radioactive waste are massive and tough with design features that comply with strict regulatory requirements that ensure the casks perform their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

With regard to the containment or control of accident events, DOE would rely on a number of actions including the training of public safety officials and the implementation of safeguards and security plans. Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training public safety officials and appropriate units of local government and tribes through whose jurisdictions DOE shipments would pass. DOE anticipates financial and technical assistance to eligible jurisdictions to begin at least 4 years before the commencement of shipments to the repository.

Concerning safeguards and security plans, DOE would comply with all requirements of 10 CFR Part 73, including preshipment planning, communications, armed escorts and tamper-indicating devices on shipping casks. Regarding shipment routes, pursuant to U.S. Department of Transportation regulations, 49 CFR 397.101 and NRC (DIRS 154766-1980), added protection would be afforded by the selection of routes which exhibit certain criteria including the likelihood of swift law enforcement response, avoidance of tactically disadvantageous locations such as long tunnels or bridges spanning heavily populated areas, and flexibility to adjust schedules to accommodate unexpected situations.

8.7 (8404)
Comment - EIS001124 / 0001
For transportation by truck are the waste package weights within the allowable range for the freeway/bridge/overpass/underpass systems of the proposed travel routes.

Response
Section 6.1.1 of the EIS describes the weights and permitting of all forms of transportation being considered by DOE. The gross vehicle weight of the truck, trailer, transportation cask, and waste for legal-weight trucks would be less than approximately 36 metric tons (40 tons or 80,000 pounds). This is the weight allowed by all states for routine truck transportation. Therefore, the weights of shipments of spent nuclear fuel and high-level radioactive waste would be within the allowable range.

8.7 (8970)
Comment - EIS002127 / 0012
Transportation issues: Why has DOE failed to address impact associated with the type of transportation vehicle and failed to provide assurances that taxpayers will not be burdened with increases to repair damaged by the project? Why is there no mention of the increased cost to Clark County or to any other location along the transportation route should there be an accident with radioactivity released into the environment?

Response
DOE could use two types of vehicles to transport spent nuclear fuel and high-level radioactive waste through Nevada to Yucca Mountain – trucks and trains. Impacts from two types of trucks were considered in the EIS. Section 6.2.3 of the EIS describes the impacts of legal-weight trucks, which would meet requirements for travel without a special weight permit. The current limit in all states is approximately 36 metric tons (40 tons or 80,000 pounds). There are thousands of comparable-weight trucks on the highways every day; DOE cannot determine how much damage to roads and bridges the relatively few shipments of spent nuclear fuel would cause. However, fees and taxes are paid by every truck that uses national or state highways. These fees and taxes are, in part, to maintain these highways.

The other type of truck is the heavy-haul truck that can have a total weight of up to 500,000 pounds. These trucks require special permits and must be operated under special requirements. DOE would pay to upgrade roads to properly handle these trucks and would support maintenance of the roads. The tracks on which trains operate are the private property of the railroads; therefore, taxpayers have no responsibility for their maintenance or repair.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $9.4 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

Although the studies project high costs for cleanup following severe accidents, the accidents evaluated would be very unlikely and, as a consequence, DOE believes the economic risks of transportation accidents are very small. The shipping casks used to transport spent nuclear fuel and high-level radioactive waste are massive and tough with design features that comply with strict regulatory requirements that ensure the casks perform their safety functions even when damaged. Furthermore, the high-level radioactive waste would be in a solid form that would not be easily dispersed (ceramics, metals, or glasses).

Numerous tests and extensive analyses, using the most advanced analytical methods available, have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

The economic costs of accidents where there was no release of radioactive material would not be expected to be substantial. The health and safety consequences of a maximum reasonably foreseeable transportation accident are discussed in Section 6.2.4.2 of the EIS. The EIS analysis did not include the restorative effects of postaccident recovery, remediation, or cleanup in estimating the health and safety impacts, and would therefore tend to overestimate, rather than underestimate, actual radiological impacts.

The Price-Anderson Act establishes a system of financial protection (compensation for personal injury and property damage, including loss of use of property) for the public in a nuclear accident, regardless of who causes the damage. See Section M.8 of the EIS for a discussion of the Price-Anderson Act. The Price-Anderson Act would indemnify any person held liable for damage including cleanup of released radioactive materials. Persons indemnified would include DOE contractors, subcontractors, suppliers, state, local or tribal governments, emergency response workers, health care workers, other workers, victims and other citizens who might be held liable.

8.7 (9033)
Comment - EIS001290 / 0003
The League of Women Voters of Ohio has adopted the position that hazardous materials should be handled in a responsible manner, in the following order of priority:

a. strict enforcement of container regulation;
b. mandatory reporting to state and local authorities of spills of reportable quantities, including those involving intra-state carriers;
c. strict enforcement of placarding, labeling, and documenting requirements;
d. permits for trucking companies carrying hazardous materials with ability to suspend or revoke such permits;
e. routing requirements for certain selected extremely hazardous materials, including:
    1) the specification and/or the disapproval of some routes for some shipments,
    2) requirements for an escort for some shipments, and
    3) prenotification for some shipments
f. state regulated training for drivers and loaders;
g. collection, coordination, and analysis of data.

Response
Transportation of hazardous materials in the United States is a very highly regulated activity, and transportation to a repository would be conducted under the umbrella of these regulations with oversight, as applicable, of various local, tribal, state, and Federal agencies. This would ensure that all shipments would be made safely (see Section M.2 of the EIS). Section 2.1.3.2 states that DOE would comply with all applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission, as well as applicable state and local regulations.

Because of the public's interest in transportation in general, the Department has included a new Appendix M in this EIS. Appendix M provides general background information about transportation-related topics, such as transportation operations, cask testing requirements, and emergency response.

All of the items in the comment will be considered in the design of the transportation system. Specifically,

- The NWPA requires that DOE use casks certified by the Nuclear Regulatory Commission when transporting spent nuclear fuel and high-level radioactive waste to a repository. The Commission certifies that a cask meets the requirements of 10 CFR Part 71, which prescribes radiological performance standards for test conditions that represent the kinds of forces that a cask would encounter in a severe transportation accident (see Section M.4).

- DOE would comply with all Federal and applicable state, local, and tribal reporting requirements for incidents involving shipments of nuclear waste (see Section M.2).

- All U.S. Department of Transportation (49 CFR Part 172) and Nuclear Regulatory Commission requirements (10 CFR Part 71) for placarding, labeling, and documentation would be followed (see Section M.2.2).

- At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. Section M.3 contains more information on the operational procedures and protocols DOE would use if the Yucca Mountain site received approval. Section M.3.1 contains more detail on the proposed role of the Regional Servicing Contractor.

- U.S. Department of Transportation routing regulations (49 CFR Part 397), which require all of the items in the comment, would be followed by DOE with approval of routes by the Nuclear Regulatory Commission. DOE would comply with physical security regulation promulgated by the Commission in 10 CFR Part 73 (see Sections M.3.2.1.2 and M.7.

- Drivers and other crew would be trained in accordance with Federal requirements (49 CFR Part 172) (see Section M.2.2.6. However, it would not be possible to allow state regulation because of the interstate nature of the shipments.

- Data on all shipments would be collected and analyzed so that the experience could be used to improve shipping practices.

8.7 (9598)
Comment - EIS001888 / 0272
Waste Form and Waste Acceptance

There is no discussion of waste acceptance procedures and waste form and acceptance at the generator site. In previous discussions, the DOE made waste acceptance one of its critical system components, yet the DEIS does not address either the risks of generator-site waste handling or the procedures necessary to transfer waste from the DOE or generator to the waste carrier. Experience with DOE has made decontamination and decommissioning contractors wary of the DOE. It is likely that companies contracted to handle and manage the waste at the generator sites will be reluctant to do so without specific guarantees and careful compliance standards. Important questions are not addressed: Who is responsible for ensuring the waste is in the proper form? How will the waste be transferred to the RSC carrier for shipping? What are the handling procedures? Will there be similar handling procedures at each intermodal site? Are handling procedures going to be standardized? When? There are numerous important concerns with waste handling, none of them are addressed by the DEIS. The DEIS must address the issue of waste acceptance and waste form both at the generating site and at the acceptance site.

Response
Section 6.2.2 of the EIS addresses potential impacts from loading spent nuclear fuel and high-level radioactive waste in transportation casks and on to transportation vehicles at the 72 commercial and 5 DOE sites. Chapter 4 addresses impacts from unloading operations at the repository. Preparation of spent nuclear fuel at commercial sites is controlled by provisions of the Standard Contract that DOE has with each generator.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations (see Section M.3.1 of the EIS). The contractor providing transportation services would be required to prepare a transportation plan that would discuss the various steps it would take to ensure the shipments are conducted in a safe and efficient manner. The specific processes and protocols for accepting and transferring the spent nuclear fuel to transportation vehicles are the responsibility of the Regional Servicing Contractor. The contractor would develop specific conditions, schedules, and operations with generators and other responsible agencies prior to any shipping activities. These plans would be reviewed and approved by DOE. Similar and compatible processes and protocols would be specified for intermodal operations, if required, and at the repository acceptance facility.

8.7 (9770)
Comment - EIS001888 / 0356
[Clark County summary of comments it has received from the public.]

Commenters requested that the EIS justify the selection of the alternatives, and that the alternatives and options be sufficiently defined to comprehensively describe the affected environment, and to allow an equivalent analysis (between alternatives) of potential positive and negative impacts to human health and the environment (e.g., groundwater, air, socioeconomics) from routine operations and accidents during construction, operation, and closure. The types of detail identified include: (11) agency responsibilities for transportation and accident/emergency response.

Response
Section J.3 of the EIS describes the selection criteria for identifying route and modes for implementing alternatives for Nevada transportation. The various references in this section provide the data and information for making the selections. Specific references include:

- DIRS 104737-YMP 1997, *Location of Alternate Heavy-Haul Routes and Future Las Vegas Beltway*
- DIRS 104743-YMP 1998, *Nevada Routes for Legal-Weight Truck Shipments of SNF and HLW to Yucca Mountain*
- DIRS 104560-YMP 1998, *Potential Rail Alignments*
- DIRS 103718-DOT 1998, *Final Report, Identification of Factors for Selecting Modes and Routes for Shipping High-Level Radioactive Waste and Spent Nuclear Fuel*

Several other references of Section J.3 of the EIS describe engineering characteristics and environmental characteristics of alternative routes. Selected implementing alternatives are described in detail in Section J.3 for heavy-haul truck and rail implementing alternatives (those alternatives that would require new or modified corridors or alignments. Each candidate route is described by a dozen pertinent environmental characteristics including ground water, air, and socioeconomic impacts.

The U.S. Department of Transportation and the Nuclear Regulatory Commission share responsibilities for the regulation of the transportation of spent nuclear fuel and high-level radioactive waste. The shipper and the carrier have the responsibility to obey the regulations of the Department of Transportation and the Nuclear Regulatory Commission, including safety and physical security. The regulations governing transportation of radioactive materials implemented by these agencies are consistent with international transport safety standards.

The Hazardous Materials Transportation Act of 1975, as amended in 1994, directed the U.S. Department of Transportation to develop transportation safety standards for hazardous materials, including radioactive materials (see Title 49 of the Code of Federal Regulations). These regulations set the standards for packaging, transporting, and handling radioactive materials for all modes of transportation. Standards for labeling, shipping papers, placarding, loading, and unloading, allowable radiation levels, and limits for contamination of packages and vehicles, among other requirements, are included in the regulations. The regulations specify training needed for personnel who perform handling and transport of hazardous materials, liability insurance requirements for carriers, and safety requirements for vehicles and transport operations.

The Nuclear Regulatory Commission regulates the packaging and transportation related operations of its licensees, including commercial shippers of radioactive materials. It sets design and performance standards for packagings (shipping casks) that carry materials with higher levels of radioactivity. In addition, The Commission establishes safeguards and security regulations to minimize the possibility of theft, diversion, or attack on shipments of spent nuclear fuel and special nuclear materials. These requirements are detailed in Title 10 of the Code of Federal Regulations. As required by the NWPA [Section 180(c)], all shipments to Yucca Mountain would be made in Nuclear Regulatory Commission-certified packages and in accordance with Commission regulations regarding advanced notification of state governments.

The primary responsibility for emergency response lies with the local law enforcement agency of the jurisdiction in which the emergency occurs (see additional information on emergency response in Section M.5 of the EIS). DOE and its Regional Servicing Contractors would be available to provide assistance and technical information about the shipment (see additional information on procedures and protocols in Section M.3). DOE would have furnished technical and financial assistance in accordance with Section 180(c) of the NWPA for the training of public safety officials in procedures for safe routine transportation and for emergency response procedures (see additional information in Section M.6).

Comment - EIS001888 / 0448
[Clark County summary of comments it has received from the public.]

Internet and hard copy annual reports to include identification of carriers, sources & destinations of each shipment, number and volume of shipments for, each substance, routes, incident/accidents and mitigative actions, evaluation of each ship shipment.

Response
As described in Section M.3.2.1.6 of the EIS, DOE Regional Servicing Contractors would provide reports with detailed information on each shipment. The information in the reports would be available to the public in a timely manner. The exact form and content of such reports have not been determined.

8.7 (10448)
Comment - EIS001567 / 0001
As you've heard tonight in the presentation, there are still a lot of questions; technical, legal, and political questions that have to be resolved and at this point in time it's not even a certainty that these movements will actually take place. The Commission's position on this is very simple. The Commission's believes that if these shipments are to be made at all, then it is critical that these shipments be made in the very safest manner possible to protect the citizens of Ohio.

Given the uncertain state of affairs, it's very difficult to get into a lot of detail and respond in detail. But there are a few general points that I think needs to be made. First of all the Commission is going to have three primary responsibilities with respect to this activity. The first of these is that we're going to be responsible for ensuring that these shipments are made in compliance with all the existing federal motor carrier safety regulations for motor carriers, the railroad safety regulations and also the hazardous material safety regulations that cover both modes of transportation.

As the agency that is responsible for supervising both of those modes of transportation that would be foreseeably used in this activity, we have experienced personnel and we have an active program that is involved in inspecting at roadside locations, track locations and other facilities of these carriers.

The second major component of our work is that we must ensure that the routes that are going to be used minimize the potential risk to the public and the environment. And we have begun on that task already. We, this fall, presented a grant to the Ohio State University to begin preliminary work as to how to attack the problem, how to analyze these possible routes, the factors to be looked at and other public policy considerations that should go into that. We intend to, eventually at the appropriate time, involve the local communities in this process. And, I would just comment in that regard as far as the routing itself, that the Commission is going to follow two principles in carrying out it's responsibilities.

The first is that we will insist on an involvement of all the local communities that are involved in a routing decision and we will not leave a community out in helping us to arrive at that decision. The kind of the flip side of that is, we will also not permit a route to be established merely to export the risk into a neighboring community and we will insist that whatever routes are finally designed, are those that minimize the total risk and exposure in the movement.

The final component of this is the fact that we intend to work with the local communities on emergency response. We have funding programs to help local communities to train their emergency responders. We work with the Cleveland State University in [its] HAZMAT [hazardous materials] program and we will continue to fund these efforts and ensure that all local communities have the necessary training for their response efforts.

The final point that I would make is, that it is our intention and our expectation that the DOE will not only provide adequate funding to assist us in this effort, but they will also complete their work and give us sufficient time to put that training in place and to ensure that these movements are made in a safe manner.

Response
DOE agrees with the objectives of the Ohio Public Utilities Commission and looks forward to the Commission's cooperation in assuring the safety of spent nuclear fuel and high-level radioactive waste shipments through Ohio. Based on the results of the impact analyses presented in Chapter 6 and Appendix J of the EIS, as well as the results published in numerous other studies and environmental impact analyses cited in the EIS, DOE is confident that spent nuclear fuel and high-level radioactive waste can be and would be safely transported to Yucca Mountain. DOE believes, as the EIS reports that the potential impacts of this transportation would be so low for individuals who live and work along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured.

In Section 2.1.3.2 of the EIS, DOE states that the transportation of spent nuclear fuel and high-level radioactive waste to the proposed repository at Yucca Mountain would comply with applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission, as well as applicable state and local regulations. Strict compliance with all applicable safety regulations is a fundamental element in ensuring the safety of the shipments. DOE would cooperate with the Commission in the enforcement of these regulations.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began. DOE would select highway routes in accordance with U.S. Department of Transportation regulations in 10 CFR 397.101. If the State of Ohio has designated alternate routes in accordance with 10 CFR 397.103, DOE would include these alternate routes in the selection process.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Department has issued a draft Request for Proposals requiring the Regional Servicing Contractor to prepare a transportation plan that describes the Contractor's operational strategy and delineates the steps it would implement to ensure compliance with all regulatory and other DOE requirements. This includes identification of proposed routes and associated routing considerations, coordination and communication with all participating organizations and agencies, including other Regional Servicing Contractor(s), DOE, state, tribal, and local governments, and interactions with appropriate Federal and state organizations (see Section M.3 of the EIS). The route and mode determinations would be interactive. If, during the course of the mode or route determinations, one of the previously determined factors changed, the site-specific mode and route analysis would be reevaluated to ensure consistency.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and Native American tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress. The schedule in the proposed policy and procedures (63 *FR* 23753, April 30, 1998) for implementation of Section 180(c) of the NWPA is designed to provide adequate time for training of first responders in advance of the first shipments. Should a decision to proceed with the development of a repository at Yucca Mountain be made, Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

8.7 (10904)
Comment - EIS000357 / 0023
What are the impacts of this increase of traffic on the tourism trade? Particularly, when would shipments be made? Would there be an effort for shipments to occur during low-season traffic times? Has the changing demographics of Snow Birds been taken into account? What are the attitudes of Snow Birds to this additional traffic? Would shipments be scheduled during low-traffic or high-traffic hours? Being moved at night or during the day?

Response
See Table J-1 of the EIS for estimated numbers of shipments for the various inventory and national transportation analysis combinations. In response to public comments, DOE has included maps of the representative highway routes and rail lines for the 45 states it used for analysis in the EIS (see Section J.4). Section J.4 includes potential health and safety impacts associated with shipments for each state through which shipments could pass. For the Proposed Action, the estimated number of truck shipments under the mostly legal-weight scenario would be 52,786, with 300 rail shipments, and under the mostly rail scenario there would be an estimated 9,646 rail shipments plus 1,079 legal-weight truck shipments. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

In response to these and other public comments, DOE has added information on proposed transportation activities to the EIS (see Appendix M). Appendix M includes additional information on the regulations that govern spent nuclear fuel and high-level radioactive waste transportation, the proposed process that DOE would use to acquire commercial transportation services, and the expected operational details and protocols DOE would follow if the Yucca Mountain site was approved (see Sections M.2 and M.3).

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.7 (11192)
Comment - EIS001557 / 0003
The second item that we are going to being focusing on is the routes that are going to be used to make sure that those are the safest possible routes that minimize the potential risk to the public. That is, as a part of our role as the designated routing agency for the State of Ohio that would be involved with the local communities and to ensure that all voices are heard and all concerns are considered in this area in the fine tuning of how these shipments will be made.

We've taken some first initial step in that regard to start gathering the data and gathering the processes to logically follow in that area. This fall the [Public Utility] Commission [of Ohio] granted a -- issued a grant, I should say, to the Ohio State University to begin this process of examining potential routes and examining issues that need to be considered in making a proper evaluation. And at the appropriate time that can be used to involve the local communities and the local emergency planners.

Response
DOE supports the process being followed by the Ohio Public Utility Commission to evaluate potential routes for the shipment of nuclear waste. Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use. Before such shipments began, state governments could designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Department has issued a draft Request for Proposals requiring the Regional Servicing Contractor to prepare a transportation plan that describes the Contractor's operational strategy and delineates the steps it would implement to ensure compliance with all regulatory and other DOE requirements. This includes identification of proposed routes and associated routing considerations, coordination and communication with all participating organizations and agencies, including other Regional Servicing Contractor(s), DOE, state, tribal, and local governments, and interactions with appropriate Federal and state organizations (see Section M.3.2.1.2 of the EIS). The route and mode determinations would be interactive. If, during the course of the mode or route determinations, one of the previously determined factors changed, the site-specific mode and route analysis would be reevaluated to ensure consistency.

8.7 (11504)
Comment - EIS002137 / 0005
DOE needs to address impact mitigation, environmental, socioeconomic, transportation. Transportation. We all know about transportation in all of our communities. Anybody that's looked at a Nevada map knows all the mountain ranges run north and south. There aren't a hell of a lot of routes left. This is where we're at. I think the DOE, the people involved ought to provide more moneys to the rural counties for oversight and impact studies.

Response
Section 6.3 of the EIS addresses transportation impacts in Nevada for the proposed action and. Section J.3 provides additional information on methods and data used. Section 9.3 lists potential management actions that could be implemented to mitigate transportation impacts.

DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

8.7 (11909)

Comment - EIS000996 / 0004

If after this testimony and in due process of consideration, the Department of Energy decides to go ahead with the relocation process, my recommendation is to consider the safety issues associated with the transportation of radioactive materials. Create a road safety department, which evaluates and approves each shipment timetable and safety associated with road conditions, weather conditions, accounting for traffic congestion and vacation travel. Further, consideration should be made for the safest movement through the least populated areas.

However, wherever shipments going from point A to point B, they are more likely to fall within the Mississippi River drainage system and will most definitely affect billions of lives at some level of our living continuation.

Response

Although there are no plans to create a road safety department, all of the factors listed by the commenter will be considered and evaluated by DOE in planning for shipments to the proposed repository. At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. The Regional Servicing Contractor would be required to provide detailed written procedures for how it would respond to an incident and arrange for repair/replacement of equipment or recovery, as appropriate. In accordance with ANSI N14-27 (DIRS 156289-ANSI 1987), the carrier is expected to provide appropriate resources for dealing with the consequences of an accident, isolating and cleaning up contamination, and maintaining working contact with the responsible governmental authority until the latter has declared the incident to be satisfactorily resolved and closed. Section M.3 of the EIS contains more detail on the proposed role of the Regional Servicing Contractor.

The shipping casks used to transport these spent nuclear fuel and high-level radioactive waste are massive and tough with design features that comply with strict regulatory requirements that ensure the casks perform their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. In addition, since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

8.7 (11977)

Comment - EIS001923 / 0005

Maybe if the insurance liabilities limits were removed and the power companies forced to carry insurance that would cover an accident like I projected, the power companies and the Congress people in support of this project wouldn't be so positive. We have seen how well in the past oil tankers have been operated to protect the environment. There is absolutely no assurance from this poorly written DEIS that the DOE can plausible show how a terrorist attack using state of the art weapons will not cause a major disaster in an area like the Inland Empire.

Response

Although DOE anticipates accidents would occur in transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain, it does not anticipate that an accident would lead to a release of radioactive materials from a shipping cask. Nonetheless, the Price-Anderson Act provides for indemnification of liability up to $9.43 billion to cover claims that might arise from an accident in which radioactive materials were released or one in which an authorized precautionary evacuation was made (see Section M.8 of the EIS for a more complete discussion of the Price-Anderson Act). If the damage from a nuclear incident appears likely to exceed that amount, the Price-Anderson Act contains a congressional commitment to thoroughly review the particular incident and take whatever action is determined necessary to provide full and prompt compensation to the public.

For the Final EIS, DOE reexamined, for both rail and truck casks, the consequences of an attack that results in a release of material (in other words, the cask's shield wall is penetrated)(see Section 6.2.4.2.3 of the EIS), and estimated consequences exceeded those presented in the Draft EIS. Differences in the consequences between the Draft EIS and the Final EIS are due to using "representative" spent nuclear fuel isotopics (verses "typical" in the Draft EIS) and an escalation of impacts to represent population growth to 2035. In addition, in the Draft EIS, the consequences of the sabotage event were bounded by those of the maximum reasonably foreseeable accident. However, the Final EIS analyses estimated that a sabotage event could cause 48 latent cancer fatalities if a legal-weight truck cask was penetrated and 9 latent cancer fatalities for a rail cask. DOE believes that a shipment of spent nuclear fuel or high-level radioactive waste is an unlikely target in part due to the physical security measures imposed by the Nuclear Regulatory Commission regulations. Under certain conditions, armed escorts either follow or ride in the truck cab or an escort railcar. DOE monitors its spent nuclear fuel and high-level radioactive waste shipments through a satellite-based tracking system.

8.7 (12137)
Comment - EIS001887 / 0439
The EIS did not assess the costs of severe accidents when assessing the transportation costs involved in the Yucca Mountain Project. In order to aid in the adequate preparation for potential accidents, an estimate of the true cost of remedying such an accident is essential. This assessment must include, but is not limited to, the following: emergency costs, surface cleanup costs, decontamination costs (of roadways, buildings, groundwater, surface water, etc.), hospital costs to injured parties, lost workdays due to building contamination, economic losses due to fear of contamination, loss of tourism (e.g., in the event of an accident in Las Vegas), evacuation costs, relocation costs, contaminated food embargo costs, insurance costs, legal costs, governmental costs, and so forth.

Response
In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $9.4 billion. Cost data used in the studies, reviewed in Section J.1.4.2.5, included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

Although the studies project high costs for cleanup following severe accidents, the accidents evaluated would be very unlikely and, as a consequence, DOE believes the economic risks of transportation accidents are very small. The shipping casks used to transport spent nuclear fuel and high-level radioactive waste are massive and tough with design features that comply with strict regulatory requirements that ensure the casks perform their safety functions even when damaged. Furthermore, the high-level radioactive waste would be in a solid form that would not be easily dispersed (ceramics, metals, or glasses).

Numerous tests and extensive analyses, using the most advanced analytical methods available, have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

The economic costs of accidents where there was no release of radioactive material would not be expected to be substantial. The health and safety consequences of a maximum reasonably foreseeable transportation accident are discussed in Section 6.2.4.2 of the EIS. The EIS analysis did not include the restorative effects of postaccident recovery, remediation, or cleanup in estimating the health and safety impacts, and would therefore tend to overestimate, rather than underestimate, actual radiological impacts.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. In addition, DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.7 (12185)
Comment - EIS000707 / 0002
The truck transportation route involves a number of different states.

These trucks will be parked overnight at some motel, what provisions are being made to ensure that no one will be able to tamper with the trailers carrying the nuclear waste? Who is responsible for the cost of upgrades for these highways? Who will incur the cost of damage done to roads and bridges?

Response
Regulations of the Nuclear Regulatory Commission [10 CFR 73.37 (b)] require a physical protection system that, among other things, must provide at least one escort with visual surveillance of the shipment when the vehicle is stopped. In addition, shipment planning must avoid scheduled intermediate stops to the extent practicable. The trucks would have sleeper berths, so overnight parking at motels would not be necessary. In addition, any time a truck stopped for any reason, it would be under continuous visual surveillance.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. DOE would ensure that its contractors providing transportation services for the repository abide by all applicable regulations at the time of transport. The transportation contractor would be required to prepare a transportation plan that would include proposed routes and other information such as safe, en route emergency parking areas and other planned stops. DOE would make the plan available to states and tribes for comment before the shipments take place. The carrier would be able to communicate to its dispatch center and others through various means of communication, including the satellite-based tracking system. This would enable the carrier to communicate problems even in remote areas (see Section M.3).

With the exception of the heavy-haul truck scenario, the shipments would use vehicles (trucks, railcars, and barges) similar in weight, size, and operation to vehicles that transport other commodities. As a result, potential impacts on transportation infrastructure (infrastructure typically includes bridges, roadways, railroad track, switchyards, locks, navigation aids, etc.) of a vehicle used in transporting spent nuclear fuel and high-level radioactive waste across the United States would be similar to the impacts of other commercial vehicles that use the nation's transportation systems. Because there would be few vehicles transporting spent nuclear fuel and high-level radioactive waste in comparison to other vehicles using the transportation system, the impacts on transportation infrastructure of shipments to Yucca Mountain would not be discernible. In addition, because the annual number of shipments that would be made to Yucca Mountain is less than 0.001 percent of the more than 300 million annual shipments of hazardous materials in the United States, impacts on state, local, and Native American tribal law enforcement and emergency response resources would be small.

As discussed in Section 6.3.3 of the EIS, heavy-haul truck transport in Nevada could affect transportation on roads in the State. As discussed in that section, Nevada highways along a route, including roads, bridges and culverts, would be upgraded for heavy-haul truck use, if DOE selected heavy-haul truck transport. Upgrades would include reconstruction of some highway sections, especially in areas where spring and fall thaws and freezes make highways susceptible to damage by heavy vehicles. In addition, new turnout lanes at frequent intervals along two-lane highways would be constructed to allow other traffic to pass the slower heavy-haul vehicles. The location and frequency of turnouts would be determined in consultation with State and tribal jurisdictions s after a specific route was selected. Highway shoulders would be widened and road surfaces would be improved in many areas. Section 6.3.3.1 discusses impacts heavy-haul trucks would have on the flow of traffic on roads in Nevada.

8.7 (12465)
Comment - EIS000497 / 0022
In order to develop a safe and effective system for accepting commercial spent nuclear fuel and high-level radioactive waste (HLW), the federal government must expand its focus beyond siting, and develop, in coordination with the states and tribes, a logical and timely transportation program. This requires DOE policy commitments to:

a. fix the shipping origins and destination points as early as possible;

b. ensure the availability of rail and truck shipping casks;

c. conduct full-scale testing of casks to be used to transport spent nuclear fuel and high-level radioactive waste;

d. prepare a comprehensive transportation plan that includes the analysis of all needed transport-safety activities

e. develop responsible criteria for selecting shipping routes; and

f. develop a sound methodology for evaluating optional mixes of routes, and transportation modes.

Response
DOE agrees that detailed, comprehensive planning would be required prior to the start of shipments to a repository. The level of planning suggested by the commenter would be more appropriate once a repository site had been selected and approved.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. Sections M.2 and M.3 of the EIS contain more information on routing regulations and operational procedures and protocols DOE would use if the Yucca Mountain site received approval. Section M.3 also contains more detail on the proposed role of the Regional Servicing Contractor. Operational protocols for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain are presented in the Draft Request for Proposal for the *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153487-DOE 1998). These protocols were adopted from the *Waste Isolation Pilot Plant Transportation Safety Program Implementation Guide* (DIRS 156384-WGA 1995). The Department expects to interact with all affected stakeholders on routing and related local issues as transportation plans develop.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. At this point in time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway routes or rail lines could be used. In the interim, state or trbal governments may designate alternate preferred highway routes, and highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in this EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate) that reduce time in transit. DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials.

The NWPA requires DOE to use casks certified by the Nuclear Regulatory Commission when transporting spent nuclear fuel and high-level radioactive waste to a repository. The Commission's certification regulations indicate that cask testing must represent the kinds of forces that a cask would encounter in a severe transportation accident. A cask's ability to survive the tests prescribed by the regulations (10 CFR Part 71) can be demonstrated either through component analysis or through scale-model and full-scale testing to demonstrate and confirm the performance of the casks. The Nuclear Regulatory Commission would decide which level of physical testing or analysis was appropriate for each cask design submitted. Section M.4 of the EIS contains additional information of cask safety and testing.

DOE submitted a plan to the House Committee on Appropriation on the Energy and Water Development Act, 2001 entitled *Plan for Transportation Cask Fabrication and the Deployment of Waste Acceptance* Capabilities (DIRS 156802-DOE 2001). The plan provides, in part, the DOE strategy for the timely fabrication of transportation casks. In this report, DOE concluded that current industry performance has shown that manufacturing capacity is available to meet present and future cask fabrication needs.

DOE believes that the mostly rail scenario, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada. In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

Nonetheless, in response to comments, DOE has analyzed the effects of different mixes of rail and truck shipments (see Section J.1.2.1.4 of the EIS). The results of this analysis confirm DOE's estimate that the mostly rail and mostly legal-weight truck scenarios represent a reasonable range (lower and upper bound) of potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

Comment - EIS002250 / 0004
If the nuclear energy is so safe, why did Congress place limits on liability for the nuclear industry? So, therefore, they could not be sued to a higher level for damages.

Maybe if the insurance liability limits are removed and the power companies are forced to carry insurance that would cover an accident like I projected, that power companies and Congress people support, other projects wouldn't be so positive.

We have seen how well in the past oil tankers have been operated to protect the environment. There is absolutely no assurance from this poorly written EIS that the DOE can plausibly show how a terrorist attack will not cause a major disaster in an area like the Inland Empire.

Response
Although DOE anticipates accidents would occur in transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain, it does not anticipate that an accident would lead to a release of radioactive materials from a shipping cask. Nonetheless, the Price-Anderson Act provides for indemnification of liability up to $9.43 billion to cover claims that might arise from an accident in which radioactive materials were released or one in which an authorized precautionary evacuation was made (see Section M.8 of the EIS for a more complete discussion of the Price-Anderson Act). If the damage from a nuclear incident appears likely to exceed that amount, the Price-Anderson Act contains a congressional commitment to thoroughly review the particular incident and take whatever action is determined necessary to provide full and prompt compensation to the public.

Nuclear Regulatory Commission (10 CFR Part 73) and U.S. Department of Transportation (49 CFR Part 173) regulations both include requirements to ensure the physical security and protection of shipments from diversion and attack. For the Final EIS, DOE reexamined, for both rail and truck casks, the consequences of an attack that results in a release of material (in other words, the cask's shield wall is penetrated)(see Section 6.2.4.2.3 of the EIS), and estimated consequences exceeded those presented in the Draft EIS. Differences in the consequences between the Draft EIS and the Final EIS are due to using "representative" spent nuclear fuel isotopics (verses "typical" in the Draft EIS) and an escalation of impacts to represent population growth to 2035. In addition, in the Draft EIS, the consequences of the sabotage event were bounded by those of the maximum reasonably foreseeable accident.

In the Final EIS, DOE estimated that the greatest consequences would occur if the sabotage event occurred in the center of a highly populated metropolitan area. The dose from such an event to a maximally exposed individual (about 110 rem over the person's lifetime) would increase his or her lifetime risk of a fatal cancer from about 23 percent to about 28 percent. However, doses to most affected individuals would be much lower than that to the maximally exposed individual; these individuals' increased risk of a latent fatal cancer would also be lower. It was not predicted that there would be any prompt fatalities from very high levels of exposure, and immediate health consequences from radiation exposure would be unlikely, but by combining the large number of small individual risks in the population of a metropolitan area, DOE estimated that a sabotage event could lead to as many as 48 latent fatal cancers. Although not estimated in the analysis, injuries and deaths from blast effects of a device that might be used would be expected for individuals who would be as close to the event as the hypothesized maximally exposed individual. However, exposure to radioactive materials sufficient to lead to an individual lifetime dose of 110 rem could result in a need for medical attention. DOE designed the analyses to identify the maximum consequences that a severe accident that could reasonably be expected to produce (reasonably expected is defined as a likelihood greater than, but on the order of, 1 in 10 million in a year), but the analysis here did not make extreme assumptions that would identify the worst possible consequences that could be imagined.

DOE believes that a shipment of spent nuclear fuel or high-level radioactive waste would be an unlikely target in part due to the physical security measures imposed by the Nuclear Regulatory Commission regulations. Under certain conditions, armed escorts would either follow or ride in the truck cab or an escort railcar. DOE would monitor its spent nuclear fuel and high-level radioactive waste shipments through a satellite-based tracking system. Additional information on the physical protection of spent nuclear fuel and high-level radioactive waste during transportation can be found in Section M.7 of the EIS.

8.8 Transportation Analyses

8.8 (4383)
Comment - EIS001523 / 0002
The Yucca Mountain Repository Site should not be approved since a safe method for transportation of nuclear waste materials to the site has not been determined. In the Environmental Impact Statement (EIS), the DOE has not accurately assessed the potential risk of the proposed transportation methods of either rail or highway. Several factors that must be reconsidered and reevaluated are the frequency and severity of accidents, proposed population growth in the areas near the transportation routes, and a recent increase in traffic speeds. The potential environmental impact resulting from the transportation of waste to the site have also been underestimated in this statement due to incomplete and outdated data. The DOE needs to conduct more accurate and complete studies in order to formulate a more complete assessment of the potential risks.

Response
The Nuclear Regulatory Commission has determined that the transportation of radioactive materials is safe if the shippers follow Commission and U.S. Department of Transportation requirements. The history of radioactive material transport in this country has proven this to be correct. Future shipments would occur under the same regulations that have contributed to the safe transport of more than 2,700 shipments in this country over the last 30 years. The accident analysis includes estimates of the number of accidents that could occur during shipments, estimates of the radiological risk of transportation accidents for populations along transportation routes, and a description of the consequences of maximum reasonably foreseeable transportation accidents. The maximum reasonably foreseeable accidents have an estimated frequency of occurrence of about 2.8 per 10 million years for rail shipments under the mostly rail scenario analyzed in the EIS and 2.4 per 10 million years for the mostly

legal-weight truck scenario. DOE based its estimates of accident risks and consequences of maximum reasonably foreseeable accidents on data presented in a report issued by the U.S. Nuclear Regulatory Commission (Sprung, et al., 2000). The accident analysis in the EIS addresses accidents from all sources including long duration fires, high-speed impacts, airplane crashes, and mountain rollovers. Appendix J of the EIS provides additional detailed descriptions of the analyses. The analysis used the latest reasonably available data and methods as well as cautious but realistic assumptions. For example, DOE used forecasts of population growth to estimate populations along routes. For purposes of analysis, DOE used populations forecasted to 2035 in estimating impacts. In addition, in response to public comments, DOE has added information to, and improved the clarity of transportation sections in Chapter 6 and Appendix J. The additional information includes more specific data on along-route populations as well as additional information used in analyzing potential impacts on biological resources, land use, soils, aesthetics, cultural resources, noise, ground vibration, flood plains, wetlands, air quality, environmental justice, waste management, and socioeconomics.

8.8 (4833)
Comment - EIS001226 / 0007
Locally, Illinois is expected to receive the third largest number of shipments as many as 13,000 over the next 30 years, or an average of 8 per week, every week, for 30 years, all requiring costly escort services.

Response
As presented in Section J.4 of the EIS, the number of legal-weight truck shipments through Illinois used by DOE to estimate impacts is about 38,500. About 5,300 would originate in the State. Illinois presently charges a fee of $2,500 per cask for truck shipments and a fee of $4,500 for the first cask and $3,000 for each additional cask for train shipments. Presumably, these fees adequately cover the costs of the current Illinois inspection and escort program. Should the repository transportation program go forward, DOE would consult with affected states on activities and fees appropriate at the time.

8.8 (12091)
Comment - EIS002307 / 0005
Section 6 of the DEIS is incorrect in its analysis of transportation safety because the DEIS users average weather conditions rather than conditions that would produce the greatest effects.

Response
The objective of the analyses in the EIS is to produce realistic yet conservative estimates of risks, not the largest possible estimates of risks as suggested by the commenter. The analysis provided in Section 6.2.4 of the EIS uses cautious assumptions and the latest reasonably available methods and data to provide conservative estimates of the potential radiological consequences of severe accidents and successful sabotage attacks on spent nuclear fuel shipments. The details of the calculations are provided in Section J.1.4.2. There could be specific locations along the transportation corridors in Nevada leading to the Yucca Mountain Repository that appear to be more vulnerable to an accidental release of radioactive material from a shipping cask. However, the computer models and data used in the accident consequence assessments result in estimates that consider the associated range of any location-specific conditions. Examples include the assumption that maximum reasonably foreseeable accidents would occur in the center of highly populated urban areas; evaluation of dose received by maximally exposed individuals (which addresses close proximity of the highway to hotels, casinos, retail businesses, schools, churches and residences); use of low-probability weather conditions that lead to the greatest consequences for maximum reasonably foreseeable accidents; and the assumption that no medical or other interdiction would occur to reduce concentrations of radionuclides absorbed or deposited in human tissues after a potential accident.

8.8.1 GENERAL

8.8.1 (172)
Comment - 11 comments summarized
Commenters said that DOE's analysis of transportation impacts is unrealistic because it is overly conservative. By considering almost every possible accident scenario during spent nuclear fuel and high-level radioactive waste transport, DOE has given credence to the virtually impossible and has, therefore, overestimated the impacts of transporting to Yucca Mountain. For example, the "maximum reasonably foreseeable accident" scenario modeled in the EIS has a likelihood of occurrence of about 1.4 in 10 million years. Considering that spent nuclear fuel and

high-level radioactive waste would be transported for only about 24 years, the chances that such a “worst case accident” could occur are essentially zero–less than the chances of a loss of life due to a meteor impact which has a probability of occurrence of 1 in 100,000 years (DIRS 107795-NRC 1975). These commenters cited the safety record of the commercial nuclear power industry during the past 35 years, during which time about 3,000 shipments of spent fuel have been transported across U.S. highways and railroads with no injuries, fatalities, or environmental damage. The EIS should take into account this enviable safety record, rather than using an ultraconservative accident scenario–one that is likely to occur 1.4 times in 10 million years.

Response
DOE believes that the EIS is consistent with National Environmental Policy Act and NWPA requirements. The level of information and analyses, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions to address incomplete or unavailable information or uncertainties, provide a meaningful assessment of environmental impacts consistent with the applicable requirements. DOE agrees with the comment that maximum reasonably foreseeable accidents analyzed in the EIS are extremely unlikely. Analyzing such accidents, nevertheless, provides useful information for decisionmakers and the public, and demonstrates that DOE took a hard look at the potential risks.

In March 2000, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung 2000). The purpose of the study was to reexamine the risks associated with the transport of spent nuclear fuel by truck and rail and compare the results to those published in *Final Environmental Impact Statement on the Transportation of Radioactive Material by Air and Other Modes* (DIRS 101892-NRC 1977) and *Shipping Container Response to Severe Highway and Railway Accident Conditions* (DIRS 101828-Fischer et al. 1987). The Draft EIS used techniques and assumptions based on Fischer et al. (1987). The new Nuclear Regulatory Commission study concluded that both NRC (1977) and Fischer et al. (1987) made a number of very conservative assumptions about spent nuclear fuel and cask response to accident conditions, which caused their estimates of accident source terms, accident frequencies, and accident consequences to be very conservative. The new study concluded:

“Based on this more detailed analysis, cask leakage is found to be even less likely than the estimates of the Modal Study, and retention of particles and condensable vapors by deposition onto cask interior surfaces is found to be substantial. Accordingly, both source term probabilities and magnitudes decrease further, and consequently accident population dose risks are reduced further by factors of 10 to 100.” (DIRS 152476-Sprung et al. 2000)

In response to comments, DOE has updated the EIS transportation impact analysis to incorporate some of the findings of the updated Nuclear Regulatory Commission analysis. Sections 6.2.4 and J.1.4 of the EIS concerning analyses of transportation accidents have been revised to incorporate data from that analysis (DIRS 152476-Sprung et al. 2000). The EIS no longer relies on the data from the Modal Study, with the exception of the data used in Sprung et al. (2000). This report contains revised estimates of probable releases from spent nuclear fuel casks during severe transportation accidents that involve long duration fires accompanied by high impact forces.

The Nuclear Regulatory Commission is considering including an assessment of the importance of human factors in cask design, manufacturing, and use in its planned Package Performance Study. The planned study, which is scheduled for completion in 2004, will provide an updated evaluation of the level of safety provided by spent nuclear fuel transport packages under a variety of railway and highway accident conditions.

8.8.1 (187)
Comment - 5 comments summarized
Commenters were critical of the RADTRAN model used to analyze transportation risks, stating that it does not adequately evaluate radiological impacts to populations along transportation routes. Commenters were unconvinced that the outputs of the model truly represent the impacts of spent nuclear fuel and high-level radioactive waste transportation because the model uses little site-specific information. Some said that the EIS should describe the underlying assumptions and shortcomings inherent in the RADTRAN 4 model and justify its use in the EIS, including if and how the model is applicable to undeveloped routes where spent nuclear fuel and high-level radioactive waste transport vehicles would pass slowly along narrow roadways through populated areas close to businesses and residences. Some said that because no database exists for such a large and long-lived shipping

campaign, the risk numbers generated by RADTRAN might be fundamentally flawed, and there is no scientific basis for proving whether the estimated risks are too low or too high.

Commenters identified specific flaws in the RADTRAN 4 model, stating that it is (1) outdated compared to even the most rudimentary desktop Geographic Information Systems, (2) not able to verify the worst possible threats, and (3) not sufficiently sensitive to local conditions such as the actual location of population centers and system operating characteristics such as average speeds and stop times of heavy-haul trucks in local communities. Commenters said that individuals who reside, work, or attend school at certain locations within 6 to 40 meters (20 to 130 feet) of a spent nuclear fuel and high-level radioactive waste route could receive exposures in excess of the average annual dose of background radiation. DOE has failed to investigate whether such conditions exist near school zones and pedestrian crossings, left turn lanes and at traffic signals, congested intersections, and uphill grades.

Others requested site-specific analyses, including a recalculation of the annual and cumulative collective dose and maximum individual dose to people in Tonopah and Goldfield assuming that each heavy-haul truck would travel at an average speed of 8 kilometers (5 miles) per hour and would stop at certain intersections for 2 to 5 minutes. The analysis must consider the actual location of all occupied buildings and people within 400 meters (0.25 mile) of the route, including children in schools and nonresidents in hotels and commercial establishments.

Response

In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. For instance, DOE selected the RADTRAN 5 computer program to estimate radiological impacts to populations from incident-free transportation and from accidents. RADTRAN, which was originally developed by Sandia National Laboratories in the late 1970s, has been used in many DOE EISs, and it has undergone periodic review and revision. In 1995, an independent review of RADTRAN 4 (immediate predecessor to RADTRAN 5) demonstrated that it yielded acceptable results when compared to "hand" calculations. More recently, an independent review found that RADTRAN 5 overestimates the measured radiation dose to an individual from moving radiation sources. The RADTRAN 5 analyses included the inhalation, external exposure, resuspension, and ingestion pathways.

To manage the large amounts of transportation data used in the EIS, DOE chose to use database software, not a geographic information system. However, a geographic information system was used to generate the maps presented in Appendix J of the EIS and to estimate populations along routes in Nevada.

Substantial amounts of site-specific data were used in the RADTRAN 5 analyses. For example, *Road Upgrades for Heavy Haul Truck Routes - Design Analysis* (DIRS 154448-CRWMS M&O 1998) includes tables of the speeds and times used for every section of highway for heavy-haul trucks for the entire route from the intermodal facility to the repository. It shows that travel speeds at intersections and in towns such as Tonopah and Goldfield, are as low as 8 kilometers (5 miles) per hour. However, DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

In response to comments, additional information on potential state-specific routes and local and regional impacts are provided in Section J.4 of the EIS. The EIS includes estimated public health impacts along transportation routes. This analysis accounts for factors such as the locations of commercial establishments and residences.

DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE has assessed the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste, or other large reactor-related components. In addition, DOE considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada.

Nevertheless, in response to comments, DOE has analyzed the effects of different mixes of rail and truck shipments. The results of this analysis confirm the Department's estimate that the mostly rail and mostly legal-weight truck scenarios represent a reasonable range (lower and upper bound) of potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

8.8.1 (189)

Comment - 5 comments summarized

Several commenters stated that the EIS was inadequate because it presented health impacts only in terms of deaths. There was no assessment of quality of life, traffic-related injuries, genetic effects, or other potential negative health, environmental, and economic impacts.

Response

As discussed in Section F.1.1.5 of the EIS, cancer is the principal potential risk to human health from exposure to low or chronic levels of radiation. It is well accepted within the risk assessment and health physics community to use latent cancer fatalities as the measure of impact from radiation exposure. However, other health effects such as nonfatal cancers and genetic effects can occur as a result of chronic exposure to radiation. These are discussed in Section F.1.1.5.

The transportation analyses in the EIS present the total impact of the Proposed Action and the No-Action Alternative. Fatalities were used as the measure of the total impact because non-radiation-related traffic fatalities can be combined with radiation-related latent cancer fatalities to yield an estimate of the total number of fatalities for the Proposed Action and the No-Action Alternative. In contrast, combining non-radiation-related measures of impact such as traffic-related injuries, illnesses, and other environmental impacts with radiation-related latent cancer fatalities would not yield an easily understandable estimate of total impacts. For the same reason, genetic effects, nonfatal cancers, and other radiation effects were not included in the estimates of the total impact.

Based on comments, a discussion of the economic impacts of severe transportation accidents has been added to Section J.1.4.2.5 of the EIS.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

8.8.1 (192)

Comment - 5 comments summarized

Several commenters objected to the comparisons made of the impacts of transporting spent nuclear fuel and high-level radioactive waste to the proposed repository with the cumulative transportation impacts in Section 8.4.1 and with cancer statistics in Section 6.2.4.2.1. Another commenter stated that the conclusion of "no significant impacts" was based on averaging transportation impacts across the entire U.S. population. Another commenter stated that the comparisons of Modules 1 and 2 with the Proposed Action are invalid because there are 600 percent more shipments and only 17 percent additional impacts. Several commenters stated that comparing transportation impacts to national cancer statistics is invalid. Another commenter stated that 1943 is an arbitrary date and inappropriate for beginning the calculation of the cumulative impacts of transporting radioactive materials. The commenter also stated that dividing the total cancer fatalities by 100 years is misleading. Commenters stated that these comparisons caused the skepticism that the public has about DOE and the project and that the use of statistics and comparisons in this manner is deceitful, deceptive, scandalous, and a twist on the truth.

Response

DOE believes that comparing the transportation impacts calculated in the EIS with national cancer incidence statistics is valid and properly places any transportation-related increased risk of contracting a fatal cancer in perspective to the cancer risks inherent in everyday life. Section 8.4 of the EIS provides the results of cumulative impact analyses conducted to ensure that the environmental impacts of the Proposed Action (or alternative actions) and other actions that involve the same regions or resources are provided to decisionmakers. The information is used to minimize or avoid adverse consequences and to develop an appropriate mitigation strategy and monitor its effectiveness. In developing these comparisons and cumulative impacts, attempts were made to ensure that the comparisons were on a consistent basis.

The transportation impacts in the EIS were not averaged over the entire population of the United States. In addition, the exposed population was not 50 million people. Rather, the transportation impacts were integrated over the exposed population along the transportation routes analyzed in the EIS. As discussed in Sections 6.2.3.1 and 6.2.3.2 of the EIS, these exposed populations ranged from 10 million for truck shipments to 16 million for rail shipments. For perspective, the population of the United States was about 250 million in 1990 and 280 million in 2000. In addition, the cumulative impacts in Section 8.4.2.1 were not divided by 100 years, as suggested by one commenter. All of the impacts presented in this section are estimates of the sums of impacts from past, present, and reasonably foreseeable actions, and no attempt was made to divide them by 100 years.

With regard to the comment on Module 1 and 2 impacts, the commenter is incorrect in the interpretation that the impacts only increase 17 percent while the numbers of shipments increase by 600 percent (The actual increases in the number of shipments for Modules 1 or 2 are approximately 200 percent, as listed in Table J-1 of the EIS). As listed in Table 8-58, for example, the collective worker dose for the mostly legal-weight truck scenario would be 14,000 person-rem for the Proposed Action and 28,000 person-rem for Module 1 or 2. This represents about 100-percent higher impacts for Module 1 or 2. The number of shipments would increase by about the same amount, as listed in Table J-1. Smaller percentage increases, noted by the commenter, are observed only when cumulative doses from past transportation activities are added to the impacts of the Proposed Action and Modules 1 or 2. This is because the impacts of general radioactive material transportation not related to a particular action (310,000 person-rem are estimated in Table 8-58) are much larger than the Proposed Action and Modules 1 or 2.

DOE used 1943 as a starting point for the cumulative impacts analysis because this corresponds to the time when spent nuclear fuel shipments between nuclear facilities started.

8.8.1 (196)
Comment - 15 comments summarized
Several commenters stated that the EIS significantly, woefully, and systematically underestimates transportation risk. The program involves an unprecedented number of trucks and trains. One commenter stated that use of old, cool spent fuel misrepresents the true risk. A commenter stated that detailed studies of routes should be included. The Nation should wait for 50 years to allow the spent fuel to decay to less radioactive levels. Commenters stated that the generic analyses do not account for potentially long stop times, slow speeds, intersections, traffic lights or unique highway characteristics, and community characteristics, such as locations of hotels, schools, and churches. In addition, the corridor widths are too narrow for radiological impact analyses. Another commenter stated that the 400-meter (0.5-mile) corridor used in the incident-free risk assessment underestimates risks. Another expressed concern with large amounts of long-lived radioactive materials in spent nuclear fuel and potential exposures to unshielded fuel elements.

Response
DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. For instance, DOE selected the RADTRAN 5 computer program to estimate radiological impacts to populations from incident-free transportation and from accidents. RADTRAN, which was originally developed by Sandia National Laboratories in the late 1970s, has been used in many DOE EISs, and it has undergone periodic review and revision. In 1995, an independent review of RADTRAN 4 (immediate predecessor to RADTRAN 5) demonstrated that it yielded acceptable results when compared to “hand” calculations. More recently, an independent review found that RADTRAN 5 overestimates the measured radiation dose to an individual from moving radiation sources.

To ensure that the EIS analyses reflect the latest reasonably available information, DOE has either incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relied on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data.

Although the EIS analyses are based on the latest reasonably available information and state-of-the-art analytical tools, not all aspects of incident-free transportation or accident conditions can be known with absolute certainty. In such instances, DOE has relied on conservative assumptions that tend to overestimate impacts. For instance, DOE assumed that the radiation dose external to each vehicle carrying a cask during routine transportation would be the maximum allowed by U.S. Department of Transportation regulations. Similarly, DOE assumed that an individual, the “maximally exposed individual,” would be a resident living 30 meters (100 feet) from a point where all truck shipments would pass. Under these circumstances, the maximally exposed individual would receive a dose of about 6 millirem from exposure to all truck shipments (6 millirem represents an increased probability of contracting a fatal cancer of 3 in 1 million). Although it can be argued that individuals could live closer to these shipments, it is highly unlikely that an individual would be exposed to all shipments over the 24-year period of shipments to the repository, even though DOE incorporated this highly conservative assumption in the analysis.

However, in response to comments, DOE has considered locations at which individuals could reside nearer the candidate rail corridors and heavy-haul truck routes in Nevada as a way of representing conditions that could exist anywhere in potentially affected communities. For example, DOE assumed that a maximally exposed individual could reside as close as 4.9 meters (16 feet) to a candidate heavy-haul truck route. During the 24-year period of repository operations this maximally exposed individual would receive an estimated dose of about 29 millirem, resulting in an increased fatal cancer probability of 2 in 100,000.

These exposures would be well below those received from natural background radiation, would not be discernible even if corresponding doses could be measured, and would not add measurably to other impacts that an individual could incur. For comparison, the lifetime likelihood of an individual incurring a fatal cancer from all other causes is about 1 in 4.

Based on public comments, DOE has revised the spent nuclear fuel used in the transportation analysis to use spent nuclear fuel with less cooling time (15 years versus 26 years and fuel with higher activity (50,000 megawatt-days per MTHM rather than 40,000 megawatt-days per MTHM). The radionuclide inventory contained in spent nuclear fuel is presented in Appendix A of the EIS. The typical rail cask would contain 4.5 million curies of radioactive material and the typical truck cask would contain 800,000 curies. While it is true that spent nuclear fuel would be less radioactive in 50 years, the impacts from transporting spent nuclear fuel are already very low, so waiting 50 years would not provide a practical reduction in the already very low risks.

Unshielded spent nuclear fuel is hazardous and, for this reason, would be shipped in heavily shielded casks. The maximum radiation dose rate from a spent nuclear fuel cask would be about 10 millirem per hour at 2 meters (6 feet) from the transport vehicle. For perspective, the radiation dose from a single chest X-ray is about 8 millirem. Therefore, the radiation dose from a spent nuclear fuel cask is equivalent to a little more than one chest X-ray per hour and is much lower than a lethal radiation dose.

The 800-meter (0.5-mile) distance was used only for estimating the incident-free transportation impacts. Because radiation levels fall off rapidly with distance from the source, this distance is adequate for estimating exposures from incident-free transportation. Consistent with accident analyses conducted at nuclear powerplants, the EIS analyzes the impacts from transportation accidents out to 80 kilometers (50 miles).

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of the Comment Response Document for more information.

8.8.1 (198)
Comment - 3 comments summarized
Commenters stated that DOE has underestimated the environmental damage that would result from routine transportation and spills of hazardous waste. The EIS used incomplete and outdated data and underestimated the

effects on groundwater and surface water, community water supplies, land use, and disruption of wild game habitat. DOE must examine the entire study area rather than limit the impact assessment to the area within the right-of-way. Another commenter requested information on environmental contamination outside the rail corridors, the dose rate to people living outside the corridors, and the long-term effects on animals, waterways, and wetlands.

Response

Section 6.2 of the EIS describes impacts of preparing to transport and transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain. The impacts are those that could occur to people and environmental media, including groundwater and surface water, land use, wetlands, biological resources, cultural resources, and effects on domestic and wild animals. DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. For instance, DOE selected the RADTRAN 5 computer program to estimate radiological impacts to populations from incident-free transportation and from accidents. RADTRAN, which was originally developed by Sandia National Laboratories in the late 1970s, has been used in many DOE EISs, and it has undergone periodic review and revision. In 1995, an independent review of RADTRAN 4 (immediate predecessor to RADTRAN 5) demonstrated that it yielded acceptable results when compared to “hand” calculations. More recently, an independent review found that RADTRAN 5 overestimates the measured radiation dose to an individual from moving radiation sources.

To ensure that the EIS analyses reflect the latest reasonably available information, DOE has incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relied on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data.

The analysis of national transportation of spent nuclear fuel and high-level radioactive waste evaluated impacts to populations along routes shipments could use.). DOE concluded that the impacts in these resource areas from nationwide transportation (outside Nevada) would not be discernible because shipments would use existing highways and railroads and would contribute only minimally to the volume of national transportation (0.007 percent of railcar kilometers and 0.008 percent of truck kilometers).

In Nevada, where a new branch rail line could be constructed or roads could be upgraded for use by heavy-haul trucks and an intermodal transfer station could be built and operated, the analysis addressed impacts on land use and ownership; air quality; hydrology; biological resources (including wild game habitat) and soils; public health and safety; socioeconomics; noise; cultural resources; aesthetics; utilities, energy, and materials; waste management, and environmental justice (Sections 6.3.2 and 6.3.3 of the EIS). In general, the impacts were assessed for regions of influence that extend beyond the area that would be within a rail corridor or highway right-of-way or site area of an intermodal transfer station (Sections 6.3 and J.1 discuss regions of influence used in the analyses). For example, human health effects from accidents were evaluated for populations living within 80 kilometers (50 miles) of a route (see Section 6.3.1.3.2).

As discussed in Section J.1.4.2.1 of the EIS, there would be no environmental contamination unless a severe accident resulted in a breach of containment of the shipping cask. Under incident-free conditions, there would be no environmental contamination because the spent nuclear fuel and high-level radioactive waste would not be released from shipping casks. In addition, the radiation emitted from shipping casks under incident-free conditions would have no discernible impacts on any ecological attribute (for example, groundwater and surface water, air quality, and wildlife habitat).

Plants and animals are no more sensitive to the effects of radiation than humans. Acute and chronic radiation doses that do not adversely affect humans are not known to affect terrestrial species of plants and animals. The International Atomic Energy Agency reports that there is no convincing evidence that indicates that the current radiological dose standards for humans would harm animal or plant populations (DIRS 103277-IAEA 1992). In other words, if humans are adequately protected, plants and animals are likely to be adequately protected.

The EIS does not specifically analyze a transportation accident involving contamination of surface water or groundwater. Analyses performed in previous EISs (see Section 1.5.3 and Table 1-1 of this EIS) have consistently shown that the airborne pathway has the greatest potential for exposing large numbers of people to radioactive material in the event of a release of radioactive materials during a severe transportation accident. An analysis of the potential importance of water pathway contamination for spent nuclear fuel transportation accident risk using a worst-case water contamination scenario (DIRS 157052-Ostmeyer 1986) showed that the impacts of the water contamination scenario were about one-fiftieth of the impacts of a comparable accident in an urban area.

The shipping casks used to transport spent nuclear fuel and high-level radioactive waste would be massive and tough with design features that complied with strict regulatory requirements that would ensure the casks performed their safety functions even when damaged. The casks would be designed to be watertight even after a severe accident. Furthermore, the high-level radioactive waste would be in a solid form (ceramics, metals, or glasses) that would not be easily dispersed.

Numerous tests and extensive analyses, using the most advanced analytical methods available, have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

Comment - EIS000124 / 0012
I also think that the transportation issues need to be addressed much more widely. I agree with the former speakers that Pahrump needs a new opportunity to address this.

Response
DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada if the site was approved. However, follow-on implementing decisions, such as the selection of a specific rail alignment in a corridor, or the specific location of an intermodal transfer station in Nevada or the need to upgrade heavy-haul truck routes, would require additional field surveys, State and local government, and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

8.8.1 (1007)
Comment - EIS000262 / 0003
The EIS needs to include a risk analysis comparing, at a national level, all probable primary and secondary shipment routes coming into Yucca Mountain. Again, absent information on the range of impacts expected to accrue to the project, we, as citizens, and the Federal and State decision makers expected to use the EIS, are left without the tools to weigh risks, evaluate alternatives, or recognize what constitutes an unavoidable transportation impact.

Route choice will affect the safety, cost and timing of transport operations. DOE needs to engage in a comprehensive study of this issue in order to develop a scientifically defensible, least-risk-based determination of routes. Private carriers should not be burdened with the responsibility to evaluate and choose routes. The preferred corridors should be mapped by DOE and the required roadway and emergency response improvements identified. In this way, the total impact and cost of the project can be laid out for public review.

Response
Section 2.1.3.2 of the EIS describes the national transportation shipping scenarios. Section 6.2.3 analyzes the impacts of transporting spent nuclear fuel and high-level radioactive waste using two scenarios: mostly legal-weight truck and mostly rail. The routes selected for the analyses met U.S. Department of Transportation regulations (49 CFR 397.101) and conformed to railroad routing practices. While these might not be the routes used in the future because of infrastructure changes or other variables, they are representative and therefore the analyses provide sufficient information on which to make decisions. Appendix J provides state-by-state maps of routes used in the analysis. The maps include tables of numbers of shipments originating in and passing through the state and the impacts of incident-free and potential accidents from these shipments. State or tribal designated alternate routes meeting Federal regulations were considered in the analysis. Section 2.1.5 provides information on the cost of the Proposed Action including costs of waste acceptance, storage, and transportation (nationally, $4.5 billion, and within Nevada, $0.8 billion). These costs are based on the mostly rail implementing alternative. Detailed costs of specific routes and modes cannot be estimated until the modes and routes are identified and approved.

Chapter 6 and Appendix J of the EIS provide the impacts and methods used to derive the impacts of the various mode and route alternatives for the life of the project. Impacts and risks for individuals, populations, and a variety of situations and accident conditions are addressed.

Route selection would not be left to the carriers alone. The current concept is that the shipping contractors would select routes and submit them to DOE for approval prior to their submittal to the Nuclear Regulatory Commission. The route selection process is discussed in greater detail in Section M.3.2.1.2 of the EIS. Requirements and protocols to be followed by the contractors in developing and implementing emergency response plans are described in Sections M.3.2.2.5 and M.5. DOE is required by Section 180(c) of the NWPA to provide technical and financial assistance to states and Native American tribes to support training for emergency responders. Part of this support is the determination of needed training that is based on plans developed by responsible jurisdictions. DOE anticipates that training would cover procedures required for safe routine transportation of spent nuclear fuel and high-level radioactive waste, as well as procedures for dealing with emergency response situations. Training would be instituted before beginning shipments to the repository. Additional information of Section 180(c) requirements and other emergency response capabilities and responsibilities are provided in Sections M.5 and M.6.

8.8.1 (1259)
Comment - EIS000228 / 0003
The DEIS transportation section fails to address the "range of alternatives" as required by the Council on Environmental Quality (CEQ) (Council on Environmental Quality. "Forty Most Asked Questions Concerning CEQ's NEPA Regulations." Wash D.C.). The DEIS does not address bounding scenarios in assessing the transportation risk. Among the ranges of alternatives that should be included in the analysis are:

- the use of dedicated versus general rail freight,
- consolidated shipping that would remove all of the SNF [spent nuclear fuel] from one region of the country versus a diffuse shipping program that leaves most of the country affected for long periods of time (advocated by the DOE),
- the use of uniform cask types versus a mix of cask types (proposed by DOE),
- analysis of the health effects of the "shortest path" from the reactors versus the health effects of routes that avoid highly populated urban areas,
- the shipment of ten versus twenty-five year old spent fuel.

Response
Section J.2.3 of the EIS discusses these two options, and Table J-25 provides a comparison of dedicated and general freight shipment by rail. The analysis for Chapter 6 did not consider the type of train service that could be used to deliver shipments to Nevada, because the available data for rail accident and fatality rates from the U.S. Department of Transportation is insufficient for this purpose and because other information is not sufficient to address differences in the impacts that might arise from differences between the two types of service. The Department of Transportation data do not present accident information for different kinds of rail service. A qualitative comparison

of attributes of general rail freight to dedicated train service in Table J-25 and in Section J.2.3, which is based in part on results of a recent Department of Transportation study, does not indicate a clear advantage for the use of either type of rail service. Thus, impacts discussed in the EIS are estimated based on typical railroad operations. In these operations, railroads transport freight cars, including cars carrying hazardous materials, along with other freight in trains that average 67 cars in length. The Department believes the analysis presented in the EIS supports use of either general rail freight or dedicated train service.

As discussed in Section M.3 of the EIS, the Department has determined that contractors could be directed to use dedicated train service where it can be demonstrated to enhance operations efficiency and cost-effectiveness.

There are several factors that make “consolidated shipping” a nonviable alternative. DOE is required by the terms of the Standard Contract for Disposal of Spent Nuclear Fuel and/or High-Level Radioactive Waste (10 CFR Part 961) to assign priority to those waste generator sites whose fuel was discharged earliest. This is usually called the “Oldest Fuel First” priority. DOE must pick up fuel from sites designated by those waste generators with the oldest fuel regardless of the location. In addition, spent nuclear fuel would continue to be generated for many years after the repository begins operation; even if one region were cleared out early, additional shipments would have to be made as more spent nuclear fuel is generated.

All casks that would be used would be designed to meet Nuclear Regulatory Commission and U.S. Department of Transportation regulations, and approved by the Commission prior to use. DOE would rely on private industry to design, license, and fabricate the casks to be used to transport commercial spent nuclear fuel to the proposed repository at Yucca Mountain. Many of these casks have already been designed and some have been fabricated. Although these casks are not of a uniform design, the major handling and shipping parameters such as weight and size are essentially the same. DOE sees no benefit in attempting to impose a common design on all casks.

Highway routes would be selected in accordance with U.S. Department of Transportation regulations in 49 CFR 397.101 and as approved by the Nuclear Regulatory Commission following regulations in 10 CFR Part 73. Among other things, these regulations require the routes to be selected to reduce time in transit. Department of Transportation regulations require highway shipments to use Interstate System beltways and bypasses around cities although this might not be the “shortest path.” Rail shipments would be routed over the best available track, to minimize the number of interchanges between railroads, and to minimize time in transit. This routing might or might not result in the “shortest path.”

Based on comments received and DOE’s additional review of technical documents and conduct of hazard analyses, the basis for the transportation impact analysis has been revised to consider commercial spent nuclear fuel that has median hazard. Spent nuclear fuel having median hazard would be discharged from a reactor approximately 14 years before shipment to Yucca Mountain. The radionuclide inventories of the representative spent nuclear fuel used in the analysis are presented in Tables A-9 and A-10 of the EIS. Five- or 10-year-old spent nuclear fuel shipped to the repository would be a small fraction of the total shipments. This is an example in which “average” data are used in the EIS as opposed to bounding assumptions. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing accident scenarios. Other elements of the impact analyses (for example, radiation dose rates, atmospheric dispersion modeling, release fractions) are such that the transportation impact results presented in the EIS are representative, yet not so conservative that the true differences among alternatives are masked.

8.8.1 (1264)

Comment - EIS000228 / 0007

In 1995, the DOE indicated in a report Cited as a DEIS reference (OCRWM. “Nevada Potential Repository Preliminary Transportation Strategy Study 1.” April 1995 P 10), that input from the affected counties would be a consideration in selecting a route through Nevada to Yucca Mountain. Clark County believes none of the implementing alternatives proposed in the DEIS are acceptable without further study. Clark County contends that without a detailed description of the packaging, handling, transportation, and mitigation systems necessary to implement the Yucca Mountain program it is impossible to assess the impacts of this program.

Response
DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada. DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada if the site was approved. However, follow-on implementing decisions, such as the selection of a specific rail alignment in a corridor, or the specific location of an intermodal transfer station in Nevada or the need to upgrade heavy-haul truck routes, would require additional field surveys, State and local government, and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

Comment - EIS000340 / 0003
Many aspects of the Yucca Mountain Project don't seem to make much sense. For instance, the transportation of nuclear waste through residential streets greatly increases the risk of radiation to civilians.

Response
Highway routes would be selected in the future in accordance with the U.S. Department of Transportation regulations in 49 CFR 397.101. In addition, the routes would be submitted to the Nuclear Regulatory Commission for approval. The Department of Transportation regulations in 49 CFR 397.101 require that highway shipments use preferred routes, which are defined as Interstate System highways and beltways or bypasses around cities and alternative preferred routes designated by state or tribal routing agencies. A shipment could deviate from a preferred route only to pick up or deliver the shipment, or for required food, rest, or refueling stops, to make repairs, or in emergencies in which the preferred route is unavailable or unsafe.

8.8.1 (1546)
Comment - EIS000357 / 0005
Risk assessment of the waste isolation pilot project. Can the experience of transport of low-level nuclear waste and impacts be used as a model for the Yucca Mountain repository? Can this be used to assess community impacts and transport accident rates?

Response
Some experience gained from low-level waste transportation would be applicable to the transportation of spent nuclear fuel to the proposed repository. For example, estimated accident rates should not be significantly different, because both spent nuclear fuel and low-level waste transportation accident rates should not differ much from the general commerce truck and general freight rail accident rates used in the EIS. Other areas would not be applicable, such as the level of hazard of spent nuclear fuel compared to that of low-level waste, packaging and handling operations, types of shipping containers, security, escorts, and routing.

DOE experience with shipping transuranic waste to the Waste Isolation Pilot Plant is more like shipping spent nuclear fuel than would be experience in shipping low-level radioactive waste. Spent nuclear fuel transportation shares more fundamental features with the Waste Isolation Pilot Plant transportation program than with a low-level waste shipping program. For example, DOE ships transuranic waste in accident-resistant packages, uses the TRANSCOM shipment tracking and communication system, follows similar routing guidelines and transportation protocols (see Appendix M of the EIS), just as it would for spent nuclear fuel shipments. However, not every aspect of the transuranic waste shipping program is identical to the proposed spent nuclear fuel shipping program, such as remote handling requirements, the possibility of rail transport of spent nuclear fuel, internal packaging used, approval of routes by the U.S. Nuclear Regulatory Commission, and waste form characteristics (such as ignitability, gas generation, fissile material concentrations).

8.8.1 (2355)
Comment - EIS000645 / 0001
Although everybody here in Crescent Valley has addressed this because of the spur, first fire alarm that goes off in my head and heart is that existing rail line that is going to feed that spur goes through all four major cities in my

county. Ninety percent of our population is based on that cargo, that is Wendover, Wells, Elko, and Carlin. So right there and then I know that is something that we have to be concerned about.

Second point is that the main stopover for our area for crew changes, if that is the case that these trains would require crew changes, is in Elko. That is where all the major trains stop and all the crews stay. If they are allowed to have 48-hour stopover there, that means that these trains with hot loads will be sitting right there in the heart of the downtown area. I can empathize with people having homes up close to these rail lines. But I have an entire 35,000 people right there. And that's a very big concern to us.

Lastly, because of these range fires that we have had, we have had a lot of right-of-way fences destroyed. Now our commission has begged three different letters to have railroads to please replace your right-of-way fencing. They haven't responded to us once. I can imagine what would happen later on here if we had something like this and some right-of-way fencing was destroyed. It would take us forever to get this fencing back up, and God knows what would happen at that point.

We have had people killed on our rail lines here in Elko County. And I know there is many unexpected crossings we have. It goes through some very stiff terrain, over the Pequots and so on. High elevations, cold weather.

And if something happens, whether it is flash flooding, snow, or something, and these trains are backed up, where do they back up? Are they just going to stop at each one of our main cities and then we're going to have one of these trains sitting at each one of our towns?

Response
The EIS assessment of maximally exposed individuals considered stopovers at railyards (see Section J.1.3.2.2 and Table 6-9). The radiation dose to a resident 200 meters (660 feet) from a railyard and exposed for 20 hours to every shipment that passed would received as much as 0.31 rem over 24 years. This is a small radiation dose; approximately equal to the annual radiation dose this hypothetical individual would receive from natural background radiation in 1 year. It is conservative, in that this person would be unlikely to be present in an unshielded location for every passing shipment. DOE anticipates that potentially long stopovers to wait for adverse weather conditions would be rare.

Maintenance of existing rail rights-of-way, such as rebuilding damaged or destroyed fences, is the responsibility of the railroad. If DOE decided to build and operate its own branch rail line to connect the existing railroad with the proposed repository, it would be DOE's responsibility to maintain the right-of-way.

8.8.1 (2403)
Comment - EIS000674 / 0006
At the best, I think use of that route through Esmeralda and Nye County is going to cause a lot of people to get an extra 10 to 50 millirem per year just from heavy-haul trucks.

That's like two to five extra chest x-rays a year, assuming you've got a properly calibrated machine. That's a low enough exposure that no one can really see what the cancer impacts or the genetic impacts are. But it is a measurable dose to the general population that is like saying, "Let's increase your natural radiation from all sources by ten percent or more." That's something that the DEIS has to look at using different tools and different analytical techniques.

Use of a RADTRAN model is crude. It doesn't give you the kind of analysis you need.

Response
In responding to public comments regarding individuals in Nevada who live close to candidate transportation routes, DOE used information from a recent report prepared for the City of North Las Vegas (DIRS 155112-Berger Group 2000). This report presents suggested assumptions for a hypothetical maximally exposed individual who lived 15 meters (49 feet) from a roadway used by heavy-haul trucks and who would be present and stay at that location, when, over the 24 years, each shipment stopped for 1 minute. DOE believes that such an exposure scenario is highly unlikely and therefore unrealistic. Nonetheless, DOE estimated the maximum cumulative radiation dose to this hypothetical individual would be about 520 millirem over 24 years of the Proposed Action (see Section

J.1.3.2.2.1 of the EIS). This dose would lead to an estimated increase in risk of cancer of 1 in 4,000, over the individual's lifetime. The analysis in the EIS considered other maximally exposed individuals who could live along routes in Nevada. These included:

- A person in Alamo living in a residence approximately 5 meters (15 feet) from U.S. 93 where heavy-haul trucks could pass who could receive a dose of 25 millirem over 24 years

- A person who could be in the courthouse or fire station in Goldfield, Nevada approximately 5 meters (15 feet) from U.S. 95 where heavy-haul trucks could pass, who could receive a dose of 56 millirem over 24 years.

For perspective, cancer from all other causes is fatal to about 1 in 4 persons. DOE believes this increase in radiation exposure poses no undue risk to the population surrounding the proposed routes for heavy-haul trucks.

In this EIS, DOE has used computer models it has used in previous EISs and other studies (see Sections 6.2.1 and J.1.1). These models are widely accepted by the national and international scientific and regulatory communities. For instance, DOE selected the RADTRAN 5 computer program to estimate radiological impacts to populations from incident-free transportation and from accidents. RADTRAN, which was originally developed by Sandia National Laboratories in the late 1970s, has been used in many other previous DOE EISs, and it has undergone periodic review and revision. In 1995, an independent review of RADTRAN 4 (immediate predecessor to RADTRAN 5) demonstrated that it yielded acceptable results when compared to "hand" calculations (DIRS 101845-Maheras and Pippen 1995). More recently, an independent review found that RADTRAN 5 overestimates the measured radiation dose to an individual from moving radiation sources.

8.8.1 (2404)
Comment - EIS000653 / 0001
A thorough assessment of the impacts of the proposed action is necessary. We believe the Draft Environmental Impact Statement falls far short of this goal.

Section 1502.22 of the National Environmental Policy Act calls for agencies to disclose the unavailability of information in evaluating reasonably foreseeable significant adverse effects on the human environment. The absence of operational safety performance data for any component of the transportation system needed to move waste from generator sites to Yucca Mountain is a major gap in available information and should have been cited and discussed in the DEIS.

The DEIS describes some areas in which gaps in information exist, but it does not make those gaps clear. Sections of the DEIS where the gaps in information should be highlighted and implications of these gaps and the validity of conclusions of the DEIS should be thoroughly discussed.

In 1995, the DOE indicated in a report cited as a DEIS reference -- the report title is Nevada Potential Repository Preliminary Transportation Study 1. It indicated that input from the affected counties would be a consideration in selecting a route through Nevada to Yucca Mountain. Based on the concerns I've described above, Clark County believes that none of the implementing alternatives proposed in the DEIS are acceptable without further study.

Clark County contends that without detailed description of the packaging, handling, transportation and mitigation systems necessary to implement the Yucca Mountain transportation program, it's impossible to assess the impacts of this program.

Response
In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. For instance, DOE selected the RADTRAN 5 computer program to estimate radiological impacts to populations from incident-free transportation and from accidents. RADTRAN, which was originally developed by Sandia National Laboratories in the late 1970s, has been used in many other previous DOE EISs, and it has undergone periodic review and revision. In 1995, an independent review of RADTRAN 4 (immediate predecessor to RADTRAN 5) demonstrated that it yielded acceptable results when compared to "hand" calculations. More recently, an independent review found that RADTRAN 5 overestimates the measured radiation dose to an individual from moving radiation sources.

To ensure that the EIS analyses reflect the latest reasonably available information, DOE has either incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relies on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

DOE could ship spent nuclear fuel and high-level radioactive waste in several configurations, all of which would require a shipping cask designed to standards established by the Nuclear Regulatory Commission. There is substantial empirical data on the performance of shipping casks designed for the safe transport of spent nuclear fuel and high-level radioactive waste. In tests, casks have been rammed by high-speed trains, smashed into solid concrete structures, immersed in high-temperature fires, and submerged underwater. The results of these tests have confirmed that Type B casks can sustain severe transportation accidents while maintaining their safety functions. An analysis of the cask response to accident forces, referred to in the EIS as *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000), estimates that less than 0.01-percent of all accidents would generate forces that could lead to a release of radioactive material from a Type B shipping cask. Based on the evaluation in the EIS, no radiological impacts are projected for either the mostly legal-weight truck or mostly rail scenarios.

There were 60 accidents involving Type B packages between 1971 and 1997 (DIRS 102172-McClure and Fagan 1998). Of these, seven involved spent nuclear fuel. In each of these accidents the structural integrity of the cask remained intact and there was no release of radioactive contents. DOE would use legal-weight or heavy-haul trucks that met U.S. Department of Transportation requirements (49 CFR Parts 171 through 180).

DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada if the site was approved. However, follow-on implementing decisions, such as the selection of a specific rail alignment in a corridor, or the specific location of an intermodal transfer station in Nevada or the need to upgrade heavy-haul truck routes, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and the appropriate National Environmental Policy Act reviews.

8.8.1 (3114)
Comment - EIS000726 / 0008
The entire issue of calculated risk is a major concern. There is no mention of the degree of uncertainty associated with any of your calculated risk assessments. With no data to the contrary, I can only assume that the degrees of uncertainty are high.

The calculated risk must use accurate data and better estimates. It must include all risk factors, and must consider all known impacts to quality of life, the health of people and of the environment, and economic activity in the region.

Response
DOE is aware that there are uncertainties associated with the transportation impact results presented in the EIS. There are uncertainties associated with route characteristics, demographics, weather, atmospheric dispersion models, waste characteristics, accident rates, release fractions, and many other elements of the risk assessments. Because one of DOE's goals is to choose between alternatives, the consistent consideration of uncertainty among alternatives means that the relative differences in impact estimates among alternatives should not be affected. To account for uncertainties in the data, conservative assumptions were made so the impacts reported in the EIS would tend to overestimate the potential impacts. Examples of conservative assumptions include: accident release fractions which were selected from the high end of the distribution of experimental results, regulatory maximum radiation dose rates

were assumed for all shipments, even though the actual dose rates would be significantly lower for most shipments, consequences of severe accidents to maximally exposed individuals were presented for 50 percent and 95 percent (that is, consequences exceeded only 5 percent of the time) meteorological conditions, and evacuation and sheltering, which could reduce radiological exposures, were not included in the accident risk calculations. Although DOE has chosen to use conservative assumptions, the assumptions are not unrealistic to ensure that estimated impacts are as realistic as possible. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing environmental impacts. Such practices mask the real differences and would not produce suitable results to support choices among the alternatives.

8.8.1 (3170)
Comment - EIS001194 / 0001
As an engineer, I was deeply troubled not so much by what was revealed in the fact sheets and policy briefs concerning the proposed transit route for commercial nuclear waste, but by what they surreptitiously attempted to obscure. Combing through this public relations hype, I was given over to the impression that legal jargon had been substituted for much more precise scientific notation. An example would be the suffix "person-rems," which appears in this literature. Were this term intended to indicate the approximate quantity of rems per total number of individuals within a contaminated perimeter, it would - when applied to a population center with a concentration as dense as that of Cleveland - denote a radiation hazard many times in excess of that which Hiroshima suffered in August of 1945. If instead the term is more properly interpreted as the average rem dosage to which any individual within a certain proximity might be exposed, the figure, while remaining unacceptably high, becomes indicative of a contamination level significantly less catastrophic than the aforementioned. I have a suspicion, however, that the term was coined to designate not quite one nor exactly the other.

Response
The radiological impact evaluation terms and techniques used in the EIS are consistent with the typical practices of the Environmental Protection Agency, the Nuclear Regulatory Commission, and DOE. These terms are explained in more detail in Section 3.1.8.1 of the EIS. The terms and their usage are also consistent with the practices set forth by the United States and international radiation protection organizations.

The term person-rem is used to convey the total collective radiation doses received by a population exposed to radioactive material. For example, the Latent Cancer Fatalities textbox in Section S.4.1.8 of the EIS Summary states, "…if each individual in a population of 100,000 received a total dose of 0.001 rem, the collective dose would be 100 person-rem…"

The 100 person-rem collective dose value is the product of the 100,000 persons and 0.001 rem received by each person. Alternatively, it can be viewed as the sum of the doses received by each person of a given population exposed to radiation.

8.8.1 (3253)
Comment - EIS000981 / 0001
Has the DOE conducted the necessary HAZARD ANALYSIS, VULNERABILITY ANALYSIS and RISK ASSESSMENT in the City of St. Louis for the rail and highway routes identified in the newspaper article? If so, can we obtain a copy of that assessment. If not, will the assessment be conducted and will the City of St. Louis receive a copy of the assessment and/or be a part of the assessment team?

Response
Although the EIS contains an assessment of national transportation impacts for shipping spent nuclear fuel and high-level radioactive waste to the proposed repository, location-specific assessments have not yet been performed. Highway routes would be selected in the future in accordance with the U.S. Department of Transportation regulations in 49 CFR Part 397. Rail routes would be selected to reduce time in transit, minimize number of railroad to railroad interchanges, and use high quality mainline track. Use of routes would be subject to review by the Nuclear Regulatory Commission under regulations in 10 CFR Part 73. However, it is premature at this time to analyze the hazards, vulnerabilities, and risks of specific routes and locations to identify preferred routes. The highway routes presented in the EIS are used for illustration purposes and to provide technically defensible route characteristics data to support the calculation of transportation impacts. In DOE's judgment, the routes used in the

EIS represent reasonable information available at this time and the use of other routes would not change the results of the transportation impact calculations substantially.

Should a decision to proceed with the development of a repository at Yucca Mountain be made, shipping routes would be identified at least 4 years before shipments began and Section 180(c) assistance would be made available approximately 4 years prior to shipments through a jurisdiction. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

8.8.1 (3337)
Comment - EIS001121 / 0003
Putting aside the obvious dangers (accident, terrorists, etc.) I am disturbed by your prediction of 18 latent cancer fatalities by truck, and 5 latent fatalities by rail. I would like to know how you came up with these figures, without any of these CASKS having been built? I know that you test by scale but I can't believe that this would apply in this situation.

With these predictions in mind it tells me that you are anticipating a leakage in these CASKS. I would like to know who are these predicted fatalities? What is the risk to the drivers of these trucks?

Response
Section 6 and Appendix J of the EIS provide comprehensive information on the techniques and assumptions used in the analysis of worker and public health safety risks. Transportation of spent nuclear fuel and high-level radioactive waste is an integral part of the ultimate disposition of these wastes in a geologic repository and the EIS addresses the potential impacts associated with a transportation campaign (see Chapter 6 and Appendix J). In determining whether to recommend the Yucca Mountain site to the President, the Secretary of Energy will take transportation impacts into account. Section 6.2.3.1 indicates that there would be 2.5 latent cancer fatalities among members of the general public along routes from legal-weight truck transport of spent nuclear fuel and high-level radioactive waste for the 24-years of operation. DOE recognizes the potential for transportation accidents and analyzed impacts resulting from transportation accidents in Section 6.2.4. Although, given the number of shipments, traffic accidents would be probable, DOE does not believe that any accident would result in the release of radioactive material, primarily because of the structural integrity of the casks in which the material would be transported. In the more than 2,700 shipments involving spent nuclear fuel over the past 3 decades, there have been seven accidents, with no release of radioactive materials to the environment. Though an accident resulting in release of radioactive material is not expected to occur, the Department analyzed the maximum reasonably foreseeable accident would involve the release of material from a transportation cask. This would be an extremely unlikely event (an annual probability of 2.8 [rail] to 2.4 [truck] in 10 million). The leaking of a transportation cask could only occur if mechanical forces (impact) and heat (fire) exceeded the design limits of the transportation cask structures and materials. The EIS states that an accident involving the leaking of a transportation cask could result in approximately 5 latent cancer fatalities in an urban area under stable (slowly dispersing) atmospheric conditions. The air pathway is the most likely mode of exposure to radioactive materials though other pathways, including water and contaminated food sources are included. A severe accident in another population zone (for example, rural) or in other atmospheric conditions would have lower consequences.

Section M.4 of the EIS provides additional information on shipping cask design, safety, and testing. Shipping casks of various designs have been built and used for the shipment of spent nuclear fuel in the United States and worldwide. The Nuclear Regulatory Commission has certified several new cask designs in recent years and other designs are in the review process. These designs and current regulatory requirements are sufficient to provide the cask-related input parameters that DOE used to calculate incident-free radiation exposures. These include the external dose rate emitted from the shipping cask, which DOE assumed at the maximum limit allowed by U.S. Department of Transportation and Nuclear Regulatory Commission regulations, and the cargo capacity of the shipping casks that would determine the number of shipments required to transport spent nuclear fuel and high-level radioactive waste to the repository. With regard to the maximum allowable external radiation dose rate, actual shipments would be likely to emit lower dose rates, but could not emit a higher dose rate. DOE based shipping cask capacities on the certified casks and those in Nuclear Regulatory Commission review.

8.8.1 (3621)
Comment - EIS001101 / 0002
The DEIS is incomplete in that there is no description and analysis of the affected environment for each Nevada transportation route. National transportation routes for rail and highway shipments are not identified and analyzed. The EIS should include analyses of potential impacts and hazards of all alternatives in order to support a selection from among the alternatives.

Response
Complete descriptions of the affected environment can be found in Sections 3.2.2, 6.3.2, and 6.3.3 of the EIS for the heavy-haul truck and rail implementing scenarios, including descriptions and analyses of the impacts of highway and rail improvements, as well as construction and operation of intermodal transfer stations. Section J.3 provides descriptions of potential legal-weight truck, heavy-haul truck, and rail routes in Nevada. National transportation routes and associated environmental impacts are addressed in Section 6.2. In response to comments on the Draft EIS, DOE revised Appendix J to include state-by-state route maps, the numbers of shipments in each state, and state-specific health and safety impact estimates (see Section J.4). This is in addition to the route maps that were already included in the Draft EIS (see Section 2.1.3.2 for national routes and Section 2.1.3.3 for Nevada maps).

With respect to alternatives, in the Draft EIS and the Supplement to the Draft EIS, DOE analyzed a variety of scenarios that offer a range of options in which to implement the Proposed Action to construct, operate (including transportation) and monitor, and eventually close a repository at Yucca Mountain. These scenarios, which reflect potential repository design and operating modes, waste packaging approaches, and transportation options for shipping spent nuclear fuel and high-level radioactive waste to the Yucca Mountain site, bounded the environmental impacts likely to result from the Proposed Action. DOE conducted hearings to obtain public input on the scope of this EIS and has reviewed previous public comments on repository-related transportation alternatives (for example, comments on the Draft Environmental Assessments). As stated in Section J.3.1.2 of the EIS, one of the rail corridor alternatives analyzed in the EIS was identified on the basis of public comments submitted during scoping hearings.

DOE evaluated the potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste from 5 DOE and 72 commercial sites to a repository at Yucca Mountain. At this time, many years before shipments to a repository could begin, it is impossible to predict the exact number of shipments that would be made by either truck or rail. For this reason, in the Draft EIS, DOE evaluated two scenarios for moving the materials to Nevada:

- Transport using mostly legal-weight trucks
- Transport using mostly rail

In DOE's judgment, the EIS considers a reasonable range of scenarios that cover the full spectrum of transportation system alternatives, and bounds the potential environmental impacts associated with the transportation of spent nuclear fuel and high-level radioactive waste.

8.8.1 (3896)
Comment - EIS001286 / 0006
A recent study from the Texas Transportation Institute of traffic in Greater Cleveland and 67 other metropolitan areas found that traffic jams are getting more frequent and severe. In 1997, 50% of traffic was congested. Freeways are also more crowded. The number of miles traveled daily on freeways rose 66.5% from 1982 to 1997 (clipping enclosed). DOE must account for non-accident exposures that will become routine when casks are trapped in heavy traffic with other vehicles for long time periods.

Response
The estimated exposure of a person stuck in a traffic jam for 1 hour sitting 1.2 meters (4 feet) from a spent nuclear fuel cask is given in Section 6.2.3 of the EIS. Additional information on the potential transportation impacts is presented in Appendix J.

8.8.1 (4063)
Comment - EIS001181 / 0001
The potential environmental risk based on every aspect, from shipping loads cross country to unstable recommendations for radiation levels, are cause for reevaluation. I-15 in California, just one of many proposed routes, is one of California's most dangerous sections of highway, near the proposed site. Also the EPA [Environmental Protection Agency] has challenged the proposed limits for radiation exposure posed by the DOE.

Response
The highway routes for shipment of waste to the proposed repository at Yucca Mountain would be selected in accordance with U.S. Department of Transportation regulations in 49 CFR 397.101. Interstate-15 in California could be used because it is an Interstate System highway that could be part of one or more preferred routes that would reduce time in transit for shipments, and if so would meet requirements listed in the regulation. Radiation exposure limits during transportation are set by the Department of Transportation regulations in 49 CFR 173.441 and by the Nuclear Regulatory Commission in 10 CFR 71.47; they are not posed by DOE. The Environmental Protection Agency has not challenged these limits.

8.8.1 (4130)
Comment - EIS001473 / 0001
It is apparent that if Yucca Mountain is realized, and that's still a problem that has to be addressed, has to be technically established, the transportation will be a profound impact on the state of Utah.

Response
In response to public comments, DOE has included in Section J.4 of the EIS maps of the highway routes and rail lines it used for analysis. It also included potential health and safety impacts associated with shipments for each state through which shipments could pass.

8.8.1 (4205)
Comment - EIS001160 / 0027
The DEIS does not adequately address issues raised and substantiated by White Pine County during the scoping process. For example:

The analysis should evaluate the risk management benefits of time-of-day travel restrictions (i.e. to avoid transport past the White Pine County High School during school hours). The DEIS does not consider time-of-day travel restrictions as a risk management option.

Response
Section M.3 of the EIS describes DOE's acquisition process for Waste Acceptance and Transportation Services Contractors. This section also describes the protocols that would be used by DOE and the Regional Servicing Contractors for highway route determination for transporting spent nuclear fuel and high-level radioactive waste to the proposed repository. In addition to the requirements of the U.S. Department of Transportation for highway routing of highway route controlled quantities of radioactive materials, which would include spent nuclear fuel and high-level radioactive waste (49 CFR 397.101), the Regional Servicing Contractors should consider, among other things, preferred time of day travel through urban areas. However, alternate routes may be designated by the State of Nevada.

8.8.1 (4207)
Comment - EIS001160 / 0028
The DEIS does not adequately address issues raised and substantiated by White Pine County during the scoping process. For example:

The EIS should assess the regional economic benefits of using of local versus non-local trucking firms. The DEIS does not provide a comparative assessment of the regional economic benefits of using local v. non-local trucking concerns.

Response
DOE has developed a draft Request for Proposal for waste acceptance and transportation services (DIRS 153487-DOE 1998), as discussed in Section M.3 of the EIS. As outlined in this draft, each successful responder to the final request, called a Regional Servicing Contractor, would be responsible for all shipping arrangements and transportation services in its servicing region(s). DOE anticipates that it would invite national, regional, and local transportation companies to participate in the selection process for the contractor and potential subcontractors to provide specific services. DOE believes that it should defer an evaluation of the use of local versus nonlocal trucking firms to provide heavy-haul truck services to the contractor selection process or the selected contractors. Such an evaluation would not affect the comparison of alternatives or decisions DOE would make using the results presented in the EIS.

8.8.1 (4208)
Comment - EIS001160 / 0029
The DEIS does not adequately address issues raised and substantiated by White Pine County during the scoping process. For example:

The impacts of alternative vehicle payloads upon highway infrastructure, maintenance costs and traffic safety should also be addressed within the EIS. The DEIS does not appear to assess added maintenance costs or the change in crash rates per vehicle miles traveled as a result of slow-moving vehicles (i.e. heavy-haul trucks).

Response
The estimated costs shown in Section 6.3.3.2.1 of the EIS are based on detailed engineering estimates, which include lane widening, truck lane and turnout construction, pavement upgrades, intersection upgrades, and shoulder upgrades. The cost estimates developed for highway upgrades associated with candidate heavy-haul truck transport implementing alternatives include costs for annual maintenance of the roads that would be used. The impact estimates were based on engineering and cost studies documented in *Cost Estimate for Heavy Haul Truck Transportation* (DIRS 154675-Ahmer 1998), including detailed cost estimate for the design, construction, and management of the initial road upgrades for public roads for each of the five candidate heavy-haul truck transport routes.

As described in Section J.1.1.4.2 of the EIS, crash rates and accident severities used in the EIS accident analyses were not adjusted for lower speeds of heavy-haul trucks.

8.8.1 (4212)
Comment - EIS001160 / 0026
The DEIS does not adequately address issues raised and substantiated by White Pine County during the scoping process. For example:

Legal weight truck operational alternatives, which should be considered within the EIS, include escorted versus unescorted shipments. The DEIS does not consider the risk benefit/cost implications of escorted vs. unescorted shipments.

Response
In Section 2.1.3.2 of the EIS, DOE states that the transportation of spent nuclear fuel and high-level radioactive waste would be in accordance with U.S. Department of Transportation and Nuclear Regulatory Commission requirements and that all shipments would be monitored. Commission regulations for in-transit physical protection (10 CFR 73.37) require escorts for all spent nuclear fuel shipments. Within highly populated areas, the vehicle must be occupied by two individuals, one of whom serves as an escort. In addition, the vehicle must be escorted by an armed member of the local law enforcement agency in a separate vehicle. Another option is for the transport vehicle to be led and trailed by vehicles each occupied by at least one armed escort. A transport vehicle travelling through an area not considered highly populated must have as a minimum a driver and another individual who acts as an escort. Another option is for the vehicle to be occupied by a driver and escorted by a separate vehicle occupied by at least two escorts. Given these Commission requirements, unescorted shipments are not an alternative. Additional information on physical protection of spent nuclear fuel shipments is provided in Section M.7.

8.8.1 (4215)
Comment - EIS001160 / 0032
The DEIS does not adequately address issues raised and substantiated by White Pine County during the scoping process. For example:

The DEIS should consider those environmental features which may affect safe transport of radioactive materials. Examples include weather conditions, wildlife conflicts with vehicles, and flood prone areas, among other possibilities. The DEIS only considers these environmental features as such may be impacted by construction and operation of the transportation system. The extent to which these environmental characteristics may impact upon safe transportation is not addressed within the characteristics DEIS.

Response
While the EIS does not specifically evaluate scenarios such as those mentioned in this comment, the transportation accident statistics used in the assessment of nonradiological impacts include accidents where the environmental features described by the commenter are included. Adverse weather conditions and impacts with wildlife are frequently cited as causes or contributors to vehicular accidents. DOE would use a satellite tracking and communications system, such as the TRANSCOM system, for spent nuclear fuel and high-level radioactive waste shipments to provide truck crews and escorts with warnings of upcoming poor weather conditions, allowing the shipment to take an alternate route or proceed to a designated safe in-transit parking area to await better conditions. In addition, routine en route communications would provide warnings of pending floods that could affect a shipment. Accidents involving a vehicle and wildlife would not be a significant threat to release radioactive material from spent nuclear fuel and high-level radioactive waste shipments.

More detailed information on transportation planning and operations is provided in Section M.3 of the EIS.

8.8.1 (4282)
Comment - EIS001160 / 0089
Page 2-80: The third point on this page states, "Impacts from the transportation of spent nuclear fuel and high level radioactive waste from the commercial and DOE sites to the Yucca Mountain Site would be low for either national shipping mode." This statement is unsubstantiated in as much as the table it references is both unclear in its statistics and does not account for worst case scenarios. A better statement would be that statistical probability of impacts would be low, but actual impacts are not only unknown, but liable to random accident, man caused incidents and acts of nature. While these are addressed later in the study, they should at least be prefaced here.

Response
The impacts to the maximally exposed individuals listed in Table 2-7 would be, at worst, an incremental probability of 1 chance in 50 (0.02) of contracting a fatal cancer. This risk is for truck crews who are assumed to receive a maximum dose of 2 rem per year for 24 years. DOE expects these individuals would be subject to occupational exposure limits and their exposures would be monitored. The probability of a member of the public contracting a fatal cancer would be much smaller than that for the truck crew, as lis7ed in Table 2-8.

The consequences to the maximally exposed individual from maximum reasonably foreseeable transportation accidents would be low. This is based on a 1-in-about-70 chance (0.015) of contracting a fatal cancer following a maximum reasonably foreseeable rail accident. These are small probabilities in relation to the probability that an individual would contract a fatal cancer from all potential causes [22 percent or 0.22, according to the American Cancer Society (DIRS 101482-American Cancer Society 1998)], including carcinogens in the environment, natural background radiation, and all other radiation sources. Therefore, DOE believes the data in Table 2-7 are sufficient to support the conclusion that the transportation of spent nuclear fuel and high-level radioactive waste to the proposed repository would represent a low risk.

8.8.1 (4299)
Comment - EIS001160 / 0108
Page 6-31, Paragraph 3, Last Line of this page states, "The maximally exposed individual, assumed to be about 360 meters (I 180 feet) from the accident would receive a dose of about 3.9 rem (Table 6-1 1)." The assumption of the maximally expose individual at nearly 1200 feet is an unrealistic assumption. Where was this derived from? Is there a national standard that references that distance as a common reference? If an average lane, on an average

US Highway is 14 feet, and the average setback distance in any given municipality is about 50 feet, (I have no reference for this, but could probably produce one), then the maximally exposed individual might be an average (not including people who came in for closer a look) of 64 feet from the accident site. Assuming that the radiation dose is inversely proportional to the square of the distance from the source (Sourcebook on Atomic Energy, Glasstone 1979, pp 752 footnote) it is conceivable that a maximally exposed individual might receive perhaps 800 to 1000 rem. Even a brief exposure at this distance would most probably prove fatal. Extended exposures, (greater than an hour) would certainly prove fatal. The estimates of dose do not appear realistic and could be easily exceeded.

Response
As discussed in Appendix J of the EIS, the principle radiological exposure in a very severe transportation accident would be long term exposure to radioactive materials inhaled following release from a cask. Release of radioactive material from a cask would be unlikely in transportation accidents, occurring in only about 0.01-percent of accidents (DIRS 152476-Sprung et al. 2000). The small particles, gasses, and volatile radionuclides would be transported by the smoke and winds and deposited downwind from the accident. Direct exposure to gamma and neutron radiation penetrating the cask would only be the dominant exposure pathway if the shielding of the cask was heavily damaged in a so-called loss of shielding accident. The analysis in the EIS includes estimates of dose to a first responder to a rail accident where the involved cask has lost a portion of its radiation shield. The dose estimated for this first responder is 0.83 rem. This dose is smaller than the dose of 29 rem to a maximally exposed individual who would be 330 meters (1,100 feet) downwind from the accident and would be exposed to a passing cloud of radioactive particles, gasses, and volatile materials.

DOE evaluated doses to the maximally exposed individual from the maximum reasonably foreseeable accident for 50- and 95-percent atmospheric dispersion conditions (that is, consequences would not be exceeded 50 and 95 percent of the time, respectively). The atmospheric dispersion model used in the calculations accounted for several phenomena that would affect the timing and concentrations of released material as the plume dispersed. Some of these phenomena (such as plume rise from the thermal condition of the released material) would cause the concentrations of radioactive material in the plume to be higher at distances farther from the release point than they would be near the release. The model determined the distance at which the maximum concentration would occur, and calculated the consequences to an individual at that distance.

8.8.1 (4363)
Comment - EIS001157 / 0008
The transportation, assumptions must be reevaluated to reflect the transportation system development that is most likely to be in place during the transportation phase. This analysis should account for the effects of major construction activities on the shipments.

Response
The EIS reflects transportation system development in several ways. First, accidents that are caused by or have contributing factors related to highway construction are included in the state-specific accident rates used in the calculations. Second, the EIS performed an analysis that accounted for future construction of the Las Vegas Beltway (see Section J.3.1.1). Third, the EIS presents several alternatives for construction of rail corridors and heavy-haul truck routes, in addition to construction and operation of intermodal transfer stations. Fourth, population data is adjusted to account for projected population growth at the time the shipments are planned to take place. Based on this, DOE believes the EIS adequately accounts for known and projected future transportation system development. However, for purposes of estimating a conservative range of the likely impacts of transportation, the EIS does not attempt to speculate on potential improvements to the highway infrastructure and vehicles that could increase safety, such as intelligent vehicles, enhanced traffic monitoring and control, improved braking systems, improved tires, etc.

8.8.1 (4651)
Comment - EIS001462 / 0002
I agree with most of the statements except for one thing. The use of the linear no-threshold models predict health risks and deaths to the public, grossly exaggerates the risks inherent to storage and moving nuclear waste.

Response
Sections 6.1.1 and J.1.1 of the EIS provide the definitions of accident risk and dose risk used in the EIS impact analyses. DOE recognizes that, although studied extensively for over 75 years, there is still much that is not understood about the health effects of exposures to low level radiation. However, the Department is not aware of any substantial, peer-reviewed literature that indicates disproportionate harm associated with exposure to low-level radiation.

Because of uncertainties in the low-dose/dose-region of the dose effect curve, DOE has selected, for use in the EIS, dose-to-risk factors recommended by the National Council on Radiation Protection and Measurements (DIRS 101856-NCRP 1993) and the International Commission on Radiological Protection (DIRS 101836-ICRP 1991) for estimating the risk of latent cancer fatality from exposure to ionizing radiation. These factors were developed based on the linear no-threshold hypothesis, which assumes that adverse health effects could occur from exposure to ionizing radiation regardless of how small the dose.

DOE, as well as national and international scientific advisory organizations such as the Federal Radiation Council (FRC 1960), the International Commission on Radiation Protection (DIRS 147927-ICRP 1966), the National Council on Radiation Protection and Measurements (DIRS 101857-NCRP 1993), the National Academy of Sciences/National Research Council Committee on the Biological Effects of Ionizing Radiation [BEIR V] (DIRS 100473-National Research Council 1990), and the National Academy of Sciences/National Research Council Committee on an Assessment of CDC Radiation Studies (NRC 1995), have recognized for many years that the use of dose-to-risk conversion factors based on the linear no-threshold hypothesis to estimate stochastic effects (such as latent cancer fatalities) from very low exposures to ionizing radiation might overestimate the actual risk. These organizations have been careful to point out over the years that the use of the risk factors derived using the linear no-threshold hypothesis will provide reasonable assurance the actual effect would not be underestimated. For these reasons, the linear no-threshold hypothesis has been accepted for use by Federal agencies—including DOE, the U.S. Environmental Protection Agency, and the Nuclear Regulatory Commission—for radiation protection and for estimating risk from exposure to ionizing radiation. Until such time as these advisory committees change their acceptance of the linear no-threshold hypothesis and the Federal agencies agree that these changes should be incorporated, DOE will continue to use risk factors recommended by the national and international advisory groups that are based on the linear no-threshold hypothesis.

8.8.1 (4889)
Comment - EIS000337 / 0029
Page 6-24, Table 6-6. I want to know the exposure to a person with a baby who is next to a mostly legal-weight truck that is stopped next to her in a traffic jam where she is not more than 10 feet from the truck. This should be included in the Table 6-6.

Response
The actual exposure would be less than 0.02 rem indicated in the cited table. The exposure distance used in the assessment was 1.2 meters (4 feet), rather than the 3 meters (10 feet) suggested by the comment. The calculated doses are listed in Tables 6-9 (mostly legal-weight truck scenario) and 6-12 (mostly rail scenario). The exposure to a pregnant woman would be the same as the exposure to another individual the same distance from a shipment. Section J.1.3.2.2 of the EIS provides more details on the methods used to evaluate radiological doses to maximally exposed individuals.

8.8.1 (5145)
Comment - EIS001911 / 0004
An analysis of Yucca Mountain must include a complete analysis of transportation issues, including routes, transportation packages, and health and safety concerns.

Response
A complete analysis of transportation issues is presented in Chapter 6, Appendix J, and Appendix M of the EIS. Specifically addressed are issues such as routes, packages (casks), and health and safety.

8.8.1 (5192)
Comment - EIS001443 / 0017
Specific Recommendation: The DEIS should include results of a comprehensive national-scale risk analyses to determine least-risk based solutions to the question of which roadway and rail corridors to use to increase the predictability of waste transportation operations. The risk analysis should provide the quantitative information necessary to confirm or deny the value of each reasonable potential transportation scenario. Impacted populations and resources should be clearly identified in the DEIS. DOE should use the results of this analysis to systematically dictate routes to private carriers. The value of the Chalk Mountain Route for achieving major reductions in risk to civilian populations should be quantified and discussed. The specific assumptions used by the RADTRAN4 model should be discussed by the DEIS.

Response
Chapter 6 and Appendix J of the EIS present the results of a comprehensive national-scale risk analysis. This Final EIS expresses the DOE preference for the mostly rail as mode of transportation, both nationally and in Nevada. However, the purpose of the EIS is not to choose or identify national transportation routes, select a rail corridor, or dictate routes to private carriers. As discussed in Section M.3.2.1.2, carriers would follow U.S. Department of Transportation and Nuclear Regulatory Commission requirements in determining their routes. These routes would be part of the transportation plan that the carrier would prepare and that DOE would provide to states for comment. DOE and the Nuclear Regulatory Commission would approve the final routes.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site is approved. The introduction to Chapter 8 of this Comment-Response Document contains additional information.

The results of the transportation analyses described in Chapter 6 and Appendix J show that the impacts of using any of the candidate routes would be low. Appendix J summarizes the specific assumptions used in the RADTRAN computer code. The references cited in Appendix J provide more details.

8.8.1 (5289)
Comment - EIS001887 / 0035
The use of the all train scenario is especially problematic because, given the lack of rail access to Yucca Mountain, there is no justification for it. The Draft EIS, as discussed elsewhere in these comments, does not demonstrate that rail or intermodal (rail to heavy-haul truck) access to Yucca Mountain is feasible. Therefore, assuming that all spent fuel and HLW [high-level radioactive waste] can be shipped to the site via rail is inappropriate.

Response
The feasibility of constructing a branch rail line to the proposed repository was evaluated in *Nevada Potential Repository Preliminary Transportation Strategy* (DIRS 104795-CRWMS M&O 1995) and CRWMS M&O (DIRS 101214-1996). The results of these studies identified four candidate rail corridors deemed feasible based on AREA (American Railway Engineering Association) guidelines. An additional (fifth) corridor was added in 1997.

The two documents listed above evaluated and confirmed the feasibility of heavy-haul truck transportation in Nevada, based on current regulations, highway conditions, and Nevada Department of Transportation history associated with heavy-haul truck permitting.

8.8.1 (5291)
Comment - EIS000968 / 0008
A traffic safety study should be included.

Response
DOE interpreted this comment as a criticism of the scope of the transportation impact analysis in the EIS. The Department believes that the scope of the analysis is adequate. It based the development of the scope on current repository planning, reviews of past National Environmental Policy Act documentation related to the permanent disposal of spent nuclear fuel and high-level radioactive waste [for example, the *Nuclear Waste Policy Act*

(Section 112) Environmental Assessment, Yucca Mountain Site, Nevada Research and Development Area (DIRS 101314-DOE 1986)], and public scoping meetings. In 1995, DOE conducted 15 public scoping meetings across the U.S and solicited comments on the scope of this EIS, and used this information to shape the scope and analytical approaches used in the EIS.

DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada if the site was approved. However, follow-on implementing decisions, such as the selection of a specific rail alignment in a corridor, or the specific location of an intermodal transfer station in Nevada or the need to upgrade heavy-haul truck routes, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

In general, traffic safety studies support detailed designs of new transportation infrastructure (highways, crossings, traffic signals, bridges, etc.), select specific routes, and provide useful insights to infrastructure alignment in a corridor.

8.8.1 (5374)
Comment - EIS001887 / 0091
Page 2-40; Section 2.1.3.2 - National Transportation

The analysis of national transportation impacts associated with the Proposed Action contained in the Draft EIS is both legally and substantively deficient. The Draft EIS presents an inappropriately generic analysis of impacts; fails to identify cross Country shipment modes and routes that would be necessary to implement the Proposed Action; ignores impacts to corridor cities and communities across the nation; misrepresents actual shipment volumes; underestimates the impacts of worse case accidents and terrorist/sabotage events; understates the potential health effects of routine, non-accident shipment operations; employs unrealistic shipping scenarios as the basis for analysis; ignores potentially significant and pervasive socioeconomic impacts associated with the massive and unprecedented shipping campaign required to move waste from generator locations to Yucca Mountain; and generally understates risks to health, safety, and the environment.

Response
The EIS analyzes the potential environmental and socioeconomic impacts that could occur, directly and indirectly, as a result of the construction, operation, and eventual closure of the monitored geologic repository at the Yucca Mountain site. Quantitative human health and safety impacts, as well as other environmental and socioeconomic impacts (for example, impacts on land use, water resources, biological resources, employment), for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain are presented in Chapter 6 and Appendix J of the EIS. The transportation impact analysis in the EIS is consistent with the requirements of the National Environmental Policy Act, Council on Environmental Quality guidelines, and DOE policies and guidance.

The EIS was designed to provide the quantitative information necessary to support the decisions to be made based on the EIS. As stated in the Overview of the EIS Summary:

"DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada…Other transportation decisions, such as selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews."

The commenter is correct in that the EIS does not present the impacts to specific people, specific communities, and specific elements of the environment along the national transportation routes, although this information is presented for the State of Nevada. The scope and level of detail for the transportation impact analysis is consistent with National Environmental Policy Act requirements, Council on Environmental Quality guidelines, and DOE policies and procedures.

The analysis is route- and location-specific to the extent needed to support the decisions to be made on the basis of the information contained in this EIS. Development and presentation of impacts to each potentially affected community along the transportation routes would not materially affect the comparisons of alternatives and decisions to be made with regard to construction and operation of the proposed repository. Transportation routing decisions would occur in the future, and would be conducted in accordance with U.S. Department of Transportation routing guidelines and Nuclear Regulatory Commission regulations governing safeguards and security for shipments of spent nuclear fuel.

Because the risks of the entire shipping campaign are small in relation to other risks commonly encountered and accepted by the public, DOE does not believe that nationwide, location-specific impacts for all highway and rail routes would provide any useful insights or beneficial information required to make the decisions to be made from this EIS. Potential impacts to the environment along these routes, such as impacts to water, biological resources, land use, etc., are not quantified in the EIS because no new land acquisition or construction is required to accommodate these shipments. Potential environmental impacts within Nevada are quantified because new construction will be needed to implement the rail and heavy-haul truck alternatives.

The analysis is route-specific to the extent needed to support the decisions to be made on the basis of the information contained in this EIS. Although some "generic" data is used, the analysis used route-specific population distributions, shipping distances, numbers of shipments, etc., and state-level information on accident rates. Special considerations are given to calculating the transportation impacts in Nevada. Nevertheless, in response to comments, DOE has provided in Appendix J of the EIS the detailed state-by-state maps of highway and rail routes used in the analysis in the EIS leading from generator sites to the Yucca Mountain site, the numbers of shipments on each route, and state-by-state impacts (see Section J.4).

DOE has used the best information that was reasonably available on spent nuclear fuel and high-level radioactive waste characteristics and quantities to evaluate transportation impacts (see Appendix A of the EIS). DOE has performed extensive evaluations to project shipping cask capacities that were used in the EIS to determine shipment volumes (see Section J.1.2). In addition, the transportation scenarios were constructed to bracket the total shipment volumes, which would be maximized for a near 100 percent mostly legal-weight truck scenario and minimized for a near 100 percent mostly rail scenario. Transport mode selection is further explained in Section M.3 and in the Request for Proposals for Waste Acceptance and Transportation Services (DIRS 153487-DOE 1998) and located at *http://www.rw.doe.gov/wasteaccept/wasteaccept.htm*.

The National Environmental Policy Act requires assessment of reasonably foreseeable impacts from proposed agency actions. In its various EISs, DOE has defined a reasonably foreseeable accident as one that has a frequency of occurrence of at least once in 10 million years (1×10^{-7} per year). The concept of a maximum reasonable foreseeable accident is sometimes misinterpreted as being a "worst-case" accident.

While the character of the spent nuclear fuel shipments for the project could appear to present opportunity for sabotage, DOE believes these shipments would not be attractive targets in that they would not provide the opportunity for a large number of fatalities or a symbolic blow against a symbol of the nation. DOE also believes that a shipment of spent nuclear fuel or high-level radioactive waste would be an unlikely target in part due to the physical security measures imposed by the Nuclear Regulatory Commission regulations. Under certain conditions, armed escorts would either follow or ride in the truck cab or an escort railcar. DOE would monitor its spent nuclear fuel and high-level radioactive waste shipments through a satellite-based tracking system.

For the Final EIS, DOE reexamined, for both rail and truck casks, the consequences of an attack that results in a release of material (in other words, the cask's shield wall is penetrated) (see Section 6.2.4.2.3 of the EIS), and estimated consequences exceeded those presented in the Draft EIS. Differences in the consequences between the Draft EIS and the Final EIS are due to using "representative" spent nuclear fuel isotopics (as opposed to "typical" in the Draft EIS) and an escalation of impacts to represent population growth to 2035. In addition, in the Draft EIS, the consequences of the sabotage event were bounded by those of the maximum reasonably foreseeable accident. However, the Final EIS analyses estimated that a sabotage event could cause 48 latent cancer fatalities if a legal-weight truck cask was penetrated and 9 latent cancer fatalities for a rail cask.

DOE is aware that there are uncertainties associated with the transportation impact results presented in the EIS. There are uncertainties associated with route characteristics, demographics, weather, atmospheric dispersion models, spent nuclear fuel characteristics, accident rates, release fractions, and many other elements of the risk assessments. Because one of DOE's goals is to choose between alternatives, the consistent consideration of uncertainty among alternatives means that the relative differences in impact estimates among alternatives should not be affected. To account for uncertainties in the data, conservative assumptions were made so the impacts reported in the EIS considers the range of associated potential impacts (that is, they would produce results higher than the true risk). However, DOE has chosen not to use assumptions that would result in overestimation of impacts in all cases, as this practice tends to produce unrealistic and improbable results. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing environmental impacts. Such practices mask the real differences and would not produce suitable results to support choices among the alternatives.

The EIS presents potential environmental and socioeconomic impacts that could occur, directly or indirectly, as a result of the proposed siting, construction, operation, and eventual closure of a monitored geologic repository at Yucca Mountain, including transportation activities. The scope and level of detail of the socioeconomic impact analysis is consistent with the National Environmental Policy Act, Council on Environmental Quality guidelines, and DOE policies and guidance.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments, and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $9.4 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

Should Yucca Mountain be selected as the site for the monitored geologic repository, DOE would continue to provide clear, accurate information to the public regarding the potential risks of a repository at the site and of transporting waste to the site so members of the public could understand the level of risk that actually existed (rather than perceived) associated with construction, operation, and closure of the Yucca Mountain Repository and related transportation activities.

8.8.1 (5449)
Comment - EIS001887 / 0138
Page 2-79; Section 2.4.4.1 - National Transportation

The summary of national transportation impacts is based on inadequate and incomplete data and analyses and does not reflect the impacts posed by the Proposed Action to people, communities, and the environment along national shipping routes. Since specific routes are never identified, analyses of impacts to at-risk communities are never attempted in the Draft EIS. No effort is made to identify and evaluate the potential for substantial socioeconomic impacts in corridor states and communities (see comments relative to Sections 4, 5, and 6 below). The use of fatalities (either latent cancer fatalities (LCFs) or accident fatalities) as the measure of transportation impacts is inadequate and serves to grossly understate the full range of negative impacts on people and the environment associated with the Proposed Action. As noted in subsequent comments, the models and assumptions used to generate LCFs, transportation accident rates, and accident probabilities and severity are deficient and understate the consequences of a national shipping campaign of the size, complexity, and duration needed to implement the Proposed Action. In addition, entire categories of potential impacts (such as socioeconomic impacts, morbidity, quality of life, etc.) are simply ignored.

Response
The commenter is correct in that the EIS does not present the impacts to specific people, specific communities, and specific elements of the environment along the national transportation routes, although this information is presented for the State of Nevada. The scope and level of detail for the transportation impact analysis is consistent with National Environmental Policy Act requirements, Council on Environmental Quality guidelines, and DOE policies and procedures. However, in response to comments, DOE has revised Appendix J of the EIS to include the state maps showing routes used in the analyses in the EIS, estimated numbers of shipments in each state, and the impacts in each state (see Section J.4).

The transportation impact analysis in the EIS was designed to provide the quantitative information necessary to support the decisions to be made in the EIS. As stated in the Overview to the EIS Summary:

"DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada…Other transportation decisions, such as selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews."

The analysis is route- and location-specific to the extent needed to support the decisions to be made on the basis of the information contained in this EIS. DOE does not intend to designate routes based on the EIS. Rather, this would occur in the future, in accordance with U.S. Department of Transportation routing guidelines. The routes would be submitted to the Nuclear Regulatory Commission for approval.

Potential impacts to the environment along the routes, such as impacts to water, biological resources, land use, etc., are not quantified in the EIS because no new land acquisition or construction is required to accommodate these shipments (see Section 3.2.1 of the EIS). Potential environmental impacts within Nevada are quantified because new construction would be needed to implement the Nevada rail and heavy-haul truck implementing alternatives.

Throughout the EIS, the standard unit for measure of human health impacts is the risk of fatality. This approach was adopted for both radiological hazards and nonradiological hazards (for example, traffic accidents) to simplify the presentation of human health impacts and to facilitate the comparison of impacts among the alternatives. "Fatality" is an easily understood objective measure used historically in EISs prepared by DOE.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty
- Much of the uncertainty is irreducible, and
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents,

which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.8.1 (5889)
Comment - EIS001901 / 0003
California citizens have not had an opportunity to comment on the substance of the section on transportation of the draft EIS (DEIS). An example of the flaws in the DEIS is the method used by DOE to calculate the extent of a dust cloud. They used the average wind speed for the entire United States and the average model for the entire United States. This type of analysis reduces the impact of the local winds and atmospheric conditions found in California.

Response
As discussed in Section J.1.4.2.1, the EIS uses atmospheric conditions that are generally applicable throughout the contiguous United States because it is not possible to predict specific locations for accidents. These data were used to determine the most likely atmospheric conditions to prevail during a severe accident or act of sabotage. Two meteorological conditions were included in the assessment of the consequences of the maximum reasonably foreseeable accident. These included neutral or stable conditions, in which the consequences would not exceed 50 percent of time, in addition to stable conditions in which the consequences would be exceeded only 5 percent of the time. This was done to ensure that no accident scenarios that are otherwise credible would be excluded from the assessment of the maximum reasonably foreseeable accident because of a low probability of encountering stable atmospheric conditions. In other words, the already low frequency of occurrence of a severe transportation accident, when multiplied by the probability of stable atmospheric conditions, could have caused the accident scenario frequency to drop below the 1×10^{-7} per year cutoff that defines the frequency of the maximum reasonably foreseeable accident. Thus, the EIS attempts to ensure that maximum reasonable accident scenarios are not eliminated from the assessment in the EIS because of a low probability of specific weather conditions.

8.8.1 (5949)
Comment - EIS001622 / 0051
The DEIS lacks a complete and accurate project description. There is no description of transportation of radionuclide waste through California, no environmental consequences evaluation, and no mitigation offered. The DEIS should disclose the potential level of shipments through California, and evaluate potential impacts. In particular, transportation routes could potentially impact habitat for the Amargosa nitrophila, Nitrophila mohavensis, Amargosa vole, Microtus californicus scirpensis, State and Federal Endangered, and desert tortoise, Gopherus agassizii, State and Federal Threatened. The DEIS should include a description of transportation routes, improvements, impacts to these species as well as other State Species of Special Concern, and proposed mitigation measures to offset these impacts.

Response
The transportation impact analysis in the EIS was designed to satisfy the requirements of the National Environmental Policy Act, Council on Environmental Quality guidelines, and DOE policies and guidance. It was also designed to provide the information necessary to support the decisions to be made in the EIS. Lists of the threatened and endangered species, sensitive species, game habitat, springs, and riparian areas known to occur within 5 kilometers (3 miles) of rail corridors have been added to Appendix J of the EIS and those resources have been described more fully in Section 3.2.2.1.4. Sections 6.3.2.1 and 6.3.2.2 have been modified to better describe the impacts to biological resources within 5 kilometers of corridors.

Potential impacts to the environment along the national transportation routes, such as impacts to water, biological resources, land use, etc., are not quantified in the EIS because no new land acquisition or construction is required to accommodate these shipments (see Section 3.2.1 of the EIS). As a result, the EIS focuses on potential impacts to human health and safety along these routes. An environmental baseline characterization of every shipment corridor would not be practical nor would the information be needed to support the decisions to be made from this EIS. In response to comments on the Draft EIS, DOE revised Appendix J to include state route maps, the numbers of shipments in each state, and state-specific health and safety impact estimates, including data for California (see J.4). This is in addition to the route maps that were already included in the Draft EIS (see Section 2.1.3.2 for national routes and Section 2.1.3.3 for Nevada maps).

With regard to evaluating the impacts on specific species, the EIS follows the National Environmental Policy Act and the Council on Environmental Quality guidance on evaluating potential impacts to biota. Basically, plants and animals are no more sensitive to radiation than humans. Both acute and chronic radiation doses that do not adversely affect humans are not known to affect terrestrial species of plants and animals. The *Effects of Ionizing Radiation on Plants and Animals at Levels Implied by Current Radiation Protection Standards* (DIRS 103277-IAEA 1992) reports that there is no convincing evidence that indicates that the current radiological dose standards for humans will harm animal or plant populations. In other words, if humans are adequately protected, plants and animals are likely to be adequately protected.

Additional site-specific information would be necessary prior to construction of a branch rail line or road upgrades to support heavy-haul truck shipping. However (and as stated in the Overview in the EIS Summary), DOE believes that the EIS provides sufficient information on impacts (such as those to biological resources) necessary to make cetrtain decisions regarding the basic approaches (for example, mostly rail or mostly truck shipments) as well as the choice among alternative transportation corridors. Follow-on implementing decisions, such as selection of a specific rail alignment within a corridor, would require additional field surveys, state, local, and tribal government consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

Chapter 9 of the EIS provides DOE's initial list of commitments available at this time, identifies DOE-determined impact reduction features, procedures and safeguards, and mitigation measures under consideration for inclusion in the project plan and design. Chapter 9 also identifies ongoing studies that could eventually influence mitigation measures related to the project plan and design.

As indicated in Chapter 6 of the EIS, more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews would be prepared if a decision was made to select a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes. This would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. Besides field surveys, this would include (as applicable) more detailed assessments and analyses of wetlands and other waters; floodplains; sensitive species; effects of habitat fragmentation, interruption of movements, mortality, and harassment on wildlife, horses, and burrows; loss of hunter-generated revenue, spread of noxious weeds, and soils.

8.8.1 (5991)
Comment - EIS001879 / 0017
The Draft EIS assumes that the typical spent fuel assembly has been enriched to less than 3.7 percent and has been stored on site at least 25 years after discharge from a nuclear reactor (pg. A-14). However, waste acceptance criteria permit shipment of more highly enriched, more highly irradiated and much younger (more radioactive) fuel to be shipped to Yucca Mountain. Nye County believes that a revised EIS should examine the effects of shipment of more highly radioactive material. Furthermore, the EIS should consider mitigating policies by which such fuel would be shipped only in sealed canisters that would not be unsealed for either storage or emplacement.

Response
The EIS now analyzes impacts of shipping younger, hotter fuel to the proposed repository at Yucca Mountain. It is true that DOE could ship some spent nuclear fuel that is more radioactive than the 26 year-old pressurized water reactor spent nuclear fuel analyzed in the Draft EIS scenario. Based on comments received and DOE's additional review of technical documents and conduct of hazard analyses, the basis for the transportation impact analysis has been revised to consider commercial spent nuclear fuel that has median hazard. Pressurized water reactor spent nuclear fuel having median hazard would be discharged from a reactor approximately 15 years before shipment to Yucca Mountain. The radionuclide inventories of the representative spent nuclear fuel used in the analysis are presented in Tables A-9 and A-10 of the EIS.

Fuel would be shipped either as uncanistered assemblies or in a sealed canister. The sealed canisters currently (January 2001) certified by the Nuclear Regulatory Commission can be used for storage and transport, but not for ultimate disposal. Therefore, the canisters would need to be unsealed at the repository and the fuel transferred to a waste package. If multipurpose (storage, transport, disposal) canisters were certified by the Commission, DOE would utilize them for disposal.

8.8.1 (6021)

Comment - EIS001679 / 0001

Railway in US is predominately privately owned. There is currently no responsibility of the Dept of Transportation to regulate Americas railways. DOE has relied only on CALTRANS to report on the safety of the railway in California. I submit to you that the DOE does not have adequate information regarding the safety of the rails and whether they are capable of safely carrying this dangerous material. Before moving forward I request that DOE commission an independent study on the safety of rails that are supposed to be used. Accident records and worker safety and staffing. The railways in Calif. are not being studied by anyone. How can you move forward without this valuable information?

Response

The U.S. Department of Transportation is the regulatory agency responsible for establishing and enforcing the standards for rail transportation. The Federal Railroad Administration, which is a branch of the U.S. Department of Transportation, is responsible for safety of the rail system, including track, locomotives, highway crossings, incident reporting, brake systems, etc. The Federal Railroad Administration regulations are provided in 49 CFR Parts 200 to 266.

Adequate rail lines, crossings, bridges, and tunnels exist to support the transportation of materials described in the EIS. The shipment of radioactive materials requires no special transportation infrastructure that is not necessary for safe transport of commodities in the United States today.

8.8.1 (6040)

Comment - EIS001580 / 0006

We believe they [DOE] have misrepresented the radiologic risk by using older, cooler, less radioactive fuel as their waste. We believe they've grossly underestimated routine radiation exposures, particularly at the end of the transportation funnel in Nevada. We believe they've significantly underestimated both the human health consequences and the economic costs of severe accidents, which they acknowledge could release significant amounts of radioactive materials.

Response

The EIS has been revised to use 15-year old, 50,000 megawatt-days per metric ton of heavy metal burnup spent nuclear fuel in the analysis of transportation risk. The EIS has also been revised to estimate impacts based on populations projected for 2035.

A discussion on the costs of cleanup has been added to the EIS. According to the Nuclear Regulatory Commission report *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152456-Sprung et al. 2000), in 99.99 percent of accidents involving transportation of spent nuclear fuel there would be no release of radioactive material from the cask. The economic costs of these accidents would be small.

In 0.01 percent of accidents some radioactive material could be released from the cask. Based on the studies discussed in Appendix J of the EIS, the economic costs of severe transportation accident involving spent nuclear fuel could be in the range of as little as $200,000 to $270 billion. However, extreme cost estimates are for accidents where all factors are assumed to combine in the most detrimental way to maximize consequences. Such extreme, or worst-case, accidents are not reasonably foreseeable so the estimates of cost are not useful for comparisons. The probability of the accidents analyzed in the studies range from about 1 in 1 million per year to less than one in 1 trillion (1 followed by 11 zeros) per year.

The current insured limit of responsibility for an accident involving releases of radioactive materials to the environment is $9.43 billion. Section M.8 of the EIS provides additional information on accident liability.

8.8.1 (6050)

Comment - EIS001580 / 0010

DOE has significantly overestimated the extent to which this waste can be moved by rail. They are optimistic and think they can move 90 percent of it by rail. We've looked at the same information site by site. We think they will only be able to move 50 to 60 percent by rail. The result is there will be many tens of thousands of truck shipments occurring at the same time that there are about ten thousand rail shipments.

Response
Page 6-1 of the Draft EIS clearly states the assumptions used to estimate the impacts of transportation. The mostly rail scenario assumes all waste generator sites with the capability to handle a heavy rail cask would ship by rail. The mostly legal-weight truck scenario assumes all waste except Navy fuel would be shipped by truck. These two scenarios represent the associated range of the possible combinations of rail and truck shipments.

DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE considered the capabilities of the sites to handle larger (rail) casks, the distances to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste or other large reactor-related components. DOE also considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada. In addition, DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada.

Nonetheless, in response to comments, DOE has analyzed the effects of different mixes of rail and truck shipments. The results of this analysis confirm DOE's estimate that the mostly rail and mostly legal-weight truck scenarios represent a reasonable range (lower and upper bound) of potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

8.8.1 (6152)
Comment - EIS001654 / 0033
The potential for transportation of the waste to "affect workers and the public through exposure to radiation and vehicle emissions, and through traffic accidents" is listed as an unavoidable adverse impact. There is substantial and adequate detailed information and analysis on that potential in Chapter 6. While there are less vehicle emissions and traffic accident impacts in the No Action Alternatives, the radiological impacts are substantially less under the Proposed Action than by leaving the waste at the 77 sites for 10,000 years under either scenario.

Response
Section 7.2.1.7.3 of the EIS discusses the radiological impacts of the No-Action Alternative. Table 2-7 in the EIS compares the estimated impacts of the Proposed Action and the No-Action Alternative. The table demonstrates that the total life-cycle health impacts of the Proposed Action are smaller than those of the No-Action Alternative even though the No-Action Alternative does not include impacts from transporting spent nuclear fuel and high-level radioactive waste to the repository.

8.8.1 (6326)
Comment - EIS001609 / 0002
During the Q and A session I asked several questions about transport. One of the questions I asked was regarding the assessment, regarding the environmental impact based on transport, you know, what traffic flow models were used. And the answer that I got, were no traffic flow models were used. The exposure, the risk was based on exposure per cask by number of casks, not taking into account traffic flow whatsoever. I think that's a little weird.

Response
The radiological impact modeling presented in Section J.1.3 of the EIS of the included the effects of reduced traffic flow, including the impact on an individual stuck in traffic. In addition, Section J.1.3 provides the average transporter speeds for rural and urban travel.

The estimated exposure of a person stuck in a traffic jam for 1 hour sitting 1.2 meters (4 feet) from a spent nuclear fuel cask is given in Section 6.2.3 of the EIS.

8.8.1 (6502)
Comment - EIS001632 / 0037
Impact on ground water from transport spills. The draft EIS assesses the impact of spills on surface water, but the final EIS should also assess ground water contamination from a surface spill. The transportation impacts analysis should consider ground water recharge zones and the proximity of transportation corridors to ground water supplies and community water systems.

Response

DOE does not specifically analyze a transportation accident, such as a spill, involving contamination of surface water or groundwater because the casks are designed to be water tight and spent-nuclear fuel and high-level radioactive waste are not easily dispersed in water. While small particles could be generated by the impact forces of an accident, and driven out of a shipping cask by a severe fire, the amount of contamination that might ultimately enter groundwater would be much lower than that which would initially enter surface waters. Factors such as soil sorption of radionuclides, rate of flow into recharge areas, dilution by rain water and surface water, dilution by the large volume of ground water, and delay associated with infiltration would mitigate and greatly reduce any contamination that might occur. Although DOE's analyses in Chapter 6 take into account the proximity of surface waters and ground water basins (see Section 6.3.2.2.1 of the EIS as an example), water pathway contamination, including subsequent contamination of food and natural resources, would not be a significant contributor to the radiological risks of transporting spent-nuclear fuel. Analyses performed in previous EISs (see Section 1.5.3 and Table 1-1) have consistently shown that the airborne pathway has the greatest potential for exposing large numbers of people to radioactive material in the event of transportation accident resulting in the release of radioactive materials. DOE has, however, identified potential mitigation measures for surface water and groundwater from the construction and operation of transportation systems. The reader is referred to Sections 9.3.3.1 and 9.3.3.2.

While DOE believes the information presented in these sections of the EIS are sufficient to assess the relative merits of the alternatives, the Department acknowledges additional environmental reviews would be required to assess the potential impacts of such things as specific alignments through a transportation corridor.

8.8.1 (6511)

Comment - EIS001241 / 0014

Does low-level radiological exposure decrease proportionally as rail speed increases?

Does low-level radiological exposure increase proportionally as rail speed decreases.

Would nuclear waste rail cars travel slower in densely populated?

Response

Radiation doses to individuals and populations in areas shipments pass through are inversely proportional to the speed of the transport vehicle through the area. In other words, radiological exposures decrease as speed increases, and increase as speed decreases. See the RADTRAN 4: Volume 3, User Guide (DIRS 101888-Neuhauser and Kanipe 1992) for additional information on the formulae used to calculate incident-free exposures from a moving shipment.

Trains travel slower in densely populated areas than in rural areas. Section J.1.3.2.1 of the EIS provides the shipment speeds used in the transportation impact analysis. As shown, the shipment speed in urban areas is slower than that in suburban areas, which are in turn slower than the speed in rural areas.

8.8.1 (6569)

Comment - EIS001632 / 0057

Page 6-20, third bullet: The term "dose risk" is not a standard term. What does it mean when used in the phrase, "to estimate radiological dose risk to populations"?

Response

DOE defined "dose risk" in a text box in Section 6.1.1 of the EIS as follows:

"Dose risk is the sum of the products of the probabilities (dimensionless) and the consequences (person-rem) of all potential transportation accidents."

8.8.1 (6634)

Comment - EIS001878 / 0027

Impacts of transportation alternatives pre-judged. Before the DEIS even describes the proposed action, the environment that would be affected, or the anticipated environmental impacts, it concludes that "environmental impacts do not appear to be a major factor in the selection of transportation mode, route, or corridor in Nevada for incoming rail shipments." (p. 2-81) Such a conclusion is inappropriate under the description of the proposed action and no-action alternative and, in any event, is unsupported by any evidence and therefore conclusory. The DEIS acknowledges that there are differences in environmental impacts for the 10 implementing alternatives for rail shipments in Nevada.

Response

The statement referred to by the commenter appeared in Section 2.4 of the Draft EIS. Under 10 CFR 1502.14, the recommended format for preparing an EIS is to provide such a summary of findings along with the description of alternatives for the proposed action. As the title of Section 2.4 indicates, this section is a summary of information and impact estimates that appear elsewhere in the document that provide the supporting evidence for DOE's conclusions. The EIS fully describes the Proposed Action for Nevada transportation in Section 2.1.3.3, the environment that would be affected in Section 3.2.2, and the impacts of Nevada transportation in Section 6.3. The commenter is correct in that the EIS acknowledges that there are differences in environmental impacts between the 10 implementing alternatives for rail shipments in Nevada. However, the EIS states that these differences would be small, with the exception of land-use and environmental impacts for each of the 10 implementing alternatives (Section 2.4.4.2).

8.8.1 (6638)

Comment - EIS001160 / 0088

Page 2-80, Table 2-8: This table is unclear to the reader in that it doesn't define time parameter being measured. Does the table imply that the Maximally exposed individual receives 48 rem per year; over the course of all shipments; and so on? Units of measure should be defined over what time period, number of individuals exposed (i.e. collective dose stats) or in percentages based on shipments. The DEIS lacks sufficient information to allow the reader to deduce from either the table or appendices how these figures were arrived at. A maximally exposed individual receiving 48 rem per year (about 10 times maximum allowed under U.S. Federal Radiation Counsel Guidelines and 24 times the maximum accepted as safe practice by DOE) would have significant health risks. Even if this individual was exposed over the course of 10 years, his latent cancer probability should, on the basis of the logic in the DEIS, be about 10 times what the table predicts. The table itself should reference the appendices and how this data was developed and how those figures were arrived at, including related references.

Response

The commenter is correct in that Table 2-8 in the Draft EIS (Table 2-9 in the Final EIS) did not clearly identify the time period over which the exposure occurs. The actual estimate is based on the entire period of transportation operations supporting the repository. Thus the 48 rem calculated for the maximally exposed worker would be the dose received over 24 years and is appropriately expressed in units of rem. This dose is a conservative upper limit dose to a maximally exposed individual worker and is based on a maximum annual dose of 2 rem for a worker at a DOE facility permitted under current DOE radiological safety guidance (2 rem for 24 years equals 48 rem). Section 6.2.3.1 of the EIS discusses the basis for this estimate. The table was clarified in the Final EIS.

Comment - EIS001466 / 0003

I want to talk a little bit about the shipments, because there were speakers who said, this is perfectly safe, we're very confident that there's not going to be any problem; and I just want to talk about what these things represent, because that was something that I found amazing at the Yucca Mountain project information center in Las Vegas.

I went through the whole place looking for a definition of radioactivity or what its significance is, and the closest thing I found was a place where it was talking about the radioactive particles, and there was one sentence that said "radiation can cause changes in human tissue." And that was the closest thing to an admission that there might be health effects associated with radioactivity in the whole Yucca Mountain project information center.

Response

Appendix F of the EIS provides a primer that explains the nature of radiation and toxic materials, radiation sources in the environment, radiation effects on human health, and toxic material effects on human health

The EIS contains numerous statements that operation of the proposed repository and associated transportation of spent nuclear fuel and high-level radioactive waste could result in health effects. For example, Section 6.1.1 of the

EIS states that an estimated 2.5 latent cancer fatalities could occur in the general population along transportation routes from radiation exposures resulting from the 24-year campaign of incident-free transport of spent nuclear fuel or high-level radioactive waste.

8.8.1 (7009)
Comment - EIS000402 / 0005
The equipment used, the trucks, trains, caskets, barrels and roads are they 100 percent safe. Has the weather and other environmental factors been taken into account? Would you allow your family to be nearby as the waste is transported?

Response
Although DOE expects that accidents would occur during the transportation of spent nuclear fuel and high-level radioactive waste, families would not be subjected to undue risks from the transportation of spent nuclear fuel and high-level radioactive waste to the proposed repository. To ensure the safe transportation of these materials, DOE would use shipping casks built to the rigorous design standards for Type B containers established by the Nuclear Regulatory Commission (see 10 CFR Part 71). Type B containers are designed and built to retain their radioactive contents in both normal and accident conditions. In addition, there is substantial empirical data on the performance of shipping casks designed for the safe transport of spent nuclear fuel and high-level radioactive waste. In tests, casks have been rammed by high-speed trains, smashed into solid concrete structures, immersed in high-temperature fires, and submerged underwater. The results of these tests have confirmed that Type B casks can sustain severe transportation accidents while maintaining their safety functions. An analysis of the cask response to accident forces, referred to in the EIS as *Reexamination of Spent Fuel Shipment Risk Estimates* (Sprung et al. 2000), estimates that less than 0.01 percent of all accidents would generate forces that could lead to a release of radioactive material from a Type B shipping cask. Based on the evaluation in the EIS, no radiological impacts are projected for either the mostly legal-weight truck or mostly rail scenarios.

Weather and other environmental factors might contribute to the occurrence of accidents. Weather-related accidents are included in the state-specific accident rates use in the EIS to calculate the impacts of transportation accidents and are thus taken into account in the EIS.

DOE is confident that the transportation of spent nuclear fuel and high-level radioactive waste can be conducted in a safe and environmentally acceptable manner. The doses to maximally exposed individuals from routine (incident-free) transport, as well as the impacts from maximum reasonably foreseeable accidents, would not result in any radiation-induced prompt fatalities or latent cancer fatalities.

8.8.1 (7066)
Comment - EIS001337 / 0022
The County [Lincoln] and City [Caliente] recommended that the DEIS consider operational alternatives including escorted versus unescorted shipments; time of day travel restrictions versus unrestricted transport; and use of local versus non-local trucking firms. The first two were suggested for consideration for their contribution to risk management. The third option set was recommended for evaluation to determine regional economic benefits. The DEIS does not consider operational alternatives for legal weight trucks as recommended by the County and City during scoping.

Response
All legal-weight truck transport would have to meet the requirements of 10 CFR Part 73 for physical protection (including escorts) for shipment of regulated quantities of irradiated reactor fuel. Highway routes would be selected in accordance with U.S. Department of Transportation regulations (49 CFR 397.101) for transporting highway route controlled quantities of radioactive materials. States or tribes may designate alternative preferred routes under 49 CFR 397.103. Additional information on regulatory requirements, security requirements, and proposed operational protocols for spent nuclear fuel and high level radioactive waste transportation to Yucca Mountain have been added to the EIS in Appendix M.

Appendix M of the EIS summarizes the draft request for proposal for waste acceptance and transportation services (DIRS 153487-DOE 1998).

8.8.1 (7157)

Comment - EIS001337 / 0053

The County [Lincoln] and City [Caliente] and comments to the scope of the EIS pointed out that risks associated with transportation of radioactive wastes through the County and City have been an important topic of local inquiry. The City and County pointed to research they sponsored which was performed by the University of Nevada, Las Vegas Transportation Research Center to evaluate the risks of transporting waste by highway and by rail through the area.* The study did conclude that the total accident risk (person rem) in the County for rail and highway transport was significantly greater than that estimated for other like areas around the United States. Total risk associated with rail and highway waste transport in rural areas of the County was also found to be significantly than that estimated for other like areas across the United States. In their comments, the County and City noted that although absolute levels of risk may be considered low, this study clearly indicates that residents of Lincoln County may be exposed to significantly greater levels of risk. The County and City urged DOE to recognize that the repository EIS must consider these differences as a means to ascertain viable options for reducing risk to levels commensurate with other regions of the United States. The DEIS does not provide a comparative assessment of transportation risks through Nevada, or more importantly Lincoln County and other regions of the United States. As a consequence important differences between levels of risk are not revealed. Within Nevada, the DEIS does demonstrate that risks of transporting waste through rural areas is riskier than through urban areas. However, the DEIS does not provide sufficient identification and evaluation of measure to mitigate greater risk levels in rural areas.

*Sathisan, Shasi et. al., Risk Analysis for Spent Nuclear Fuel Transportation Through Lincoln County Volume I: Rail Shipments, Volume IIA: Highway Shipments, Volume IIB: Technical Appendix, Transportation Research Center, Howard Hughes College of Engineering, University of Nevada, Las Vegas, February 1995.

Response

More than 9,000 rail shipments would pass through Caliente and Lincoln County over 24 years under the national mostly rail scenario. In addition, Caliente is under consideration as the location of an intermodal transfer station and is the starting point for several rail corridor and heavy-haul truck implementing alternatives. However, no shipments would pass through Caliente or Lincoln County under the mostly legal-weight truck scenario. The impacts from incident-free transportation and accidents would be low for either national transportation scenario (see Section 2.4.4.1 of the EIS). Therefore, the EIS demonstrates that the transportation of spent nuclear fuel and high-level radioactive waste would pose no undue risk to individuals or populations, either in Nevada or nationally.

DOE has not performed a comparative risk assessment of transportation through Caliente and Lincoln County with other areas of the country. The results of such an assessment are not necessary to support the comparison of alternatives and decisions to be made in the EIS. However, the Final EIS includes state-specific impacts, so this information is available on a state-by-state basis.

With regard to risk reduction and mitigation, DOE is committed to protecting human and environmental health as its first priority. Transportation of spent nuclear fuel and high-level radioactive waste would be conducted and risks would be managed in accordance with Federal regulations. These regulations are established to protect human health and safety. However, DOE will consider the costs and benefits of additional protective measures as it conducts more detailed transportation planning and studies to support the proposed repository. Section 9.3 of the EIS discusses potential measures under consideration to mitigate the impacts of transporting spent nuclear fuel and high-level radioactive waste to the proposed repository. Section M.3 presents information about DOE's current planning for transportation of spent nuclear fuel and high-level radioactive waste.

8.8.1 (7209)

Comment - EIS001337 / 0088

Pages 3-1 and 3-2 The listing of topics included in the description of the affected environment is not consistent with the topics assessed in the environmental consequence section. For example, under socioeconomic, housing and community services were considered as affected environment. In the environmental consequences section for Nevada transportation no estimates of the consequences to housing and community services is provided. This implies that the analysis of environmental consequences is incomplete in that it has not considered all aspects of the affected environment.

Response
Legal-weight truck shipments in Nevada would use existing highways. Because no new land acquisition or construction would be required, this EIS focuses on potential impacts to human health and safety and the potential for accidents involving legal-weight trucks.

For development of branch rail lines and heavy-haul truck capabilities, including an intermodal transfer station, Sections 6.3.2 and 6.3.3 of the EIS have been modified to discuss impacts to the various aspects of the potentially affected environment, including housing and community services.

8.8.1 (7459)
Comment - EIS001912 / 0034
Pg. 2-81 First Bullet states, "Environmental Impacts for each of the 10 implementing alternatives will be small." How can DOE make this statement when site-specific analysis for each route has not been completed?

Response
In Section 2.4 of the EIS, DOE summarizes that environmental impacts for each of the 10 implementing alternatives for shipments coming into Nevada by rail would be small. DOE bases this conclusion upon analysis of the existing information available for analysis; a full description of the proposed action for Nevada Transportation is found in Section 2.1.3.3; a full description of the environment that would be affected is described in Section 3.2.2; and the impacts of Nevada Transportation are more fully described in Section 6.3.

Based on the results of the impact analyses presented in Chapter 6 and Appendix J of the EIS, as well as the results published in numerous other studies and environmental impact analyses cited in the EIS, DOE is confident that spent nuclear fuel and high-level radioactive waste can be and would be safely transported to Yucca Mountain. DOE believes, as the EIS reports, that the potential impacts of this transportation would be so low for individuals who live and work along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured. The analysis presented in the EIS factored in the characteristics of spent nuclear fuel and high-level radioactive waste, the integrity of shipping casks that would be used in transport, and the regulatory and programmatic controls that would be imposed on shipping operations (see Appendix M of the EIS). The EIS analytical results are supported by numerous technical and scientific studies that have been compiled through decades of research and development by DOE and other Federal agencies of the United States, including the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as by the international community, including the International Atomic Energy Agency.

8.8.1 (7643)
Comment - EIS001912 / 0101
Modules 1 and 2 nearly double the amount of waste shipped to Yucca Mountain-but no additional latent cancer fatalities. Please explain how this can occur. Wouldn't it be reasonable to assume additional latent cancer fatalities would occur with an increase in shipments?

Response
The number of latent cancer fatalities from transportation does increase with the amount of waste shipped to the Repository. Section 6.2 of the EIS presents summaries of the impacts of transporting spent nuclear fuel and high-level radioactive waste for the Proposed Action. Section 8.4 presents the impacts of transportation for the Inventory Modules. The impacts presented in Section 8.4 are greater than those listed in Chapter 6.

8.8.1 (7655)
Comment - EIS001928 / 0012
Pg. S-53-3rd para. – There is some confusion on what constitutes a rail shipment. It is stated that the "…mostly rail scenario would involve approximately 13,400 cask shipments (10,800 rail shipments and 2,500 legal-weight truck shipments)". If it takes 10,800 rail shipments to transport 10,800 casks, then obviously, the load is only one cask per train. Surely, rail transport will be more efficient that that. Please clarify.

Response
Because DOE cannot predict the exact number of rail casks that would be transported in each train, it assumed conditions that would represent the upper range of the impacts of transportation. In completing its analysis, DOE

assumed that each rail cask would be shipped on a single railcar. Accident rates were used for general freight transport on a railcar-per-mile basis. This accident rate information is independent of the number of railcars containing casks that are transported in a single train. The analysis thus assumed that 10,800 shipments of rail casks would be made by 10,800 railcars, so all probable accident occurrences could be considered within the range of possible consequences.

8.8.1 (7671)
Comment - EIS000817 / 0016
Your EIS makes all the same mistakes NRC [Nuclear Regulatory Commission] made in certifying so called "generic" cask designs. You think you can create a scenario on paper that bounds all "generic" analysis of transportation so you don't look at specifics. You don't even know if rail or truck will be the priority mode. You don't even really consider the no action alternative as reasonable for implementation. You need to analyze impacts to specific national transportation routes based on available information and compare transport to leaving it in the states that created the waste.

Response
It is impossible for DOE to specify the exact mode of transportation for all shipments or the exact routes that would be used years before shipments would be made. However, even though DOE prefers that most shipments be made using rail, it should be recognized that some truck shipments would be required. This is why the EIS analyzes both truck and rail as modes of transportation.

The EIS compares the impacts of the Proposed Action and the No-Action Alternative. Section 2-4 of the EIS summarizes this comparison.

Because the specific casks that would be used for truck and rail shipments of spent nuclear fuel and high-level radioactive waste have not been designated, the EIS addresses the performance of generic cask designs in estimating transportation impacts. The important factors needed for this impact assessment are cask performance under normal and accident transport conditions and cask capacity. Any cask used by DOE would have to be certified by the Nuclear Regulatory Commission.

The transportation analysis presented in the EIS is not a generic analysis of transportation impacts. For example, the number of shipments is based on site-specific estimates of spent nuclear fuel discharges, not generic estimates. The analysis of transportation impacts was based on specific routes using route-specific population densities and distances, and state-specific information such as accident rates.

8.8.1 (7948)
Comment - EIS001903 / 0012
The list of bullet items on page J-39 and/or the discussion on pages J-40 and J-41 regarding the "second kind of information" and the third kind of information" should be clarified. For example, the first full paragraph on page J-41 states, "The third kind of information--the distances individuals live from the route used in the analysis--is the estimated the [sic] number of people who live within 800 meter…of the route." Is the "third kind of information" distances? If so, this information is not explicitly used in RADTRAN4, which assumes uniform population density within a 1-mile corridor. Or is the "third kind of information" population density? If so, How does this differ from the "second kind of information"?

Response
In response to comments, the transportation analyses in Appendix J of the EIS have been substantially revised to improve readability. The third kind of information – the distances individuals live from the route used in the analysis – is the distance from the transportation route that people live within the 800-meter (0.5-mile) corridor. This information is used to define the population density distribution inputted into RADTRAN5. The EIS has been changed to correct this error.

8.8.1 (8059)
Comment - EIS000391 / 0016
Mineral County wants it put on record that a "health assessment" (at the cost of DOE) should be done now of all the affected counties. This assessment would reflect what is out there now. By showing the present health situations

now, a case may be made for not adding to a potential number of latent cancer fatalities, and for documenting current health conditions prior to a radioactive waste accident.

Response
The EIS provides information on the radiation environment in the Yucca Mountain region in Section 3.1.8.2 and health-related mineral issues in Section 3.1.8.3. Additional information on the current conditions in the environment in the Yucca Mountain region can be found in the *Environmental Baseline File for Human Health*) (DIRS 104544-CRWMS M&O 1999). The region of influence for which data has been collected consists of land within 80 kilometers (50 miles) of the proposed repository site. Mineral County falls outside the region of influence for the proposed repository site. Mineral County is, however, within 80 kilometers of candidate transportation corridors to Yucca Mountain. However, it would not be practical to conduct a "health assessment" of all potentially affected transportation routes between the waste generator sites and the proposed repository.

8.8.1 (8139)
Comment - EIS001653 / 0084
Pg. 6-22 It does not appear that DOE considered the greater waste volume scenario in its transportation analysis, why? This should be part of the proposed action.

Response
Sections 8.4, J.3.4, and J.3.5 of the EIS quantify the transportation impacts of the greater waste volume scenarios, referred to in the EIS as Inventory Modules 1 and 2.

8.8.1 (8171)
Comment - EIS001653 / 0100
[Chapter 8] Modules 1 and 2 nearly double the amount of waste shipped to Yucca Mountain-but no additional latent cancer fatalities. Please explain how this can occur. Wouldn't it be reasonable to assume additional latent cancer fatalities would occur with an increase in shipments?

Response
The number of latent cancer fatalities from transportation does increase with the amount of waste shipped to the Repository. Section 6.2 of the EIS presents summaries of the impacts of transporting spent nuclear fuel and high-level radioactive waste for the Proposed Action. Section 8.4 presents the impacts of transportation for the Inventory Modules. The impacts presented in Section 8.4 are greater than those listed in Chapter 6.

8.8.1 (8218)
Comment - EIS001021 / 0006
I am concerned in general about the lack of DOE's solicitation of input from the academic medical community on medical safety issues regarding the overall Yucca Mountain plan. In particular, I worry about the potential adverse health effects on people who must load, unload and move the high-level radioactive waste across the country, and I worry especially about the people who inhabit the towns and cities like St. Louis, Missouri and Belleville and East St. Louis, Illinois, where the railroads pass and derailments are well known and common occurrences. We need a lot more information on nuclear transport accidents that have occurred in the 2,500 "successful" shipments of similar high-level radioactive wastes that I have read have already taken place in the U.S. Where can I get this information?

Response
Potential adverse health effects to cask handling personnel, truck and rail crews, and the general public are quantified in Chapter 6 and Appendix J of the EIS. A discussion of the basis for the health effects estimates from exposures to radioactive materials and toxic chemicals is provided in Appendix F. Information on past accidents that occurred in the transportation of all radioactive materials, including spent nuclear fuel, are available from several sources, as discussed in Section J.1.4.2.3.1.

Transportation by legal-weight truck would involve shipments along Interstate System highways in accordance with U.S. Department of Transportation regulations (49 CFR 397.101). These regulations limit shipments to Interstate System highways and require shippers to use Interstate System beltways and bypasses where available. DOE recognizes that even an incident-free transportation campaign could adversely affect people who live or work near transportation routes. Section 6.2.3.1 of the EIS indicates that there would be 2.5 latent cancer fatalities from legal-weight truck transport of spent nuclear fuel and high-level radioactive waste for the 24-years of operation. DOE also recognizes the potential for transportation accidents and analyzed impacts resulting from transportation accidents in Section 6.2.4. Although, given the number of shipments, traffic accidents would be probable, DOE does not believe that any accident would result in the release of radioactive material, primarily because of the structural integrity of the casks in which the material would be transported. In the more than 2,700 shipments involving spent nuclear fuel over the past 3 decades, there have been seven accidents, with no release of radioactive materials to the environment.

The EIS states that approximately four traffic fatalities could occur in the course of transporting high-level radioactive waste and spent nuclear fuel under the mostly legal-weight truck scenario during the 24 years of operation and 350 million kilometers (220 million miles) of highway travel. In the mostly rail scenario, there could be approximately 3 traffic and train accident fatalities. Though an accident resulting in release of radioactive material would be unlikely, DOE analyzed the maximum reasonably foreseeable accident that would involve the release of material from a transportation cask. This would be an extremely unlikely event (an annual probability of 2.8 [rail] to 2.4 [truck] in 10 million). A leaking transportation cask could only occur if mechanical forces (impact) and heat (fire) exceeded the design limits of the transportation cask structures and materials. The EIS states that in an accident involving a leaking transportation cask could result in approximately 5 latent cancer fatalities in an urban area under stable (slowly dispersing) atmospheric conditions. The air pathway is the most likely mode of exposure to radioactive materials, although the analysis included other pathways, including water and contaminated food sources. A severe accident in another population zone (for example, rural) or in other atmospheric conditions would have lower consequences.

8.8.1 (8288)
Comment - EIS000817 / 0105
P. 4-86. I frankly think that basing your analysis on some old Navy representative site from 5 manufacturers at that time probably isn't very valid. Manufacture of containers is just coming into its "heyday" with lots of new designs up for NRC [Nuclear Regulatory Commission] generic certification. Who are these 5 facilities you base your analysis on? Just what do they actually make? ("Components" are not "casks.")

Response
Section 4.1.15.1 of the EIS describes the overall approach and analytical methods used for the environmental evaluation of the baseline data from the *Department of Navy Final Environmental Impact Statement for a Container System for the Management of Naval Spent Nuclear Fuel* (DIRS 101941-USN 1996). As pointed out, cask designers have submitted designs to the Nuclear Regulatory Commission for a number of transportation casks. Manufacture of casks following issue of certificates of compliance by the Commission could be accomplished by several qualified manufacturers. For this reason and to provide information for use in the analysis, five sites, having existing buildings and equipment needed to manufacture cask components, were used to provide a representation of cask manufacturing sites. The representative sites used are located in Westminster, Massachusetts; Greensboro, North Carolina; Akron, Ohio; York, Pennsylvania; and Chattanooga, Tennessee. It is common for cask manufacturing companies to purchase certain cask components rather than manufacture the entire cask in-house. As such, impact analysis in the EIS conservatively assumed that all manufacturing would occur at a single site to overemphasize potential impacts.

8.8.1 (8376)
Comment - EIS001873 / 0061
P. 6-24 & 26. The DEIS should state in which community the "maximally exposed" resident will live and on which section of the route the worker will work.

Response
Information on how radiological impacts to workers and members of the general public from incident-free transportation and severe accidents were evaluated are explained in Chapter 6 and Appendix J of the EIS. Individuals modeled are hypothetical members of the workforce supporting transportation activities and members of the general public at a specified distance from the shipment or other transportation activity. As detailed in the EIS, specific transportation modes and routes have not yet been determined. At this time, many years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use for all

shipments that would be made. Before such shipments began, states or tribes may designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified. Therefore, it is not possible to identify in which community the maximally exposed resident live or on what section of the route the maximally exposed worker would work.

8.8.1 (8470)
Comment - EIS000817 / 0142
P. 6-20. Unloading storage casks and loading transport casks will be a big concern at beginning and end of transport route. Fuel handling repeatedly will have an effect on the assemblies and they must be checked. Can you predict these effects? I don't think so. Loading operations are not "routine" and unloading has not been done!! And transportation cask testing needs to be redone. Sabotage event evaluation needs to be redone. The world has changed a lot -- these need updating as to road and rail hazards and new weapons available.

Response
The impacts of loading spent nuclear fuel and high-level radioactive waste into transportation casks at 72 nuclear powerplants and 5 DOE sites are evaluated in Section 6.2.2 of the EIS. The impacts of unloading operations at the proposed repository are evaluated in Section 4.1.7.3.

Significant experience in both wet (that is, underwater) and dry (that is, within heavily shielded enclosures) handling of spent nuclear fuel, including loading and unloading storage and transportation casks has been accumulated in the United States and Europe. This experience has been applied to the design and operation of cask and fuel handling systems. This experience confirms that handling operations can be conducted safely without undue risk to the public and workers and without causing significant damage to spent nuclear fuel assemblies.

The NWPA requires that DOE use casks certified by the Nuclear Regulatory Commission when transporting spent nuclear fuel and high-level radioactive waste to a repository. The Commission certifies that a cask meets the requirements of 10 CFR Part 71, which prescribes radiological performance standards for casks subjected to specific test conditions. These test conditions represent the kinds of forces that a cask would encounter in a severe transportation accident. A cask's ability to survive the tests prescribed by 10 CFR Part 71 can be demonstrated in several ways. These options include component, scale-model, and full-scale tests to demonstrate or confirm the performance of the casks. As part of its detailed technical review, the Commission decides what level of physical testing or analysis is appropriate and necessary for each cask design. If the applicant for a certificate fails to demonstrate compliance with the regulations, the Nuclear Regulatory Commission would not issue a certificate. Therefore, if full-scale testing was necessary, it would be done before the Commission issues a certificate of compliance. For a more complete discussion of cask testing, see Section M.4 of the EIS. DOE has the option of evaluating the need for a full-scale cask test demonstration in the future.

The Nuclear Regulatory Commission is currently considering in the Package Performance Study (DIRS 155571-Best 1999), which is an update of the *Shipping Container Response to Severe Highway and Railway Accident Conditions* (DIRS 101828-Fischer et al. 1987; also called the Modal Study) used in the EIS, a request to conduct full-scale testing of a present generation cask to demonstrate the validity of computer models used in cask design and certification activities. DOE will evaluate the results of the Package Performance Study when it is published.

The impacts of acts of sabotage on spent nuclear fuel shipping casks are evaluated in Section 6.2.4.2.3 of the EIS.

8.8.1 (8603)
Comment - EIS001837 / 0007
You heard on Tuesday, 2/22/00 at the hearing in San Bernardino, our California Governor's office, the State Departments and the County have found the Yucca Mt. DEIS document to be inadequate and deficient. The document is so deficient that it needs to be redrafted and recirculated.

Clearly, a rewrite is needed to address alternative routes that should have been included in the DEIS, for example, there are no alternate routes proposed for the area between Barstow and parts east. If the railroad line is closed down for some reason in the Needles area, what will be done with the shipment. Will roads be used? If so, alternate routes must be assessed. The routes through Nevada are no longer considered alternatives due to pressure from people in Nevada. So they forced a single funnel through Needles and left Needles totally out of the hearings. This is unacceptable and a clear case of environmental injustice.

Response
National transportation routes and associated environmental impacts are addressed in Section 6.2 of the EIS. Section 6.2.3 analyzed the impacts of transporting spent nuclear fuel and high-level radioactive waste using two scenarios: mostly legal-weight truck and mostly rail. The routes selected for the analyses met U.S. Department of Transportation regulations (49 CFR 397.101) and conformed to normal routing railroad practices. While these might not be the routes used in the future because of infrastructure changes or other variables, they are representative and therefore the analyses provide sufficient information on which to make decisions. In response to comments on the Draft EIS, DOE revised Appendix J to include state route maps, the numbers of shipments in each state, and state-specific health and safety impact estimates, including data for California (see Section J.4). This is in addition to the route maps that were already included in the Draft EIS (see Section 2.1.3.2 for national routes and Section 2.1.3.3 for Nevada maps).

Because there are not very many rail routes to choose from in the Southern California area, there is no reasonable route between Barstow and parts east. The maps available on the Yucca Mountain Internet site (*http://www.ymp.gov*) and in Appendix J of the EIS do not show any rail routes through Needles. However, if a railroad line was closed down anywhere, shipments would be stopped and protected until the line was opened.

8.8.1 (8647)
Comment - EIS001889 / 0002
The DEIS fails to consider the impacts of legal-weight truck transportation through White Pine County, and even goes on to demonstrate (Table J-78) that the risks of transporting SNF and HLRW through the County are significantly greater than risks associated with current routes used to transport low level radioactive waste (LLWR). This could possibly warrant significant cumulative impacts.

Response
Section J.3.1.3 of the EIS presents a sensitivity analysis to assess the affect on the impacts in Nevada of use of candidate alternative highway routes for legal-weight trucks. This analysis includes one route that would travel through White Pine County and provides estimates of impacts for Nevada if this route was used. The impacts are greatest for this route principally because it is the longest route. None of the transportation implementing alternatives analyzed by DOE in the EIS involves White Pine County. Under the mostly rail scenario, no shipments would travel through White Pine County, so there would be no impacts. In addition, unless the State of Nevada designated a preferred route that passed through the County no truck shipments would pass through White Pine County on the way to the proposed repository so there would be no impacts. None of the rail or heavy-haul truck implementing alternatives travels through White Pine County. Therefore, it can be concluded that no transportation impacts would occur in White Pine County under any implementing alternatives analyzed in the EIS. However, should the State of Nevada submit alternate routes to DOT and these routes meet DOT requirements, these routes could be used by DOE.

8.8.1 (8657)
Comment - EIS001837 / 0023
PARD demands to know exactly how many REMs are being emitted from the casks and what the effect of the exposure would be upon people working at the downtown Needles depot and to the people living on California Avenue and Front Street. The change over at the Needles depot is likely to be long, with security personnel, engineers, and conductors switching and with fueling.

Response
U.S. Department of Transportation regulations [49 CFR 173.441(b)] limit the amount of radiation that a cask can emit to 10 millirem per hour at a distance of 2 meters (6.6 feet) from the side of the transport vehicle. The dose rate at 30 meters (98 feet) would be less than 0.2 millirem per hour. In reality, the measured dose rates from actual shipments would probably be lower than the maximum allowable under current limits but would not be higher. Nevertheless, DOE used the maximum allowable dose rate to calculate exposures to the public along routes, which included people living or working within 0.8 kilometer (0.5 mile) on each side of the route. In addition, the analysis determined collective doses to the public while a shipment was stopped in railyards along the route. The EIS

analyzed impacts to maximally exposed individuals such as rail crew members, inspectors, and railyard workers. Section J.1.3.2 describes these analyses, and Section 6.2.3.2 contains their results.

8.8.1 (8717)
Comment - EIS002119 / 0005
About half of the -- about half of the document is devoted to transportation, to impacts related to transportation. There is little consideration of the feasibility of transportation plans. For example, there was no -- there's no thought it seems of what effect heavy-haul operations would have through rugged terrain on insufficient infrastructure through congested urban areas on insufficiency analyzed routes in conflict with present planned land uses. We would imagine that even a minor incident would lead to -- to congestion not even seen during the worst of commute hours.

Response
DOE has taken into consideration the impacts of heavy-haul truck transportation and they are discussed in Section 6.3.3.1 of the EIS and the subsequent subsections that address the specific impacts of heavy-haul truck implementing alternatives (routes), including land use and ownership and socioeconomics, including current urban and transportation plans. Since proposed heavy-haul truck routes are on existing highways that could require upgrades (see Section J.3.1.2), the analysis found no current conflicts with existing or planned land use. Some of the measures that could lessen these potential impacts are outlined in Section 2.1.3.3.3.2, which discusses the proposed road upgrades to accommodate heavy-haul truck traffic.

Operating policies and protocols that would be implemented for the transportation program are those required by the U.S. Department of Transportation, the Nuclear Regulatory Commission, and the Department, as outlined in the request for proposal for Regional Servicing Contractors and summarized in Section M.3 of the EIS. These protocols address routing procedures through rugged terrain and during severe weather and road conditions. The impacts analyzed in the EIS include impacts of traveling through urban areas including slow speeds, congested traffic and sharp turns (DIRS 154675-Ahmer 1998).

DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

8.8.1 (8786)
Comment - EIS001907 / 0021
Nuclear power plants are required to have a 50 mile radius emergency planning zone. How come the DEIS only looks at a half mile radius of these transportation routes?

Response
Emergency planning zones for nuclear powerplants in the United States are actually much smaller, with a typical radius of about 16 kilometers (10 miles). Radiological impacts of accidents, however, are typically calculated out to about 80 kilometers (50 miles), because that is the extent to which most particulates would be dispersed from near ground-level releases. This is the typical practice of Nuclear Regulatory Commission, Environmental Protection Agency, and DOE analyses. This EIS used techniques consistent with accident analyses conducted at nuclear powerplants and analyzes the impacts from transportation accidents out to 80 kilometers. Radiological impacts of incident-free transport were calculated out to 800 meters (0.5 mile) from the road or branch rail line. This is because the radiation dose rate emitted by the shipping casks would be vanishingly small and individual and population exposures would be essentially zero beyond this distance.

8.8.1 (8946)
Comment - EIS001922 / 0010
The DEIS grossly underestimates the transportation risks from the unprecedented 53,000 truck shipments (estimated) of nuclear waste over 24 years of operation. Containers have not yet been constructed or tested.

Therefore realistic estimates of radiation leakage or container performance in an accident are not possible. The DOE's assumption that accidents will not occur is entirely unreasonable. In sum, EPA's [Environmental Protection Agency's] analysis of transportation impacts is entirely unreliable and should not be used as a basis for decisionmaking. It is important to reiterate here the potential benefits of waiting fifty years before transporting irradiated nuclear fuel so that the material will be much less radioactive and thus less deadly in the likely event of an accident.

Response
The transportation analysis presented in the EIS is based on the latest reasonably available information on the performance of spent nuclear fuel casks during transportation accidents. The EIS does not assume that accidents would not occur. Instead, the EIS evaluates both the radiological and nonradiological impacts of transportation accidents (see Chapter 6 and Appendix J of the EIS). The EIS uses standard, well-accepted methods to estimate transportation impacts in a realistic, yet conservative manner, and consequently DOE does not believe that impacts are underestimated or are unreliable, and does believe that the estimates are appropriate for decisionmaking.

While it is true that spent nuclear fuel would be less radioactive in 50 years, the impacts from transporting spent nuclear fuel are already very low, so waiting 50 years would not provide a practical reduction in the already very low risks.

8.8.1 (8975)
Comment - EIS001040 / 0017
Where are the evaluations of costs, risks and route specific data on possible accidents, population density, weather?

Response
Section 2.1.5 of the EIS provides information on the costs of the Proposed Action, including the cost of waste acceptance, storage, and transportation (nationally $4.5 billion and in Nevada $0.8 billion). Section 6.2 addresses the impacts of transporting spent nuclear fuel and high-level radioactive waste from generation or storage facilities to the proposed repository. The analyses in that section covered both incident-free transportation and potential accidents. Appendix J discusses the methods and data used for those analyses, including population and weather data.

8.8.1 (9055)
Comment - EIS001284 / 0007
WHEREAS, there are many unanswered questions regarding the safety of transporting and storing radioactive waste.

Response
Based on the results of the impact analyses presented in Chapter 6 and Appendix J of the EIS, as well as the results published in numerous other studies and environmental impact analyses cited in the EIS, DOE is confident spent nuclear fuel and high-level radioactive waste can be and would be safely transported to Yucca Mountain. DOE believes, as the EIS reports, that the potential impacts of this transportation would be so low for individuals who live and work along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured. The analysis presented in the EIS factored in the characteristics of spent nuclear fuel and high-level radioactive waste, the integrity of shipping casks that would be used in transport, and the regulatory and programmatic controls that would be imposed on shipping operations (see Appendix M). The EIS analytical results are supported by numerous technical and scientific studies which have been compiled through decades of research and development by DOE and other Federal agencies of the United States, including the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as by the international community, including the International Atomic Energy Agency.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site is approved. The reader is referred to the introduction to Chapter 8 of the CRD for additional information.

8.8.1 (9215)
Comment - EIS001938 / 0004
The DEIS fails to detail and analyze the transportation corridors that will be utilized to transport high-level nuclear waste to Yucca Mountain, which are an integral part of the repository project.

The DEIS fails to adequately address the issue of transport of high-level radioactive waste along state and U.S. highway systems, saying that it is not relevant to the decision being made. Without a decision to store radioactive waste at Yucca Mountain this EIS would not be prepared, thus not only is the issue of waste transport relevant, it must be analyzed in this EIS. See 40 CFR 1508.25 (Re: Scope of an EIS. Connected actions, e.g., those which are interdependent part of a larger action and depend on the larger action for their justification, should be analyzed in the same impact statement.) Without a detailed assessment of proposed routes for the transportation of high-level radioactive waste, it is impossible for the reader of the document or the decisionmaker to fully understand the (in this case) likely and significant impacts of the proposed action on the human and natural environment.

For instance, it is our understanding that State Route (SR) 127 is one of the routes of choice for transport of waste to Yucca Mountain. How will transport of high-level radioactive waste along this key access route to DVNP [Death Valley National Park] affect visitation to the Park? How, in turn, will a possible decrease in visitation to DVNP via SR 127 affect the economies of communities that lie along the transportation corridor (e.g., Tecopa, Shoshone, Death Valley Junction)? Is SR 127 a feasible route for transport of high-level radioactive waste from an engineering standpoint? Are the communities along SR 127 adequately equipped, from an emergency response standpoint, to handle likely catastrophic consequences to both humans and the environment in the event of a reasonably foreseeable accident-related spill? The DEIS has failed to address and resolve these significant issues.

Impacts to natural resources of DVNP, Ash Meadows NWR and designated Wilderness from a transportation-related accident could likewise be disastrous and should be considered in the revised EIS. Were a spill to occur in or near the Amargosa River it would destroy this important desert riparian system. Spills could -- and would -- decimate vegetation and kill wildlife. Death Valley National Park is likewise put at risk, since much of SR 127 constitutes the boundary of Death Valley National Park.

It is unclear what other routes of travel might be used beyond SR 127. Information indicates that Great Basin National Park and Lake Mead National Recreation Area might also enjoy the dubious distinction of being within the realm of transport of high-level nuclear waste. What are possible impacts to these protected areas in the event of a hazardous spill? Beyond the possible impacts to the human and natural environments from a hazardous spill, how might transport of high-level waste adjacent to other protected places in the country affect visitation to Parks and local attractions, local economics, etc?

In conclusion, the threat of disastrous accidents from transportation-related spills is very real, and needs to be comprehensively addressed in this document. The revised DEIS needs to include a clear description of transportation routes that reflects a careful consideration of potential hazards and problems with each selected route, and a thorough description of the stringent safety and mitigation measures that will be adopted in order to ensure protection of both natural resources and communities in the Death Valley region and beyond.

Response
At this time, years before shipments could begin, it is impossible to predict accurately which highway routes or rail lines DOE could use for all shipments. Before such shipments began, states and tribes could designate alternate preferred highway shipping routes, and highways and rail lines could be built or modified. Therefore, for the analysis in this EIS, DOE selected potential highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (typically highways and bypasses that are part of the Interstate Highway System). The Department based its selection of potential rail routes for use in the analysis on current rail practices, because there are no comparable Federal regulations applicable to the selection of rail routes for the shipment of radioactive materials.

In response to public comments, DOE included maps of the highway routes and rail lines it used for analysis in Section J.4 of the EIS. It also included potential health and safety impacts associated with shipments for each state through which the routes used in the analysis pass. These numbers should be considered tentative, as there are many factors that could cause the modes and routes to change including reactor operations, trading of pickup allocations, selection of a different transportation mode for shipments by the reactor operator, or recommendation of alternate routes by states or tribes. Impacts in individual states could be different if the actual routes from generator sites to Yucca Mountain are different from those analyzed. However, it is not likely that the total impacts from transportation would be changed significantly or that any particular route connecting an origin/designation pair would present a significant difference in impact from any other.

Following U.S. Department of Transportation regulations, truck shipments in Nevada would enter the State on Interstate-15 and proceed to the planned beltway and then to U.S. 95 and the repository unless the State designated alternate routes. In addition to analyzing the impacts of using highway routes that would meet Department of Transportation requirements for transporting spent nuclear fuel, DOE evaluated how the estimated impacts would differ if legal-weight trucks used other routes in Nevada. As a sensitivity analysis, six other routes identified by a Nevada DOT study were evaluated. Two of these routes used SR 127. The results of this analysis are reported in Section J.3.1.3 of the EIS. None of these routes would be used unless they were designated by the routing agencies of the affected states.

"Real-life conditions" that would involve various types of collisions (such as airplanes and military trucks with explosives), various natural disasters, specific locations (such as mountain passes), or various infrastructure accidents (such as track failure) in effect constitute a combination of cask failure mechanisms, impact velocities, and temperature ranges, which the EIS does evaluate. DOE has revised the EIS to describe the maximum reasonably foreseeable accident in terms of cask failure mechanisms, range of impact velocities, and temperature range.

As described in Section M.5 of the EIS, as with any transportation accident, state and tribal governments have primary responsibility to respond to and protect the public health and safety in their jurisdictions in accidents involving radioactive materials. This includes providing, managing, and maintaining responsibility for emergency response capabilities. Although DOE would originally provide the funding for training, each state and tribe would determine how it wants to administer that funding. Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using an up-front planning grant and based on availability of funds in annual Program budgets specified by Congress.

8.8.1 (9265)
Comment - EIS000325 / 0004
Now, we know the industry here will do a good job to start off with, but we're talking about a 30-year program. And so those shipments in Germany have been canceled and they're on hold because of the kind of sloppiness that you can except to see in a program here. So I'm just saying if we're going to talk about the international experience, let's talk about all of it.

Response
In response to comments, DOE has provided information in Appendix M of the EIS on the regulations that govern the transportation of spent nuclear fuel and high level radioactive waste. Details on the proposed operational aspects of the transportation program are also provided in Appendix M. Together, the strict transportation regulations and the detailed operational program should ensure that that a high level of quality is maintained throughout the transportation program.

DOE recognizes that human and organizational factors are important contributors to the occurrence of accidents, including transportation accidents, and recognizes that there is a potential for the performance of one or more transportation system components to degrade over time as operations become routine and repetitive. However, the contributions of human and organizational factors to the total accident risks are not explicitly analyzed in the EIS. Because the truck and rail accident rates used in the EIS include accidents from all potential causes, including those with human or organizational root causes, providing additional details on such factors would not appreciably change the results presented in the EIS.

8.8.1 (9303)
Comment - EIS001888 / 0028
The DEIS used outdated databases, geographic data files, and inaccurate or misleading maps to support the conclusions of the transportation, health effects and public safety analyses.

Response
In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. For instance, DOE selected the RADTRAN 5 computer program to estimate radiological impacts to populations from incident-free transportation and from accidents. RADTRAN, which was originally developed by Sandia National Laboratories in the late 1970s, has been used in many other previous DOE EISs, and it has undergone periodic review and revision. In 1995, an independent review of RADTRAN 4 (immediate predecessor to RADTRAN 5) demonstrated that it yielded acceptable results when compared to "hand" calculations. More recently, an independent review found that RADTRAN 5 overestimates the measured radiation dose to an individual from moving radiation sources.

To ensure that the EIS analyses reflect the latest reasonably available information, DOE has either incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relies on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site is approved. The introduction to Chapter 8 of this Comment-Response Document contains additional information.

8.8.1 (9401)
Comment - EIS001888 / 0099
The DOE adopted an unorthodox strategy in preparing the DEIS. Ignoring thirty years of best practice in the preparation of environmental impact statements, DOE chose to adopt the narrowest possible definition of an EIS and its purpose. In doing this, the DOE ensured that it found no impacts. The transportation analysis is typical of this approach. For example, the DEIS did not study traffic impacts that are normally considered in an EIS, choosing to base the estimation of transportation Impacts solely on the risk of population and worker exposure to radiation. Congestion, lane widths, shoulder widths, peak hour traffic, roadbed conditions, and other conventional measures of traffic impacts were ignored. By narrowing the range of impacts studied, DOE made certain that the DEIS would identify no substantive transportation impacts.

Response
DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

In addition to radiological health impacts, the transportation analysis presented in the EIS considers traffic congestion and peak-hour traffic in EIS Sections 6.3.1 and 6.3.3.1. The preliminary design analyzed in the EIS included an analysis of lane and shoulder width along with roadbed conditions, see CRWMS M&O (DIRS 154448-1998). Thus, the EIS considers potential impacts other than fatalities where it is necessary to support the broad transportation-related decisions given above.

8.8.1 (9406)
Comment - EIS001888 / 0102
There is an increased interest in risk assessment methodologies that better characterize and quantify uncertainty. The National Academy of Sciences has stated that, "Whenever possible, (upper bound potency estimates) should be supplemented with other descriptions of cancer potency that might more adequately reflect the uncertainly associated with the estimates." The National Research Council has made a similar call for a characterization of uncertainty. However, the estimates in the DEIS were presented as authoritative statements of risk, and the high degree of uncertainty in the estimates was left unstated. In order for the DEIS to have credibility with the public and policymakers, the DOE should have pursued an assessment strategy that addressed uncertainty rather than ignored it.

Response
DOE is aware that there are uncertainties associated with the transportation impact results presented in the EIS. There are uncertainties associated with route characteristics, demographics, weather, atmospheric dispersion models, waste characteristics, accident rates, release fractions, and many other elements of the risk assessments. Because one of DOE's goals is to choose between alternatives, the consistent consideration of uncertainty among alternatives means that the relative differences in impact estimates among alternatives should not be affected. To account for uncertainties in the data, conservative assumptions were made so the impacts reported in the EIS would bound the potential impacts. Examples of conservative assumptions include: accident release fractions which were selected from the high end of the distribution of experimental results, regulatory maximum radiation dose rates were assumed for all shipments, even though the actual dose rates would be significantly lower for most shipments, consequences to maximally exposed individuals were presented for 50 percent and 95 percent (for example, consequences exceeded only 5 percent of the time) meteorological conditions, and evacuation and sheltering, which could reduce radiological exposures, were not included in the accident risk calculations. DOE has chosen not to use conservative assumptions in all cases, as this practice tends to produce unrealistic and improbable results. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing environmental impacts. Such practices mask the real differences and would not produce suitable results to support choices among the alternatives.

8.8.1 (9552)
Comment - EIS001888 / 0225
The DOE adopted a peculiar strategy in preparing the DEIS. Ignoring thirty years of best practice in the preparation of Environmental Impact Statements, the DOE chose to adopt the narrowest possible definition of impacts. By narrowly defining what an EIS is and what an EIS is supposed to do, the DOE ensured that it found no impacts. The transportation analysis is emblematic of this approach. The DEIS did not study traffic impacts that are normally considered by an EIS. Congestion, lane widths, shoulder widths, peak hour traffic, roadbed conditions, and other conventional measures of traffic impacts are ignored. By narrowly defining impacts as solely radiological health impacts this ensures no substantive impacts will be identified by the DEIS. Another example is the emergency management section. By insisting that the DEIS is not an emergency planning document, the DOE avoided preparing any estimates of the costs necessary to mitigate the impacts of emergency response. This approach to impact assessment is consistent with other DOE impact assessments (notably the Nevada Test Site EIS), but does not conform to best practice in the field of impact assessment. While this approach may have facilitated speedy preparation of the DEIS, it did not result in a thorough analysis of the impacts of the program and violates the letter and spirit of NEPA [the National Environmental Policy Act].

Response
Section 6.3 of the EIS describes the various categories of information acquired to assess impacts of transportation in Nevada. These are the general categories usually addressed in National Environmental Policy Act documents. They include assessment of impacts of construction and operation on land use and ownership (including access, hunting, mining, and ranching), water resources, biological resources (including endangered species), occupational health

and safety, socioeconomics, noise, cultural resources, utilities and energy, flood plains, and other potential impact areas.

The EIS reflects a similar philosophy in its analyses to those that have been used in the past. In addition to radiological health impacts, the transportation analysis presented in the EIS considers traffic congestion and peak-hour traffic in EIS Sections 6.3.1 and 6.3.3.1. The preliminary design analyzed in the EIS included an analysis of lane and shoulder width along with roadbed conditions, see CRWMS M&O (DIRS 154448-1998). DOE believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada if the site was approved. However, follow-on implementing decisions, such as the selection of a specific rail alignment in a corridor, or the specific location of an intermodal transfer station in Nevada or the need to upgrade heavy-haul truck routes, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and the appropriate National Environmental Policy Act reviews.

It is the Department's opinion that the EIS adequately analyzes impacts of and emergency planning for transporting spent nuclear fuel and high-level radioactive waste.

8.8.1 (9554)
Comment - EIS001888 / 0227
There is an increased interest in risk assessment methodologies that better characterize and quantify uncertainty. The National Academy of Sciences has stated that, "Whenever possible, (upper bound potency estimates) should be supplemented with other descriptions of cancer potency that might more adequately reflect the uncertainly associated with the estimates." The National Research Council has made a similar call for a characterization of uncertainty. However, the estimates in the DEIS were presented as authoritative statements of risk, and the high degree of uncertainty in the estimates was left unstated. In order for the DEIS to have credibility with the public and policymakers, the DOE should have pursued an assessment strategy that addressed uncertainty rather than ignored it.

Response
DOE is aware that there are uncertainties associated with the transportation impact results presented in the EIS. There are uncertainties associated with route characteristics, demographics, weather, atmospheric dispersion models, waste characteristics, accident rates, release fractions, and many other elements of the risk assessments. Because one of DOE's goals is to choose between alternatives, the consistent consideration of uncertainty among alternatives means that the relative differences in impact estimates among alternatives should not be affected. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing environmental impacts. Such practices mask the real differences and would not produce suitable results to support choices among the alternatives.

8.8.1 (9572)
Comment - EIS001888 / 0246
The software used to analyze transportation risk in the DEIS was RADTRAN version 4.019. Extensive criticism of RADTRAN has been made in other venues. Although courts have allowed RADTRAN's analysis of risk, the many shortcomings of this approach should be examined in the DEIS. In particular, the DEIS should have provided the

full RADTRAN outputs and interpreted their meaning. A portion of these outputs would have been the decontamination costs should an accident occur.

Response

Sections 6.2.1 and J.1.1 of the EIS describe in some detail the codes used, including RADTRAN, and the results they generate. Criticisms of RADTRAN were specifically discussed in Sections 3.3 and 4.3 of the report *Validation of the Transportation Computer Codes HIGHWAY, INTERLINE, RADTRAN4, and RISKIND* (DIRS 101845-Maheras and Pippen 1995). Many of the criticisms were related to previous versions of RADTRAN. Other criticisms were related to data used in other analyses, and as such are not directly related to the analyses presented in the EIS. RADTRAN 4 output for the analyses in the Draft EIS and RADTRAN 5 analyses in the Final EIS were provided to the commenter on compact disk. DOE conducted a literature review on the subject of potential cleanup costs and summarized the results in Section J.1.4.2.5.

8.8.1 (9585)

Comment - EIS001888 / 0260

Transportation System Description

The DEIS is insufficient because it fails to provide any description of the complex system that will be needed to transport SNF on the scale proposed in the DEIS. Without such a description, an assessment of the impacts of transporting waste is impossible. DOE has recognized the importance of this problem in the past, but has not addressed it in the DEIS. In previous documents, DOE identified the following components of the transportation system: Transportation Cask Systems, Service and Maintenance Support, Field Operations, and Planning and Control.

Substantial questions are raised in the DEIS but not answered. The response of the DOE to questions about the system used to move waste from origin sites to the final repository has been that there are many unknowns in the transportation system and that final study of the system requires determination of site suitability. There are two problems with this argument.

First, is that the information contained in the DEIS will be used by Congress to make decisions about the disposal program. By presenting admittedly piecemeal and incomplete information, the DOE opens itself to charges that it was disingenuous with Congress and the American people. The DOE should remedy this problem by clearly labeling those areas in the DEIS where the information is untrustworthy and incomplete. The second flaw in the DOE’s argument is that it assumes that once the site is selected, it will be possible to transport the waste. By failing to provide a comprehensive, credible study of the transportation system, the DOE gives the misleading impression that only site characterization is an important issue. In other words, only site characterization is a relevant issue. Given the quality of the DEIS’ analysis, this does not seem likely.

Response

DOE believes that the EIS adequately analyzes environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

DOE is aware of the hazards associated with spent nuclear fuel and high-level radioactive waste. DOE is also aware that the transportation system needed to ship these materials to the proposed repository would be complex, consisting of many interrelated components. However, the single most important components of the transportation system would be the Type B shipping casks. DOE would use casks certified by the U.S. Nuclear Regulatory Commission to meet the requirements of the Commission’s transportation regulations in 10 CFR Part 71.

Another important component of the transportation system would be field operations, planning, and control of the shipments. DOE has developed a draft Request for Proposal for Regional Servicing Contractor(s) for waste acceptance and transportation. Section M.3 of the EIS describes the draft Request for Proposal. The selected contractor(s) would be responsible for shipping arrangements and transportation services in the servicing region(s).

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

8.8.1 (9589)
Comment - EIS001888 / 0263
Specialty Casks

A fundamental advantage of intermodal handling is to reduce accidents through uniform packaging. The questions raised about the MPC [multipurpose canister] are equally pertinent to the numerous specialty casks that must be designed to meet the needs of the other waste forms the DEIS proposes to dispose of in Yucca Mountain. Questions about the characteristics, designs and certification for the other waste forms are the same as for the MPC. The DEIS is mute on the significant problems of handling different waste forms and potentially different waste packages at Yucca Mountain and the intermodal facilities where the waste will be handled.

Response
DOE has considered the potential difficulties in handling different waste forms and waste packages at Yucca Mountain and different models of shipping casks the candidate intermodal transfer facilities. The Department is aware that special handling equipment and procedures could be necessary for each type of waste, waste package, and shipping cask it would handle and foresees no significant problems associated with handling at the proposed repository or an intermodal transfer facility. According to the Draft Request for Proposal for Waste Acceptance and Transportation Services (see Section M.3 of the EIS), a Regional Service Contractor(s) would be responsible for providing the equipment to handle and prepare each transportation cask for unloading. The contractor(s) would provide training on the use of the equipment and operating procedures and maintenance procedures for the equipment (including shipping casks and ancillary handling equipment). The contractor(s) would develop more detailed planning for providing these services at the repository and the selected intermodal transfer facility in the initial phase of the contract(s).

8.8.1 (9596)
Comment - EIS001888 / 0270
In-Transit Storage

It is inevitable that delivery schedules will be delayed or interrupted. The impacts of moving waste uninterrupted from the origin to the destination for a single shipping campaign are different from a complex, multi-state shipping campaign that will take place over a period of years. The DEIS transportation plan should have addressed the likely effects of in-transit storage on the risks of transporting waste. Storage in-transit is a likely event and the DEIS should describe the DOE's plans to manage that requirement and describe the amount of waste that may have to be stored in transit to the Yucca Mountain facility.

Response
In-transit storage of spent nuclear fuel and high-level radioactive waste shipments would not occur. Shipments would travel nonstop from waste generator facilities to the proposed repository, with necessary stops for food, refueling, rail classifications, and en route inspections. However, DOE recognizes that not all shipments would proceed uninterrupted. Weather, traffic, and road and rail conditions could interrupt continuous movement of a shipment from its origin to the destination. For this reason, DOE would use a satellite tracking communication system such as TRANSCOM and for the shipments. The TRANSCOM system is capable of real-time communications with truck crews and rail escorts and DOE could use it to warn them of upcoming delays and other adverse conditions. It would then be possible to reroute a shipment over an alternative route to avoid the adverse conditions. As an alternative, shipments could proceed to safe parking areas where they could wait until the condition cleared and the trip could continue. Safe parking areas would be identified for each route and the information made available to crew members and carried with the shipment, as discussed in Section M.3.2 of the EIS.

An incident that required the use of a safe parking area would be unlikely. The radiation doses from such an incident would be small, because the number of people exposed and the likely exposure durations would be smaller than those for a routine shipment. DOE believes that the combined low likelihood of occurrence and low radiation doses from a safe parking incident would not contribute significantly to the transportation impacts presented in the EIS. As a consequence, DOE has not evaluated such impacts in the EIS.

8.8.1 (9612)
Comment - EIS001888 / 0284
The DEIS should be rescinded and a new DEIS issued that 1) assesses traditional transportation impact concerns, 2) State of Nevada identified routes, 3) bypass routes (should the northern beltway become unavailable), 4) describe why the Air force was awarded special status and Clark County was not, and 5) describe the process used to select one or more implementing alternatives.

Response
The EIS addresses "traditional" transportation impacts (traffic congestion, accident rates, and traffic volume) at a level of detail sufficient for DOE to make a mode and route selection (see Section 6.3). DOE's analyses for legal-weight truck transport concludes that existing highways are sufficient and, though upgrades would be necessary for a selected heavy-haul truck route, existing rights-of-way would be sufficient. Section J.3.1.3 contains an analysis of State of Nevada-identified routes.

Public comments submitted to DOE during hearings on the scope of the EIS resulted in the addition of a fifth rail corridor and heavy-haul truck route, the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route. However, the U.S. Air Force has expressed concern that for reasons of national security it cannot envision any route through the Nellis Air Force Range that would not conflict with its training and testing mission. For this reason, the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route are listed in the EIS as nonpreferred alternatives.

Protocols for Regional Servicing Contracts given in Section M.3 of the EIS describe how the contractors would develop transportation plans, including selection of routes and modes.

If the Yucca Mountain site was approved, DOE would issue at some future date a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

8.8.1 (9613)
<u>Comment</u> - EIS001888 / 0285
National Route Selection

The DEIS is incomplete due to its failure to analyze the impact of transporting SNF [spent nuclear fuel] across the nation. Of 146 pages in the transportation section of the report, only 17 pages are devoted to national transportation of Spent Nuclear Fuel. The Problem of selecting routes on which to transport radioactive materials has incited litigation and defied every attempt at reaching consensus. The problems associated with route selection begin with construction at Yucca Mountain and flow back to each of the generating sites. Each suite of routes poses different risk characteristics nationally as well as in the State of Nevada. The DEIS assumes that truck and rail shipments on different routes possess the same risk characteristics. The DEIS presents the shortest distances to transport the waste without considering any of the likely alternatives to shortest distance.

<u>Response</u>
Chapter 6 and Appendix J of the EIS contain substantial analyses related to the national transportation of spent nuclear fuel and high-level radioactive waste. However, in response to comments, considerable state-by-state information has been added to Appendix J, which now includes maps for each state, including Federally recognized Native American Reservations, that show routes used in the analyses of impacts presented in the EIS, tables listing rail and truck shipments originating in and passing through each state, and incident-free and accident risk impacts for each state. Appendix M provides additional supplemental information related to the transportation of radioactive material, such as regulations, cask safety and testing, transportation services and protocols (including planning and route selection), emergency response, physical protection, and liability.

As discussed in Section J.1.4.2.3 of the EIS, state-specific accident rates and route-specific population density data were used to estimate transportation impacts. As a consequence, truck and rail shipments on different routes would possess different risk characteristics. In addition, the EIS does not present the shortest distance routes. For example, the truck routes were based on U.S. Department of Transportation routing regulations that recommend the use of beltways around cities. Using beltways around cities often results in routes that are longer than passing directly through these same cities. More details on transportation routing are in Section J.1.2.2, M.2.4, and M.3.2.1.2. Maps of the transportation routes analyzed in the EIS are in Section J.4.

8.8.1 (9630)
<u>Comment</u> - EIS001888 / 0299
In order for the DEIS to be a sufficient document, the practice of risk assessment used in the DEIS should conform to best practice in the field. Based on a comparison with the GEIS, it is not clear how a probabilistic risk assessment for transporting high level radioactive should be done. A primary requirement for the DOE is to recognize the unique circumstances of the planned transportation operations for which there is little or no historical experience and empirical data. The transportation of spent fuel from reactors to the proposed repository at Yucca Mountain has no parallel. Previous spent fuel transportation experience is qualitatively different from the proposed action. The DEIS should be withdrawn and replaced by new DEIS that performs a complete probabilistic risk assessment that is found to be sufficient by a qualified peer review committee.

<u>Response</u>
Over the past 3 decades, there have been more than 2,700 shipments of spent nuclear fuel in the United States with no releases of radioactive material due to a transportation accident. This excellent safety record is consistent with the overall highway and rail accident data. DOE used standard accepted analysis methods in the EIS, including probabilistic risk assessment, to estimate transportation impacts. Risk assessment accident data for commercial transport have been used in conjunction with analyses of cask performance to estimate risks associated with spent nuclear fuel transport. The approach is appropriate and widely accepted as the basis for credible risk assessment.

8.8.1 (9978)
<u>Comment</u> - EIS001888 / 0483
[Clark County summary of comments it has received from the public.]

Commenters said that the EIS should include a detailed description of all affected environments and impacts to those environments. More specifically, the analyses should include: (1) worst-case and mile-by-mile assessments of potential impacts along transportation routes and the emergency-response measures along these routes; (2) the effects of the environment on the safety of waste shipments, including a discussion of the controversial nature of waste transport; (3) Retrievability of the waste, along with the disposition of the retrieved waste; (4) the economic, social, health, and psychological costs of transporting and storing the waste, including the costs of accidents; (5) negative effects on property values, businesses, and tourism near the site and along transportation routes; and (6) risk, risk perception, and stigmatization.

Response

1. Section J.1.4.2 of the EIS has been revised to include a description of the maximum reasonably foreseeable accident. As in the Nuclear Regulatory Commission report *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000), the description is in terms of cask failure mechanism, impact velocity range, and temperature range for the accident. Accidents are not described in terms of specific circumstances, because various accidents could lead to the same combination of cask failure mechanism, impact velocity range, and temperature range. However, event trees illustrate the different combinations of events that occur during an accident. This approach to accident analysis precludes the necessity for analyzing numerous specific cases involving various collisions (such as air planes and military trucks with explosives), various natural disasters, specific locations (such as mountain passes), or various infrastructure accidents.

   As described in Section M.5 of the EIS, as with any transportation accident, state and tribal governments have primary responsibility to respond and to protect the public health and safety in their jurisdictions in accidents involving radioactive materials. This includes providing, managing, and maintaining responsibility for emergency response capabilities. Although DOE would provide funding for training, each state and tribe would determine how it wants to administer that funding. Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. Section 180(c) is discussed in Section M.6.

2. Section M.3 of the EIS provides a discussion of the protocols and procedures to be implemented by a Regional Servicing Contractor and its subcontractors under adverse weather or road conditions. Shipments would not be dispatched on a route where expected conditions would not comply with the requirements in the procedures. Weather forecasts would be obtained by the Regional Servicing Contractor as part of the preshipment planning. Forecasts for rain, snow, fog or high winds and tornado warnings would be considered in the determination of the shipment schedule. Shipments would not travel when severe weather conditions along routes or adverse road conditions made travel too hazardous to proceed.

   Nuclear Regulatory Commission regulations do not specifically address natural disasters such as earthquakes, floods, or tornadoes. However, numerous tests and extensive analyses, using the most advanced analytical methods available, have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents that occur. A study completed by Sandia National Laboratories for the Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000) concluded that casks would continue to fully contain spent nuclear fuel in more than 99.99 percent of all accidents. DOE believes that information on planning and management of shipments for normal conditions as well as abnormal conditions caused by natural and manmade phenomena provided in the EIS is sufficient.

3. Section 122 of the NWPA requires DOE to maintain the ability to retrieve the materials emplaced in the repository in the event that a decision were made to retrieve them to protect public health and safety or the environment or to recover constituent parts of spent nuclear fuel. Although DOE does not anticipate that retrieval would be necessary, it would utilize the repository design to maintain the ability for future generations to retrieve these materials for at least 50 years and possibly for as long as 300 years after emplacement operations have begun (see Section 4.2.1 of the EIS).

4. In response to public comments, DOE has included a discussion on the costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews costs for cleanup presented in past studies, including a report used in the 1986 environmental assessment as well as information submitted by the State of Nevada in its public comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $9.4 billion. Cost data used in the studies included data compiled from

case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities. Although the studies project high costs for clean up following severe accidents, the accidents evaluated are very unlikely and, as a consequence, DOE believes the economic risks of transportation accidents is very small.

5&6 In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty
- Much of the uncertainty is irreducible, and
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.8.1 (10023)
Comment - EIS001888 / 0517
[Clark County summary of comments it has received from the public.]

Transportation risk assessment methodology biased toward shortest path not optimal path. DOE needs to incorporate calculated risk, collateral risk, contectural [sic] risk, and perceived risk not just use probabilistic risk analysis (PRA).

Response
The transportation risk analysis is based on U.S. Department of Transportation routing regulations for trucks and railroad operating practices for trains. This does not necessarily yield the shortest path for a route from a particular origin to a destination. The EIS uses standard and well-accepted transportation analysis methods, including probabilistic risk assessment, to estimate transportation impacts.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.8.1 (10025)
Comment - EIS001888 / 0520
[Clark County summary of comments it has received from the public.]

DOE's approach to risk assessment is limited to PRA [probabilistic risk assessment]. Should include Calculated Risk, DOE's approach Risk, Contextual Risk, and Perceived Risk. Suggested starting point 1993 draft Identification of Factors for Selecting Modes and Routes for Shipping HLW [high-level radioactive waste] & SNF [spent nuclear fuel].

Response
As described in Section 6.2.1 and J.1.1 of the EIS, DOE uses standard and well-accepted transportation analysis methods, including probabilistic risk assessment, to estimate transportation impacts. Consistent with the *Final Report, Identification of Factors for Selecting Modes and Routes for Shipping High-Level Radioactive Waste and Spent Nuclear Fuel* (DIRS 103718-DOT 1998), the EIS evaluated incident-free radiological exposures, accident-induced radiological exposures, and the nonradiological consequences of accidents.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.8.1 (10034)
Comment - EIS001888 / 0521
[Clark County summary of comments it has received from the public.]

Calculated risk (i.e. PRA [probabilistic risk assessment]) needs to be broader in scope and cumulative like RADTRANS.

Response
As discussed in Appendix J of the EIS, Version 5 of the RADTRAN computer code was used in estimating radiological risks of transportation activities. As discussed in Section 8.4, a comprehensive analysis of the cumulative impacts of transportation was performed. In addition, a broad range of impacts was evaluated: (1) radiological and nonradiological impacts, (2) incident-free and accident impacts, (3) individual impacts and population impacts, and (4) radiological risks and consequences.

8.8.1 (10035)
Comment - EIS001888 / 0522
[Clark County summary of comments it has received from the public.]

Contextual Risk results from unanticipated changes in risk environment. Example, an incident that delays movement of vehicle carrying HLW [high-level radioactive waste] increases risk to public/workers. Assessments should incorporate realistic public safety capabilities.

Response
The incorporation of public safety capabilities in the EIS analyses would reduce the reported impacts of transporting spent nuclear fuel and high-level radioactive waste to the proposed repository. As discussed in Section J.1.4.2 of the EIS, to bound the potential impacts of accidents the analyses did not take credit for or assume the mitigation effects provided by such public safety capabilities as accident prevention, emergency response interdiction, dose mitigation, or evacuation to reduce accident consequences. As described in Sections J.1.3.2 and J.1.4, scenarios like those described in the comment, such as an individual stuck in a traffic jam near a truck carrying spent nuclear fuel, and accidents where the cask was not damaged but would be delayed for a period before continuing to the repository, were analyzed in the EIS.

8.8.1 (10060)
Comment - EIS001888 / 0541
[Clark County summary of comments it has received from the public.]

Commenters asked questions about the methods or data to be used in the transportation assessments in the EIS, The use of "comprehensive risk assessment" was advocated by some commenters. Other commenters advocated a comprehensive systems analysis or a traffic impact analysis. Commenters stated that the EIS should rely upon previously published studies when possible.

Response
In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. For instance, DOE selected the RADTRAN 5 computer program to estimate radiological impacts to populations from incident-free transportation and from accidents. RADTRAN, which was originally developed by Sandia National Laboratories in the late 1970s, has been used in many previous DOE EISs, and it has undergone periodic review and revision. In 1995, an independent validation review of RADTRAN 4 (immediate predecessor to RADTRAN 5) demonstrated that it yielded acceptable results when compared to "hand" calculations. More recently, an independent review found that RADTRAN 5 overestimates the measured radiation dose to an individual from moving radiation sources.

To ensure that the EIS analyses reflect the best latest reasonably available information, DOE has either incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relies on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data.

Although the EIS analyses are based on the best latest reasonably available information and state-of-the-art analytical tools, not all aspects of incident-free transportation or accident conditions can be known with absolute certainty. In such instances, DOE has relied on cautious assumptions that tend to overestimate impacts. For instance, DOE assumed that the radiation dose external to each vehicle carrying a cask during routine transportation would be the maximum allowed by U.S. Department of Transportation regulations. Similarly, DOE assumed that an individual, the "maximally exposed individual," would be a resident living 30 meters (100 feet) from a point where all truck shipments, or 200 meters (660 feet) from a point where all rail shipments, would pass. Under these circumstances, the maximally exposed individual would receive a dose of about 6 millirem from exposure to all truck shipments, and a dose of about 2 millirem from exposure to all rail shipments (6 millirem represents an increased probability of contracting a fatal cancer of 3 in 1 million). Although it can be argued that individuals could live closer to these shipments, it is highly unlikely that an individual would be exposed to all shipments over the 24-year period of shipments to the repository, even though DOE incorporated this highly conservative assumption in the analysis.

The methods used to calculate transportation impacts are state-of-the-art. As a consequence, DOE believes the EIS adequately analyzes the environmental impacts that could result from the Proposed Action, including transportation. DOE believes the EIS fulfills all legal obligations required for an EIS and a "comprehensive risk assessment" or a "comprehensive systems analysis or traffic impact analysis" as advocated by the commenter is neither required nor necessary.

8.8.1 (10075)
Comment - EIS001888 / 0551
[Clark County summary of comments it has received from the public.]

Commenters were generally concerned that the EIS address various aspects of transportation, such as: cost; pre-notification requirements; insurance; comprehensive analysis of impacts; credible scenarios and alternatives; environmental effects; effects on infrastructure; planning; cask testing; safety; security; emergency response; routing; historical and future shipments; impacts on Native Americans; compliance with regulations and identification of assumptions.

Response
The commenters should refer to the following sections of the EIS in which the requested information is presented:

- Transportation costs are summarized in Section 2.1.5 for the Proposed Action (there are no transportation costs for the No-Action Alternative). See CRWMS M&O (DIRS 104980-1999) *Environmental Impact Statement Cost Summary Report*, for additional details.

- Prenotification requirements are addressed in Section M.2.5.

- Insurance is addressed in Section M.8.

- Comprehensive analyses of impacts, environmental effects, and effects on infrastructure are addressed in Chapter 6 and Appendix J.

- Planning for the shipments is discussed in Section M.3.

- Cask safety and testing is discussed in Section M.4.

- Security is discussed in Section M.7.

- Emergency response is addressed in Section M.5.

- Routing is addressed in Sections M.2.4 and M.3.2.1.2.

- Historic shipments are discussed in Section 8.4.1.2. Accident data for past radioactive material shipments are discussed in Section J.1.4.2.3.1 and in *Transportation Accidents/Incidents Involving Radioactive Material* (DIRS 102172-McClure and Fagan 1998). Future shipments of spent nuclear fuel and high-level radioactive waste to the proposed Yucca Mountain Repository are presented in Section J.1.2.

- Impacts on Native Americans are addressed as follows: the Ruby Valley Treaty issue is discussed in Section 3.1.1.4; Native American interests are presented in Section 3.1.6.2; Section 3.1.13 of the EIS describes the minority or low income populations in Nevada; and Sections 6.3.4 and 8.4.2.12 address environmental justice impacts. Maps showing where minority or low-income populations are in relation to the site and the transportation corridors are provided in Section 3.1.1.3.

- Compliance with regulations is addressed in Chapter 11.

- Assumptions are explicitly identified throughout the EIS. A summary of DOE's approach to describing, documenting, and evaluating the effects of assumptions made where incomplete or unavailable data currently exists is presented in the EIS Section 2.5.

With respect to the comment on credible scenarios and alternatives, the transportation scenarios were constructed to bracket the total shipment volumes, which would be maximized for a nearly 100-percent mostly legal-weight truck scenario and minimized for a nearly 100-percent mostly rail scenario. DOE recognizes that many factors influence the selection of transport modes for the shipments, many of which are beyond its control, such as waste generator site operating characteristics, trading of acceptance rights, and cask handling capabilities at commercial nuclear powerplants. Since the actual mix of truck and rail shipments cannot be determined at this time, DOE evaluated two national transportation scenarios (mostly legal-weight truck and mostly rail) that bracket the actual mix of truck and rail shipments. DOE states in Section 2.1.1.3 of the EIS that it would determine the number of shipments by either mode as part of future planning efforts. Transport mode selection is further explained in Section M.3 and in the Request for Proposals for Waste Acceptance and Transportation Services (DIRS 153487-DOE 1998), located at *http://www.rw.doe.gov/wasteaccept/wasteaccept.htm*. Therefore, DOE believes it has employed realistic shipping scenarios that provide the information necessary to support the decisions to be made based on this EIS.

With respect to impacts on infrastructure, Section 3.2.1 of the EIS states that the shipments of spent nuclear fuel and high-level radioactive waste to the proposed repository represents a small fraction of current highway and rail traffic (0.006 percent of truck miles and 0.007 percent of rail miles per year). In addition, spent nuclear fuel and high-level radioactive waste truck and rail shipments would require no special highway or rail infrastructure that is not required for other hazardous commodities. The EIS presents the impacts of new infrastructure development within Nevada (see Section 6.3) because land acquisition and new construction would be needed to implement the Nevada rail and heavy-haul truck alternatives.

8.8.1 (10077)
Comment - EIS001888 / 0554
[Clark County summary of comments it has received from the public.]

Commenters stated that radiological and non-radiological impacts from transporting SNF [spent nuclear fuel] and HLW [high-level radioactive waste] should be evaluated in the ETS, for both workers and members of the public (including people along the route and people sharing the route). Cumulative health impacts and shipment of multi-purpose canisters also should be evaluated.

Response
The transportation impact analysis in Chapter 6 and Appendix J of the EIS includes the assessments for both workers and members of the public including people along the route and people sharing the route. The transportation impacts for several shipping casks, including multipurpose canisters are provided in Section 6 of the EIS. Cumulative impacts are given in Chapter 8.

8.8.1 (10142)
Comment - EIS001865 / 0017
Furthermore, the analysis in Appendix J appears to contain factual errors or misrepresentations. For example, it can be calculated from Table J-5 (page J-16) that 1,667 truck shipments from all four California commercial sites would take place during the 24-year operational period. However, when referring to Figure J-10 (page J-85) a small notation indicates that 6,250 truck shipments will enter Nevada on I-15 from California. Where do the extra 4,583 truck shipments come from? Likewise, it can be calculated from Table J-6 (page J-18) that 408 rail shipments from all four California commercial sites would take place during the 24-year operational period. However, when referring to Figure J-11 (page J-86) a small notation indicates that 1,837 rail shipments will enter Jean, Nevada from California. Where do the extra 1,429 rail shipments come from?

Response
Chapter 6 and Appendix J of the EIS contain substantial analyses related to the national transportation of spent nuclear fuel and high-level radioactive waste. However, in response to comments, considerable state-by-state information has been added to Appendix J which now includes maps for each state, including Federally recognized Native American Reservations, showing routes used in the analyses for the EIS and tables listing rail and truck shipments estimated to originate in and pass through each state, and incident-free and accident risk impacts for each state (see Section J.4).

8.8.1 (10300)
Comment - EIS001873 / 0080
Lincoln County Independent Research:

The County, under its federally funded Nuclear Waste Oversight Program, has produced numerous studies containing information concerning local impacts of the Yucca Mountain Project. As the County has stated in comments on the DEIS, the DOE has evidently not made any use of the County effort, which has cost approximately five million dollars to date. Following are some of the findings of the County studies. (My own observations are in parentheses.)

From Analysis of 46 mile rail corridor in Lincoln County 1986.

The study notes that 40% of the rail line is curved due to rugged terrain.

Braking is required for most of the route going south.

There is potentially a problem of the rail line being washed out due to flow from several side canyons under low clearance bridges. (One such low clearance bridge drains the site of the proposed Caliente Intermodal Facility. -LB)

A good percentage of the time the wind is towards Caliente from Rainbow Canyon (and the intermodal site) and would carry fallout from an accident to the town.

There is an average of 12 trains daily, and the average speed through the area is 32 mph.

There were 18 derailments between 1979 and 1981 involving 67 cars. Subsequently the record improved. (The current derailment record should be reviewed.)

Rocking of the cars on curves at 17 mph is a main cause of derailments, but trains must travel at this speed as they frequently speed up or slow down to negotiate the curves.

Sabotage potential is increased due to the remote and rugged nature of the area.

Emergency response in parts of the canyon areas would be next to impossible.

The Union Pacific RR Co. is not prepared to provide the needed level of emergency capability.

Mitigation measures identified include (1) a new rail line bypassing the area. (2) Implementing special train operations procedures. (3) Creation of a new organization to oversee HLW [high-level radioactive waste] shipments and react to sabotage threats.

Response
The types of information on the Caliente Corridor that Lincoln County produced are valuable for rail operations but are more detailed than necessary to support the decisions DOE would make based on this EIS. DOE would not base the choice of a rail corridor solely on environmental impacts; factors such as cost, schedule, procurement regulations, and others would influence the decision. The Department would continue to involve stakeholders in the decisions.

DOE believes that there are adequate rail lines, crossings, bridges, and tunnels nationally and in Nevada to support the transportation of materials described in the EIS. The shipment of radioactive materials requires no special transportation infrastructure that is not necessary for safe transport of commodities in the United States today.

Regional Servicing Contractor(s) for Waste Acceptance and Transportation Services would conduct detailed planning for rail service. DOE has issued a Draft Request for Proposal for one or more such contractors (available on the Internet at *http://www.rw.doe.gov/wasteaccept/wasteaccept.htm*; see Section M.3 of the EIS). Section C, Appendix 8, Paragraph 1.1 of the Draft Request for Proposal, "Mode Selection," states: "DOE requires, whenever possible, rail transport shall be used." As defined in Paragraph 2.2.7 of Section C, the transportation contractor must prepare a Transportation Plan that provides for "… maximum use of special train service and advanced rail equipment features where this type of service or equipment can be demonstrated to enhance operating efficiency, dependability, cost effectiveness or lessen the potential of adverse railroad equipment incidents."

DOE does not foresee a need to create a new organization to oversee shipments and react to sabotage threats. The U.S. Department of Transportation and the Nuclear Regulatory Commission provide independent Federal oversight of the transportation of spent nuclear fuel and high-level radioactive waste, including approval authority for the design, fabrication, and use of shipping containers, route selection, security, and other safety-related elements. States participate in and provide independent oversight of certain safety-related aspects of transportation, such as emergency preparedness and route selection.

8.8.1 (10356)
Comment - EIS001927 / 0007
The DOE must publish clear, truthful maps of the high-level waste/irradiated nuclear fuel transport routes to the proposed Yucca Mountain repository. The EIS must rigorously examine the risk involved in these shipments, and it must specify the exact mode of transportation – by train, truck, or barge. Site specific risk and potential impacts must be identified, to schools, hospitals, colleges, population centers, urban areas, agricultural lands, water and food storage, other vital resources, and natural areas along the routes. Increased risks of accidents due to extremes of weather or terrain must be analyzed, as well as the history of problems on these specific routes. In short, DOE should redo the entire national transport section of the EIS, and do it justice this time. DOE's failure to adequately assess transport impacts constitutes grounds for the withdrawal of the DEIS, and its re-issuance along with a new 180 day public comment period. Literally tens of millions of Americans have been kept in the dark by DOE – DOE concealed that fact that they live on irradiated fuel/high radioactive waste transport routes. Why did DOE do this?

Response
Comprehensive analyses of impacts, environmental effects, and effects on infrastructure are addressed in Chapter 6 and Appendix J of the EIS. In response to public comments, the transportation analysis in Appendix J was substantially revised. The EIS now includes maps of the truck and rail routes used in the analysis. Routing is addressed in Sections M.2.4 and M.3.2.1.2. These routes were used for analyzing transportation impacts in the EIS and are representative of the actual routes that would be used, which could be different. It is impossible for DOE to specify the exact mode of transportation for all shipments or the exact routes that would be used years before shipments began. As a result, DOE evaluated two national transportation scenarios (mostly legal-weight truck and mostly rail) that bracket the actual mix of truck and rail shipments. DOE states in Section 2.1.1.3 that it would determine the number of shipments by either mode as part of future planning efforts. Transport mode selection is further explained in Section M.3 and in the Draft Request for Proposals for Waste Acceptance and Transportation Services (DIRS 153487-DOE 1998), located at *http://www.rw.doe.gov/wasteaccept/wasteaccept.htm*. However, the Request for Proposals directs contractors to use special train service where it can be demonstrated to enhance operating efficiency and cost-effectiveness.

The EIS has been revised to include the estimated number of shipments and impacts for each state through which the analyzed routes would pass. The impacts at a particular location within a state, such as a town or city, would be less than the total for the state. The truck and rail accident rates used in the EIS include accidents of all causes and therefore account for past accidents, and extremes of weather and terrain.

DOE has provided information concerning the transportation routes used in the EIS in several different ways. For example, maps of the transportation routes were presented at each of the Draft EIS public hearings and a complete set of transportation maps was placed on the Yucca Mountain Project web site well before the end of the public comment period. The state maps are provided in Section J.4 of the EIS.

8.8.1 (10575)
Comment - EIS001310 / 0006
Transportation of SNF [spent nuclear fuel] and HLW [high-level radioactive waste] is inherently risky business. The DEIS systematically and significantly understates the risks associated with shipments to the proposed repository in the following ways:

- The DEIS grossly underestimates routine radiation exposures to transportation workers, safety inspectors, and members of the public, especially along highway routes in Nevada.

- The DEIS significantly underestimates the human health consequences of severe transportation accidents resulting in release of radioactive materials, and ignores the social and economic impacts of severe accidents and post-accident cleanup activities.

- The DEIS significantly underestimates the human health consequences of successful terrorism and sabotage incidents involving high-energy explosive devices, and ignores the social and economic impacts of successful terrorism and sabotage incidents and post-incident cleanup activities.

Response
The transportation impact analysis, including the impacts of routine radiation exposures and consequences of severe accidents, was performed using current, reasonable, and valid methods and data available to DOE. DOE believes the analysis does not underestimate the impacts and, in fact, there are many instances in which the analysis is conservative, tending to overestimate impacts.

DOE is aware that there are uncertainties associated with the transportation impact results presented in the EIS. There are uncertainties associated with route characteristics, demographics, weather, atmospheric dispersion models, waste characteristics, accident rates, release fractions, and many other elements of the risk assessments. Because one of DOE's goals is to choose between alternatives, the consistent consideration of uncertainty among alternatives means that the relative differences in impact estimates among alternatives should not be affected.

To account for uncertainties in the data, conservative assumptions were made, so the impacts reported in the EIS considered the associated range of potential impacts. Examples of conservative assumptions include:

- Accident release fractions selected from the high end of the distribution of experimental results

- Regulatory maximum radiation assumed for all shipments, even though the actual dose rates would be significantly lower for most shipments

- Consequences to maximally exposed individuals presented for 50 percent and 95 percent (that is, consequences exceeded only 5 percent of the time) meteorological conditions

- Evacuation and sheltering, which could reduce radiological exposures, not included in the accident risk calculations

However, DOE has chosen not to use assumptions that would contain the same high degree of conservatism in all cases, as this practice tends to produce unrealistic and improbable results. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing environmental impacts. Such practices mask the real differences and would not produce suitable results to support choices among the alternatives. Thus, for example, DOE has chosen to use realistic waste characteristics information, accident rates, highway and rail distances between waste generators and the proposed repository, and population demographics. DOE believes that the impacts presented in the EIS are not so conservative that the true differences among alternatives are masked.

The shipping cask performance data used to estimate the radiological risks of transporting spent nuclear fuel are from the *Reexamination of Spent Fuel Risk Estimates* (DIRS 152476-Sprung et al. 2000). These data represent the most recent and most thoroughly evaluated available information on the performance of shipping casks during severe transportation accidents.

The shipping cask performance data used to estimate the impacts of a successful sabotage event are from *Projected Source Terms for Potential Sabotage Events Related to Spent Fuel Shipments* (DIRS 104918-Luna, Neuhauser, and Vigil 1999). This report estimated maximum releases of radioactive material from the action of sabotage against a shipping cask containing spent nuclear fuel. The report considered 15 devices and chose two for detailed analyses. These data represent the most current and reasonable available information on the performance of shipping casks during a sabotage event.

Based on public comments on the Draft EIS, a discussion on the costs of cleanup has been added to Appendix J of the EIS. According to the Nuclear Regulatory Commission report, there would be no release of radioactive material from the cask in 99.99 percent of transportation accidents involving spent nuclear fuel (DIRS 152476-Sprung et al. 2000). The economic costs of accidents that did not have a release of radioactive material would be small.

In 0.01 percent of accidents some radioactive material could be released from the cask. Based on the studies discussed in Appendix J of the EIS, the economic costs of severe transportation accidents involving spent nuclear fuel could be in the range of as little as $200,000 to $270 billion. However, extreme cost estimates are for accidents where all factors are assumed to combine in the most detrimental way to maximize consequences. Such extreme, or worst-case, accidents are not reasonably foreseeable so the estimates of cost are not useful for comparisons. The probability of the accidents analyzed in the studies range from about 1 in 1 million per year to less than 1 in 1 trillion (1 followed by 11 zeros) per year.

For perspective, the current insured limit of responsibility for an accident involving releases of radioactive materials to the environment is $9.43 billion. The annual cost of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain would be about $200 million.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.8.1 (11010)
Comment - EIS001896 / 0008
Section 6.1.1 Impacts of Incident-Free Transportation

States that over 24 years of the proposed action, an estimated 18 latent cancer fatalities could occur in general populations along transportation route from radiation exposure under legal-weight truck scenario, and estimated 2 deaths under rail scenario. With the most heavily traveled routes being through urbanized areas in Southern Nevada and on congested highways, and the relatively slow speed of the trucks, there is a higher than normal potential for risk to our residents. Also, security and emergency response have not been adequately addressed.

Response
The transportation risk analysis in the EIS used state-specific truck and rail accident data from the U.S. Department of Transportation, supplemented by data obtained from the State of Nevada. In addition, the transportation analysis accounts for slower speeds by trucks in urban areas. The results of these analyses show that the risk to residents of Nevada would be low. Estimated radiological incident-free doses to individuals that might receive exposures, including truck crew members, inspectors, individuals stuck in traffic, and nearby residents are presented in Appendix J of the EIS. Appendix M contains an expanded discussion of security (see Section M.7) and emergency response (see Section M.5).

8.8.1 (11012)
Comment - EIS001896 / 0010
Section 10.1.2.5

The construction and operation of the rail and heavy-haul alternative will have adverse impacts on workers and the general public which are not addressed.

Response
DOE believes that Section 10.1.2.5 of the Draft EIS (Section 10.1.3 in the Final EIS) adequately summarizes the unavoidable adverse impacts of the heavy-haul truck and rail implementing alternatives within Nevada. In addition, this section references the sections of the EIS that describe estimated impacts.

8.8.1 (11424)
Comment - EIS002234 / 0008
Furthermore, the analysis in Appendix J appears to contain factual errors or misrepresentations. For example, it can be calculated from Table J-5 (page J-16) that 1,667 truck shipments from all four California commercial sites would take place during the 24-year operational period. However, when referring to Figure J-10 (page J-85) a small notation indicates that 6,250 truck shipments will enter Nevada on I-15 from California. Where do the extra 4,583 truck shipments come from? Likewise, it can be calculated from Table J-6 (page J-18) that 408 rail shipments from all four California commercial sites would take place during the 24-year operational period. However, when referring to Figure J-11 (page J-86) a small notation indicates that 1,837 rail shipments will enter Jean, Nevada from California. Where do the extra 1,429 rail shipments come from?

Response
Chapter 6 and Appendix J of the EIS contain substantial analyses related to the national transportation of spent nuclear fuel and high-level radioactive waste. However, in response to comments, considerable state-by-state information has been added to Appendix J, which now includes maps for each state, including Federally recognized Native American Reservations, showing routes used in the analyses for the EIS and tables listing rail and truck shipments estimated to originate in and pass through each state, and incident-free and accident risk impacts for each state (see Section J.4). These numbers should be considered tentative, as there are many factors that could cause the modes and routes to change including reactor operations, trading of pickup allocations, selection of a different transportation mode for shipments by the reactor operator, or recommendation of alternate routes by states. Impacts in individual states could be different if the actual routes from generator sites to Yucca Mountain were different from those analyzed. However, it is not likely that the total impacts from transportation would be changed significantly or that any particular route connecting an origin/designation pair present a significant difference in impacts from any other.

The number of shipments from generators in California identified in tables in Appendix J of the EIS are not the same as the number of shipments that would enter Nevada from California identified on figures in the appendix because shipments from generators in other states would also enter Nevada from California. For purposes of analysis in the EIS, DOE used methods described in Section J.1.1 to estimate routes shipments would use to transport spent nuclear fuel and high-level radioactive waste from commercial and DOE generator sites to a Yucca Mountain Repository. Using these methods, routes for rail and truck shipments used in the analyses included ones from generator sites that are not in California but that would enter Nevada from California either on the Union Pacific Railroad mainline or by legal-weight truck on Interstate-15.

An example of a generator site that would ship through California would be the Palo Verde Nuclear Plant in Arizona. In the mostly rail analysis scenario in the EIS, the calculated route for rail shipments from this site used Union Pacific mainlines. This route crosses the Arizona-California border near Yuma, Arizona, then travels to southeastern Nevada through San Bernardino and Barstow, California.

In the mostly legal-weight truck scenario, the route for shipments was calculated using rules in U.S. Department of Transportation regulations (see Sections M.2.4 and M.3.2.1.2 of the EIS). In this case, the required route under current regulations and following preferred routes currently designated by states and the Department of Transportation would be Interstate-10 from Arizona to San Bernardino, California, where it intersects with Interstate-215, Interstate-215 to Interstate-15, and Interstate-15 from California into Nevada.

Altogether, for the mostly rail scenario and a Jean branch rail line or Sloan/Jean heavy-haul truck route, the analysis in the EIS used rail routes from 13 generator sites outside California that would travel through the State. For the mostly legal-weight truck scenario, the analysis used routing that would travel through California for shipments from eight generators outside the State.

8.8.1 (11700)
Comment - EIS001597 / 0005
Obviously, if a spent nuclear fuel repository at Yucca Mountain is opened some time in the future, the number of shipments of spent fuel traversing Illinois will logically increase. But it seems to us that the frequency of shipments through Illinois appears to be skewed, and we wonder whether or not that skewing is not intentional. By skewing, we mean that they appear to be greater than they should be.

Response
In response to public comments, DOE has included maps of the highway routes and rail lines it used for analysis in Section J.4 of the EIS. Along with the maps the Department included potential health and safety impacts associated with shipments for each state through which shipments could pass, including Illinois.

8.8.1 (11752)
Comment - EIS001226 / 0009
I am concerned about environmental protection, safety, liability, disaster management, worker safety, incidental radiation exposure, property values. How will 30 years of nuclear waste shipments through Illinois impact the Chicago area, and what plans do you have for shipping accidents?

Response
The impacts of transportation are discussed in Chapter 6 and Appendix J of the EIS, which discuss issues such as those identified by the commenter.

In response to public comments, DOE has included maps of the highway routes and rail lines it used for analysis in Section J.4 of the EIS. Along with the maps, the Department included potential health and safety impacts associated with shipments for each state through which shipments could pass, including Illinois. The impacts in the Chicago area would be less than those for the State. Section M.5 discusses transportation emergency response.

8.8.1 (11824)
Comment - EIS001887 / 0389
In addition, the one hundred percent rail transportation scenario contained in the Draft EIS is impossible without substantial investments at reactor sites for infrastructure to accommodate large rail casks. Many reactor locations

cannot currently accommodate these types of transportation casks. Information as to which generator sites will require such upgrades is available. The Draft EIS should have evaluated the costs and impacts of such improvements.

Response
Section 2.1.3 of the EIS discusses the transportation scenarios. DOE believes that the mostly rail case, in which more than 95 percent of spent nuclear fuel and high-level radioactive waste would be shipped by rail, would most closely approximate the actual mix of truck and rail shipments. In reaching this conclusion, DOE has assessed the capabilities of the sites to handle larger (rail) casks, the distance to suitable railheads, and historic experience in actual shipments of nuclear fuel, waste, or other large reactor-related components. In addition, DOE considered relevant information published by sources such as the Nuclear Energy Institute and the State of Nevada. The mostly rail scenario would not require infrastructure improvements at commercial nuclear reactor sites.

Even if infrastructure improvements were required at some generator sites, the impacts and costs of such improvements are not in the scope of this EIS.

8.8.1 (12265)
Comment - EIS001888 / 0257
One of the primary reasons this examination is confined to truck analysis, is because the heavy rail casks assumed to be used in the DEIS do not exist at all. Several of the DEIS references were prepared assuming use of the Multiple Purpose Canister (MPC). The MPC was proposed by the DOE as a heavy transportation canister in 1994. It was later withdrawn after the preparation of an EIS. The reference documents cited to support the conclusions in the DEIS rely on the MPC canister for their conclusions. Therefore, the rail transportation scenario contained in the DEIS is almost entirely hypothetical. Past rail transportation experience, specifically data used in a risk assessment is wholly irrelevant to the proposed action.

Response
Section 2.1.3.4 of the EIS addresses shipping cask manufacture, maintenance, and disposal. In this section, DOE indicates that one or more qualified companies specializing in metal structures, tanks, and other heavy equipment would manufacture new shipping casks. Section 4.1.15.1 identifies five sites of component and/or full cask manufacturers in the United States (not to mention overseas capabilities) and the number of shipping casks needed for the truck and rail transportation program (Table 4-45). Additional detailed information is provided in the DOE report to Congress, *Plan for Transportation Cask Fabrication and the Deployment of Waste Acceptance Capabilities* (DIRS 156802-DOE 2001). In Appendix A of the plan, DOE provides three tables of existing casks and casks under development for truck transport, for rail transport, and for storage and transportation casks. The tables indicate that there are 14 truck casks built and three being fabricated, 6 rail casks built, and 11 dual-purpose casks built and nine being fabricated. A fourth table provides details of two U.S. manufacturers, indicating their capability to produce 20 casks per year after a 6-month lead-time.

The Nuclear Regulatory Commission has recently issued a 10 CFR Part 71 Certificate of Compliance for three transportation casks for rail transport. At present, one MP-187 and four HI-Star 100 casks have been produced. To date, no NAC-STC transportation casks have been produced. In addition, Transnuclear submitted a 10 CFR Part 71 application for its TN-68 rail cask in May 1999. Based on this demonstrated performance and capabilities, DOE believes the acquisition of adequate casks for the mostly rail scenario is reasonable.

8.8.1 (12302)
Comment - EIS001925 / 0004
Will the DOE agree not to ship the nuclear waste with other hazardous cargo?

Response
As described in Sections 6.1 and 6.2 of the EIS, spent nuclear and high-level radioactive waste shipped by trucks would be shipped with no other hazardous cargo present. Should spent nuclear fuel and high-level radioactive waste be shipped by trains, other hazardous cargo could be present. U.S. Department of Transportation regulations would prevent these other hazardous cargoes from being a hazard to the spent nuclear fuel and high-level radioactive waste, and the spent nuclear fuel and high-level radioactive waste would not be a hazard to these other cargoes.

8.8.1 (12361)

Comment - EIS002233 / 0002

We [San Bernardino County] border the southern portion of Nevada, and unfortunately, expect that high-level nuclear waste will be transported through this county as part of the proposal; and we are deeply concerned about potential significant consequences and impacts that an accident, sabotage, or other adverse events could have on our county. While the risk of an accident may be small, the result of even one accident could have enormous and grave consequences on the portion of the county where the accident occurred. We are not talking about an oil spill and fire. This would have long-term, wide-spread, devastating effects on our county.

If the Federal government cannot guarantee zero tolerance against the risk of accident in the transport of high-level radioactive waste across our county, then this project should not be approved and should not proceed.

We are deeply concerned that the EIS inadequately and only superficially evaluates the transporting of spent nuclear fuel and high-level nuclear waste to Yucca Mountain. The waste is controlled and supervised where it is currently located, as an example, in San Onofre. It will be controlled and supervised at Yucca Mountain. A good deal of that control and supervision is lost, however, once the fuel waste is placed in a truck or in a truck and a railroad car.

Hence, it is critical that extreme measures are taken to protect this high-level radioactive waste during transport across our county. And yet we find precious little evaluation of this risk in the EIS. It is only discussed in general terms. It gives us very little assurance that an accident during transport will not occur and how an accident will be mitigated, if it does occur.

The EIS is deficient in its current approach which fails to address the possible consequences of transportation over even plausible specific routes that are currently known or reasonably predictable. This type of evaluation is critical to local jurisdictions, such as our county, and should not be deferred until some uncertain future point in time.

The potential for release of high level radioactive materials through accidents or deliberate acts of sabotage are of grave concern to this county. The implications are far-reaching, and only minimally addressed in the EIS.

So we urge you, we implore you, to place this process on pause and undertake the needed detailed analysis of the transport of nuclear waste so that we can achieve a level of assurance that our homes, our schools, our churches, for that matter our whole living environment, is adequately protected in the years to come.

Response

The EIS acknowledges that transportation accidents can occur during the transport of radioactive materials to the proposed Yucca Mountain Repository. In Section J.1.4.2.3, the EIS estimates that there could be as many as 70 accidents under the mostly legal-weight truck shipping scenario and 8 accidents could occur under the mostly rail scenario. A study recently conducted by the Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000) concluded that only a tiny fraction of all accidents, less than one in 10,000, would be severe enough to fail a spent nuclear fuel shipping cask. The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. Based on these statistics, DOE does not expect an accident to occur that would involve radiological consequences.

DOE acknowledges that all accidents cannot be prevented, even if unlimited funds and time are provided to complete an activity. However, assuring the safety of the public, workers, and the environment is the most important priority for the spent nuclear fuel and high-level radioactive waste shipping program. Many safety-related measures in addition to the use of accident-resistant Type B shipping casks would be employed to provide this assurance, including route selection to reduce risks, driver training, shipping cask and vehicle inspection and maintenance, emergency preparedness programs, prenotification requirements, preshipment planning, and others. In addition, safety incentives are included in the September 1998 Draft Request for Proposals for Waste Acceptance and Transportation Services (see Section M.3 of the EIS and *www.rw.doe.gov/wasteaccept/wasteaccept.htm*). Thus, while the risk of this or any other activity cannot be reduced to zero, DOE believes that adequate preventive, protective, and mitigative measures are or would be in place to ensure that the shipments pose no undue risks to the public, workers, and environment.

In terms of control and supervision, DOE is aware that spent nuclear fuel is better controlled at fixed locations, such as waste generator sites and the repository, than it is while being shipped. Access controls, guards, locked gates, and monitoring systems are examples of controls that are applied at fixed facilities to protect spent nuclear fuel. This is the main reason why special safeguards and security requirements (see 10 CFR Part 73) are applied to shipments of spent nuclear fuel to prevent their theft or diversion in transit. DOE would comply with all requirements of 10 CFR Part 73, including preshipment planning, communications, armed escorts, and tamper-indicating devices on shipping casks. In addition, a satellite tracking system such as the TRANSCOM system would be deployed to provide real-time tracking of the shipments and preshipment and in-transit communications. With all these controls in place, as well as the use of massive Type B containers that would provide considerable protection of spent nuclear fuel and high-level radioactive waste contents, DOE believes the shipments and the radioactive cargo would be adequately protected from theft, diversion, or acts of sabotage. See Section M.7 of the EIS for additional information on physical protection requirements.

The transportation impact analysis in the EIS is consistent with the requirements of the National Environmental Policy Act, Council on Environmental Quality guidelines, and DOE policies and guidance. It was also designed to provide the information necessary to support the decisions to be made based on the EIS. As stated on page S-2 of the Draft EIS Summary:

"DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada…Other transportation decisions, such as selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews."

DOE believes that use of location-specific data and development of location-specific impact estimates such as the commenter suggests would not be practical or possible and would not materially affect the comparisons of alternatives and decisions to be made with regard to construction and operation of the proposed repository. Nevertheless, in response to comments on the Draft EIS, DOE has revised Appendix J of the EIS to include state maps of routes used in the analyses of impacts, the numbers of shipments in each state used in the analyses, and state-specific impact estimates.

8.8.1 (12369)
Comment - EIS010207 / 0001
The "Supplement to the Draft Environmental Impact Statement for a Geologic Repository...at Yucca Mountain" does not adequately address the hazards and problems of transporting nuclear wastes through populated areas to the Yucca Mountain site. Although St. Louis is centrally located for shipment of nuclear wastes, transporting irradiated fuel rods through downtown seems unsafe. On May 31, fourteen laden coal cars derailed and dumped their contents in a St. Louis suburb. Accidents happen. The accidental spilling of nuclear wastes could be lethal. Moreover, the plutonium and uranium are vulnerable to theft during transport.

Response
DOE issued the Supplement to the Draft EIS to provide updated information to the public. While aspects of the design have evolved from those in the Draft EIS, the basic elements of the Proposed Action to construct, operate and monitor, and eventually close a geologic repository at Yucca Mountain (such as transportation of spent nuclear fuel and high-level radioactive waste) remain unchanged. For this reason, the Supplement focused on the most recent design enhancements, including various operating modes to manage heat generated by emplaced spent nuclear fuel and high-level radioactive waste.

As discussed in Appendixes J and M of the EIS, most real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask into a river, and similar extreme accident conditions, would not be likely to result in release of radioactive materials from the shipping casks. Spent nuclear fuel casks are much more robust than the coal cars. If a spent nuclear fuel rail cask had been on the train that derailed and crashed into the river, the accident conditions would not have been more severe than the design standards for the cask. No release of radioactive materials from the cask would have been expected. The performance standards for the casks prescribed by the Nuclear Regulatory Commission (see Section M.4) were selected to ensure that the chance that a real-world accident would result in loss of cask integrity and release of radioactivity from the cask is extremely remote. These standards ensure that the casks would be extremely robust.

Based on the revised analyses, DOE has concluded in the EIS that casks would continue to fully contain spent nuclear fuel in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that there would be less than a 1-percent chance over 24 years of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain by truck of an accident that could result in a release of radioactive material from a cask. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be much less than 1 percent.

In the Draft EIS DOE considered six categories of increasingly severe and increasingly unlikely accident scenarios. The analyses hypothesized one accident scenario to represent each category, along with a corresponding projection of the amount of radioactive material that could be released from a transportation cask. The analyses estimated impacts of postulated releases in three population zones – urban, suburban, and rural – and under two weather conditions – slowly dispersing conditions, and moving-air conditions. The analyses also estimated the impacts from an unlikely but severe accident scenario called a maximum reasonably foreseeable accident. In response to public comments and to clarify this discussion for the reader, DOE has revised the EIS to describe the maximum reasonably foreseeable accident in terms of cask failure mechanisms, range of impact velocities, and temperature range for the accident.

The probabilities of the maximum reasonably foreseeable truck and rail accidents are stated in Sections 6.2.4.2.1 and 6.2.4.2.2 of the EIS. For the maximum reasonably foreseeable truck accident, the probability is about 2.4 in 10 million per year. For the maximum reasonably foreseeable rail accident, the probability is about 2.8 in 10 million per year. Radioactive materials are easily detected and there are proven methods for cleaning up spills and releases of radioactive materials. Like hazardous materials, any released radioactive materials would be cleaned up to existing standards in a reasonable length of time.

The Nuclear Regulatory Commission regulates the packaging and transportation related operations of its licensees, including establishing safeguards and security regulations to minimize the possibility of theft, diversion, or attack on shipments of spent nuclear fuel and special nuclear materials (10 CFR Part 73). DOE would comply with all requirements, including preshipment planning, communications, armed escorts, and tamper-indicating devices on shipping casks. Physical protection requirements are described in Section M.7 of the EIS.

8.8.1 (12577)
Comment - EIS001622 / 0016
Need for a Comprehensive transportation Analysis of Public Risks and Costs

The DEIS does not provide any meaningful quantitative transportation risk assessment, but instead refers to other agencies' regulatory authority. For example, DOE addresses transportation accident hazards by simply stating that transport of wastes will occur in accordance with U.S. Department of Transportation regulations.

Any analysis of transportation risks associated with shipping spent nuclear fuel is extremely sensitive to the assumptions made regarding, for example, routing, the amount of material shipped by rail versus truck, and the number of people along the routes and at various stops. The DEIS uses the "Modal Study" (NRC 1987) to predict very low probabilities of release of radioactive materials from a spent fuel cask under accident conditions. These analyses and risk analysis tools such as RADTRAN, although accepted by federal agencies for assessing transportation risks, have been criticized because of changing assumptions about cask capacity (new-generation casks will have much larger capacities), the radioactive characteristics of the spent fuel (radioactivity varies with fuel age and burn-up levels), the role human error may play in manufacturing quality control and operation of the casks, and the risk of sabotage or terrorist threat against a shipment.

In addition, tools such as RADTRAN incorporate critical assumptions about roadway geometrics and maintenance standards that require review if non-interstate routes are to be considered. The large projected increase in the numbers and operational complexity of spent fuel shipments to the proposed repository, in comparison with past shipments, may result in greater opportunities for human error in construction and operation of the spent fuel shipping casks. These factors should be taken into consideration in the DEIS' transportation risk assessment.

Further, the DEIS should provide a route-specific evaluation of the increased transport risk as the result of earthquakes, flooding, poor road conditions, and weather conditions. In addition, some routes leading to the Nevada Test Site/Yucca Mountain area are heavily traveled tourist and recreational routes. These routes can be greatly impacted by increased traffic. Increased truck traffic could influence the safety, reliability and congestion characteristics of these routes. The EIS should evaluate such potential impacts.

Recommendation: DOE should conduct a comprehensive risk analysis of routes and transport modes including public risks and costs to states, tribes and local communities to prepare for these shipments. When the proposed routes are identified in California, future EIS analyses should include a complete environmental review, including route-specific environmental analyses, in accordance with the requirements of the Clean Air Act, NEPA [National Environmental Policy Act], and the California Environmental Quality Act. This routing analysis of the primary and secondary routes should include structural and geometric road characteristics, emergency response capabilities along these routes, socio-economic impacts, wildlife, habitat, and public parts impacts, as well as risks to human populations along these routes. The DEIS should identify the significant fiscal impacts of emergency response preparation for these shipments and necessary road and rail improvements.

Response

DOE disagrees with the comment that the EIS does not provide a meaningful quantitative transportation risk assessment. Furthermore, DOE disagrees with the commenter's statement that transportation accident hazards are dismissed by referring to U.S. Department of Transportation regulations. Quantitative human health and safety impacts, as well as other environmental and socioeconomic impacts (for example, impacts on land use, water resources, biological resources, employment), for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain are presented in Chapter 6 and Appendix J of the EIS. This included quantification of the radiological and nonradiological impacts of transportation accidents as well as the impacts of routine transportation. The transportation impact analysis in the EIS is consistent with the requirements of the National Environmental Policy Act, Council on Environmental Quality guidelines, and DOE policies and guidance. It was also designed to provide the quantitative information necessary to support the decisions to be made based on the EIS.

The transportation analysis in the EIS used state-of-the-art risk assessment tools and the currently available information that is reasonable to estimate the impacts of transporting spent nuclear fuel and high-level radioactive waste to the repository. For example, the computer programs used in the transportation analysis have been used extensively in other environmental impact statements and environmental assessments and have been evaluated to determine their validity for this purpose. The data used in the EIS to estimate transportation impacts are those that are available, reasonable, current, and adequate. In many instances special studies were conducted to collect additional data. For example, transportation accident and fatality rates were updated for the EIS in *State-Level Accident Rates of Surface Freight Transportation: A Reexamination* (DIRS 103455-Saricks and Tompkins 1999) and source terms from potential sabotage events were updated for the EIS in *Projected Source Terms for Potential Sabotage Events Related to Spent Nuclear Fuel Shipments* (DIRS 104918-Luna, Neuhauser, and Vigil 1999). The shipping cask performance data used to estimate the radiological risks of transporting spent nuclear fuel are from the Nuclear Regulatory Commission report *Reexamination of Spent Fuel Risk Estimates* (DIRS 152476-Sprung et al. 2000). These data represent the most recent, extensively researched available information on the performance of shipping casks during transportation accidents.

DOE recognizes that human errors cannot be totally eliminated during the fabrication and operation of shipping casks. Section J.1.4.2.1 of the EIS presents a discussion of the potential effects of human error, including undetected defects, on accident impacts. The shipping casks would be fabricated under Nuclear Regulatory Commission-approved quality assurance programs. As indicated in the GA4/9 shipping cask Certification of Compliance, each shipping cask would be extensively tested prior to its first use, including radiographic and ultrasonic inspections of welds, load testing of lifting trunnions, pressure testing of the cask containment boundary, gamma scans of the depleted uranium shield, and other tests. Trained and qualified personnel would conduct all testing. The shipping casks would be subjected to periodic in-service testing and maintenance, such as seal replacement, visual inspections of seals and sealing surfaces, and leakage testing. In addition, all shipping cask handling, loading, unloading, testing, and maintenance operations would be conducted in accordance with detailed written procedures and by trained and qualified personnel. These testing, maintenance, procedural, and personnel training requirements would minimize the likelihood and consequences of human errors during cask fabrication and operation.

The shipping cask performance data used to estimate the impacts of a successful sabotage event are from *Projected Source Terms for Potential Sabotage Events Related to Spent Fuel Shipments* (DIRS 104918-Luna, Neuhauser, and Vigil 1999). This report estimated maximum releases of radioactive material from sabotage against a shipping cask containing spent nuclear fuel. The report considered 15 devices and chose two for detailed analyses. These data are reasonable, available, and appropriate information on the performance of shipping casks during a sabotage event.

Substantial amounts of site-specific data were used in the transportation analyses. For example, *Road Upgrades for Heavy Haul Truck Routes - Design Analysis* (DIRS 154448-CRWMS M&O 1998) includes tables of the speeds and times used for every section of highway for heavy-haul trucks for the entire route from the intermodal transfer station to the repository and it shows that travel speeds at intersections and in towns such as Tonopah and Goldfield, would be as low as 8 kilometers (5 miles) per hour. Based on public comments, the EIS now includes impacts representative of impacts in small communities along transportation routes. This analysis accounts for factors such as the locations of intersections, commercial establishments and residences, and traffic signals.

If data were unavailable, DOE made cautious yet reasonable assumptions to estimate impacts. These assumptions are discussed in Chapter 6 and Appendix J of the EIS, and in references for these sections. DOE is aware that there are uncertainties associated with the transportation impact results presented in the EIS. There are uncertainties associated with route characteristics, demographics, weather, atmospheric dispersion models, spent nuclear fuel characteristics, accident rates, release fractions, and many other elements of the risk assessments. Because one of DOE's goals is to choose between alternatives, the consistent consideration of uncertainty among alternatives means that the relative differences in impact estimates among alternatives should not be affected. To account for uncertainties in the data, conservative assumptions were made so the impacts reported in the EIS would consider the associated range of the potential impacts. However, DOE has chosen not to use assumptions that tend to overestimate in all cases, as this practice tends to produce unrealistic and improbable results. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing environmental impacts. Such practices mask the real differences and would not produce suitable results to support choices among the alternatives. Thus, for example, DOE has chosen to use realistic waste characteristics information, accident rates, highway and rail distances between waste generators and the proposed repository, the number of people along the route and at stops, and shipping cask capacities. DOE believes that the impacts presented in the EIS are not so conservative that the true differences among alternatives are masked.

Section M.3 of the EIS includes a discussion of the protocols and procedures to be followed under adverse weather or road conditions and describes how safe parking areas are to be determined. The procedures are in two parts. One relates to pretrip planning that would use available data relating to expected conditions. Shipments would not be dispatched on a route where expected conditions would not comply with the requirements in the procedures. For in-route problems, it is expected that those with the shipment would best be able to discuss and report expected and encountered conditions. The transportation contractors are to develop detailed procedures for use by the drivers/crews in making determinations regarding adverse weather and road conditions. The procedure states that DOE would coordinate diversion to a safe area if delay was required.

With respect to the risk of transportation accidents from earthquakes, the frequency of such an event is below the 1×10^{-7} accidents per year that are considered by DOE to be reasonably foreseeable. This is because a series of events would need to occur simultaneously for a spent nuclear fuel shipment to become involved in an accident severe enough to fail the packaging system as a result of an earthquake. First, a relatively severe earthquake would need to occur. As a rule of thumb, an earthquake would not disturb drivers unless it is about Richter Magnitude 6 or greater (ground acceleration in excess of 0.1*g* or 0.1 times the acceleration due to gravity). This magnitude of earthquake is severe enough to cause extensive damage to buildings (depending on quality of construction) and cause chimneys to fall. Second, a spent nuclear fuel shipment would need to be close enough to the epicenter of the earthquake to be affected. Third, the earthquake would need to be strong enough to cause the spent nuclear fuel or high-level radioactive waste shipment to become involved in a severe accident. A ground acceleration of 0.1*g* would not be severe enough, in general, to cause highway or bridge failures that could lead to a severe accident. However, it would be noticeable to a truck driver and could cause the driver to swerve or engage in an unsafe action. Most likely, this magnitude of earthquake would cause drivers to pull over and await further instruction. Finally, the accident would need to be severe enough to cause functional failure of the shipping cask. As discussed in the EIS, spent nuclear fuel and high-level radioactive waste would be shipped in extremely accident-resistant shipping casks. Even under severe accidents, the shipping cask would be likely to remain intact and retain its radioactive cargo. As a result, DOE has concluded that the frequencies of transportation accidents initiated by earthquakes are not reasonably foreseeable and, thus, are not required by the National Environmental Policy Act to be analyzed in the EIS.

The commenter requested additional information on emergency response provisions. Two regulations address the concern. First, NWPA Section 180(c) requires DOE to provide funds for training emergency response personnel in eligible jurisdictions along selected transportation routes. These requirements are discussed in detail in Sections M.5 and M.6 of the EIS. Second, there is a Federal Radiological Program outlined in the Federal Radiological Emergency Response Plan and the Federal Radiological Monitoring and Assessment Plan. These plans outline the policies, procedures, roles, and responsibilities of Federal, tribal, state, and local agencies in planning for and responding to emergencies involving releases or suspected releases of radiological materials from government and commercial facilities or operations. Under Section 180(c), DOE will fund eligible jurisdiction planning activities to determine current capabilities and needs and fund training for emergency response activities.

With regard to road and rail improvements outside Nevada, the shipment of radioactive materials requires no special transportation infrastructure that is not necessary for safe transport of commodities in the United States today. The U.S. Department of Transportation is the regulatory agency responsible for establishing and enforcing the standards for the transportation infrastructure. Adequate highways, rail lines, crossings, bridges, and tunnels exist to support the transportation of materials described in the EIS. In Nevada, upgrades to roads for heavy-haul truck shipments and the construction of a branch rail line to the repository are discussed in Chapter 6 and Appendix J of the EIS.

8.8.1 (12694)
<u>Comment</u> - EIS001898 / 0006
In the absence of a preferred route and mode of transportation, it is unclear whether the non-radiological impacts related to transportation of SNF [spent nuclear fuel] and HLW [high-level radioactive waste] within Nevada, including impacts from construction and operation of intermodal transfer stations and rail lines, have been bounded.

Basis:

The DEIS identifies the transportation of SNF and HLW as one of the components necessary for a repository. As such, transportation is a connected action (40 CFR 1508.25(a)(1)) and should be considered an integral part of the Yucca Mountain project. The NRC [Nuclear Regulatory Commission] understands that DOE would like to benefit from public input, through comments on the DEIS, when considering preferred transportation modes and routes. However, an integrated impact assessment that connects transportation to disposal needs to be included as part of any evaluation of the Proposed Action in the FEIS.

The current analysis for transportation within Nevada provides a general discussion of impacts, but does not fully assess the non-radiological impacts. Further, it is not apparent that the transportation analysis in the DEIS bounds the non-radiological impacts (e.g., socioeconomic impacts and impacts to air quality, cultural and biological resources, and land and water use). Moreover, although DOE has identified a number of options, it has not clearly defined which options (e.g., rail line construction, mode of transportation, need for intermodal transfer stations, preferred routing within Nevada, and type of trucks) it will use to support the Proposed Action.

As noted in Comment 1, the FEIS should show that, once decisions on transportation routes and modes are made, no new information or circumstances exist that could result in significant changes to the impacts assessed in the FEIS.

Recommendation:

Transportation impacts (including non-radiological and cumulative impacts) should be discussed in sufficient detail to support selection of a Proposed Action. The FEIS should contain either a complete, integrated assessment of the connected transportation actions or sufficient information and analyses on the various options to show that the impacts of the Proposed Action have been bounded.

Response

DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. At this time, however, the Department has not identified a preference among the five candidate rail corridors in Nevada.

If the Yucca Mountain site was approved, DOE would issue at some future date, a Record of Decision to select a mode of transportation. If, for example, mostly rail was selected (both nationally and in Nevada), DOE would identify a preference for one of the rail corridors in consultation with affected stakeholders, particularly the State of Nevada. In this example, DOE would announce a preferred corridor in the *Federal Register* and other media. No sooner than 30 days after the announcement of a preference, DOE would publish its selection of a rail corridor in a Record of Decision. A similar process would occur in the event that DOE selected heavy-haul truck as its mode of transportation in Nevada. Other transportation decisions, such as the selection of a specific rail alignment within a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. For instance, DOE selected the RADTRAN 5 computer program to estimate radiological impacts to populations from incident-free transportation and from accidents. RADTRAN, which was originally developed by Sandia National Laboratories in the late 1970s, has been used in many other previous DOE EISs, and it has undergone periodic review and revision. In 1995, an independent validation review of RADTRAN 4 (immediate predecessor to RADTRAN 5) demonstrated that it yielded acceptable results when compared to "hand" calculations. More recently, an independent review found that RADTRAN 5 overestimates the measured radiation dose to an individual from moving radiation sources.

To ensure that the EIS analyses reflect the best latest reasonably available information, DOE has either incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relies on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data.

Although the EIS analyses are based on the best latest reasonably available information and state-of-the-art analytical tools, not all aspects of incident-free transportation or accident conditions can be known with absolute certainty. In such instances, DOE has relied on conservative assumptions that tend to overestimate impacts. For instance, DOE assumed that the radiation dose external to each vehicle carrying a cask during routine transportation would be the maximum allowed by U.S. Department of Transportation regulations. Similarly, DOE assumed that an individual, the "maximally exposed individual," would be a resident living 30 meters (100 feet) from a point where all truck shipments, or 200 meters (660 feet) from a point where all rail shipments would pass. Under these circumstances, the maximally exposed individual would receive a dose of about 6 millirem from exposure to all truck shipments, and a dose of about 2 millirem from exposure to all rail shipments (6 millirem represents an increased probability of contracting a fatal cancer of 3 in 1 million). Although it can be argued that individuals could live closer to these shipments, it is highly unlikely that an individual would be exposed to all shipments over the 24-year period of shipments to the repository, even though DOE incorporated this highly conservative assumption in the analysis.

8.8.2 NEVADA GENERAL

8.8.2 (121)
Comment - 4 comments summarized
Commenters stated that the EIS did not consider scoping comments, advice, and reference documents submitted to DOE from affected counties and State agencies in Nevada. As a consequence, the EIS ignores a host of important community issues that would reasonably be expected to be considered in a project of this scope and significance. Another commenter said that the information necessary to make an accurate assessment of the impacts to Nevada from spent nuclear fuel and high-level radioactive waste transport is available, not exorbitant to gather, and should be obtained and included in the EIS prior to any agency decision, as required by the National Environmental Policy Act.

Response
In analyzing potential impacts of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain, DOE evaluated the potential for impacts in Nevada and counties within the region of influence in multiple environmental resource areas considered in the environmental impact analyses. These resource areas, described in Section 6.3 of the EIS, include land use; air quality; hydrology; biological resources and soils; cultural resources; human health and safety; socioeconomics; aesthetics; noise; waste management; utilities, energy, and materials; and environmental justice.

To analyze the potential for impacts that could affect environmental resources, DOE collected and considered large amounts of information, including information provided by the State of Nevada and counties in the State. For the analyses, DOE used information that it judged to be relevant and reasonable. For example, based on comments submitted during scoping hearings for the EIS, DOE added consideration of the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route. In response to public comments on the Draft EIS, DOE used projections of population growth in Nevada provided by Clark and Nye Counties and the Nevada State Demographer for updated information presented in the Final EIS. DOE reviewed many documents produced by Lincoln County and other county and State agencies. The transportation-related information contained in those documents was considered for inclusion in the EIS. Nevada highway traffic information was collected from the Nevada Department of Transportation (DIRS 103405-NDOT 1997). DOE obtained and used accident rates for Nevada highways from the Department of Motor Vehicles and Public Safety, State of Nevada (see Section J.1.4.2.3 of the EIS). DOE used information contained in a report prepared for the City of North Las Vegas (DIRS 155112-Berger Group 2000). The information in that report provided DOE with an estimate of the cost of advancing completion of the Las Vegas Beltway for use by heavy-haul trucks, an estimate of the populations that could live along the Beltway, and a basis for estimating the dose to a maximally exposed individual in a Nevada community from transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. DOE also used information in *Statewide Radioactive Materials Transportation Plan, Phase II* to identify candidate alternative highway routes for shipments of spent nuclear fuel and high-level radioactive waste that the State of Nevada has considered in the past (DIRS 103072-Ardila Coulson 1989).

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

8.8.2 (135)

Comment - 18 comments summarized

Several commenters identified the economic and multi-use benefits of sharing a branch rail line. The commenters stated that rail routes could enhance access to mining and mineral resource areas. One commenter offered specific considerations for the placement of a rail line near Pahrump to the west near the Von Schmidt survey line. The commenter contended this location would offer safety, aesthetic advantages, and multiple-use transportation benefits. Several commenters asked about ownership of the tracks and rights-of-way, and the final disposition of the branch rail line. Other commenters expressed concern about shared use negatively affecting the safety and environmental risk of transportation. Commenters remarked that because shared use was not specifically addressed, the true impacts of such situations are not known and decisions cannot be made. One commenter stated that the Draft EIS was a legally insufficient assessment of rail transportation risks and impacts because it provided incomplete and contradictory information on rail operating assumptions and failed to address the safety and environmental implications of potential shared use of the rail line for shipments of commercial explosives, military weapons and munitions, petroleum products, and other hazardous materials.

Response

If the Yucca Mountain site was approved, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada. However, follow-on implementing decisions, such as the selection of a specific rail alignment in a corridor, would require additional field surveys, State and local government and Native American tribal consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews.

DOE identified the potential for shared use in Section 8.4.2 of the EIS as a reasonably foreseeable future action. This section states "DOE would have to consider these impacts [of shared use] in any decision it made to allow shared use of the branch rail line." If the Yucca Mountain site was approved, then decisions regarding ownership and shared use would be made. Line ownership, however, would not affect potential environmental impacts.

Regarding rail corridor alignments different from those identified in the EIS, as discussed in Sections 6.3.2 and J.3.1.2 of the EIS, DOE has narrowed its consideration for a branch rail line to five candidate rail corridors through a process of screening rail alignments it has studied. The sections identify six earlier studies. For example, in the *Nevada Potential Repository Preliminary Transportation Strategy, Study 2, February 1996*, the Department evaluated a rail alternative called the Stewart Valley Alternate (DIRS 101214-CRWMS M&O 1996). This corridor alignment west of Pahrump was removed from further consideration because of the greater potential for land-use conflicts than in the corridors evaluated in the EIS. Chapter 4 of that report discusses potential operations of a branch rail line. Because use of the branch rail line to transport materials to Yucca Mountain would continue until 2034 under the Proposed Action, it would be premature at this time for the Department to make a decision on the use or disposition of the branch rail line after emplacement operations were completed.

Impacts, including impacts to human health and safety, biological resources, land use, aesthetics, and multiple other resource areas, of constructing and using a branch rail line for transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain are discussed in Section 6.3.2 of the EIS. In response to public comments, DOE has enhanced and clarified its analyses and discussions of these impacts. The Department's *Rail Alignment Analysis* provides evaluations of branch rail lines in each of the five candidate rail corridors (DIRS 131242-CRWMS M&O 1997). The evaluations are based on requirements and standards contained in the American Railway Engineering Association and U.S. Department of Transportation regulations and Federal Railroad Administration Track Safety Standards. Included are standards for railroad crossings over highways.

Comment - 3 comments summarized

Commenters said that the EIS should discuss past and current impacts to Nevada residents from the transportation of radiological materials and hazardous materials along the candidate routes for spent nuclear fuel and high-level radioactive waste shipments to Yucca Mountain. By so doing, the EIS can then determine the cumulative impacts to populations in Nevada who have been repeatedly exposed to these materials.

Response
Section 8.4.1.2 of the EIS presents the cumulative impacts of radioactive material transportation in the United States since 1943. These cumulative impacts include the impacts of historic DOE shipments, which include shipments associated with the Nevada Test Site (see Table 8-58). Table 8-58 lists the impacts for the expanded use of the Nevada Test Site. Even if all the impacts from historic DOE shipments were allocated to Nevada, the impacts would be extremely small, about a 0.1 chance of a latent cancer fatality among members of the affected population.

Section 8.4.2.7 of the EIS describes the Nevada transportation impacts and states that the estimated total collective worker dose from the entire DOE low-level radioactive waste intermodal shipping campaign, including transportation impacts, would be about 4.2 person-rem. The population dose associated with low-level radioactive waste shipments by truck would be about 7.6 person-rem for the entire shipping campaign. These impacts are extremely small, less than about a 0.01 chance of a single latent cancer fatality among members of the affected population.

Comment - 2 comments summarized
Commenters stated that the proposed repository raises a number of concerns for the citizens of Nye County. These include a number of transportation issues. The national transportation network shown in the Draft EIS points to the fact that shipment of spent nuclear fuel and high-level radioactive waste by truck, rail, or intermodal routes would funnel all of the shipments through Nye County. The United States must take all steps necessary to ensure safe transport methods are implemented, that Nye County residents are not subjected to additional risk, whether radiological or safety related, and Nye County be given the capability to respond to any accidents within its jurisdiction.

The transportation analysis and Draft EIS fails to consider the safety hazards along specific routes. Furthermore, by not including the mitigation measure required to safely use these roads for such a shipping campaign, DOE has failed to inform the decisionmakers of the implications of impacts that would accompany repository operations.

Response
As discussed in the EIS, accidents involving spent nuclear fuel or high-level radioactive waste shipments could occur. However, of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. Of the thousands of shipments completed in the United States over the last 30 years, none has resulted in an injury through the release of radioactive materials.

Regardless, in response to comments, DOE has revised the EIS by adding Appendix M to provide information on DOE funding for improvements in emergency response training and capabilities along the routes (see Section M.5 of the EIS). State and tribal governments have primary responsibility to respond to and to protect the public health and safety in their jurisdictions from accidents involving radioactive materials. Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. In 1998, DOE published a Notice of Revised Proposed Policy and Procedures in the *Federal Register* (63 *FR* 23753; April 30, 1998) that sets forth the proposed mechanisms for implementing the requirements of Section 180(c). As part of this program, about 4 years prior to the first shipments, eligible jurisdictions would receive a one-time planning grant to assess their training needs. In accordance with the Section 180(c) Policy and Procedures, jurisdictions could use a certain percentage of their financial assistance to purchase appropriate (for example, training-related) equipment that can be used for training, inspections, and emergency response. This could include the detection equipment mentioned in the comment. See Section M.6 for a detailed discussion of the Section 180(c) provisions and emergency response programs. If requested, DOE and other Federal agencies can assist in responding to an incident.

DOE has several programs available to provide assistance to state, tribal, and local governments in response to radioactive material accidents. The Radiological Assistance Program, for example, provides trained personnel with equipment to evaluate, assess, advise, and assist in the mitigation and monitoring of potential immediate hazards associated with a transportation accident. As part of the program, DOE maintains eight Regional Coordinating Offices across the country that are staffed 24 hours a day, 365 days a year. The staff consists of nuclear engineers, health physicists, industrial hygienists, public affairs specialists, and other personnel who provide field monitoring, sampling, decontamination, communications, and other services, as requested. In addition, DOE's Radiation Emergency Assistance Center/Training Site (REAC/TS) focuses on providing rapid medical attention to people involved in radiation accidents. REAC/TS maintains a 24-hour response center to provide direct support, including deployable equipment and personnel trained and experienced in the treatment of radiation exposure, to assist Federal, state, tribal, and local organizations.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

8.8.2 (419)
Comment - EIS000071 / 0017
Again, DOE has placed their federal emission requirements over the health and safety concerns of the citizens of Nye County.

Response
DOE believes that there is a transcription error in this comment and that "emission" should be "mission." The Yucca Mountain Project Manager, Russell Dyer, in testimony before the Nevada Senate Transportation Committee on March 22, 2001, stated, "I want to reaffirm that protection of public health and safety is our foremost objective for a potential repository and related transportation system. We remain committed to completing our ongoing scientific and technical evaluation before determining whether to recommend approval of Yucca Mountain to the President." He further stated, "We are committed to safe transportation of radioactive materials within Nevada and throughout the country, whether by highway or rail and have demonstrated our ability to work cooperatively with state authorities in conducting the Department's transportation of radioactive material."

8.8.2 (1170)
Comment - EIS000229 / 0003
The DEIS discussion of HHT [heavy-haul truck] safety issues is also deficient. Because of the lack of actual experience with long distance HHT shipments, no meaningful empirical data is available to support the DEIS assertion that accidents risks "are low for all five [route] alternatives." [p.6-96] HHT operations on the routes identified in the DEIS may experience substantially higher accidents frequencies and consequences. For example, using Nevada average accident rates, and projected shipment-miles for DOE's Module 2 scenario, the expected number of HHT accidents on the Caliente route would be about 24 (12 loaded, 12 empty) over 39 years. The severity and consequences of accidents could be greater because of unique local hazards. Steep upgrades and downgrades (especially in combination with horizontal curves less than 800 feet radius) and critical side slopes and steep drop-offs (common near the summits of mountain passes) could subject casks to extreme accident impact forces and make emergency response, cask recovery, and post-accident cleanup difficult. Such conditions appear to exist near Oak Springs Summit on US 93, near Hancock Summit on SR 375, and at several other locations along the Caliente HHT route.

Response
Heavy-haul truck impacts were calculated using the Primary road rates in Saricks and Tompkins (DIRS 103455-1999). Although the document does not explicitly address heavy-haul truck accident rates, DOE believes this document provides the best available consistent data set for the impact analyses. The accident rates used in the analysis were conservative because of the special precautions taken by heavy-haul truck shipments to prevent accidents, such as restricting travel to daylight hours and providing escort vehicles in front of and behind the trucks. The heavy-haul trucks could affect the accident rates for other vehicles. However, the additional precautions described above in addition to the planned road improvements would mitigate these effects. As a result, DOE believes the analysis of heavy-haul truck accident frequencies is adequate for its intended purpose.

The commenter expressed concern that the severity and consequences could be greater because of unique local hazards. In the analysis of accidents, these events are termed “initiating events.” A large number of specific initiating events can be identified by review of historic transportation accidents or by the imagination. These include collisions with fixed objects (bridge abutments, walls, barriers, etc.), collisions with other vehicles and animals, rollovers, jackknifes, derailments, and collisions at grade crossings. Any initiating event can be characterized in terms of its mechanical forces and heat, and the event can then be categorized according to the matrix shown in Figure J-8, which is the transportation accident risk model used in the EIS. This model was taken from Sprung et al. (DIRS 152476-2000). As a consequence, it is not necessary to analyze every possible initiating event individually because the range of accidents included in the report encompasses all credible initiating events.

Regardless of the specific initiating event and type or transport vehicle, the severity of a transportation accident can be characterized by the combination of mechanical forces and heat involved in the accident and imposed on the cask. Mechanical forces account for the severity of the crash itself, while heat accounts for the severity of fire that could be involved in the accident. The Nuclear Regulatory Commission report concluded that only a tiny fraction of all accidents, less than one in 10,000, would be severe enough to fail a spent nuclear fuel shipping cask (DIRS 152476-Sprung et al. 2000). The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. This study reaffirmed that the spent nuclear fuel transportation regulations provide adequate protection of public health and safety. The report is an update of the accident risk model used in the Draft EIS that was referred to as the Modal Study (DIRS 101828-Fischer et al. 1987).

8.8.2 (1796)
<u>Comment</u> - EIS000616 / 0003
And the last thing I would like to say is I tried to find a more detailed map on exactly where the railroads go, particularly Lander County, and that wasn’t available.

<u>Response</u>
Appendix J of the EIS refers to the *Nevada Potential Repository Preliminary Transportation Strategy, Study 1* (DIRS 104795-CRWMS M&O 1995) and the *Nevada Potential Repository Preliminary Transportation Strategy, Study 2* (DIRS 101214-CRWMS M&O 1996), among others, which provide information on the rail corridor alignment including detailed maps. Detailed maps of the alternative routes are included in Appendix J.

8.8.2 (3067)
<u>Comment</u> - EIS000619 / 0008
Another area where the draft is deficient is in its treatment of existing rail and highway within Nevada. For example, from West Wendover to Beowawe, the interstate and Union Pacific rail line go through several communities and cross the Humboldt several times, and you would never know that from reading the draft.

<u>Response</u>
The portions of routes that use existing rail and highways within Nevada were analyzed for each of the transportation implementing alternatives in Nevada as part of the national transportation analysis discussed in Sections 6.2.3.1 and 6.2 3.2 of the EIS. The range of impacts associated with this analysis can be found in Tables 6-8 and 6-9 for legal-weight trucks and Tables 6-11 and 6-12 for railroads. Maps of the representative national routes analyzed are given in Figures 6-11 and 6-12. In addition to analyzing the impacts of using routes that would meet U.S. Department of Transportation requirements for transporting spent nuclear fuel, DOE evaluated how the estimated impacts would differ if legal-weight trucks or railroads used other routes in Nevada in Section J.3.1. This section describes alternate routes and alignments within Nevada, identifies differences in lengths and population distributions, lists potential infrastructure upgrade needs, and assesses the impacts to individuals and populations along each of these routes. Comparisons of impacts based on populations along specific highways in Nevada are provided in Table J-48. Both the rail and highway transportation analyses have taken into account the population of the communities along the routes and the estimated accident characteristics of the given routes. Specific incident rates for Nevada routes were provided by the State and used in the analyses.

8.8.2 (4125)
Comment - EIS001458 / 0002
DOE could improve its transportation analysis by including a strong statement in the final environmental impact statement regarding the inherent safety of used fuel transportation and robust packages used to transport nuclear fuel and high-level radioactive waste. DOE should also put the risks associated with spent fuel transportation in perspective such that it's evident to members of the public and policy makers and clearly identifies that transportation risks associated with the proposed action are small.

Response
The results presented in the EIS demonstrate that the impacts of transporting spent nuclear fuel and high-level radioactive waste would be low, in large part due to the use of robust packaging. The EIS attempts to place these risks in perspective in the Summary and in Chapter 6 of the EIS. A discussion of cask safety and testing and operational protocols designed to enhance safety has been added in Appendix M.

8.8.2 (4168)
Comment - EIS000544 / 0002
As far as the infrastructure impacts are concerned, we found no inventory of locations that need remedial activity within the DEIS. There were no calculations to determine these costs. No comparisons of the benefit costs for rail as opposed to heavy-haul. And pretty much that the verbiage around heavy-haul assumes that this is something that our highway system now can sustain.

There's been a plethora of media coverage about the autoclave deliveries that we have had and these vehicle configurations to haul these amounts into our state. There's been an assumption that our heavy-haul casks, heavy-haul operations would be somewhat like that.

And the public should really realize that we only really permit about one of those vehicles a year and that we're looking at something on the neighborhood of two loaded vehicles a day going into the site and then two unloaded vehicles that are only 200,000 pounds of less weight going out of the site back to the intermodal facility. It's not a campaign that is run smoothly or efficiently, I guess is the word I can use.

Lastly, as far as the operations considerations of heavy-haul, we found absolutely no estimate of what traffic queues would be accumulated behind these convoys.

Response
Section J.3.1.2 of the EIS addresses the routes in Nevada for transporting rail casks, including heavy-haul trucks and railroads. Additional details of the rail and heavy-haul truck system infrastructure requirements and assumptions used to establish their preliminary designs are included in the EIS references listed in Section 12 as *Transportation Engineering File: Road Upgrades for Heavy Haul Truck Routes–Design Analysis* (DIRS 154448-CRWMS M&O 1998), and *Rail Alignment Analysis* (DIRS 131242-CRWMS M&O 1997). These analyses contain plan and profile drawings of the five rail corridors, and rail alignment maps showing land usage with respect to the location of the rail corridor.

Sections 6.3.3.1 and 6.3.2.1 of the EIS contain cost ranges of the five rail corridors and heavy-haul truck routes with a life-cycle cost for rail ranging from $283 million to $880 million, and for heavy haul truck life-cycle costs ranging from $387 million to $669 million. Detailed costs associated with these systems are included in *Cost Estimate for Heavy Haul Truck Transport Design* (DIRS 154675-Ahmer 1998) and *Nevada Transportation Study Construction Cost Estimate* (DIRS 154822-CRWMS M&O 1998).

DOE has identified mostly rail as its preferred mode of transportation, both nationally and in Nevada. However, should heavy-haul truck transport be selected as the preferred mode, detailed engineering and environmental studies, including dynamic traffic analysis, would be performed on the selected road route. A detailed dynamic traffic analysis would identify potential traffic queues for each route section. The road upgrades listed in Section J.3.1.2 of the EIS that have been proposed would then be modified to minimize traffic impacts. A specific cost/benefit analysis of the two scenarios, rail versus heavy-haul truck, has not been performed and is generally not necessary to support current decisionmaking.

8.8.2 (4286)
Comment - EIS001160 / 0094
Page 3-99, Section 3.2.2 address legal weight truck shipments on U.S. Highway 95. Does failure of the DEIS imply that legal weight shipments would not be allowed on other routes without supplemental NEPA [National Environmental Policy Act] documentation? The DEIS should indicate what, if any, supplemental NEPA documentation would be required for a route other than those assessed within the DEIS.

Page 3-99, Section 3.2.2 implies that only data for U.S. Highway 95 was used in the analysis. If this is the case, the analysis may not accurately represent risks of shipping fuel on other Nevada highways. Nevada's highways are characterized by unique traffic patterns, load levels, seasonal environmental conditions and physiography.

Response
The routes chosen for analysis for the legal-weight truck case were selected based on U.S. Department of Transportation rules for routing shipments of spent nuclear fuel. Briefly stated, these rules require shipments to use Interstate System highways wherever possible. When it is necessary to leave the Interstate Highway System, the rules require using the shortest route to the destination. Thus, the EIS analyzed Interstate-15 and then U.S. 95 to the repository. Additional information on route selection can be found in Appendix M of the EIS. If a state wishes, it can designate alternate routes using Federal guidelines. Nevada has not done so. If the State was to designate alternate routes, which would include conducting a safety analysis, DOE would follow those routes.

In addition to analyzing the impacts of using highway routes that would meet U.S. Department of Transportation requirements for transporting spent nuclear fuel, DOE evaluated how the estimated impacts would differ if legal-weight trucks used other routes in Nevada. Six other routes identified in a 1989 study by the Nevada Department of Transportation were used in the analysis. A discussion of this analysis can be found in Section J.3.1.3 of the EIS.

8.8.2 (4300)
Comment - EIS001160 / 0109
Page 6-38, Section 6.3.1. Although proposed shipments using legal weight trucks would represent only a fraction (about 1 percent) of total truck traffic on Nevada highways, because of the nature of the material shipped, the impact on such things as socioeconomics, aesthetics and perception by the public could be significant. The relationship to regular commercial traffic is only applicable in the amount of fossil fuels burned and related impacts. Truck volume and other impact experiences from transport of spent fuel and other nuclear and hazardous wastes should be used to determine impacts of transportation.

Response
As described in Section 6.3 of the EIS, DOE's analysis of impacts from legal-weight trucks on Nevada highways does include socioeconomics and aesthetics. The topics considered for socioeconomics include changes in employment, personal income, populations, Gross Regional Product, and state and local government expenditures. The region of influence for the analysis included Clark, Lincoln, and Nye Counties. The other Nevada counties were included collectively. The topics considered for aesthetics included visual sensitivity of view-sheds, ratings for scenery, and ratings for adjacent land use. The regions of influence included landscapes along candidate rail corridors and highway routes and near possible intermodal facilities, and aesthetics qualities that construction and operations could affect. The ratings were based on the Bureau of Land Management Visual Resource Management System.

Truck volumes are considered based on analyses provided in Section J.1.2 of the EIS. Impact experience for Nevada was considered based on incident rates provided by the State, as discussed in Section J.1.4.2.

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty
- Much of the uncertainty is irreducible, and
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

Based on these analyses, DOE believes that the relationship between a repository and related transportation activities, and subsequent individual behavior is speculative because it does not necessarily depend on actual physical effects on individuals or the public at large. Moreover, the potential indirect effects of the proximity of a repository or of transportation activities on tourism or quality-of-life indicators would vary by individual, cannot be precisely defined, and are not reasonably foreseeable.

However, DOE will continue to work with local communities and tribal nations to understand and mitigate potential negative perceptions of DOE operations. These activities include the development and presentation of factual information regarding the actual (rather than perceived) risks associated with the construction, operation and monitoring, and eventual closure of a repository at Yucca Mountain and related transportation activities.

Given the integrity of the casks transporting the waste, and the fact that more than 2,500 shipments of spent nuclear fuel have been safely transported in the last 25 years with no fatalities, injuries, or environmental damage caused by the radioactive nature of the cargo, the chances of contamination of local communities and the environment from an incident involving this type of waste are extremely unlikely and not expected to occur. DOE believes that this waste can be transported safely.

8.8.2 (4357)
Comment - EIS001157 / 0002
Because Yucca Mountain is about 90 miles north of Las Vegas, the greatest impact to North Las Vegas will be the material transport phase. Specific impacts to North Las Vegas were not sufficiently addressed in the DEIS.

Response
Section 6.3 of the EIS provides DOE's analysis of transportation routes and their alternatives within Nevada. Note specifically that Table J-48 describes Case 6 that uses the proposed Las Vegas Beltway from Interstate-15 to U.S. 95. DOE used the best information on populations, infrastructure, planned improvements, and incident rates available at the time of the analysis. As part of the basis for the analysis, DOE evaluated *Assessment of the Hazards of Transporting Spent Nuclear Fuel and High Level Radioactive Waste to the Proposed Yucca Mountain Repository Using the Proposed Northern Las Vegas Beltway* (DIRS 155112-Berger Group 2000), which provided information specific to North Las Vegas.

8.8.2 (4365)
Comment - EIS001157 / 0011
If a rail line is built through the north end of the Las Vegas Valley, grade-separated crossings should be included as part of the project. The air quality and traffic congestion consequences of delaying vehicular traffic through the Las Vegas Valley are understated and mitigation measures need to be identified.

Response
Air quality and traffic congestion due to the operation of a branch rail line northeast of Las Vegas or any of the other branch rail line alternatives would not be a significant problem (see Section 6.3.2.2.5 of the EIS). If DOE used general freight service to transport the shipment to the branch rail line, the spent nuclear fuel or high-level radioactive waste railcars would be part of a potentially much larger train with commensurate delays at grade crossings regardless of the addition of a few railcars. However, if DOE chose dedicated rail, the train probably would consist of three to five railcars with little or no traffic buildup at grade crossings. Once the shipment(s) were on the branch rail line, the size of the train would result in little or no traffic buildups. At this time, DOE has not

determined the commercial arrangements it would request from railroads for shipment of spent nuclear fuel and high-level radioactive waste.

8.8.2 (4370)
Comment - EIS001157 / 0016
The vehicle emission analysis for the Las Vegas Valley was insufficient in two ways. First, it was based only on legal-weight trucks and did not consider the heavy-haul option which will create traffic congestion. Second, the reasoning for assuming only a limited impact was based on I-15 traffic volumes at Sahara Avenue, which is in the center of the City. None of the proposed routes go through this area, so a comparison using a more likely location (such as the permanent traffic recorder near the Apex interchange) should be used.

Response
Section 6.3.3 of the EIS evaluates air quality impacts due to vehicle emissions from heavy-haul trucks. In response to public comments, the EIS contains an expanded discussion of truck emissions in the Las Vegas Valley and the overall impacts on air quality.

8.8.2 (5529)
Comment - EIS001660 / 0039
The DEIS fails to adequately address impacts of the proposed action on existing surface transportation systems in affected Nevada counties. Transportation routes to Yucca Mountain would need to be improved. These routes are important for mining, interstate commerce, and mobility of all affected county residents and visitors. Also, a network of minor roads, mostly unpaved, serves affected county residents by providing access to public lands, private property, and mining claims. The DEIS must analyze and disclose the impacts of the proposed action on the railroad and the main improved highways. Specifically, it must consider: (1) the existing capacities of road and railroad links, in terms of both weight and traffic volume; (2) the anticipated increases in utilization of those links, in terms of weight and volume; (3) the impacts of those increases on rails, pavements, road beds, and travel times; and (4) whether the proposed action would create a need or demand for additional improved routes through affected counties in Nevada. Also, the DEIS must consider the impacts on the nation's rail transport system of an accident involving SNF [spent nuclear fuel] and HLW [high-level radioactive waste]. In the context of the mostly legal-weight truck scenario, I-80, US 50, NV 278, NV 376 (Lander and Nye Counties), US 6 (White Pine and Nye Counties, which is close to Mineral County), and other Nevada routes could be utilized as main alternate routes for transport of SNF and HLW. The impacts of the proposed action on the existing uses of those routes must be addressed in the DEIS, in addition to I- 15 in southern Nevada. Finally, the DEIS must disclose how access to minor roads would be affected and preserved.

Response
Sections 6.3 and J.3 of the EIS summarize the impacts of both incident-free truck and rail transportation and transportation accidents on Nevada. Section J.3.1 discusses the transportation modes, routes, and number of shipments of spent nuclear fuel and high-level radioactive waste for the different transportation implementing alternatives and their alignment variations. This information includes tables of information of potential upgrades needed for each option. This information provides the basis for the impact assessments. Details of impacts on existing surface transportation were evaluated in the following reference documents and summarized in the EIS. Impacts to traffic levels and road structures were evaluated in *Road Upgrades for Heavy Haul Truck Routes* (DIRS 154448-CRWMS M&O 1998); impacts to existing roads (paved and unpaved) were analyzed in *Rail Alignments Analysis* (DIRS 131242-CRWMS M&O 1997) where it was proposed to provide grade separations at major roads and at grade crossings at necessary minor roads. These analyses evaluated current traffic levels on existing roads, estimated increased traffic, and additional traffic due to spent nuclear fuel and high-level radioactive waste transport.

When a corridor or route was selected, detailed assessments and designs for rail alignments or heavy-haul truck road upgrades would be initiated. These studies would be part of engineering and environmental studies needed to develop detailed designs and to support specific National Environmental Policy Act reviews for the proposed actions. DOE would use routes that meet U.S. Department of Transportation requirements or routes designated by state or tribal routing agencies.

8.8.2 (6221)
Comment - EIS001904 / 0001
The primary concern of Elko County is for the health, safety, and welfare of it citizens. The draft environmental impact statement (DEIS) regarding the transportation of 70,000 metric tons of heavy metal (MTHM) of spent nuclear fuel and high-level waste through this county to connect a new railroad spur in Beowawe is not an acceptable transportation alternative. The Draft fails to address a host of concerns that this alternative might bring to Northern Nevada if this plan is accepted into the final EIS. The Draft is flawed because it has several transportation routes and methods of transport yet does not address the impacts or effects that would be incurred by these different scenarios.

The Carlin potential rail corridor alternative fails to address the fact that to get this new spur, the existing Union Pacific Rail Way lines will be used. This heavily used rail system will be furthered burdened by at least three to four of these radioactive waste trains traveling these lines each week for the next 24 years. The Draft EIS does not address the shared use of these rail lines that are also used for shipment of commercial explosives, military weapons and munitions, petroleum products, and other hazardous materials. [Nowhere] is the safety and environmental impacts considered in this Draft. The Department of Energy calls for shipping rail casks loaded with highly radioactive spent fuel in general freight trains and would require switching cars at the connection point thereby routinely parking loaded rail cask cars on side track for up to 48 hours. Further, most of the spent fuel is from the east and Midwest and if this rail line was used, these trains would pass through our most populous cities, namely Wells, Elko, and Carlin. The city of Elko is where the trains on this rail line change crews and it would follow that a crew change would be required for the radioactive waste trains as well in Elko, with a population 17,000 and an additional 10,000 people within 20 miles. [Nowhere] in the Draft EIS is our County mentioned as a potentially impacted area. There are no provisions for any type of Hazardous Material training for our emergency response personnel and no provisions for financial assistance if we were to be subjected to radiological disaster. The mention of upgrading of the existing rail lines as well as signalization upgrades, grade crossing or Right of way fencing is nonexistent in the Draft EIS.

Response
The EIS presents safety and environmental impacts (see Chapter 6 and Appendix J) of 10 implementing alternatives for transportation in Nevada by rail or heavy-haul truck including the construction of a branch rail line from Beowawe to Yucca Mountain. In addition, the use of legal-weight truck in Nevada is analyzed, including the sensitivity analysis of six alternative legal-weight truck routes. The analysis includes both construction-related impacts and operational impacts (including transportation of materials to the repository). As the analysis indicates, the impacts would be small regardless of which alternative was chosen. This indicates that impacts along any specific route and through any specific community would be small. In addition, the EIS presents an analysis of a generic community along the transportation route that indicates that community specific impacts would be small.

Decisions regarding the selection of a branch rail line for transporting spent nuclear fuel and high-level radioactive waste have not been made. However, it is in DOE's interest and in the interest of communities along a branch rail line to consider shared use of the line. This could involve shipments of other materials to Yucca Mountain, the Nevada Test Site, or shared usage with commercial interests. Before decisions would be made on the transportation alternatives associated with the Yucca Mountain Repository, the impacts such as shared use, would be evaluated. The specific conditions of any railway would be analyzed once specific decisions were made and potential upgrades implemented.

As requested, DOE would assist the State, tribal, and local governments in several ways to reduce the consequences of accidents related to the transportation of spent nuclear fuel and high-level radioactive waste. In addition, under Section 180(c) of the NWPA, DOE would provide technical assistance and funding to train State, local, and tribal public safety officials in safe transport procedures and emergency response. More details about the Section 180(c) process are provided in Appendix M of the EIS.

8.8.2 (6708)
Comment - EIS001878 / 0072
The DEIS fails to adequately address the impacts of the proposed action on existing surface transportation systems in Eureka County and other counties in Nevada. Interstate 80, US 50, NV 278, and NV 306 are the main improved routes in Eureka County. They are important routes for mining, interstate commerce, and the mobility of County

residents and visitors. The Union Pacific railroad generally parallels I-80 and the Humboldt River across the northern portion of the County. It is an essential component of the transportation network for interstate commerce and national defense. A network of minor roads also serves the residents of Eureka County, providing access to public lands, private property, and mining claims.

Principal transportation routes. The DEIS must analyze and disclose the impacts of the proposed action on the railroad and the main improved highways. Specifically, it must consider: (1) the existing capacities of road and railroad links, in terms of both weight and traffic volume, (2) the anticipated increases in utilization of those links, in terms of weight and volume, (3) the impacts of those increases on rails, pavements, road beds, and travel times, and (4) whether the proposed action would create a need or demand for additional improved routes through Eureka County.

Eureka County is especially concerned that utilization of the main Union Pacific tracks and facilities in the northern county could involve the storage of rail cars carrying SNF [spent nuclear fuel] and HLW [high-level radioactive waste] on sidings near Beowawe for extended periods of time. The impacts of such storage on transcontinental rail operations and on existing sidings in the vicinity (including those at Carlin and Dunphy) must be considered. In addition, the DEIS must consider the impacts upon the nation's rail transport system of an accident involving SNF and HLW and one of the UP bridges over the Humboldt River.

Alternative routes. In the context of the mostly legal-weight truck scenario, I-80, US 50, NV 278, NV 376 (in Lander and Nye Counties), US 6 (in White Pine and Nye Counties), and other Nevada routes could be utilized as main or alternate routes for the transport of SNF and HLW. The impacts of the proposed action on the existing uses of those routes must be addressed in the DEIS, in addition to I-15 in southern Nevada. Among other information, the DEIS must disclose the alternative routes that would be used, and the anticipated impacts along those routes, when rail or legal-weight truck operations are interrupted by flooding, range fires, and other natural events.

R.S. 2477 roads and other access routes. Rights of way over public lands for many roads were granted by Section 8 of chapter 262, 14 Statutes 253 (former 43 U.S.C. Sec. 932, commonly referred to as R.S. 2477) enacted in 1866. Such roads serve the public interest; provide access for fire control, law enforcement, search and rescue, medical personnel, and public utilities; provide access to public lands for members of the general public; and enhance the taxable value of the private property they serve.

Eureka County is concerned that many R.S. 2477 roads and other roads along the proposed Carlin corridor may be affected by construction of the roadbed, access roads, and fences. The DEIS must disclose: (1) whether the proposed action would result in the closing of any of these roads, (2) whether it would restrict access to them in any way, and (3) how the proposed action would ensure the continuity of such roads, through the use of at-grade crossings, underpasses, overpasses, or other means. Subsection 1 of Nevada Revised Statutes (NRS) 405.204 authorizes Nevada's attorney general to bring an action for declaratory judgment against an agency of the United States responsible for the lands over which an accessory road runs that pursues the closing of an accessory road or demands a fee or permit for its use.

Response

The current rail traffic on existing rail lines within Nevada is large (approximately 1,000 railcars per day) compared to the railcars per week that could be expected with spent nuclear fuel or high-level radioactive waste destined for Yucca Mountain. The increase in rail traffic would have little or no impact on the existing rail infrastructure. DOE has identified rail as its preferred mode of transportation within Nevada. It is not expected that the construction of a branch rail line would affect R.S. 2477 roads and other roads along the candidate rail corridors.

The incident-free transportation analysis considers the stop of railcars in classification yards throughout its journey from origin to destination. These classification stops are assumed to occur once in the state of origin, once in the state of destination, and a number of times in between depending on the number of kilometers traveled. The population density at each of the stops is conservatively assumed to be a suburban population zone (719 persons per square kilometer). Therefore, any layover of railcars in Nevada while awaiting transfer to a train for travel to Yucca Mountain has been addressed in the EIS.

The accident analysis in the EIS considered the impacts of low probability severe accidents. If an accident was severe enough to require closing the railroad track at the location of the accident, alternative routing measures could be employed to circumvent the area of the accident.

For the mostly legal-weight truck scenario in Nevada, the analysis looked at the routing according to U.S. Department of Transportation routing regulations and analyzed the impacts of six alternative legal-weight truck routes. The analysis indicated that there were not significant differences in impacts across the legal-weight truck routing alternatives.

Following are responses to the three specific requests for disclosure:

- The closing of specific roads is not anticipated although specific routes have not been defined.
- Specific access to these roads has not been designed but access is not expected to be restricted.
- The continuity of these roads would be determined by DOE and the State using the route/mode decision process.

8.8.2 (7011)
Comment - EIS001887 / 0140
Page 2-81; Section 2.4.4.2 - Nevada Transportation

The Draft EIS states, "With the exception of Land Use, differences in environmental impacts for the ten implementing alternatives related to incoming shipments by rail would be small, so environmental impacts do not appear to be a major factor in the selection of transportation mode, route, or corridor in Nevada for incoming rail shipments." This statement is inaccurate. Rail operations associated with heavy-haul shipments present major problems for the operational highway network in Nevada. The Draft EIS ignores such impacts as traffic queuing, failing structural sections, remedial actions for reducing traffic accidents, and institutional anomalies (such as providing a portable crane capable of lifting overturned vehicles and casks).

Response
As discussed in Section J.3.1.2 of the EIS, several highway upgrades would be proposed for any of the five heavy-haul truck implementing alternatives. There is a table listing and describing the upgrades proposed for each route. Nevada highways upgraded for heavy-haul truck use would include new truck turnout lanes at frequent intervals along two-lane highways to allow other traffic to pass the slower heavy-haul vehicles in order to reduce traffic queuing. A detailed analysis of structural sections, remedial actions for reducing traffic accidents, and institutional anomalies would be conducted in subsequent engineering and environmental analyses once a mode and route were selected. As a part of these studies, government agency consultation and appropriate National Environmental Policy Act reviews would be conducted. In addition, as a part of the permitting process, the State Engineer may, as necessary, conduct an engineering evaluation (including a structural analysis) of the proposed heavy-haul truck route according to Nevada Administrative Code Chapter 484.530. Cranes and equipment used for non-NWPA rail incidents could handle NWPA equipment, including casks.

8.8.2 (7043)
Comment - EIS001160 / 0044
It is very difficult within the DEIS to evaluate impact on communities in the major zone of influence. One is hard pressed to find any quantification of how many actual legal weight truck haul loads could be expected through Ely on the US 93 or SR 318 scenario. The table on J-7 might indicate around 1500 shipments from the Idaho National Engineering and Environmental Laboratory 800 shipments from Hanford that might use a route through Ely as an alternate to Interstate routes, spread over a 20-year period (Table J-4). It would be useful if there was analysis of some key points like Ely (apparently a relatively low impact area with about 350 shipments of high-level radioactive waste a year, Table J-4) as opposed to perhaps high impact Mesquite with perhaps an average of 1700 shipments a year of commercial spent nuclear fuel (Figure J-10).

Response
As described in Section 2.1.3.2 of the EIS, the Department describes the national transportation scenarios and provides maps of the Interstate Highway System and the national rail system. Under the Proposed Action, DOE would ship spent nuclear fuel and high-level radioactive waste from 72 commercial and 5 DOE sites in some combination of legal-weight truck, rail, heavy-haul truck, and possibly barge. Because DOE cannot anticipate the exact number of shipments and mode that would be used, the EIS considers two transportation scenarios, a mostly legal-weight truck scenario and a mostly rail scenario, in order to illustrate the broadest range of operating conditions relevant to potential impacts to human health and the environment (see Table 2-2 of the EIS).

In addition to analyzing the impacts of using highway routes that would meet U.S. Department of Transportation requirements for transporting spent nuclear fuel (49 CFR Part 397), DOE evaluated how the estimated impacts would differ if legal-weight trucks used other routes in Nevada, including representative routes that would pass through the community of Ely (see Table J-47 of the EIS). This analysis was made for the range of operating conditions illustrated in the mostly legal-weight truck scenario and the mostly rail scenario (see Section J.3.1.3). Under the range of operating conditions, DOE assumed that all legal-weight shipments would travel along the given routes under each of the scenarios. The results of this analysis can be found in Table J-48, which indicates the variations in impacts between various Nevada routes. The impacts to the community of Ely would be a small fraction of the impacts to Nevada. In response to public comments on the Draft EIS, DOE has included an analysis for a maximally exposed individual of a small community in Section 6.3. Section J.4 contains maps of each state where shipments would originate or through which they would pass. Each state map lists the number of shipments used in the analysis and the impacts within the state of such shipments.

DOE expects that the mostly rail scenario best represents the mix of truck and rail transportation modes it would use. To determine this mix, DOE considered whether sites are able to handle larger (rail) casks, distances to suitable railheads, and historic precedent in actual shipments of fuel, waste or other large reactor-related components. DOE also has considered relevant information published by knowledgeable sources such as the Nuclear Energy Institute and the State of Nevada. The analysis has confirmed DOE's belief that the mostly legal-weight truck and mostly rail scenarios provide the range (lower and upper bound) of environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

8.8.2 (7141)
Comment - EIS001337 / 0038
The County [Lincoln] and City [Caliente] recommended that an assessment of paleontologic resources within alternative rail corridors and at potential borrow pit sites within Lincoln County be conducted and reported on within the scope of the repository DEIS. The DEIS does not identify potential borrow pits and therefor has not included an assessment of the paleontologic resources at such sites. Such an omission makes the document less useful as a decision-support tool, particularly in choosing among transportation corridor alternatives.

Response
As stated in Section 6.3 of the EIS, the evaluation of impacts of cultural resources considered the potential for disrupting or modifying the character of archaeological or historic sites, artifacts, and other cultural resources. The region of influence for the analysis included the lands in the 400-meter (0.25-mile)-wide rail corridors. Cultural resource impacts of each rail corridor implementing alternative are provided in Section 6.3.2.2. Should the mostly rail transportation scenario be selected and a preferred corridor identified, additional engineering and environmental studies would be initiated to select a specific alignment of the tracks within the selected corridor. Appropriate National Environmental Policy Act reviews would be conducted to support selection of a specific alignment and design. Borrow pits would not be identified and assessed for cultural resources until geotechnical surveys and other environmental studies were conducted in conjunction with subsequent design activities following the selection of a rail corridor or intermodal transfer station location. An assessment of paleontologic resources at borrow pits would be included in such National Environmental Policy Act reviews for the specific rail alignment.

8.8.2 (7521)
Comment - EIS001912 / 0050
Section 3.2.2.1. Did any member of the EIS team make site visits and site investigations for the various rail corridor alternatives? If yes, please explain the nature of the investigations?

Response
Section 3.2.2.1 of the EIS is based on a combination of published information and field observations. Based on published environmental data, 54 springs, perennial streams, and Bureau of Land Management-designated riparian areas were visited by DOE biologists to determine if those sites contain wetlands (DIRS 155378-Reilly and Smith 1997). Fifteen locations with sensitive species were visited to ensure that the sites still had suitable habitat for the species (DIRS 154825-CRWMS M&O 1997). In addition, DOE engineers made an initial visual survey of all rail corridor alternatives as a part of the routing analysis. Topography, land use, and known areas of environmental concern were observed as a part of the corridor centerline selection to minimize impacts to stakeholders (DIRS 131242-CRWMS M&O 1997). Cultural resources, noise, aesthetics, and existing visual conditions were observed by contractor personnel on a field trip along proposed heavy-haul truck routes and rail corridors. Additional interviews with responsible State and Federal agencies were conducted and additional literature searches were performed during the trip. A report has been prepared detailing the information obtained during the trip (DIRS 155826-Nickens and Hartwell 2001) and the relevant information is included in Chapter 6 of the EIS.

8.8.2 (8725)
Comment - EIS002119 / 0010
And last, I'd like to mention that should there be an incident, even if the routes do not go through Clark County, under certain governmental agreements, we do provide as a large county with a number of resources assistance to other counties, nearby counties in the event of hazardous materials or nuclear materials or waste incidents. And lastly, I'd like to say that this community, Clark County and its urban areas especially and rural areas has been built up from the desert. We have developed. There have been the talents and skills and efforts of a number of people, many of whom have testified here. This has value. There's value in the quality of life. There's value economically. There's value for the future. And these have not been given serious consideration in the DEIS.

Response
Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to state, local, and tribal governments to support training of public safety officials to help ensure safe routine transportation and emergency response for shipments to a repository. The state could provide funds allocated under Section 180(c) to support a county providing assistance to other jurisdictions through mutual aid agreements. Appendix M of the EIS contains more information on Section 180(c).

8.8.2 (9431)
Comment - EIS001593 / 0002
You have got several railroads that would go to this Yucca Mountain, proposed possible railroads, and one of them, this Chalk Mountain or Caliente Chalk Mountain Route, I believe is what it's called, would go through the Air Force's Flying Saucer Base out in Nevada.

Now, I don't know if it is so much interesting from an environmental standpoint, but you know, we hear a lot about this rogue agency, you've heard some today about this rogue agency, rogue power behind nuclear power, the Nuclear Power Industry. Well, I am, actually a little more worried about this black operation crowd out there in Nevada, and I would just love to see a knock-down, drag-out fight between the two of you.

Now that would be -- I think that could really open up -- you know, people wonder, you know, if this isn't some kind of military coup, I mean, all this secret stuff, and wondering, you know, if elected officials are really in control.

Response
DOE reevaluated whether the Caliente-Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route should be eliminated from further evaluation. DOE met with the Air Force (see Appendix C of the EIS), considered the information provided, and concluded that the Caliente-Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route implementing alternatives should remain identified as "nonpreferred alternatives" in this Final EIS.

DOE has not identified a particular rail corridor or heavy-haul truck route as "environmentally preferable." If the site was approved and a mode of transportation (rail or heavy-haul truck in Nevada) was selected in a Record of Decision, DOE would then identify an environmentally preferable corridor or route in a subsequent Record of Decision to select a rail corridor or heavy-haul truck route. In making such a determination, DOE would consider a variety of environmental factors, including many raised by the commenters. The potential environmental impacts from the construction and operation of the Caliente-Chalk Mountain Corridor and the Caliente/Chalk Mountain heavy-haul truck route are included in Sections 6.3.2.2.3and 6.3.3.2.2 of the EIS.

8.8.2 (9607)

Comment - EIS001888 / 0279

An analysis of the risks and impacts of the heavy haul transportation routes through urban Clark County. This analysis should examine the traffic impact of the transportation as well as the risks of this unprecedented program. The engineering data should be modified to include the costs to acquire right of way for the additional travel lanes. The report should also include an estimate of the costs to improve existing infrastructure to accommodate the transportation program.

Response

DOE analyzed heavy-haul truck implementing alternatives in EIS Section 6.3.3, including routes through Clark County. In this analysis, DOE assumed that heavy-haul truck shipments in Clark County would utilize the planned Las Vegas Beltway. In doing so, DOE assumed that funding would be made available to accelerate Beltway Phase II construction to meet a 2010 transport date. DOE used the best available cost estimate for Beltway Phase II construction, taken from the *Environmental Study for the Northern and Western Las Vegas Beltway Transportation Facilities and Right-of-Way Footprint* (DIRS 103710-Clark County 1997). Costs to acquire right-of-way for additional travel lanes and costs to improve existing Nevada highway infrastructure to accommodate a heavy-haul truck transportation campaign are included in the Department's cost estimate (DIRS 154675-Ahmer 1998). However, Interstate System highways, and the Las Vegas Beltway after Phase II construction, would not need improvement because they meet, or will meet, standards necessary to sustain heavy-haul truck shipments.

8.8.2 (9664)

Comment - EIS002074 / 0008

With respect to the intermodal sites that was stated in the American Indian prospectus on the Yucca Mountain Site Characterization Project that was done by the American Indian Writers subgroup, there's been no systemic ethnographic interviews that have been conducted to evaluate the epidemiological and sociological impacts to Indian people and their communities regarding cultural resources of sacred sites. The studies only focus on the impacts to the physical artifacts and no subsistence patterns, no traditional eligibility for traditional cultural properties or cultural landscape as considered in the bulletin number 30 and 38 by the National Park Service.

Response

Section 3.2.2.1.5 of the EIS discusses the existing, documented information on cultural resources along the candidate rail corridors. Limited field surveys were conducted (DIRS 155826-Nickens and Hartwell 2001). Should the mostly rail transportation scenario be selected and a preferred corridor identified, additional engineering and environmental studies would be initiated to select a specific alignment. During this process, specific data-gathering efforts and analyses would be conducted, including focused cultural resource studies and Native American consultations, as well as consultations with responsible State and Federal agencies, as applicable. Appropriate National Environmental Policy Act reviews would be conducted to support selection of a specific alignment and design.

8.8.2 (9671)

Comment - EIS002074 / 0016

With health and safety, and this is just going down on the record, is that there is concern by this group of terrorism and felt that the potential of those kind of situations occurring, as well as looking at the potential of derailments. It was felt that there was an accident that happened, I believe it was December 24th in 1997 or 1998, on the Caliente, that that was not felt that it was adequately considered or there was an indication as to how those kinds of things could occur -- I mean, how those kinds of things were considered into the decisions of looking at various sites, including the Caliente intermodal site.

Response

In the Final EIS, DOE estimated that the greatest consequences would occur if the sabotage event occurred in the center of a highly populated metropolitan area. The dose from such an event to a maximally exposed individual (about 110 rem over the person's lifetime) would increase his or her lifetime risk of a fatal cancer from about

23 percent to about 28 percent. However, doses to most affected individuals would be much lower than that to the maximally exposed individual; these individuals' increased risk of a latent fatal cancer would also be lower. It was not predicted that there would be any prompt fatalities from very high levels of exposure, and immediate health consequences from radiation exposure would be unlikely, but by combining the large number of small individual risks in the population of a metropolitan area, DOE estimated that a sabotage event could lead to as many as 48 latent fatal cancers. Although not estimated in the analysis, injuries and deaths from blast effects of a device that might be used would be expected for individuals who would be as close to the event as the hypothesized maximally exposed individual. However, exposure to radioactive materials sufficient to lead to an individual lifetime dose of 110 rem could result in a need for medical attention. DOE designed the analyses to identify the maximum consequences that a severe accident could reasonably be expected to produce (reasonably expected is defined as a likelihood greater than, but on the order of, 1 in 10 million in a year), but the analysis did not make extreme assumptions that would identify the worst possible consequences that could be imagined.

DOE believes that a shipment of spent nuclear fuel or high-level radioactive waste would be an unlikely target in part due to the physical security measures imposed by the Nuclear Regulatory Commission regulations. Under certain conditions, armed escorts would either follow or ride in the truck cab or an escort railcar. DOE would monitor its spent nuclear fuel and high-level radioactive waste shipments through a satellite-based tracking system.

8.8.2 (9771)
Comment - EIS001160 / 0123
The use of conventional highway traffic data, while convenient may have limited applicability when examining scenarios within White Pine County.

Response
The highway traffic data used to estimate impacts on the highways within Nevada are representative of the types of trucks that would be utilized to transport spent nuclear fuel and high-level radioactive waste within Nevada. National, State, and regional traffic data were used to ensure that transportation analyses were representative. Reviewing the references for Section 6 and Appendix J of the EIS shows the breadth and depth of traffic data used.

8.8.2 (10232)
Comment - EIS002115 / 0007
Other transportation issues of the waste to the site are: Mode, not clearly identified. Three possible modes of transportation are identified.

The waste could be driven on interstates using legal weight trucks. It could be sent by train, which includes five options of building a railroad to Yucca Mountain. It could be transported by heavy-haul, which is rail to a transfer point in Nevada, then transferred to 220 foot heavy-haul trucks and transported to Yucca Mountain. Routing, many possible routes not studied adequately. Rural areas do not have good or safe roads to transport this nuclear waste, especially if alternative routes are selected, nor do they have railroads to get it to Yucca Mountain. Land use. Consideration of present and planned land uses along possible routes identified.

Response
DOE used current regulations governing highway shipments and historic rail industry practices to select existing highway and rail routes to estimate potential environmental impacts. These routes are representative of the routes that the Department could use to transport spent nuclear fuel and high-level radioactive waste to Yucca Mountain. Section J.3.1.2 of the EIS discusses the rail implementing alternatives, which are the five candidate rail routes in Nevada to Yucca Mountain.

In addition, Section J.3.1.3 of the EIS describes the sensitivity of the impact analysis to the routing assumptions. With regard to land-use impacts, Sections 6.1.2.1 and J.3 discuss land-use impacts associated with the transportation implementing alternatives. If DOE selected a specific alternative, it would complete a more detailed analysis of environmental, engineering, and socioeconomic impacts along the corridor.

8.8.2 (10770)
Comment - EIS002144 / 0007
The Department of Energy operations office puts you guys to shame. They've done studies that we've told them to do. They came to us last year says, "Hey, we got studies this thick about intermodal transportation to the Nevada Test Site." We did an EA on it -- on the same thing that they had. They had $350,000.00. We had ten days to do this and about a hundred dollars a day per person to do it. When we got finished, our document was five times bigger. Our document talked about transportation. How are you going to get it there? How is it going to get there in the first place. And then after that, what's going to happen?

Our document talked about a lot farther than a half mile, because our document talked about real life. When -- when a crow flies in, he's not coming in just from a half mile; he's coming in from many miles away, and every time he goes to the bathroom, he drops that radiated part out of his body. Coyotes don't just come from a half mile away. Eagles don't just come from half mile away. They all come from a lot farther, and they don't consider that because they say -- and they're right. I'm not a scientific person. I know from my experience at home and my teachings from my people what we -- what has happened and what is going to happen, and it's a shame that we -- that I have to cry and scream and yell just like you at your site and go home.

Response
The analysis of impacts from the construction and operation of an intermodal transfer station in Section J.3.3.1 of the EIS indicated that there are no credible accidents that would result in a release of radioactive material. The analysis evaluated radiological and nonradiological impacts and found that they would be low.

8.8.2 (11277)
Comment - EIS001814 / 0011
DEIS Page 2-9
DOE is looking at three transportation scenarios for Nevada. These scenarios include legal-weight truck and rail, which are the same as the national scenarios but highlight the Nevada portion of the transportation, and heavy-haul truck.

Although DOE maintains that the "mostly legal weight truck" and "mostly rail" scenarios adequately bound the analysis for the national transportation scenarios, this is not true for the Nevada Transportation Scenarios. Under the "mostly legal weight truck" scenario, DOE must still deal with more than 300 rail shipments of high-level waste and Naval fuel (references). The Nevada Transportation Scenario fails to describe how DOE will deal with these shipments without either constructing a rail line or operating an intermodal transfer site and heavy-haul.

Response
Section 2.1.3.3.1 of the EIS states that DOE would use heavy-haul trucks and would establish an intermodal transfer capability. These 300 shipments would be spread over a 24-year period, which would arrive within Nevada by rail. Section 6.3.3 states, "This EIS assumed that DOE would not build an intermodal transfer station to handle those shipments." The intermodal transfer capability would consist of a suitable crane and an existing rail siding suitable for transferring the transportation cask (approximately 12 per year) onto a heavy-haul truck described in Figure 2-28. In this limited heavy-haul truck scenario, there would be no road upgrades required as described in this section for the mostly rail scenario. Nevada Department of Transportation currently issues approximately 400 permits on a single-trip permit basis for vehicles capable of transporting 68 metric tons (75 tons) or more payload on the five candidate heavy-haul truck routes evaluated in the EIS, excluding the use of the Las Vegas Beltway. DOE believes that the 12 additional heavy-haul truck shipments per year on these roads would not warrant large-scale, costly highway improvements that are included in the mostly rail scenario, nor would they cause significant additional highway deterioration or traffic hazards.

8.8.2 (11278)
Comment - EIS001814 / 0012
DEIS Page 2-40
These scenarios illustrate the broadest range of operating conditions relevant to potential impacts to human health and environment.

This statement is incorrect, since the "Mostly LWT [legal-weight truck]" scenario includes rail shipments. Without constructing a new rail line in Nevada or operating an intermodal transfer and heavy-haul in Nevada, the shipments dependant on rail will either have to be repackaged in smaller containers in Nevada or not shipped to the proposed repository at Yucca Mountain.

Response
As described in Section 2.1.3.2.1 of the EIS, part of the mostly legal-weight truck scenario includes the shipment of naval spent nuclear fuel that would be shipped to Nevada by rail. These shipments incorporate approximately 300 shipments over a 24-year operational period. The EIS assumed that these shipments would use the services of a commercial intermodal operator. The EIS also assumed that DOE would not build an intermodal transfer station to handle naval spent nuclear fuel shipments. Naval spent nuclear fuel shipments, equating to approximately 16 casks per year, would then be shipped from the intermodal transfer point to Yucca Mountain by heavy-haul truck as described in Section 6.3.3.1. It is the Department's opinion that the EIS adequately analyzes the mostly legal-weight truck transportation shipping scenario.

8.8.2 (11285)
Comment - EIS001814 / 0017
DEIS Page 2-49
Construction activities would include the development of construction support areas; construction of access roads to the rail line construction initiation points and to major structures to be built, such as bridges; and movement of equipment to the construction initiation points. The number and location of construction initiation points would be based on such variables as the route selected, the length of the line, the construction schedule, the number of contractors used for construction, the number of structures to be built, and the locations of existing access roads adjacent to the rail line.

The construction activities listed cannot be completed without some environmental impact, and will require appropriate mitigative measures. Without a detailed description of these activities it is impossible to conclude that they can be completed without causing unacceptable adverse environmental impacts, even with mitigative measures. Until these construction activities are specified, DOE cannot conclude that the proposed action will not result in unacceptable impacts as required by the National Environmental Policy Act.

Response
Section 6.3 of the EIS describes different categories of environmental information acquired and evaluated for Nevada transportation. The results of the evaluation of this information for each mode and route in Nevada are provided in the subsequent sections. Should the mostly rail transportation scenario be selected and a preferred corridor identified, additional engineering and environmental studies would be initiated to select a specific alignment of the tracks within the selected corridor and related construction activities. Appropriate National Environmental Policy Act reviews would be conducted to support selection of a specific alignment and design. Detailed branch rail line construction activities would be evaluated in subsequent engineering and environmental analyses in conjunction with government agency consultation and evaluated in appropriate National Environmental Policy Act reviews conducted in union with these analyses and consultations. Access roads and construction support areas would be evaluated as short-term temporary impacts.

8.8.2 (11286)
Comment - EIS001814 / 0018
DEIS Page 2-50
Railroad track construction would consist of the placement of railbed material, ties, rail, and ballast (support and stabilizing materials for the rail ties) over the completed railbed platform.

Construction of the railroad in any of the proposed rail corridors will require significant quantities of ballast and probably significant quantities of sub-ballast. The EIS does not provide a description of the source for these materials. The quantity of ballast and sub-ballast required should be accurately defined, and sources for the material described. Quarrying the ballast and sub-ballast could result in significant environmental impacts not assessed in the EIS.

<u>Response</u>
Detailed evaluations for the source of sub-ballast, ballast, and fill materials would be performed in subsequent National Environmental Policy Act evaluations, should rail be selected as the preferred mode for transportation. Determination of material sources is very route-specific, and the detailed engineering required to develop accurate source requirements is more applicable to the next level of National Environmental Policy Act activities, once a route had been selected. Preliminary quantities of fill material, sub-ballast, and ballast were evaluated in *Nevada Transportation Study Construction Cost Estimate* (DIRS 154822-CRWMS M&O 1998).

The estimated land disturbance for obtaining fill materials was included in the land disturbance quantities in the EIS. The ballast and sub-ballast materials were assumed to be available from existing quarries, either in Nevada or from quarries in neighboring states. Sub-ballast and ballast materials could be transported to the rail construction site by completed rail section. Therefore, the transportation of those materials from quarries in other parts of the country is not a great economic differentiation, unlike the transportation of the base fill materials that would have to be transported by truck. Fill material transport would a significant cost driver, which would require the use of local borrow sources. This is why the EIS includes fill borrow source disturbed land and not sub-ballast and ballast borrow source estimates.

8.8.2 (11287)
<u>Comment</u> - EIS001814 / 0019
DEIS Page 2-50
Other activities would include the following: Installation of fences along the rail line, if requested by other agencies (for example, the Bureau of Land Management or the Fish and Wildlife Service).

The description of the proposed action should include the location and type of fencing to be installed. Without this information, it is not possible to assess the impacts of the proposed action, particularly on wildlife and on land use. The two agencies listed could, in fact, request conflicting requirements for fencing based upon the impact within their area of jurisdiction. Depending on the types and locations of fencing, the proposed action could create significant impacts to wildlife, particularly where the proposed corridors cross critical habitat areas.

<u>Response</u>
Section 6.3 of the EIS addresses the potential needs for fencing under the categories of land use and ownership and biological resources, and identifies potential impacts. Should the mostly rail transportation scenario be selected and a preferred corridor identified, additional engineering and environmental studies would be initiated to select a specific alignment of the tracks within the selected corridor. Appropriate National Environmental Policy Act reviews would be conducted to support selection of a specific alignment and design. Detailed analysis of fencing locations and types would be evaluated in subsequent engineering and environmental analyses and government agency consultation and evaluated in appropriate National Environmental Policy Act reviews conducted in conjunction with these analyses and consultations. It is the Department's opinion that the EIS adequately analyzes potential needs for fencing along candidate railroads and roadways, and their use and impacts.

8.8.2 (11288)
<u>Comment</u> - EIS001814 / 0020
DEIS Page 2-50
This EIS assumes there would be about four trains per week for shipments of spent nuclear fuel and high-level radioactive waste to the repository. In addition, the rail line would enable the transport of other material to the repository, including empty disposal containers, bulk concrete materials, steel, large equipment, and general building materials. The EIS assumes one train per week for this other material for a total of about five trains per week to the repository from about 2010 to 2033.

The EIS does not include an estimate of the number of trains leaving the repository. This would presumably include return of empty shipping casks as well as additional unloaded cars that were used to ship materials to the site. One cannot automatically assume that the number of unloaded trains leaving the repository will be the same as the number of loaded trains arriving. Therefore, it is not possible to assess the impacts of the rail line from the description of the proposed action.

Although discussed in the references to the EIS, this EIS does not discuss the different options for ownership and operation of the rail line or the possibility that the rail line would be used for other purposes than the proposed action described in the EIS. Use for other types of shipments could increase the impacts of the proposed action above that is described in the EIS.

Response
All transportation in the EIS is considered to be round-trip. Therefore, the transportation discussed in the comment (the return trip from the repository) is addressed in the EIS. Section 8.4.2 of the EIS discusses the shared use of a branch rail line. Decisions regarding the selection of a branch rail line for transporting spent nuclear fuel and high-level radioactive waste have not been made. However, it is in DOE's interest and in the interest of communities along a branch rail line to consider shared use. Before decisions were made on the transportation alternatives associated with the Yucca Mountain Repository, the impacts, such as shared use, would be evaluated. In addition, the NWPA, through its section on consultation and cooperation, requires DOE to consult with affected units of local government. Potential benefits of the shared use of the branch rail line would be explored through that process.

8.8.2 (11293)
Comment - EIS001814 / 0022
DEIS Page 2-51
Intermodal transfer station operations would depend on whether the railcars that carried spent nuclear fuel and high-level radioactive waste arrived on dedicated or general freight trains.

DOE states that there will be operational differences for the intermodal transfer station between the dedicated train and general freight options. The EIS, however, does not contain sufficient information on these differences to allow an evaluation of the difference in impacts between the two options. The difference between staging requirements for the heavy-haul vehicles for the two options should be described. If general freight was used, the EIS states that the "General freight trains would switch from the main Union Pacific track to an existing or newly constructed passing track." The EIS does not state where the existing or newly constructed passing track would be located. If it is located at the intermodal transfer station, this would significantly alter the design of the station. If a new passing track is constructed at a location independent of the station, this would create potential impacts that have not been evaluated. Even if an "existing passing track" is used, this would probably require the Union Pacific to construct a new passing track for other railroad traffic.

Response
Table J-25 in the EIS presents a comparison of general freight and dedicated rail service. However, available information has not indicated a clear overall advantage of using general freight or dedicated rail service for the transportation of spent nuclear fuel and high-level radioactive waste. At this time DOE has not determined the commercial arrangements (dedicated or regular freight) it would request from railroads for shipment of spent nuclear fuel and high-level radioactive waste. Once that determination was made, the logistics of transporting the railcar(s) would be discussed with the rail carriers, states, tribes, and other stakeholders.

8.8.2 (11296)
Comment - EIS001814 / 0025
DEIS Page 2-54
Most borrow material for construction could come from existing Nevada Department of Transportation borrow areas, if the State agreed.

Most road design projects attempt to balance cut and fill requirements during construction of the roads. Therefore, it is not reasonable to assume that borrow material will be available in existing borrow areas for the extensive fill requirements necessary to construct truck climbing lanes and other road improvements. Obtaining fill material from other areas could result in significant impacts not discussed within the EIS.

Response
Section J.3.1 of the EIS discusses the transportation modes, routes, and number of shipments of spent nuclear fuel and high-level radioactive waste for the different transportation implementing alternatives and their alignment variations. This information includes tables of information of potential upgrades needed for each option. This information provides the basis for the impact assessments. Details of impacts on existing surface transportation was

evaluated in CRWMS M&O (DIRS 154448-1998) and summarized in the EIS. These analyses evaluated current traffic levels on existing roads, estimated increased traffic, and additional traffic due to spent nuclear fuel and high-level radioactive waste transport.

Costs estimated for the road upgrades associated with the heavy-haul truck transportation systems assumed that fill material would be hauled in from existing borrow areas. If the State's current borrow areas were insufficient to provide the material needed, the fill would be obtained from existing private borrow sources or quarries.

When a corridor or route was selected, detailed assessments and designs for rail alignments or heavy-haul truck road upgrades would be initiated. These studies would be part of engineering and environmental studies needed to develop detailed designs and to support appropriate National Environmental Policy Act reviews for the proposed actions. DOE would use routes that meet U.S. Department of Transportation requirements or were designated by State routing agencies.

8.8.2 (11304)
Comment - EIS001814 / 0033
DEIS Page 3-100
DOE expects waste quantities generated by rail line construction and operation to be minor in comparison to those from repository construction and operation. As such, no discussion of existing waste disposal infrastructure along the routes is provided.

It is true that waste quantities generated by rail line construction and operation should be minor in comparison to those from repository construction and operation. The comparison, however, is meaningless. Most of the rail construction would take place far from the repository, much of it in remote, sparsely populated areas. Waste generated during the rail construction will undoubtedly not be hauled to the same disposal site as waste generated during repository construction. Rather, it will be disposed in facilities along the corridor.

What is significant, therefore, is the volume and type of waste generated by rail line construction and operation in comparison to the capacity of waste disposal facilities along the various corridors. Given the remote, sparsely populated areas crossed by the proposed rail line, solid waste disposal facilities probably do not have sufficient capacity to handle waste generated during rail construction. Many times construction waste is not compatible with the waste handling facilities at existing sites. (Note: this same discussion applies to the intermodal transfer station and heavy-haul routes.)

Response
Section 6.3 of the EIS addresses waste generated by branch rail line construction and operation. It was assumed that the waste materials from construction and operation of a branch rail line would be transported to a facility with sufficient capacity to dispose of the waste material without any undue impacts. Should the mostly rail transportation scenario be selected and a preferred corridor identified, additional engineering and environmental studies would be initiated to select a specific alignment of the tracks within the selected corridor and evaluate the impacts of construction and operation of the branch rail line and supporting facilities. Appropriate National Environmental Policy Act reviews would be conducted to support selection of a specific alignment and design. Details on the location of such a facility would be further evaluated if a branch rail line was selected.

8.8.3 SPECIAL TOPICS

8.8.3 (171)
Comment - 42 comments summarized
Commenters disagreed with DOE's conclusion that there would be no environmental justice impacts from spent nuclear fuel and high-level radioactive waste transportation to Yucca Mountain and stated that the Draft EIS findings regarding environmental justice were unjustified since analysis along specific transportation routes was not conducted. Commenters stated that actual routes on a segment-by-segment basis must be considered when estimating impacts (latent cancer fatalities) to low-income or minority communities. Commenters stated that it is well known that low-income and minority communities are located along railroads and highways and that DOE would need to name the transportation routes and prepare maps to show the locations of potentially affected minority and low-income populations. As analyzed in the EIS, it is impossible to assess whether impacts would fall

inequitably on certain sectors of the population. Another commenter stated that the so-called "hypothetical" populations analyzed in the EIS in fact comprise low-income and minority populations that already have experienced disproportionate impacts and compromised their quality of life because of previous environmental decisionmaking. Commenters gave examples of specific communities that could be affected depending on the selected transportation route, such as the Duckwater and Ely Shoshone Reservations in Nevada, Interstate-70 through Denver, Interstate-90/State Route 2 "Shoreway" through Cleveland, communities in San Bernardino County, California, and the Interstate-25 corridor. Another commenter stated that certain types of trucks are barred from traveling on elevated highways (Interstate-70), and so must pass through minority neighborhoods near residences and schoolyards. Commenters stated that because of the generic nature of the national transportation analysis, DOE could not substantiate the statement that there would not be disproportionately high and adverse impacts to minority or low-income populations from the Proposed Action.

Response

Consistent with Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, DOE performs environmental justice analyses to identify and address, as appropriate, the potential for its actions to cause disproportionately high and adverse impacts to minority or low-income populations. The approach to environmental justice analysis in the Draft EIS and Final EIS is consistent with Council on Environmental Quality guidance. The goal of this approach is to identify whether any high and adverse impacts would fall disproportionately on minority and low-income populations. The approach first analyzes the potential impacts on the general population as a basis for comparison. Second, based on available information, the approach assesses whether there are unique exposure pathways, sensitivities, or cultural practices that would result in high and adverse impacts on minority and low-income populations. If such potential impacts would be high and adverse, the approach then compares the impacts on minority and low-income populations to those on the general population to determine whether any high and adverse impacts fall disproportionately on minority and low-income populations. In other words, if high and adverse impacts on a minority or low-income population would not appreciably exceed the same type of impacts on the general population, no disproportionately high and adverse impacts would be expected.

In response to comments, DOE has reevaluated available information to determine whether the Draft EIS overlooked any unique exposure pathways or unique resource uses that could create opportunities for disproportionately high and adverse impacts to minority and low-income populations, even though the impacts to the general population would not be high and adverse. Additional unique pathways and resources were identified and analyzed, although none revealed a potential for disproportionately high and adverse impacts. For example, DOE estimated the potential health impacts from a subsistence diet based primarily on game taken from lands near the repository exclusion areas and concluded that high and adverse health and safety impacts would be unlikely.

DOE has updated and refined information germane to its environmental justice analysis. The EIS now includes, for example, additional and more detailed mapping of minority populations, and additional mapping and information that describes the proximity of tribal lands and cultural and ceremonial areas to candidate rail corridors in Nevada. Based on the additional information and resulting analysis, DOE has concluded that disproportionately high and adverse impacts from the construction and operation of a branch rail line or intermodal transfer facility would be unlikely.

The EIS analyzes potential public health effects of both routine (incident-free) transportation of radioactive materials and transportation accidents involving radioactive materials. First, regarding routine transportation, the EIS considers air emissions and doses from exposure to radioactive materials during transport. The EIS estimates the impacts from air emissions to be 1 emission-related fatality. The EIS estimates that the 24-year national transportation campaign would cause fewer than about 3 latent cancer fatalities among the public, and fewer under the preferred mostly rail scenario. Although many people would be exposed nationwide over a long campaign, the radiation dose to any exposed individual would be very low. In this context, DOE does not consider such impacts to be high. In addition, DOE does not know of a plausible mechanism under these circumstances by which low-income or minority populations could incur high and adverse impacts when the general public would not. Because there could be no disproportionately high and adverse impacts on any population, including low-income or minority populations, it is not necessary to examine the composition of the population along existing transportation corridors to conclude that potential public health effects from exposure to radioactive materials during routine transportation would not involve environmental justice concerns.

The EIS estimates the number of people in the general public who could be killed by accidents involving transportation of spent nuclear fuel and high-level radioactive waste. The two mechanisms for such impacts are bodily trauma from collisions or exposure to radioactivity that would be released if a sufficiently severe accident occurred. The EIS estimates that the 24-year national campaign would cause fewer than 5 deaths among the general public from trauma sustained in collisions with vehicles carrying spent nuclear fuel or high-level radioactive waste. In this context, DOE does not consider such impacts to be high. Moreover, DOE does not know of a plausible mechanism under these circumstances by which low-income or minority populations could incur high and adverse impacts when the general public would not.

Only if a severe accident occurred that resulted in release of radioactive materials would it be possible for the affected population to sustain high and adverse health effects, but the probability of such an event occurring is remote, so the overall associated risk to the general public would be low. Moreover, as is true of all transportation accidents, it is impossible to predict where along a transportation corridor an accident might occur (unlike accidents at fixed-facility locations), and, thus, who might be affected. Therefore, as with routine transportation and trauma effects of accidents, it is not necessary to examine the composition of the population along transportation corridors to conclude that the radiological risk resulting from transportation accidents would not constitute a disproportionately high and adverse impact on low-income or minority populations.

Although the transportation of radioactive materials would not result in disproportionately high and adverse impacts on low-income and minority populations, there are reasons to examine the composition of the population along newly proposed transportation corridors (such as the alternative locations of rail corridors within Nevada) that do not apply to existing highways and railways. When considering where to locate a new transportation corridor, the impacts of the construction and use of a newly created route on land use, socioeconomics, noise, air quality, and esthetics, to name a few categories, might vary by location. For example, constructing a new highway that might benefit the population as a whole might, nevertheless, so disrupt a minority or low-income population living along the proposed route as to result in disproportionately high and adverse impacts. Selecting among alternative new routes might offer opportunities to avoid high and adverse impacts that would fall disproportionately on low-income or minority populations in relation to the general population that would not be present when considering existing transportation corridors. Therefore, even though the health effects from exposure to radioactive materials from transportation activities would not involve environmental justice concerns in selecting new routes, other factors could. For these reasons, DOE examined the composition of the populations along the five alternative routes for a rail corridor in Nevada to determine the minority and low-income populations residing along the corridors.

In the EIS analyses, DOE assumed shipments would use highway routes that would comply with U.S. Department of Transportation regulations for transporting spent nuclear fuel. With the exception of routes to the nearest Interstate System highways or state or tribal designated preferred routes used to pick up shipments from generator sites and to deliver shipments to Yucca Mountain, Department of Transportation regulations require carriers to use Interstate System highways, bypasses, and beltways, or state or tribal designated preferred routes that reduce time in transit. DOE shipments would comply with these regulations.

Comment - 4 comments summarized

Commenters disagreed with DOE's analysis of impacts at generator facilities of loading spent nuclear fuel and high-level radioactive waste into shipping casks and delivering the casks to carriers for transport to Yucca Mountain. One commenter observed that DOE's estimate of 0.1 person-rem exposure to the public from loading spent nuclear fuel and high-level radioactive waste for transportation is much lower than impacts for other accidents analyzed in the EIS. The commenter asked what units of measure apply to the 0.1-person-rem impact – per year, per accident, per hour, average? The commenter suggested the estimate of 0.1 person-rem is based on experience to date but could be expected to increase as the quantities of spent nuclear fuel that are handled and loaded increase. This commenter disagreed with DOE's assertion that risks associated with handling and loading high-level radioactive waste would be less than those from handling and loading spent nuclear fuel.

A commenter stated that the Schneider report (DIRS 101747-Schneider et al. 1987) does not provide valid information for evaluating impacts of loading spent nuclear fuel at generator sites. The commenter argued the report did not consider a much different loading scenario in which storage casks (which at the time of the Schneider report did not receive general certificates of compliance from the Nuclear Regulatory Commission) would be unloaded into transportation casks at generator sites.

A commenter stated DOE did not address risks of or procedures to transfer spent nuclear fuel and high-level radioactive waste from DOE or utilities to a carrier and must provide further analysis of waste transfer procedures, risks, modes among generators, carriers, and receiver.

A commenter observed that most accidents to date at nuclear powerplants have been industrial accidents, and asked what are DOE's grounds for asserting there would be no worker fatalities from industrial accidents in loading spent nuclear fuel for transport?

Response

Section 6.2.4.1 and Table 6-16 of the EIS provide a summary of information on the impacts associated with accidents of handling and loading spent nuclear fuel and high-level radioactive waste. DOE based its estimate of 0.1 person-rem per year to the onsite workforce, not the general population (see Table 6-16), on information presented in a report on health and safety impacts for the multipurpose canister system (DIRS 104794-CRWMS M&O 1994). This report estimated that impacts to members of the onsite workforce from a loading facility would be no more than 0.1 person-rem in the event of an accident in loading and handling a multipurpose canister system for transport. The collective dose to the public would be much less. This estimate is consistent with DOE estimates of offsite impacts from accidents at a monitored retrievable storage facility (DIRS 104731-DOE 1986). The estimated impact to workers and the public health and safety is for a single handling accident. DOE's estimate for the rate for lift-handling accidents involving spent nuclear fuel casks presented in Section 6.2.4.1 is 1 in 10,000 handling operations.

These dose risks would be lower than those for transportation accidents for several reasons. The forces involved with a handling accident would be much less severe than those postulated for the maximum reasonably foreseeable transportation accident. Handling accidents would occur inside nuclear facilities designed to protect the public from the consequences of handling accidents and much more severe reactor accidents. DOE used information from *Preliminary Preclosure Design Basis Event Calculations for the Monitored Geologic Repository* as the basis for projecting that handling accidents involving loading high-level radioactive waste for transportation would have lower consequences than those involving loading spent nuclear fuel (DIRS 103237-CRWMS M&O 1998).

DOE based its estimates of impacts of loading spent nuclear fuel and high-level radioactive waste on *Analysis of Radiation Doses from Operation of Postulated Commercial Spent Fuel Systems* (DIRS 101747-Schneider et al. 1987). The information in this report is based on analysis of loading procedures and risks among generators at commercial nuclear facilities for shipping spent nuclear fuel using truck casks and rail casks. DOE believes this report provides the latest reasonable information for estimating impacts of loading spent nuclear fuel and high-level radioactive waste at generator facilities. To estimate loading impacts, DOE assumed spent nuclear fuel and high-level radioactive waste would be available in locations where loading operations occur, for example storage pools at commercial nuclear reactors. DOE did not analyze the impacts of loading and unloading dry storage casks at nuclear facilities because these impacts are addressed in environmental analyses prepared by the Nuclear Regulatory Commission to support licensing of the independent storage facilities.

At present, DOE intends to purchase services and equipment from Regional Servicing Contractors who would perform waste acceptance and transportation operations. Operational protocols and procedures would be developed with each generator by Regional Servicing Contractors as part of the planning process to be completed prior to initiation of transport of spent nuclear fuel or high-level radioactive waste from generators to the repository. Section M.3 of the EIS contains more information on operational protocols required of the Regional Servicing Contractors.

Section 6.2.2.2 of the EIS presents an analysis of industrial safety impacts of loading spent nuclear fuel and high-level radioactive waste at generator facilities. Because the estimates suggested there would be a 1-in-50 chance (2-percent probability) of one fatality from an industrial accident for the mostly rail scenario and a 1-in-20 chance (5-percent probability) for the mostly legal-weight truck scenario over 24 years of the Proposed Action, the EIS concluded no worker fatalities from industrial accidents would be expected.

Comment - 21 comments summarized

Commenters questioned the relevancy of the 30-year safety record of transporting spent nuclear fuel and high-level radioactive waste cited in the EIS for predicting the safety of future shipments to Yucca Mountain. Reasons given by commenters included (1) the proposed number of shipments is unprecedented and (2) the types of casks, procedures, and protocols used in the past are not applicable to the Proposed Action. Commenters also questioned DOE's contention that the safety record is good, citing transportation accidents involving spent nuclear fuel and low-level waste (72 incidents from 1949 to the present according to a database at Sandia National Laboratories). Others argued that shipping casks have not yet been built and tested, so their performance is not yet known and the impacts of accidents cannot be judged. Commenters said that the EIS should have predicted accidents and described how they would be mitigated.

Commenters said DOE should use "shipment miles" rather than "number of shipments" as the measure for predicting safety, noting that the total number of shipment miles to date is very small compared to the total number of shipment miles associated with the repository. Some commenters stated that past shipments of spent nuclear fuel from a reactor's core to its storage ponds should not even be considered a "shipment."

Response

Sections J.1.1 and J.1.4.2.1 of the EIS present the approach DOE used to estimate the number of accidents and the associated impacts that would occur in transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain for the Proposed Action. As requested by public comments, DOE has included maps showing the routes used in the analysis and estimates of the state-by-state impacts based on these routes (see Section J.4). The approach, which is not based on the safety record of shipments of spent nuclear fuel over the past 30 years, uses U.S. Department of Transportation state-by-state accident and fatality statistics for highway, rail, and barge transportation. The statistics were compiled from accidents that occurred during all four seasons from 1994 through 1996 (DIRS 103455-Saricks and Tompkins 1999), which is the most current information of this type available. The approach includes the assumption that the number of potential accidents and impacts would be proportional to the number of total kilometers that shipments would travel in each state (number of cask shipments times distance traveled). Annual accident data were used and routes were assumed not to change with season. Thus, the number and impacts of accidents would be independent of the time of year travel would occur.

Total incident-free impacts for 24 years, which would be dependent on the total number of shipment kilometers, would not be affected by the time of year shipments were made if routes remained the same. Because accident rate data are not available for specialized logistical arrangements, such as convoys and dedicated trains, DOE assumed the industry-wide accident rates for individual truck, railcar, and barge shipments used in the EIS would apply. Because incident-free impacts would be proportional to the number of cask shipments over 24 years, transporting casks in multiples in convoys or dedicated trains would not affect these impacts. Because accidents at intermodal transfer facilities would not exceed cask design requirements, DOE estimated that radiological impacts would not occur for these (see Section J.3.3.1 of the EIS).

Section 6.3.3 of the EIS presents estimates for industrial safety impacts from operations at an intermodal transfer station in Nevada. In one area the approach for estimating the number and severity of accidents relied on historic experience. It assumed spent nuclear fuel and high-level radioactive waste would be properly packaged for shipment in Type B shipping casks certified by the Nuclear Regulatory Commission to comply with the performance standards contained in 10 CFR Part 71, as required by Commission and U.S. Department of Transportation regulations. Type A and strong-tight packaging, which are not accident-resistant (see 49 CFR 173.403), would not be used to ship spent nuclear fuel or high-level radioactive waste. The approach also assumed transport carriers' operations and vehicles would comply with applicable Federal, state, Native American tribal, and local regulations; occur during all four seasons of the year; and resemble those used for other commodities transported in interstate commerce. DOE would ensure that shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain and the return of empty shipping casks and vehicles for further use would comply fully with applicable Federal, state, tribal, and local regulations, including those of the Nuclear Regulatory Commission and U.S. Department of Transportation (see Section 2.1.3.2). These regulations include, among other things, requirements for operator training, vehicle safety, records, communications and tracking, and security. These measures are implemented to minimize potential human errors and other conditions that could lead to accidents.

The analyses used “fatality” as the measure of impacts to the public because it is an easily understood objective measure used historically in EISs prepared by DOE. In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $9.4 billion. Cost data used in the studies included data compiled from case studies involving actual cleanup of radioactive material contamination. The studies addressed consequences for releases of radioactive materials in communities. In response to comments from the public, DOE has included additional information on Federal, state, tribal, and local responsibilities and preparedness for emergency response to accidents involving radioactive materials shipments (see Section M.5 of the EIS). Section M.8 discusses the Price-Anderson Act, which provides for indemnification for public liability to redress costs of accidents involving releases of radioactive materials to the environment or authorized precautionary evacuations.

Comment - 7 comments summarized
Commenters stated that because the EIS does not define floodplains within rail corridors, along heavy-haul truck routes, and at potential sites for an intermodal transfer station, the analysis of floodplains and wetlands in Appendix L is insufficient to support decisions to select a transport mode or route in Nevada.

Commenters said that wetlands, which some corridors are known to cross, are valuable resources in Nevada, and that it is not sufficient to simply state in the EIS that impacts to wetlands would be mitigated. Commenters also said that the floodplain information that is in the EIS has not been verified by ground surveys.

Commenters stated that the analysis of surface-water resources in the EIS is insufficient because it does not acknowledge that flooding and flash flooding can occur along parts of the rail corridors and along the heavy-haul truck routes. In wet years, parts of any rail line in Nevada could be covered with floodwater and these routes are not in an area that is appropriate for the shipment of spent nuclear fuel and high-level radioactive waste. Referring to DOE’s commitment to temporarily stop shipments whenever flooding affected a route, commenters asked if these shipments would be parked and if a flash flood could be detected in time to stop a shipment before it was threatened by flood waters. Commenters stated that none of the candidate routes avoid designated groundwater basins. Other commenters said that flash floods entering Pahrump Valley from the Wheeler Pass area would require a large retention basin, and that the EIS did not address the impacts of this manmade structure.

Response
Sections 3.2.2.1.3 and 3.2.2.2.3 of the EIS present information concerning current conditions of potentially affected surface-water and groundwater resources along the candidate rail corridors, heavy-haul truck routes, and intermodal transfer station sites. Sections 6.3.2 and 6.3.3 identify potential impacts on surface-water and groundwater resources along each candidate route and site for an intermodal transfer station. Appendix L examines the effects on floodplains and areas that could have wetlands in Nevada of construction and operation and a branch rail line or intermodal transfer station associated with routes for heavy-haul trucks. The assessment in Appendix L did not evaluate potential floodplain or wetlands effects along highway routes because these existing roads should already be designed to meet 100-year floodplain design specifications. Appendix L states that if DOE decided to construct a branch rail line or use heavy-haul trucks in Nevada, a more detailed floodplain/wetlands assessment of the selected rail corridor or route for heavy-haul trucks and associated intermodal transfer station site would be prepared. However, DOE has added additional flood zone information to the floodplain/wetlands assessment in Appendix L. Specifically, the appendix now identifies 100-year flood zones crossed by rail corridors or their alignment variations if such information is available on maps published by the Federal Emergency Management Agency.

DOE would select the specific alignment within a corridor and design of a branch rail line or specific location and design of an intermodal transfer station to preclude flood water, including water from flash floods, from a 100-year flood from inundating rail track or facility operations areas. Engineering designs used as a basis for the EIS considered the potential for flooding along candidate routes and sites for an intermodal transfer station. The designs included culverts and bridges that would be needed to accommodate water from a 100-year flood.

If DOE decided to construct a branch rail line or an intermodal transfer station, it would require a hydrological analysis and evaluate the impacts of designing for floods for 25, 50, and 100 years. Critical areas might require the design to address a 100-year storm, based on appropriate engineering criteria.

As stated in the *Manual for Railway Engineering*, "The design flood frequency to be used is a matter of engineering judgement and economics. A number of trials should be made using a wide range of frequencies. In this way the possibilities of damage because of too small an opening can be assessed. The cost of providing for the maximum possible flood of 100 years frequency or greater can also be determined and a prudent decision made. In general practice, railroad drainage openings should be designed for floods in the range of 25 to 50 years. This does not imply that a 100-year flood design would be out of place in certain instances" (DIRS 106860-AREA 1997).

Disturbed area estimated in Chapter 6 of the EIS for each candidate branch rail line, highway route for heavy-haul trucks, and site for an intermodal transfer station includes areas for retention basins and engineered flow channels. DOE would temporarily discontinue shipments of spent nuclear fuel or high-level radioactive waste that would use a highway or rail route where flooding could compromise safety. Shipments that were underway at the time of an ongoing or potential flooding event would be temporarily delayed at a safe, secure location along the route until the affected section of track, roadway, or intermodal transfer station was determined to be safe for use. DOE would monitor weather forecasts to ensure shipments would not occur in areas where, and at times when, the potential for flash flooding could compromise safety.

Groundwater basins underlie all areas of Nevada including areas where shipments would travel. Designated groundwater basins identified in Chapter 6 of the EIS are basins for which the Nevada State Engineer has determined that permitted water rights approach or exceed the estimated perennial water or that additional administrative oversight is required. Designated Groundwater Basins are identified to provide information regarding availability of groundwater needed for constructing a branch rail line or upgrading highways for use by heavy-haul trucks. As described in Section 6.3 of the EIS, DOE would transport water by truck to construction areas if it could not obtain permits for withdrawals from a Designated Groundwater Basin.

Chapter 9 of the EIS, which provides DOE's initial list of mitigation commitments available at this time, identifies DOE-determined impact reduction features, procedures, and safeguards and mitigation measures under consideration for inclusion in the project plan and design. Chapter 9 also identifies ongoing studies that could eventually influence mitigation measures related to the project plan and design. For example, Section 9.3 discusses mitigation measures to reduce potential impacts from the transportation of spent nuclear fuel and high-level radioactive waste nationally and in Nevada. These measures address impacts from the possible construction of a branch rail line or an intermodal transfer station in Nevada; construction of other transportation routes; upgrading of existing Nevada highways to accommodate heavy-haul vehicles; transportation of spent nuclear fuel and high-level radioactive waste from existing storage sites to the proposed repository; and fabrication of casks and canisters. As suggested Chapter 6 and Section 11.2.2 (subsection on Compliance with Floodplain/Wetlands Environmental Review Requirements), more detailed field surveys, government consultation, analyses, and appropriate National Environmental Policy Act reviews would be conducted if a decision was made to select a specific rail alignment within a corridor or a specific location of an intermodal transfer station or the need to upgrade the associated heavy-haul truck routes. These would include consultations with State wildlife management agencies, the Bureau of Land Management, the Army Corps of Engineers, and other applicable government agencies. They also would include field surveys (as applicable) and more detailed assessments and analyses of wetlands and other waters; floodplains; sensitive species; effects of habitat fragmentation, interruption of movements, mortality, and harassment on wildlife, horses, and burrows; loss of hunter-generated revenue, spread of noxious weeds, and soils.

8.8.3 (177)
<u>**Comment**</u> - 8 comments summarized
Commenters stated that the EIS is inadequate because it did not consider the effects of the proposed Private Fuel Storage facility in Skull Valley, Utah, on transportation of spent nuclear fuel to Yucca Mountain. Commenters expressed concern that utilities would ship their older commercial spent nuclear fuel currently in storage to the Private Fuel Storage facility (if it is licensed), before a repository at Yucca Mountain was constructed. Therefore, at a later date, much younger and more radioactive spent nuclear fuel from commercial facilities would be shipped to the Yucca Mountain Repository. Commenters argued that DOE's Acceptance Priority Ranking (DIRS 104382-DOE 1995) did not consider the Private Fuel Storage facility in determining the order in which spent nuclear fuel would

be delivered to Yucca Mountain. Commenters stated that NUREG-1437 (DIRS 101899-NRC 1996 and DIRS 101900-NRC 1996) states that the minimum cooling time for transporting spent nuclear fuel is 5 years; however, the Draft EIS used a cooling time of 25.8 years to assess health impacts. Based on this information, the cooling time for spent nuclear fuel used in the EIS analysis of impacts should be much less than 25.8 years.

Commenters stated that the Private Fuel Storage facility and the Yucca Mountain Repository would likely be used together and the Private Fuel Storage facility could become a clearinghouse for spent nuclear fuel. This would mean that Utah could become the state of origin for more than half of the commercial spent nuclear fuel shipped to the Yucca Mountain site. The combined transport for the Private Fuel Storage facility and the Yucca Mountain Repository would be greater than that estimated in the Draft EIS, resulting in more shipment miles. This would cause a greater hazard than that reported in the Draft EIS. Commenters stated that impacts in Utah would be much greater than that estimated in the Draft EIS because of the combination of shipments to both the Private Fuel Storage facility and to Yucca Mountain. As a consequence, there would be a major impact on a national scale that would need to be assessed in the analysis of cumulative impacts. Failure to consider the Private Fuel Storage facility would segment the National Environmental Policy Act process. Commenters stated that Utah deserves special consideration in the EIS, similar to that given Nevada, because 92 percent of the spent nuclear fuel would be transported through the State and the Private Fuel Storage facility would be located there. The Draft EIS is inadequate because specific information for routes in Utah were not considered in the estimate of health and economic impacts from the transport of spent nuclear fuel and high-level radioactive waste. Commenters observed that heavy-haul trucks could be used to transport spent fuel casks to and from a rail line near the Private Fuel Storage facility, and stated that the EIS was deficient because it did not address the use of heavy-haul trucks in national transport of spent nuclear fuel to the Yucca Mountain site.

Response

On the basis of public comments that DOE received and the issuance of a draft EIS by the Nuclear Regulatory Commission, DOE determined that the proposed Private Fuel Storage, LLC, facility is a reasonably foreseeable future action whose impacts would be cumulative with those of the Proposed Action. Because licensing, construction, and operation of a private facility for storage of spent nuclear fuel would not be actions undertaken by DOE, the cumulative impacts, including potential affects on transportation impacts presented in Chapter 6, are included in Chapter 8 of the Yucca Mountain EIS. Impacts of constructing and operating a private storage facility, including impacts of transporting spent nuclear fuel from generator sites to the facility, are included in an EIS prepared and issued by the Nuclear Regulatory Commission (DIRS 152001-NRC 2000).

Based on public comments, DOE has revised the spent nuclear fuel used in the transportation analysis to spent nuclear fuel with less cooling time [15 years rather than 26 years and fuel with higher activity (50,000 megawatt-days per metric ton of heavy metal [MTHM]) versus 40,000 megawatt-days per MTHM]. The radionuclide inventory contained in spent nuclear fuel is presented in Appendix A of the EIS.

Section J.4 of the EIS presents maps showing the routes in each state, including Utah, used in the analysis of impacts of transporting spent nuclear fuel and high-level radioactive waste from generator sites to Yucca Mountain. This section also presents estimates of the impacts in each state for the routes used in the analysis. The impacts in each state were estimated using information such as projected number of shipments, along-route populations; route lengths in urban, suburban, and rural areas; and state-specific accident rates.

Based on information it has developed and information from other sources, DOE believes the mostly rail scenario described in the EIS would most closely approximate the actual mix of truck and rail shipments of spent nuclear fuel and high-level radioactive waste to a Yucca Mountain Repository. DOE considered whether sites are able to handle larger (rail) casks, distances to suitable railheads, and historic precedent in actual shipments of fuel, waste, or other large reactor-related components. It also considered relevant information published by knowledgeable sources such as the Nuclear Energy Institute and the State of Nevada. In addition, based on this information, DOE believes the mostly legal-weight truck and mostly rail scenarios bracket the range of reasonable mixes of truck and rail transportation. Furthermore, DOE believes this range of the possible mix of transportation modes that could be used is a sufficient basis for estimating the range (lower and upper bound) of potential environmental impacts from the transportation of spent nuclear fuel and high-level radioactive waste.

DOE has estimated the characteristics of commercial spent nuclear fuel that would be delivered to a Yucca Mountain Repository under the Proposed Action. For the purpose of the EIS, DOE did not have additional information it could use to estimate how shipments to a private storage facility might affect the characteristics of shipments to Yucca Mountain and potential changes in impacts from those presented. DOE agrees that use of the Private Fuel Storage facility could result in different schedules for shipping specific spent nuclear fuel to Yucca Mountain. However, if younger spent nuclear fuel was shipped to Yucca Mountain in early shipments because older spent nuclear fuel was shipped to Private Fuel Storage, older spent nuclear fuel would be shipped to Yucca Mountain in later years. Thus the cumulative impacts of transportation would be similar. DOE would evaluate information that became available to determine if shipments to a private facility would affect the results presented in this EIS. If DOE determined changes could be significant, it would perform additional National Environmental Policy Act evaluations and determine appropriate actions to be taken.

8.8.3 (205)
Comment - 5 comments summarized
Commenters noted that DOE used 25.9 years and 27.2 years for the respective ages of pressurized-water reactor and boiling-water reactor spent nuclear fuel that would be transported to Yucca Mountain. They suggested that a more realistic and conservative assumption would be 5 to 26 years to analyze the consequences of severe transportation accidents and successful acts of terrorism. Commenters said that the Nuclear Regulatory Commission approved shipments of 5-year Cooled spent nuclear fuel with up to 5-percent enrichment and 62,000 megawatt-days per metric ton uranium burnup. Commenters cited information from the DOE Statement of Position, Waste Confidence Proceeding, April 15, 1980 to argue that the single most important determinant of radiological risk is the cooling time for spent nuclear fuel. Commenters suggested the analyses should use bounding parameters for enrichment, cooling time, and burnup of spent nuclear fuel. Commenters expressed concern that exposures estimated in the EIS were based on 26-year-old spent nuclear fuel and that exposures would exceed the EIS estimates if 10-year-old fuel was shipped. Accidents and incidents involving 5-year-old fuel could have radiological consequences 5 to 10 times higher than those reported in the EIS.

Response
DOE has revised its description of spent nuclear fuel characteristics. As discussed in Section A.2.1.5 of the EIS, the revised spent nuclear fuel characteristics are

- Pressurized water reactor -- 15 years old, 50 megawatt-days per metric ton of uranium of burnup, 4.5 percent enrichment

- Boiling water reactor -- 14 years old, 40 megawatt-days per metric ton of uranium of burnup, 3.5 percent enrichment

DOE derived these characteristics through a dose-based hazard index analysis using the radionuclide inventory of the spent nuclear fuel assemblies and the screening models in *Screening Models for Releases of Radionuclides to Atmosphere, Surface Water, and Ground* (DIRS 101882-NCRP 1996). These screening models account for all exposure pathways.

Accidents modeled with these spent nuclear fuel characteristics provide a conservative estimate of the impacts of transportation accidents. While some fuel could be slightly more radioactive, most would be considerably less radioactive.

8.8.3 (2453)
Comment - EIS000679 / 0002
We said ship the oldest fuel first. It has the smallest amount of gamma neutron radiation. It's the safest from a transportation standpoint.

DOE has not only made no commitment to do this, they've actually put some scenarios in their DEIS where they have to ship hotter, more dangerous fuel in order to get hot fuel to Yucca Mountain to heat up the repository horizon.

Response
The fuel that can be shipped by the utilities is dictated by the provisions of the Standard Contract for Disposal of Spent Nuclear Fuel and/or High-Level Radioactive Waste (10 CFR Part 961). In order to be considered "Standard Fuel" under the contract, spent nuclear fuel must have been cooled for at least 5 years.

DOE is required by the terms of 10 CFR Part 961 to assign priority to those waste generators whose spent nuclear fuel was discharged earliest. This is usually called the "Oldest Fuel First" priority. At sites designated by the generators who own the oldest spent nuclear fuel, DOE must pick up fuel the generators have selected and that has been cooled for at least 5 years.

Regardless of which fuel is shipped first, it would be done safely in casks certified by the Nuclear Regulatory Commission for that type of fuel.

8.8.3 (2499)
Comment - EIS010294 / 0009
Explain how and where the Heavy Haul Shipping Casks are loaded. Current Spent Fuel [Buildings] have limits on cask size. Define the limit for all existing nuclear stations.

Response
The mostly rail scenario in the Final EIS assumes that DOE and the Navy would transport most of the spent nuclear fuel and high-level radioactive waste to Nevada by rail, with the exception of material from commercial nuclear generating sites that initially would not have the capability to load large-capacity rail shipping casks. Those sites would use legal-weight trucks to ship material to the repository. Commercial sites with the capability to load the rail shipping casks but without rail access could use heavy-haul trucks or barges to ship spent nuclear fuel to the nearest rail line.

At this time there is no rail access to the Yucca Mountain site. This means that material traveling by rail would have to continue to the repository on a new branch rail line or be transferred to heavy-haul trucks at the intermodal (that is, from rail to truck) transfer station in Nevada and then travel on existing highways.

Section 6.2.2 of the EIS describes the potential impacts from loading spent nuclear fuel and high-level radioactive waste in transportation casks and onto transportation vehicles at the 72 commercial and 5 DOE sites.

8.8.3 (3428)
Comment - EIS001160 / 0126
The FEIS should consider the changing demographics of "snow-birds".

Response
The Final EIS used population estimates based on U.S. Census data and projected the population growth along transport routes to 2035. Because the Census only counts people at their permanent residences, the effect of seasonal relocation of population ("snowbirds") is not included in the analysis. However, the analysis does assume that individuals are in their places of residence when each shipment passes. Thus, while individuals who relocated into an area through which shipments passed are not included in the Census for the area, those who would temporarily relocate from another area through which the shipments passed are included even though they would reside elsewhere at the time. Thus, the analysis is balanced, counting some who would not be along a route when shipments pass as well as not counting some who would ("snowbirds").

8.8.3 (5872)
Comment - EIS001803 / 0002
My concern about the transportation of nuclear waste is based largely on a brief career that I had several years ago. I got a job selling railroad salvage, and while I only worked at that job for a few months, I clearly remember the enormous amount of salvage that we handled. One day I asked my boss whether our business was really based on railroad salvage or was this simply a way to push goods that some company wanted to sell cheap. I was assured that the items we sold were indeed railroad salvage items. At that time I was told that there was an average of 14 to 20 accidents per week in our catchment area which, I believe, was a two-state area. The public didn't hear about these

accidents because they were not newsworthy; a crate falling off a flatcar when a car hit an uneven piece of track, a car being derailed in an unpopulated area or merchandise being damaged when one rail car slammed into another.

Since the rail tracks that run through our communities and neighborhoods are even older now and since other forms of transportation have become more popular than rail, leaving the railroad industry financially unhealthy, I cannot imagine that our rail system is in better shape now than it was then. And while the entire DOE may work hard to keep the initial nuclear load from having an accident, what about the future?

You know as well as I that while there is much ado about this initial train trip, the time will come when the transportation of nuclear waste will not even be a blip on our radar screen. Nuclear waste transported once will become an acceptable activity because after the first trip, rail transportation will have become considered an acceptable form of transportation for nuclear waste.

Response
Rail transportation is an acceptable form of transportation for spent nuclear fuel. Of the thousands of shipments completed over the last 30 years, much of it by rail, none has resulted in an identifiable injury through the release of radioactive material. DOE would work with the railroad companies to determine routes based on safety, best available trackage, schedule efficiency, and cost-effectiveness. This includes selecting routes that result in minimum time in transit, minimum interchanges, and maximum use of mainline tracks.

In 1991 the Federal Railroad Administration established an enhanced inspection policy for rail movements of spent nuclear fuel and high-level radioactive waste. This policy sets forth enhanced inspection criteria for use by Federal Railroad Administration inspectors. It requires, for example, the entire track and signal system be inspected along the designated route prior to the initial movement. Follow-up inspections for track, signal systems and operating practices would be conducted on a 6-month basis, unless information is obtained that might dictate that follow-up inspections be conducted more (or less) frequently.

8.8.3 (5992)
Comment - EIS001879 / 0018
The Draft EIS underestimates the radiological risk of routine transportation over a 30-40 year campaign of shipment through rural communities along US-95 in the site county. The factors that contribute to the underestimation include: 1) a larger proportion of current resident and workforce population is closer to the shipment route than is assumed in the EIS; 2) more current and potential future population (lodging visitors, school children in busses, pedestrians) is exposed to routine transportation than is assumed in the EIS; 3) the average shipment speed in through these communities is slower than assumed in the EIS.

As it did for the Draft EIS, Nye County offers to work with DOE in a revised analysis to develop measures that more correctly reflect local conditions in the affected Nye County communities.

Response
To address the issue of local conditions within Nye County, the EIS has been revised based on comments to use Nye County population data extrapolated to 2035 to estimate the transportation impacts of the Proposed Action (see Section 3.1.7 of the EIS).

In addition, the EIS has been revised based on comments to include impacts representative of impacts in small communities along transportation routes, such as are in Nye County. This analysis accounts for factors such as the location of people, slower speeds of shipments, locations of intersections, commercial establishments and residences, and traffic signals (see Sections 6.3.1, 6.3.2, 6.3.3, and J.1.3.2.2.1 of the EIS).

8.8.3 (6287)
Comment - EIS001727 / 0006
Let me start by saying that it's sad that they don't know their document well enough to have answered Kay Drey's question about the curies in a cask. This is on page J-36, Table J-14 of Appendix J. You'll find that a rail cask loaded with typical commercial fuel has a total of 2,000,000 curies, 800,000 of which are Cesium 137. Actually, that's an optimistic assessment because that assumes the fuel has been cooled for 26 years. We believe a lot of this

fuel will only have been cooled five to ten years, and one ten-year cooled assembly from a pressurized water reactor -- remember, they're going to ship several hundred thousand of these -- just one of those assemblies has enough Strontium-90 to contaminate all the water in Lake Mead, which is 23 trillion gallons in a good year, to twice the EPA [Environmental Protection Agency]-allowable drinking water standards, so we're talking about very hazardous radiological materials here, materials that if I had been here standing next to an assembly for, what, three minutes now, I'd already have a lethal dose of radiation, so this is even after the materials have been cooled down from the reactor for 10 years, or even 26 years as the DOE assumes, very dangerous.

Response
Spent nuclear fuel and high-level radioactive waste are transported in very robust casks, designed to withstand the impact forces and fires that could occur with very severe transportation accidents. Furthermore, the casks are designed to be watertight following severe accidents. Numerous tests and extensive analyses, using the most advanced analytical methods available, have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents that occur. A study completed by Sandia National Laboratories for the Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000) concluded that casks would continue to contain spent nuclear fuel in more than 99.99 percent of all accidents. See Section M.4 of the EIS for additional information on the safety and testing of transportation casks.

Spent nuclear fuel and high-level radioactive waste are not easily dispersed; they do not dissolve in water; they are not liquids or gasses that can be easily spilled or leaked, and, with the exception of a very small, nearly undetectable effect, radiation from them does not make other materials radioactive. Spent nuclear fuel and high-level radioactive waste are solids. They are hard, tough, and dense ceramics, metals, or glasses contained within tough metal barriers.

The radionuclide inventory contained in spent nuclear fuel is presented in Appendix A of the EIS.

Unshielded spent nuclear fuel can be hazardous and for this reason spent nuclear fuel is shipped in heavily shielded casks. The maximum radiation dose rate from a spent nuclear fuel cask is about 10 millirem per hour at 2 meters (6 feet) from its transporting vehicle. For perspective, the radiation dose from a single chest X-ray is about 8 millirem. Therefore, the radiation dose from standing 2 meters away from a shipment of spent nuclear fuel for 1 hour would be equivalent to a little more than one chest X-ray, and much lower than a lethal radiation dose.

8.8.3 (6568)
Comment - EIS001632 / 0056
Page 6-17, Section 6.1.3, second paragraph: The next-to-last sentence says that "an air quality conformity analysis [for carbon monoxide] may be required." If a conformity determination is needed, it should be made before completion of the NEPA [National Environmental Policy Act] process. EPA [Environmental Protection Agency] suggests such information be included in the final EIS.

Response
The Conformity Review discussions have been updated in all sections. Conformity Review results are summarized in Section 6.3.1.1 of the EIS for the mostly legal-weight truck scenario, in Section 6.3.2.1 for the mostly rail scenario, and in Section 6.3.3.1 for the heavy-haul truck scenario. The Conformity Review was focused on with levels of carbon monoxide and particulate matter (PM_{10}), for which the Las Vegas air basin has been classified as being in "serious nonattainment." Since the Draft EIS was published, the mostly rail scenario has been selected by DOE as the preferred transportation option. The Conformity Review found that more detailed analyses (that is, a Conformity Determination) would be required for the construction phase of a branch rail line in the Valley Modified Corridor, if that rail corridor was selected. The other corridors would not present a conflict with the General Conformity requirements for carbon monoxide and PM_{10}. Emissions for constructing a branch rail line in the Valley Modified Corridor are estimated in the Conformity Review to be up to 145 metric tons (160 tons) per year (160 percent of the General Conformity threshold level) for carbon monoxide, and up to 120 metric tons (130 tons) per year (190 percent of the General Conformity threshold level) for PM_{10}.

The carbon monoxide emissions within the nonattainment area would result from fuel use by the construction vehicles and vehicle emissions from commuter and supply traffic to the Yucca Mountain site. The PM_{10} releases would include the emissions from disturbing the ground and from fuel combustion of the construction equipment. Dust abatement measures (for example, water applications) would reduce fugitive dust PM_{10} emissions by

70 percent. The emissions estimates could be reduced further by lengthening the construction time or more detailed task planning to reduce the production of emissions.

Emissions from a branch rail line in the Valley Modified Corridor into the nonattainment area would occur during the much longer operations phase, as the locomotive passed through the nonattainment area on its way to the Yucca Mountain site. However, operations phase emissions would not exceed the General Conformity threshold levels. The estimated operations emissions for a branch rail line in the Valley Modified Corridor would be 81 percent of the carbon monoxide General Conformity threshold level and less than 3 percent of the PM_{10} General Conformity threshold levels.

In addition, the Conformity Review compared the Valley Modified Corridor carbon monoxide and PM_{10} release estimates to the Nevada carbon monoxide and PM_{10} State Implementation Plans (DIRS 156706-Clark County 2000; DIRS 155557-Clark County 2001). The construction phase Valley Modified carbon monoxide emissions estimates would be less than 0.2 percent of the total daily carbon monoxide inventory emitted into the nonattainment area. The construction phase Valley Modified PM_{10} emissions estimates would be less than 0.08 percent of the daily and annual PM_{10} inventory emitted into the Las Vegas Valley air basin.

8.8.3 (7219)

Comment - EIS010270 / 0007

Movement of large concentrations of radioactive materials may interfere with normal sub-atomic atmospheric dynamics to the extent of causing weather and climate extremes. While radioactive atomic and molecular gases have been suggested as agents of weather and climate change in work such as "Meteorological Consequences of Atmospheric Krypton-85" (SCIENCE, vol. 193, #4249, 7/16/76), sub-atomic radioactive interactions and their effects in the field (rather than the lab) are just beginning to be explored. The physics sub-atomic world of "strings," etc. is like the biology sub-viral world of "prions." Mad Cow disease (and possibly AIDS, another "wasting" disease) are poorly understood, but real nevertheless. We ignore "prions" at our peril. I think that we should not ignore the possibility that the cloudburst that drenched the three trucks here in St. Louis last week was an effect of the movement of the material. It is anecdotal, but real, that in the last three years nearly all local tornadoes have formed over the Weldon Springs nuclear storage dump where truckloads of radioactive materials from downtown St. Louis and from the airport have moved during that time. Energetic actions at a distance are the meat of modern physics. We should be looking at the pragmatic energetic effects of the movement of these immensely energetic radioactive materials, before moving huge amounts of them.

If due to tangible dangers the materials must be moved, then I would suggest as a precaution moving the materials at night and during the winter months when the atmosphere is less energetically active - and on a sparsely populated route.

Response

DOE believes that the EIS adequately analyzes the environmental impacts that could result from either the Proposed Action or the No-Action Alternative. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts that could occur, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. As the commenter stated, the meteorological phenomena described are in an early stage of observation, are poorly understood, and are not predictable. Therefore, the data and analytical methodologies that could be used for an analysis are not available and DOE has not addressed it in its analysis.

However, DOE would consider all aspects of safety in transporting spent nuclear fuel and high-level radioactive waste. Shipments of spent nuclear fuel and high-level radioactive waste to a Yucca Mountain Repository would comply with all applicable regulations and accepted standard practices to help ensure their safely. In addition, as described in Appendix M of the EIS, the Department would require its contractors to follow "Operational Protocols," which provide additional measures to enhance safety in transporting radioactive materials, including requirements for transportation under inclement weather conditions. In addition, DOE plans to require that each shipment be tracked and continuously monitored using a satellite-based tracking system. Routes that would be used would comply with U.S. Department of Transportation regulations that prescribe how routes are selected for highway shipments and railroad industry practices that emphasize use of main-line track, shortest transport distance, and fewest interchanges between railroads. Routes would be approved by the Nuclear Regulatory Commission to ensure that transportation safeguards and security objectives and requirements specified in 10 CFR 73.37 would be satisfied.

8.8.3 (7230)
Comment - EIS001337 / 0107
Page 4-88 Section 4.1.15.4. Sites for cask manufacturing should have been considered within Nevada. The FEIS should consider sites along transportation corridors in Nevada. The description of environmental setting for these facilities belongs in Section 3, Affected Environment.

Response
DOE would not develop transportation casks, but plans to contract with the private sector to provide waste acceptance and transportation services, including equipment. All cask designs must contribute to overall efficiency and operability of the entire transport systems and meet Nuclear Regulatory Commission regulations. Information on the process for acquisition of waste acceptance and transport services, including casks, through the Regional Servicing Contractors is provided in Section M.3.1 of the EIS.

Because there are existing manufacturing facilities that could meet the projected manufacturing requirements, the EIS assumed that new cask manufacturing facility construction would not be necessary and that there would be no change in land use for the manufacture of disposal containers and shipping casks. Therefore, it was not necessary to consider manufacturing sites in Nevada.

8.8.3 (7789)
Comment - EIS002093 / 0002
I'm disappointed that the DEIS largely characterizes potential waste management systems impacts in Nevada as insignificant, generally positive in terms of job creation or both. If transportation through and disposal of waste within Nevada is such a benign activity, then why is no other state in the nation willing to host a facility like Yucca Mountain? The DEIS should answer this by way of a more thorough and fair assessment of impacts, including stigma.

Beyond its deficient approach to treating equity between Nevada and the rest of the nation, the DEIS does not provide sufficient treatment of the distribution of radioactive waste transportation risks among Nevada's urban and rural communities. In 1975, Governor O'Callaghan, State Senator Richard Bryan and their respective colleagues formally requested this activity come to Nevada with one particular caveat, that transportation avoid the Las Vegas Valley.

Today Nevada's governor and congressional delegation have made clear their intent to restrict shipments of nuclear waste from highways in Nevada's urban centers. Rather, Nevada's leaders see it as in Nevada's best interest to shift transportation related risk to rural counties and communities. As a consequence, low-level radioactive waste is now and spent nuclear fuel and other high-level radioactive waste in the future will be shipped through Nevada's rural counties and communities on its way to the Nevada Test Site.

I find it ironic that just a few years ago a suggestion by Lincoln County and City of Caliente officials to avoid shipments through the Las Vegas Valley resulted in the Nevada Attorney General seeking to throw several of my colleagues and I out of office.

Response
The Nuclear Waste Policy Act, enacted by Congress in 1982 and amended in 1987, has set forth a process that requires the Secretary of Energy to undertake site characterization activities at only one site, Yucca Mountain, Nevada. An analysis of impacts associated with transportation in Nevada can be found in EIS Section 6.3. The routes analyzed in Section 6.3 represent the reasonable alternatives consistent with National Environmental Policy Act provisions, and include routes that travel through both urban and rural areas of Nevada. The use of Interstate System highways and beltways is mandated by U.S. Department of Transportation routing guidelines. State or tribal routing agencies may designate preferred routes within their jurisdictions in accordance with 49 CFR 397.103. If such routes are designated and they can be used in a manner that complies with the requirements of regulations of the Department of Transportation and the Nuclear Regulatory Commission, DOE would use them. The State of Nevada has not designated preferred routes within the State. However, DOE performed sensitivity analysis that

analyzed the impacts of using potential alternate routes identified in a report prepared for the Nevada Department of Transportation. The analysis evaluated the impacts in Nevada and the remainder of the nation for six alternate routes for legal-weight truck shipments within Nevada, including highway routes through rural areas (see EIS Section J.3.1.3.).

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty

- Much of the uncertainty is irreducible, and

- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

8.8.3 (8849)
Comment - EIS000869 / 0021
Paragraph three [of Section S.4.2.2] involves an intermodal transfer station. Caliente and Jean are both located near existing or planned correctional facilities. Any radiation exposure, intentional or accidental, to employee or inmate populations of these facilities could result in cruel and unusual punishment and potentially skyrocketing legal costs for the counties, state, and federal governments.

Response
The average radiation dose to a person residing within 800 meters (0.5 mile) of a transportation route was estimated to be less than 0.1 millirem over 24 years. For perspective, the average background radiation dose is about 300 millirem per year and the Environmental Protection Agency radiation dose limit for members of the public from all manmade sources of radiation is 100 millirem per year. A dose of 0.1 millirem would increase the risk of a latent cancer fatality over a person's lifetime by about 1 in 20 million. Therefore, health and safety impacts to an individual from a dose of 0.1 millirem over 24 years would not be discernible.

8.8.3 (8972)
Comment - EIS002127 / 0013
Radiation release causes health risk and contaminates the highway surface and the surrounding area. Using your own DOE accident and incident data, Clark County estimates that forty such incidents of surface contamination will occur within Clark County for the proposed action of this DEIS and that three incidents of radioactive contamination beyond the vehicle will occur. These figures are only within Clark County. The response to all such accidents and incidents must be addressed by the DEIS.

Response
DOE has reviewed the potential for contamination of the transport vehicles and beyond during spent nuclear fuel and high-level radioactive waste cask transportation and does not consider it a significant threat. Minor surface contamination of spent nuclear fuel casks is well understood and controllable through the use of conventional operational practices.

Surface contamination of spent nuclear fuel casks would usually be due to cask weeping. The phenomenon of cask weeping can be described as follows: a cask that has been loaded or unloaded in a spent nuclear fuel storage pool becomes contaminated with radioactivity on its surface. Before shipment, the external surface of the cask is decontaminated to levels specified by regulations, but when the cask is inspected on arrival at its destination, contamination above the levels allowed by regulations is sometimes found. It is believed that when a cask is repeatedly placed into water-filled spent nuclear fuel storage pools, it becomes increasingly contaminated over time, with the contamination penetrating deeper into the cask's surface. Routine decontamination, which removes surface contamination, is sometimes not sufficient to remove contamination that has migrated deeper into the surface. As a consequence, if decontamination prior to shipment is not aggressive enough, during transportation the level of surface contamination can increase as deep contamination weeps out of the cask's surface.

The levels of contamination associated with the weeping phenomenon are not high enough to be factored into the risk assessment for transportation. Operational procedures would be used to preclude this problem during shipments. For example, wrapping the cask in plastic before entry into spent nuclear fuel storage pools is an effective practice that is often used. Therefore, contamination weeping is not expected to be a significant contributor to risk during spent nuclear fuel transportation.

The EIS has been revised to describe the maximum reasonably foreseeable accident in terms of accident conditions such as impact velocities and fire durations as well as the failure mechanisms that could lead to releases of radioactive materials from a cask. "Real-life conditions" that would involve various types of collisions and associated impact velocities, natural disasters, specific locations (such as mountain passes), or various infrastructure accidents (such as track failure) in effect constitute a combination of events that could lead to failure of a cask to contain spent nuclear fuel or high-level radioactive waste fully. Thus, DOE has reflected real-life accident situations and conditions in its analyses.

States and tribes are primarily responsible for the health and safety of their citizens. However, in the event of an accident that released radioactive materials, a state or tribe could request assistance from Federal agencies under the Federal Radiological Emergency Response Plan and Federal Radiological Monitoring and Assessment Plan. DOE has several assets that could assist, including the Radiation Emergency Assistance Center/Training Site (REAC/TS). REAC/TS is on call 24 hours a day to provide direct or consultative help with medical and health physics problems associated with an accident or incident involving radioactive materials.

8.8.3 (9424)
Comment - EIS001888 / 0115
The DEIS failed to examine the likely interaction of the Yucca Mountain Program and other federal activities in Nevada. For example, while Clark County is in non-attainment for National Ambient Air Quality Standards (NAAQS), the DEIS did not mention the potential impact of the addition of heavy haul or legal weight trucks into the transportation system.

Response
Sections 8.2 and 8.4 of the EIS address the cumulative short-term impacts during construction, operation and monitoring, and closure of the repository and transportation in relation to other Federal activities in Nevada. Cumulative impacts on air quality also are addressed.

In response to comments, the EIS includes an expanded discussion of the potential impacts of increased truck and rail traffic on air quality in the Las Vegas Valley. Based on additional analysis and revised data, DOE has determined that an air quality conformity analysis and determination would not be required as a result of increased traffic in the Las Vegas Valley due to workers commuting between the Las Vegas area and the proposed repository at Yucca Mountain or the transportation of materials other than spent nuclear fuel and high-level radioactive waste. This modification was made to the EIS (see Sections 6.1.3, 6.3.2, and 6.3.3).

8.8.3 (9649)
Comment - EIS001888 / 0313
The DEIS' analysis of the human health risks of transporting waste through Clark County is insufficient. The DEIS understates the risks because of a failure to realistically describe the population of the affected area. Specifically, the

DEIS underestimates the current population of Clark County, the likely size and direction of population growth in Clark County, and the specific sensitive populations.

The DEIS defines the affected population as those Clark County residents living within .5 miles of the route. Unfortunately, the DEIS relies on 1990 census data, although data that is more current was available. The most current demographic information was readily available from a number of different sources in the county and should have been consulted by the DOE in preparing the estimates. This is an important issue because of Clark County's rapid population growth.

The failure to account for Clark County's population changes indicates that the DEIS underestimates risk. The DOE response will undoubtedly be that the 1990 Census remains the only official estimate of the population of Clark County. In many parts of the United States and indeed in Nevada, this is a reasonable assumption. In the case of Clark County, Nevada, however, that assumption is not reasonable. No responsible authority in the region uses the 1990 census for any planning purposes. Utilities, the school district and local planning agencies have all come to rely on the consensus estimate of the population.

The changes in Clark County's urban population have significant impacts on the exposed population considered in the DEIS. The population living within .5 miles of likely nuclear waste routes through urban Clark County using the 1990 census data is 88,745. The estimate of that same population using the year 2000-population estimate is 154,792, almost twice the 1990 population.

Even the Nuclear Regulatory Commission in its recent rulemaking, felt compelled to adjust the population figures to provide a more realistic appraisal of the public health risk. The DEIS did not take even this modest step. Based on these figures, the Department of Energy's analysis is misleading. To remedy the situation, the DOE, prepare a new EIS that uses the most relevant population figures when the 2000 Census becomes available. The current DEIS provides, at best a lower bound of the health risk.

Due to Clark County's rapid growth and uncertainties about the DOE's program, the DEIS should have based its risk estimates on a responsible forecast of population along the potential routes. There is no clear indication when the DOE will be in a position to ship high-level waste to Yucca Mountain.

The population living within .5 miles of likely nuclear waste routes through urban Clark County using the 1990 census data is 88745. The estimate of that same population using the year 2020 population estimate is 372579, more than four times the 1990 population used in the analysis contained in the DEIS. Population forecasts for the area surrounding the likely radioactive waste routes are readily available and should have been consulted in the preparation of the DEIS. The DEIS underestimates the human health effects to Nevada's population by a considerable degree.

In 1960, the State of Nevada produced tourist map of Nevada that indicates the Nevada Test Site (NTS) is 100 miles northwest of urbanized Clark County. Recent briefings by DOE staff describe the NTS as being 65 miles northwest of urbanized Clark County. This change is due to Clark County's growth. It suggests that the direction in which Clark County's urban area is growing should have been an important consideration in preparing the EIS.

The valley in which urban Clark County rests is geographically constrained. That is, the physiographic features of the region force human activity to take place in certain areas rather than others. Future population growth in Clark County must take place along potential HLW [high-level radioactive waste] transportation routes. Urban Clark County has outgrown its original bounds and one of the most contentious issues in the region is the disposal of land from the US Bureau of Land Management (BLM). The original boundaries for urban Clark County have been adjusted several times to account for this growth.

Any future population growth that occurs in Clark County will take place along likely HLW transportation routes. Because of land use plans and zoning restrictions, the nighttime population density along the beltway will be similar to the urban core densities. The only foreseeable difference in population density between the routes through Clark County will be in employment. Unfortunately, the DEIS does not consider employment population data in any of the calculations. These data are readily available from Clark County. The DEIS should anticipate the likely population growth in Clark County when preparing its risk estimates.

Past experience suggests that the center of gravity of population in urban Clark County will continue to shift to the northwest. This phenomenon has already occurred in the City of Las Vegas. It is likely that the Population growth along the route will have two effects. The first and most obvious is that the number of people exposed to radioactivity due to the proposed action will increase. The second is that the risk characteristics of the transportation routes through the area will change. The ongoing construction of homes and businesses will create heavy truck traffic and continual construction on the roads in the area. Construction zones typically increase accident rates by 50%. The DEIS fails to consider this substantial and imminent threat to public health and safety.

The special populations used for these comments are derived from the Clark County Hazardous Materials Emergency Response Plan for 1998. This report is prepared by the Local Emergency Planning Committee (LEPQ) to support emergency management activities. The sensitive population section of the report describes facilities that contain difficult to evacuate populations.

A special population of particular concern to Clark County is the nonresident population. From 1991, the number of tourists visiting Clark County grew from 23 million to 33 million. The occupants of these hotels are also at risk and should be included in the population total. Along the currently existing legal weight truck route (which for an unknown reason the DEIS did not analyze) there are 17 hotels within .5 miles of the legal weight truck route. Preliminary estimates indicate that approximately 6,000 hotel rooms are within .5 miles of potential routes through urban Clark County. Besides the human health considerations, there are two additional concerns with regard to the DEIS.

The first of these is that the nonresident population contributes to higher accident rates. Approximately 40% of the 33 million visitors to Clark County arrive by car. These drivers are unfamiliar with the road network and make a significant contribution to accidents in the valley. Most traffic accidents are caused by drivers unfamiliar with the area in which they are driving. Clark County's tourist population presents an additional accident risk that was not considered by the DEIS.

Another concern for Clark County is the problem of evacuating these nonresidents, should an accident occur. There is no discussion in the DEIS of the size of the area that may have to be evacuated or for how long that evacuation must last. The problem of evacuation in case of a radioactive emergency has been studied by the DOE and the benefits of these studies should have been applied in the DEIS. Depending on the location and size of the plume, potentially thousands of nonresidents may have to be evacuated or relocated within Clark County. The likely effect of an evacuation are considered in another section of these comments, however, it is important to point out that the problem of controlling the evacuation of a highly mobile nonresident population is extremely difficult and could easily cause impacts to the community that were not considered in the DEIS.

The DEIS does not consider the problem of radiation exposure to schoolchildren. There are currently 37 schools within .5 miles of a potential nuclear waste route in Clark County. The number of schools near these routes will increase because new schools will be constructed along the beltway to service development in the area. The risk analysis presented in the DEIS does not consider the effects of radiation on the children attending these schools. A supplemental report that presents a radiological health examination of the effects of radiation on children attending schools adjacent to nuclear waste routes should be performed.

Analysis of the Potential HLW routes indicates that the Columbia Sunrise Hospital in Summerlin is the only health facility within .5 miles of a potential nuclear waste route. No jails, group homes, drug treatment centers or senior health centers were identified. Although no special event center was identified within the .5-mile distance, Clark County believes the Las Vegas Speedway center should be considered as an effected facility. The speedway is adjacent to Interstate 15. The parking lot for the Speedway falls within .5 miles of the route. In case of an accident, it is likely that the Speedway will be affected in some way.

Response

The transportation impact analyses in Section 6.3.1 of the EIS account for population growth in Nevada. Impacts in states other than Nevada are based on 1990 census data adjusted to reflect U.S. Bureau of Census forecasts of state populations for 2025 and state census reported for 2000 and extrapolated to 2035. These forecasts account for population growth and migration of the national population and include adjustment for the 2000 Census. With the exception of areas adjacent to the Las Vegas Beltway, impacts in Nevada were adjusted using population forecasts estimated by the REMI model (DIRS 103074-BEA 1992) using forecast data provided by Clark and Nye Counties and the Nevada State Demographer and adjusted for data from the 2000 Census.

For purposes of analysis of impacts presented in Section 6.3.1 of the EIS and to account for anticipated growth in the vicinity of the Las Vegas Beltway, DOE assumed the density of populations along the Beltway in 2020 could be represented by estimates presented in the report prepared for the City of North Las Vegas (DIRS 155112-Berger Group 2000). DOE assumed this population would grow at the same rate as for all of Clark County from 2020 to 2035. To estimate impacts, the analysis used the population along highways and railroads in Nevada forecast for 2035. Figures 6-13 and 6-20 show the Las Vegas Beltway and the proposed routes for legal-weight trucks and heavy-haul trucks that would use the Beltway. Impacts in other Nevada counties, including mostly rural counties, are adjusted using REMI-generated estimates of future populations based on data provided by the Nevada State Demographer's Office. DOE used the latest reasonably available data in the analysis for use in estimating transportation impacts.

Information on locations of schools, hotels, and other special facilities as well as the condition of existing highway infrastructure (for example, pavement condition, highway capacity, width, shoulders) is a level of precision that is not necessary for DOE to evaluate impacts and provide a reasonable estimate for each alternative in the EIS. If the Yucca Mountain site was recommended and approved, at that time, prior to constructing a branch rail line in Nevada or working with the State of Nevada to upgrade highways and constructing an intermodal transfer station, DOE would conduct additional engineering and environmental studies along with consultations with responsible Federal, State, tribal, and local authorities. Appropriate National Environmental Policy Act reviews would be conducted.

The traffic accident and fatality rates used in the environmental impact analyses (DIRS 103455-Saricks and Tompkins 1999) are the latest reasonably available consistent data applicable for use in estimating impacts of transportation accidents. The data are state-specific and have been divided into accidents by road type in each state. The accident rates are developed from data taken from all areas of a given state and include accidents that occur in areas with high accident rates (for example, they include the effects of tourists on accident rates in the Las Vegas area) as well as areas with lower rates. Thus, although the results might not predict the impacts in specific areas precisely, the aggregate total impacts both nationally and within Nevada, on average, are accurate. This level of precision is all that is necessary to support the decisions to be made from this EIS.

With respect to the comment on evacuating hotels in the event of a radiological accident, State and tribal officials have the responsibility to protect persons, the environment, and property within the State or reservation from unwarranted radiation exposure or consequences of radioactive material contamination. As discussed in Section 6.2.4.2 of the EIS, if requested by a state or tribal authority, DOE would provide assistance from its Regional Coordinating Offices located across the United States to reduce the consequences of accidents related to the transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. The assistance would include providing equipment, logistical and medical resources, and qualified personnel as necessary. States and tribes can request and obtain assistance from other Federal agencies including the Federal Emergency Management Agency, Environmental Protection Agency, Nuclear Regulatory Commission, Department of Transportation, and Department of Defense. Under Section 180(c) of the NWPA, financial and technical assistance can be made available for emergency response training and preparation of emergency response plans. A portion of these funds can be used for equipment. Additional information on emergency response is provided in Sections M.3.2.2.5 and M.5.

The EIS expresses radiological health impacts as the incremental changes in the number of expected fatal cancers (latent cancer fatalities) for populations as well as the incremental increases in lifetime probabilities of contracting a fatal cancer for an individual. The estimates are based on the dose received and on the dose-to-health-effects conversion factors recommended by the International Commission on Radiological Protection. The Commission estimated that, for the general population, a collective dose of 1 person-rem would yield 0.0005 excess latent cancer fatalities. This value includes the effects on pregnant women, children under the age of 18 years, and the elderly.

8.8.3 (10345)
Comment - EIS001543 / 0005
I'm concerned about the health impact and I'll conclude with this statement. I'm concerned that the 10th district, which I represent, and beyond the 10th district is being asked to accept a massive increase in transportation and

radiological risks to transport this waste in an expedited manner to the satisfaction of the nuclear industry. While you're called upon to handle this problem with Yucca Mountain, we have a major problem in our energy policy because this waste is going to keep being created. And unless we start to look at the development of new energy technologies so this Country can transit from this wasteful and dangerous nuclear technology, which future generations will be saddled with, we will have done a disservice if we don't find other ways to create energy.

Now, this Draft Environmental Impact Statement fails to fully inform my constituents of the risks of this waste. According to the testimony from the State of Nevada, which we were able to obtain for purposes of filing a response to the DEIS. The typical characteristics of waste to be transported contained 31,000 curies of cesium-137, 21,000 curies of strontium-90 and as a powerful source of penetrating gamma and neutron radiations. A surface dose rate is estimated to at least 10,000 REM per hour or about 166 REM per minute. A person standing or sitting next to unshielded assembly that would be containing this waste would receive, at least, 100 REM per minute. And I think people would want to know if they're getting dozens of free x-rays as they're moving through traffic, as they're sitting in their living rooms with trains passing by. These issues must be looked at to protect the public health.

The first concern here should not be the transportation of nuclear waste, the first concern should be the public's health and when you can secure the public's health, without any question and in doing that through public hearing, that's the point at which I think it's logical to have a discussion about the transportation of this waste.

Response
Appendix J of the EIS has been revised to include maps of the truck and rail routes used in the analysis of impacts, the estimated number of shipments, and the estimated impacts for each state through which spent nuclear fuel and high-level radioactive waste transport was analyzed. The impacts in a particular town or city in a state would be less than those for the state. These are estimates for analyzing transportation impacts in the EIS and the actual routes, the number of shipments, and impacts for these states could be different depending on the actual routes that are chosen.

Unshielded spent nuclear fuel can be hazardous and for this reason spent nuclear fuel is shipped in heavily shielded casks. The maximum radiation dose rate from a spent nuclear fuel cask is about 10 millirem per hour at 2 meters (6 feet) from the side of the transporting vehicle. The radiation doses from shipping spent nuclear fuel and high-level radioactive waste are presented in Sections 6.2 and 6.3 of the EIS. The average radiation dose to people along transportation routes would be about 0.1 millirem over 24 years. This is equivalent to a lifetime risk of fatal cancer of 1 in 20 million. For perspective, the risk of fatal cancer from all causes ranges from 1 in 4 to 1 in 5.

In relation to public involvement in transportation planning, Section M.3.2.1 of the EIS describes the process by which transportation routes would be selected and transportation plans developed. Routes would be selected in accordance with U.S. Department of Transportation regulations and approved by the Nuclear Regulatory Commission. DOE would approve the Regional Servicing Contractor's plans prior to their submittal to the Commission for approval. In addition, at least 4 years prior to the first shipment, in the course of implementing its policy and procedures for Section 180(c) of the NWPA, DOE would notify potentially affected states and tribes of its preliminary determinations of routes that would pass through the state or tribal jurisdictions.

8.8.3 (10996)
Comment - EIS001952 / 0011
Sliding scale in calculating less harm to rural populations from accident/incident/non-event exposures from routine transport supports de-facto transportation routing through rural areas. At the same time, rural areas are receiving considerable monetary and infrastructure incentives to grow/increase populations which will actually be exposed when transportation begins. As incentives, rural areas are promoted as tourism centers which increases likelihood that non-resident populations will also be exposed to risk of transport in rural areas. The inconsistency is similar to the Las Vegas area which is promoted as one or the fastest growing populations in the nation--for tourism and real estate purposes--but, is a desert with sparse population during discussions as to where to site a HLRW [high-level radioactive waste] site!

Response
As stated in Section 2.1.3.2.2, routes for national and Nevada truck transportation were selected for the purpose of analyzing impacts in the EIS. These routes are representative of routes that would ultimately be used. At this time,

years prior to when shipments could begin, DOE has not selected routes for transporting spent nuclear fuel and high-level radioactive waste to a Yucca Mountain Repository. The routes used in the analysis were selected in accordance with U.S. Department of Transportation's highway routing regulations in 49 CFR 397.101. These regulations require the use of the Interstate Highway System for transporting spent nuclear fuel and high-level radioactive waste and selection of routes that would reduce time in transit. A key element of the regulations is that reducing time in transit would reduce radiological risk, and thus the emphasis on use of Interstate System highways. In rural areas, traffic generally flows freely at highway speeds and there are fewer delays and less traffic than suburban and urban areas. In addition, there are fewer people in the vicinity of the shipments in rural areas than suburban and urban areas, which would lead to lower radiological impacts. The radiological exposures to maximally exposed individuals, as shown in Sections 6.2.3 and 6.2.4 for the national mostly legal-weight truck scenario, would be well below the exposures for which any health effects would be expected. These impacts are stated as being a total of 6 millirem over 24 years (3-in-1-million chance of a lifetime latent cancer fatality) for legal-weight truck transport and 0.75 rem (about 4-in-10,000 chance of a lifetime latent cancer fatality) for a maximum reasonably foreseeable accident involving a legal-weight truck cask. Regardless of whether a person was a tourist, nonresident, or resident or whether a person lived in a rural, suburban, or urban area, the maximum incident-free and accident radiological exposures calculated in the EIS would lead to small impacts.

8.8.3 (11861)
Comment - EIS000764 / 0003
Since the Private Fuel Storage [PFS] project will transport its customers spent nuclear fuel to the storage facility by rail, the conclusions reached by DOE in the DEIS concerning transportation are relevant to the PFS project. For the last fifteen or so years, I have been actively supporting the ability of the nuclear industry to safely transport spent nuclear fuel. And the conclusions of the DEIS serve to re-enforce the fact that spent nuclear fuel has and can be transported safely and efficiently.

There has been ample historical evidence that safe, routine transportation of spent nuclear fuel can be accomplished. For more than three decades, the domestic nuclear industry has conducted almost three thousand shipments of spent nuclear fuel without a release of radioactive material or a failure of the transport cask. This is a remarkable safety record. I believe this is not the result of chance, but the result of a comprehensive federal regulatory regime of cask design criteria and certification regulation, and transportation regulation, and the conscious effort of the nuclear industry.

As I mentioned before, the conclusions of the DEIS with regard to transportation have relevance to the PFS project which is currently in the licensing process with the Nuclear Regulatory Commission. While the transportation of spent nuclear fuel to the PFS project from our customers is the subject of a separate NRC [Nuclear Regulatory Commission] licensing process, any future shipments to the repository from the PFS facility would be bounded by the evaluations of this DEIS.

Response
DOE agrees with the commenter's remarks about the safety record of shipments of spent nuclear fuel. Section 6.2 of the EIS provides a discussion of transportation impacts related to the potential use of the Private Fuel Storage Facility. Section J.4 provides a map of Utah showing the location of the Private Fuel Storage Facility in relation to transportation routes used in the analysis. Section 8.4 reports the cumulative impacts of the Private Fuel Storage project.

8.9 Transportation Costs

8.9 (193)
Comment - 13 comments summarized
Commenters stated that the EIS does not adequately analyze the impacts to rail lines and highways from the transport of spent nuclear fuel and high-level radioactive waste to Yucca Mountain, nor does it describe the agencies that would pay for transportation-related improvements, mitigation, and monitoring. Commenters said that these are important issues because transport would last several decades. Some said that it is DOE's responsibility to make sure that all needed upgrades of infrastructure are done.

With regard to rail shipments, commenters questioned the adequacy of rail maintenance and believed that a high likelihood exists for mechanical breakdowns and errors because of the ever-increasing numbers of trains and their adverse effects on rail ties, switches, and roadbed. Safety practices were questioned, especially considering that the trains carrying spent nuclear fuel and high-level radioactive waste would pass within 6 meters (20 feet) of other trains traveling in opposite directions at high speeds.

With regard to highway shipments, commenters said that most states are having financial difficulty keeping up with road repairs and maintenance, and that Federal monies are not available for maintenance. Others questioned how DOE can adequately assess the impacts of truck transportation on state and local highways without understanding site-specific conditions. Some said that the EIS did not examine the impacts of long, slow-moving spent nuclear fuel and high-level radioactive waste trucks on roads, bridges and culverts; highway safety and traffic disruption; and impacts to levels of service.

With regard to Nevada, commenters said that the EIS should describe road upgrades and maintenance, as well as who would pay for these upgrades and maintenance. Some said that there are no roads in Nevada that are able to withstand the weight of a single 110-metric-ton (120-ton) truck, much less 300 trucks. Because of extreme heat in southern Nevada during the summer and extreme cold in northern Nevada during the winter, some commenters said that the EIS should evaluate the potential that asphalt roads would have to be replaced by concrete roads and that the EIS should include an estimate of the costs to do so. Commenters noted that the statement on page 6-9 of *Nevada Potential Repository Transportation Strategy, Study 2*, Volume 1 (DIRS 101214-CRWMS M&O 1996), that the "estimated pavement wear would increase by 10 percent" is not substantiated by any detailed analysis, even though the EIS recognizes that pavement wear is a major cost of the heavy-haul truck option. Others wanted to know the locations of truck-turnout lanes and whether these lanes would be sufficient over the life of the repository. These commenters said that it was inappropriate for DOE to expect that upgrades that are sufficient to meet today's traffic would be adequate over the life of the repository.

Response

Projected annual shipments of spent nuclear fuel and high-level radioactive waste to Yucca Mountain by truck, rail, and barge would be a very small fraction (less than 0.01 percent) of domestic highway, railroad, and barge traffic (see Section 6.2 of the EIS). For the most-used highways and railroads, which would be those in Nevada, shipments to Yucca Mountain would be less than 1 percent of Nevada truck shipments and 0.1 percent of Nevada railcar shipments.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

In this EIS, DOE has used computer models it has used in previous EISs and other studies. These models are widely accepted by the national and international scientific and regulatory communities. In addition to ensuring that the EIS analyses reflect the latest reasonably available information, DOE has either incorporated information that has become available since the publication of the Draft EIS or modified existing information to accommodate conditions likely to be encountered over the life of the Proposed Action. For example, the analysis in the Draft EIS relies on population information from the 1990 Census. In this Final EIS, DOE has scaled impacts upward to reflect the relative state-by-state population growth to 2035, using 2000 Census data.

Although the EIS analyses are based on the latest reasonably available information and state-of-the-art analytical tools, not all aspects of incident-free transportation or accident conditions can be known with absolute certainty. In such instances, DOE has relied on conservative assumptions that tend to overestimate impacts. For instance, DOE assumed that the radiation dose external to each vehicle carrying a cask during routine transportation would be the maximum allowed by U.S. Department of Transportation regulations. Similarly, DOE assumed that an individual, the "maximally exposed individual," would be a resident living 30 meters (100 feet) from a point where all truck shipments would pass. Under these circumstances, the maximally exposed individual would receive a dose of about 6 millirem from exposure to all truck shipments (6 millirem represents an increased probability of contracting a fatal cancer of 3 in 1 million). Although it can be argued that individuals could live closer to these shipments, it is highly unlikely that an individual would be exposed to all shipments over the 24-year period of shipments to the repository, even though DOE incorporated this highly conservative assumption in the analysis.

However, in response to comments, DOE has considered locations at which individuals could reside nearer the candidate rail corridors and heavy-haul truck routes in Nevada as a way of representing conditions that could exist anywhere in potentially affected communities. For example, DOE assumed that a maximally exposed individual could reside as close as 4.9 meters (16 feet) to a candidate heavy-haul truck route. During the 24-year period of repository operations this maximally exposed individual, would receive an estimated dose of about 29 millirem, resulting in an increased fatal cancer probability of 2 in 100,000.

These exposures would be well below those received from natural background radiation, would not be discernible even if corresponding doses could be measured, and would not add measurably to other impacts that an individual could incur. For comparison, the lifetime likelihood of an individual incurring a fatal cancer from all other causes is about 1 in 4.

With the exception of the heavy-haul truck scenario, the shipments would use vehicles (trucks, railcars, and barges) similar in weight, size, and operation to vehicles that transport other commodities. As a result, potential impacts on transportation infrastructure (infrastructure typically includes bridges, roadways, railroad track, switchyards, locks, navigation aids, etc.) of a vehicle used in transporting spent nuclear fuel and high-level radioactive waste across the United States would be similar to the impacts of other commercial vehicles that use the nation's transportation systems. Because there would be few vehicles transporting spent nuclear fuel and high-level radioactive waste in comparison to other vehicles using the transportation system, the impacts on transportation infrastructure of shipments to Yucca Mountain would not be discernible. In addition, because the annual number of shipments that would be made to Yucca Mountain is less than 0.001 percent of the more than 300 million annual shipments of hazardous materials in the United States, impacts on state, local, and Native American tribal law enforcement and emergency response resources would be small.

For purposes of analysis in the EIS, DOE assumed infrastructure and practices, including maintenance and enforcement of safety standards, used in transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain by rail would be comparable to that in current service (49 CFR Part 213). In this regard, the analysis of transportation accidents included the potential for accidents involving trains passing near each other on adjacent rails, while traveling in opposing directions at high speeds. DOE believes it is reasonable to expect the safety of infrastructure and practices for shipments to Yucca Mountain for the Proposed Action would be at least equivalent to that today.

National impacts estimated in the EIS use data that incorporate statistics compiled from accidents in localities across the United States. The statistics include those for accidents where transportation infrastructure was a contributing factor. Thus, potential impacts in any locality, even one having transportation infrastructure with unusual hazards, would be much less than for the entire transportation system. As a consequence, with the exception of the heavy-haul truck scenario, DOE believes existing highway and rail infrastructure, as well as its maintenance and public safety services, would be adequate for the safe transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. DOE also believes the potential impacts to infrastructure and public safety services from transportation would be minimal. Because the estimates are based on present-day transportation conditions, DOE believes it would not be necessary to upgrade infrastructure to support shipments to Yucca Mountain.
As discussed in Section 6.3.3 of the EIS, heavy-haul truck transport in Nevada could affect transportation on designated roads in the State. As discussed in that section, Nevada highways along a route, including roads, bridges and culverts, would be upgraded for heavy-haul truck use, if DOE selected heavy-haul truck transport. Upgrades would include reconstruction of some highway sections, especially in areas where spring and fall thaws and freezes make highways susceptible to damage by heavy vehicles. In addition, new turnout lanes at frequent intervals along two-lane highways would be constructed to allow other traffic to pass the slower heavy-haul vehicles. The location and frequency of turnouts would be determined in consultation with State and Native American tribal jurisdictions after a specific route were selected. Highway shoulders would be widened and road surfaces would be improved in many areas. The potential impacts of these construction activities are analyzed in the EIS. Section 6.3.3.1 discusses impacts heavy-haul trucks would have on the flow of traffic on roads in Nevada. This section observes that heavy-haul trucks would interfere with the free flow of traffic, leading to queues behind trucks in some areas. It also discusses the level of service for Nevada highways, noting that for many of Nevada's rural highways the level of

service is A, which represents free-flowing traffic with few vehicles. In addition, in analyzing candidate routes for heavy-haul trucks, DOE projected traffic volumes for the routes (DIRS 154675-Ahmer 1998). DOE assumed that heavy-haul trucks would operate under permits issued by the State of Nevada and also assumed, for purposes of analysis in the EIS, that these permits would specify conditions of travel.

Cost estimates developed for highway upgrades associated with the heavy-haul truck transport implementing alternatives include cost for design and construction of road upgrades for public roads and for annual maintenance of the roads that would be used (DIRS 154765-Ahmer 1998). The estimated costs discussed in EIS Section 6.3.3 for each candidate route are based on detailed estimates, which include lane widening, truck lane and turnout construction, pavement upgrades, intersection upgrades, pavement type, and shoulder upgrades.

DOE would be responsible for making the funding available for the upgrades if it selected heavy-haul truck transport, and for working with the State of Nevada and Native American tribes to ensure funding was available for the road upgrades necessary to provide infrastructure for transporting spent nuclear fuel and high-level radioactive waste using heavy-haul trucks on Nevada roads. For purposes of analysis in the EIS, DOE assumed funding to upgrade routes in Nevada for heavy-haul truck transport would originate from a source or sources outside the State.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training of public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel and high-level radioactive waste. The training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. DOE would provide the assistance based on the training needs of the states and tribes, as they determined using a planning grant and based on availability of funds in annual Program budgets specified by Congress. Additional Federal response capabilities, such as expert services from the Radiological Assistance Program Team, could be activated, as requested by states and tribes. See Section M.6 of the EIS for a discussion of the DOE Section 180(c) Policy and Procedures.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was recommended and approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

8.9 (425)
Comment - EIS000103 / 0002
There are no cost estimates for the casks that will be carried on the highways or on rail. When I met Dan Ryan years ago at a transport meeting, he said they would individually cost 350,000 to 500,000 apiece and they want 10 to 11,000.

That's 50 billion dollars, so that I suggest they get in these estimates somewhere and also the cost for vitrification and other processes that they're using. This again is not explaining to the public, these enormous costs.

It would be wonderful -- and I praise DOE for this concept, because if you did real transportation studies -- and I'm sure you will such as distance between towns, topographies, number of lanes, et cetera and costs, that you will provide the upgrades for our hundreds of miles of highways, and I would love to see what those figures would be.

Response
The number of shipping casks needed would only be a small percentage of the total number of shipments made (about 11,000 rail shipments). Section 2.1.3.4 of the EIS describes the shipping cask, manufacturing, maintenance, and disposal. This section states, "The number and type of shipping casks required would depend on the predominant mode of transportation." Because the shipping casks would not be used for storage at Yucca Mountain, they would be cycled back and forth between the commercial sites and Yucca Mountain. The number of shipping casks needed would be based on the shipping logistics developed, to ensure there were a sufficient number of casks to handle the average shipping rate. For example, if one cask could make 30 trips per year, and a total of 300 shipments were made in that year, then only 10 shipping casks would be needed.

Waste vitrification and similar activities are not part of the proposed activities and thus are not analyzed in the EIS. Total life-cycle costs of the alternatives for waste acceptance, storage, and transportation are contained in *Environmental Impact Statement Cost Summary Report* (DIRS 104980-CRWMS M&O 1999).

Nevada highways would be upgraded for heavy-haul truck use, if heavy-haul truck transport was the mode selected (see Section 6.3.3.1 of the EIS). Upgrades would include reconstruction of some highway sections, especially in areas where spring and fall thaws and freezes make highways susceptible to damage by heavy vehicles. In addition, new turnout lanes at frequent intervals along two-lane highways would be constructed to allow other traffic to pass the slower heavy-haul vehicles. Highway shoulders would be widened and road surfaces would be improved in many areas.

Cost estimates developed for highway upgrades associated with heavy-haul truck transport scenarios include costs for annual maintenance of the roads used.

8.9 (2352)
Comment - EIS000707 / 0003
In regards to rail transportation there are several Intermodal Transfer Stations to be built in Nevada. I assume that the DOE would be responsible for the cost, if not who would be?

Response
If DOE selected heavy-haul truck transport, one intermodal transfer station would be necessary (see Section 6.3.3.1 of the EIS). The intermodal transfer station would not be needed if a branch rail line was constructed to the repository. If an intermodal transfer station was constructed, DOE would fund the construction activities.

8.9 (3121)
Comment - EIS000726 / 0013
There is no mention of actions to prevent, or for compensation or mitigation for increased wear and tear to our highway infrastructure, or for repair caused by accidents or incidents. In a transport 6 years ago to the low-level disposal site, there was a circus of damaged bridges and culverts left across the County, indeed, across the country. At another time, there was an incident where radiation escaped from the transport vehicle. An entire section of highway had to be dug up, containerized and shipped to the waste facility as radioactive waste. Not only is there repair to the highway, but there is marked impact to surrounding ecosystems. In particular, if there had been a riparian or spring ecosystem involved, the impact could have been tragic for endangered and threatened species. Almost all transportation routes within Clark County are through the habitat of the endangered desert tortoise. This kind of accident will indeed happen again. Using your own DOE accident and incident data, Clark County estimates that 46 such incidents of surface contamination will occur within Clark County for the Proposed Action of this DEIS, and that 3 incidents of radioactive contamination beyond the vehicle will occur. These figures are only within Clark County! The response to all such accidents and incidents must be addressed within the DEIS.

Response
If DOE selected heavy-haul truck transport, Nevada highways would be upgraded for heavy-haul truck use (see Section 6.3.3.1 of the EIS). Upgrades would include reconstruction of some highway sections, especially in areas where spring and fall thaws and freezes make highways susceptible to damage by heavy vehicles. In addition, new turnout lanes at frequent intervals would be constructed along two-lane highways to enable other traffic to pass the slower heavy-haul vehicles. Highway shoulders would be widened and road surfaces would be improved in many areas.

Cost estimates developed for highway upgrades associated with heavy-haul truck transport include annual maintenance of the roads used. The Nevada Transportation Engineering File (DIRS 154675-Ahmer 1998) includes a cost estimate for heavy-haul truck transport, including the design, construction, and management of the initial upgrades for public roads for each of the five candidate routes. DOE based the projected costs in Section 6.3.3.2 of the EIS on those detailed estimates, which include lane widening, truck lane and turnout construction, and upgrades to pavement, intersections, and shoulders.

During the 24 years of the Proposed Action, the mostly legal-weight truck national transportation scenario would involve as many as 53,000 truck shipments of spent nuclear fuel and high-level radioactive waste (see Section

J.1.4.2.3.2 of the EIS). The transportation analysis estimated that those shipments could involve as many as 66 accidents (average of 1.7 accidents per year nationally). Less than 1 percent of these accidents could generate forces capable of causing functional damage to the casks, but would have no radiological consequences. Therefore, the estimated number of accidents that could damage a cask over the 24-year period on a national basis is less than 0.5. The number of accidents that could occur in Nevada is a subset of this estimate.

Legal-weight truck shipments in Nevada to a Yucca Mountain Repository would travel over highways that cross desert tortoise habitat, but none of the routes would cross habitat that the U.S. Fish and Wildlife Service has designated as critical for recovery of this threatened species (see Section 6.3.1 of the EIS). Over the 24 years of operations under the Proposed Action and approximately 50,000 legal-weight truck shipments, vehicles probably would kill individual desert tortoises. However, under this scenario legal-weight trucks would contribute only about 1 percent to the daily volume of vehicles to and from the repository site and only about 0.15 percent of commercial truck traffic on Interstate-15 and U.S. 95 in southern Nevada. Thus, any desert tortoises killed by trucks transporting spent nuclear fuel or high-level radioactive waste probably would be only a small fraction of all desert tortoises killed on highways.

Costs from accidents during transport involving a suspected radiological release or precautionary evacuation would be covered under the Price-Anderson Act. Accidents or incidents during transport that did not involve a radiological release would be covered under the carrier's insurance.

8.9 (4918)
Comment - EIS001510 / 0003
The DEIS is problematic because it uses conservative scenarios rather than severe ones in its analysis of the costs and associated risks of transportation. In order to comprehensively estimate the risks associated with the transport of highly radioactive material from 77 sites in the U.S. for a substantial period of time, the potentiality of the "worst case scenario" must be factored into both the cost estimate and the health impact analysis. Factors such as emergency costs, decontamination costs, hospital costs, and evacuation in the event of a severe accident must be considered.

Response
As discussed in Sections 6.2.4.2 and J.1.4.2.1 of the EIS, the accident analyses included the "maximum reasonably foreseeable accident." This accident is more severe than would be likely in postulated "real" accidents, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion in a river, and similar extreme conditions. DOE selected the performance standards for casks prescribed by the Nuclear Regulatory Commission (10 CFR Part 73) to ensure that such accidents would be unlikely to result in releases of radioactivity from the cask. These standards ensure that casks would be extremely robust. The maximum reasonably foreseeable accident postulated in the EIS assumes that accident conditions would exceed the design limits of the transportation cask structure and materials. These conditions would be unlikely to occur during the 24-year transportation campaign. In addition, forces and heat would be applied to the structures and surfaces of a cask in a way that would cause the greatest damage and bring about releases of radioactive materials from the cask to the environment.

As discussed in Chapter 6 and Appendix J of the EIS, the risk of a severe accident involving a release of radioactive materials is very small, about 1 to 2 in 10 million per year. DOE is aware of the potential consequences of such an accident and has plans for training emergency responders [see the discussion on NWPA Section 180(c) in Appendix M] and systems in place to support states during emergencies, if requested (see Section M.6). In response to comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J.

Costs from accidents during transportation involving a suspected radiological release or a precautionary evacuation would be covered under the Price-Anderson Act. Costs from accidents or incidents during transportation that did not involve a radiological release would be covered under the carrier's insurance.

DOE believes that the EIS provides sufficient information on severe accidents, their potential consequences, preparations for and cleanup of potential releases, and range of costs to support current decisionmaking.

8.9 (5389)
<u>Comment</u> - EIS001887 / 0097
Other areas directly affecting the State in responding to the unprecedented spent fuel and HLW [high-level radioactive waste] shipping campaign required to implement the Proposed Action include costs and impacts associated with:

• real time vehicle tracking and the associated costs

• vehicle inspection (legal-weight trucks and heavy-haul trucks)

• equipment (initial purchase, maintenance, and replacement)

• ports of entry and vehicle inspection facilities at intermodal transfer stations

• training (initial first responder, advanced training, and ongoing training)

• accidents and incidents

• emergency response equipment and training

• private/government agency emergency response personnel

• safe havens

• designated and alternative routes

• en route repair facilities, towing of vehicles, and availability of parts to repair trucks

• security of shipping casks during en route repair of heavy-haul trucks

• possible acts of sabotage

• health exposure issues to personnel

None of these costs/impacts on the State of Nevada and local governments are addressed in the Draft EIS.

<u>Response</u>
In response to this and similar comments, DOE has provided additional information in Appendix M of the EIS on the proposed operational protocols for shipments, including planning and mobilization, en route operations, and postshipment activities. This information indicates that DOE and its Regional Servicing Contractors would perform most of the activities identified by the commenter. DOE would bear the costs for these activities. Appendix M provides additional information on emergency response planning, technical assistance and funds to states and Native American tribes as prescribed by Section 180(c) of the NWPA, physical protection of the shipments, and liability considerations from accidents.

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds for emergency response training to states and tribes that would have shipments move through their jurisdictions on the way to a repository. A percentage of these funds may be used to obtain equipment. If additional resources are required to deal with an accident, assistance can be requested from Federal agencies. See Appendix M of the EIS for additional information on Section 180(c) and emergency response.

It is the intent of Section 180(c) of the NWPA that first responders be sufficiently trained to safely respond to an incident involving the shipment of spent nuclear fuel and high-level radioactive waste. DOE has committed to providing technical and financial assistance for training as mandated by Section 180(c) of the Act approximately 4 years before shipments commenced. The *Federal Register* notices make it clear that the necessary funding would go to states and tribes. Local governments would not be eligible to receive Section 180(c) grants directly. However, states and tribes would be required to coordinate their planning with local jurisdictions, indicating in the application that the needs of local public safety officials were considered and how the training assistance would be provided to local jurisdictions and their appropriate public safety officials.

DOE recognizes that emergency preparedness capabilities and needs vary from jurisdiction to jurisdiction. To assist states and tribes to determine what their needs are and where the Section 180(c) funds and assistance can best be applied, DOE would provide a one-time planning grant to aid in making this determination.

In the event of an incident or accident involving radioactive materials, states, tribes, and local governments can request assistance from the Federal Government under the Federal Radiological Emergency Response Plan. Assistance is available from 17 different agencies. In addition, DOE maintains eight Regional Coordinating Offices across the country that are ready to provide assistance. Appendix M of the EIS provides information about these resources.

The transportation contractor would be required to provide drivers and crews with specific written procedures that clearly define detailed actions to be taken in the event of an emergency or incident. The Draft Request for Proposals, *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153487-DOE 1998), focuses in detail on these responsibilities, as well as on other related responsibilities. Appendix M of the EIS discusses carrier and shipper responsibilities regarding emergency situations.

8.9 (5561)
Comment - EIS001887 / 0192
Page 3-99; Section 3.2.1.3 - Barge and Heavy-Haul Truck Transportation

The Draft EIS does not address impacts to infrastructure at either end of the shipping stream (e.g., required improvements at reactor sites or highway upgrades in Nevada).

Response
Heavy-haul truck and barge transport from 19 commercial sites would be needed to move spent nuclear fuel to a railroad access for shipment to the repository. An intermodal transfer would be conducted in existing facilities (terminals and berths) that are remote from public access (see Section J.2 of the EIS).

Nevada highways would be upgraded for heavy-haul truck use, if heavy-haul truck transport was the mode selected (see Section 6.3.3.1 of the EIS). Upgrades would include reconstruction of some highway sections, especially in areas where spring and fall thaws and freezes make highways susceptible to damage by heavy vehicles. In addition, new turnout lanes at frequent intervals along two-lane highways would be constructed to allow other traffic to pass the slower heavy-haul vehicles. Highway shoulders would be widened and road surfaces would be improved in many areas.

Cost estimates developed for highway upgrades associated with heavy-haul truck transport scenarios include costs for annual maintenance of the roads used. *Cost Estimate for Heavy Haul Truck Transportation* (DIRS 154675-Ahmer 1998) includes a detailed cost estimate for the design, construction, and management of the initial road upgrades for public roads for each of the five heavy-haul truck transport routes. The estimated costs shown in Section 6.3.3 of the EIS are based on those detailed estimates, which include lane widening, truck lane and turnout construction, pavement upgrades, intersection upgrades, and shoulder upgrades.

8.9 (5733)
Comment - EIS001887 / 0341
Page 6-105; Section 6.3.3.2.1

Socioeconomics

Cost figures shown for upgrading the Caliente route are significant understatements. It is likely that the State of Nevada will require extensive lane additions and widening along most of the route in both directions between Caliente and Yucca Mountain. Without such additions, the presence of daily heavy-haul trucks coming and going along the narrow, rural highways would create hazards and cause major disruption along impacted highways. Costs for upgrading the Caliente route alone are likely to be upwards of $800 million.

The Draft EIS also fails to assess costs and impacts of upgrading an alternative to the Caliente heavy-haul truck route that can be used when the primary route is unavailable (due to weather, construction, accidents, etc.). To be functional, a heavy-haul truck transportation system must have at least two functional routes. Both routes will require extensive upgrades and improvements. Costs and impacts for both must be assessed in the EIS.

Response
Nevada highways would be upgraded for heavy-haul truck use, if heavy-haul truck transport was the mode selected (Section 6.3.3.1 of the EIS). Upgrades would include reconstruction of some highway sections, especially in areas where spring and fall thaws and freezes make highways susceptible to damage by heavy vehicles. In addition new turnout lanes at frequent intervals along two-lane highways would be constructed to allow other traffic to pass the slower heavy-haul vehicles. Highway shoulders would be widened and road surfaces would be improved in many areas.

Cost estimates developed for highway upgrades associated with heavy-haul truck transport scenarios include costs for annual maintenance of the roads used. The *Nevada Transportation Engineering File* Table of Contents/ Summary (DIRS 154695-Ahmer 1998), includes a detailed cost estimate for the design, construction, and management of the initial road upgrades for public roads for each of the five heavy-haul truck transportation routes. The estimated costs shown in Section 6.3.3.2.1 of the EIS are based on those detailed estimates, which include lane widening, truck lane and turnout construction, pavement upgrades, intersection upgrades, and shoulder upgrades. As shown in Table 2.5 of the EIS, an $800 million cost is identified; this cost estimate is based on construction of a branch rail line, should rail be selected as the transportation mode.

The transportation logistics for shipment of casks is flexible enough to ensure that any temporary conditions that cause the preferred routes to be unavailable for heavy-haul truck transport traffic would not affect the overall shipment process. Shipment logistics would be rigorously integrated between generator sites, carriers, the State of Nevada and the repository, and contingency plans would be developed for temporary stoppage of shipments anywhere in the system. Therefore, additional fully upgraded routes would not be necessary.

8.9 (5784)
Comment - EIS001887 / 0379
Page J-89; Table J-37 – Potential Road Upgrades for Caliente Route

The Draft EIS does not properly evaluate a range of costs for required infrastructure upgrades along the Caliente HHT [heavy-haul truck] route. Aside from construction of a short bypass in Beatty, the Draft EIS assumes that the Caliente HHT route will require only moderate pavement upgrade turnouts every 20 miles. (p. J-89) Preliminary analysis by NDOT [Nevada Department of Transportation] indicates that the life cycle costs of such upgrades may be $450-500 million. Additional upgrades may be necessary for safety and traffic control, as well as to reduce routine radiological exposures and perceived risk impacts. The State of Nevada has identified 13 route segments, with a total length of 92 miles, where slow lanes would likely be required on both sides of the road, at a cost of at least $100 million in addition to pavement upgrades. DOE must reexamine its minimum infrastructure upgrade assumptions and costs. A bounding analysis should estimate the cost of constructing slow traffic lanes on both sides of the road for the entire 331 mile route. DOE should also investigate the costs and benefits of constructing bypasses to avoid the U.S. 6 intersection with U.S. 95 in Tonopah and the extreme right turn on U.S. 95 in Goldfield.

Response
The Nevada Transportation Engineering File, *Cost Estimate for the Heavy Haul Truck Transport Design* (DIRS 154675-Ahmer 1998), includes a detailed cost estimate for the design, construction, and management of the initial road upgrades for public roads for each of the five heavy-haul truck transport routes. The estimated costs shown in Section 6.3.3.2.1 of the EIS are based on those detailed estimates, which include lane widening, truck lane and turnout construction, pavement upgrades, intersection upgrades, and shoulder upgrades. Cost estimates developed for highway upgrades associated with heavy-haul truck scenarios include costs for annual maintenance of the roads used.

Table J-91 in the EIS summarizes the proposed Caliente Route road upgrades. The details for the costs associated with those upgrades are identified in the *Cost Estimate for the Heavy Haul Truck Transport Design* (DIRS 154675-Ahmer 1998), which shows that the estimated total lifecycle costs for road upgrades, maintenance, and repair over the 24-year Proposed Action would be $239 million in 1998 for the Caliente heavy-haul truck route. As shown in the cost estimate:

- Truck turnouts are proposed on each side of the road at 32-kilometer (20-mile) intervals for the route segment from Caliente to Tonopah, and at 8-kilometer (5-mile) intervals for the route segment between Tonopah and Yucca Mountain. This results in 66 truck turnouts being constructed, at a length of 300 meters (1,000 feet) per turnout, for a total of 20 kilometers (12.5 miles) of four-lane sections along the route.

- More than 50 kilometers (31 miles) of truck passing lanes are proposed in addition to the turnouts.

- More than 290 kilometers (180 miles) of roadway would be widened to provide a minimum of 4.3-meter (14-foot)-wide lanes and 0.6-meter (2-foot)-wide paved shoulders.

- More than 270 kilometers (170 miles) of road would be completely reconstructed to eliminate frost restrictions for heavy-haul vehicles.

- Sixteen major box culverts and more than 280 standard culverts would be upgraded.

- Four major intersections (including the intersection at Tonopah and the curve at Goldfield) would be reconstructed to allow the heavy-haul transporters to maneuver safely and with minimal impact to other traffic.

- An alternate route through Beatty would be constructed to minimize impacts to traffic at the downtown corner of U.S. 95.

8.9 (5990)
Comment - EIS001879 / 0015
The Draft EIS does not fully or adequately address the costs and consequences of potential transportation incidents and accidents in the site county. Even without radiation release, these costs include: 1) emergency response and evacuation (by responders who have been trained and equipped to safely and effectively perform such functions); 2) site cleanup; 3) potential effects on the business and/or value of adjacent property. A revised EIS should identify and estimate the potential costs and consequences of transportation incidents and accidents in Nye County.

Response
The NWPA requires DOE to provide technical and financial assistance to states and Native American tribes for training public safety officials of appropriate units of local government through whose jurisdictions it would transport spent nuclear fuel or high-level radioactive waste [see Sections 116(c) and 180(c) of the Act]. Training would cover procedures for safe routine transportation of these materials and for dealing with emergency response situations. The Nuclear Waste Fund would be the source of funds for work performed under these provisions of the Act.

The EIS describes DOE policies for providing funding and technical assistance to eligible states and tribes for transportation training and emergency response planning (see Appendix M of the EIS for more details).

In the Final EIS, DOE has expanded the socioeconomic discussions in Chapter 3 to clarify the basis for understanding the magnitude of potential impacts described in Chapter 4. These discussions include a projection of baseline parameters through 2035 based on the most recently available information and assumptions. The EIS now provides a quantified estimate, to the extent possible, of school enrollment and changes in law enforcement and public service personnel requirements. The socioeconomic impact sections analyze impacts on businesses and community infrastructure for each alternative (see Section 6.3.3 of the EIS).

In light of the comments received on the Draft EIS concerning perceived risk, DOE examined relevant studies and literature on perceived risk and stigmatization of communities to determine whether the state-of-the-science in

predicting future behavior based on perceptions had advanced sufficiently since scoping to allow DOE to quantify the impact of public risk perception on economic development or property values in potentially affected communities (see Section 2.5.4 and Appendix N of the EIS). Of particular interest were those scientific and social studies carried out in the past few years that directly relate to either Yucca Mountain or to DOE actions such as the transportation of foreign research reactor spent nuclear fuel. DOE reevaluated the conclusions of previous literature reviews such as those conducted by the Nuclear Waste Technical Review Board and the State of Nevada, among others. DOE has concluded that:

- While in some instances risk perceptions could result in adverse impacts on portions of a local economy, there are no reliable methods whereby such impacts could be predicted with any degree of certainty
- Much of the uncertainty is irreducible, and
- Based on a qualitative analysis, adverse impacts from perceptions of risk would be unlikely or relatively small.

While stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

As discussed in Chapter 6 and Appendix J of the EIS, the risk of a severe accident involving the release of radioactive materials is very small, about 1 to 2 in 10 million per year. DOE is aware of the potential consequences of such an accident and has plans for training emergency responders [see the discussion on NWPA Section 180(c) in Appendix M] and has systems in place to support states during emergencies, if requested (see Appendix M). In response to public comments, DOE has included a discussion on the range of potential costs of cleanup, following a severe transportation accident, in Appendix J.

If actions compromised the integrity of the repository, mitigation activities would be funded under either the Nuclear Waste Fund or the Price-Anderson Act. The Price-Anderson Act provides liability coverage for commercial activities operating under a license from the Nuclear Regulatory Commission and for DOE activities. It establishes a system of private insurance and Federal indemnification that generally ensures that as much as $9.43 billion is available to compensate for damages suffered by the public from a nuclear incident, regardless of who causes the damage. Payment would be from Federal funds or, if public liability arose from activities funded by the Nuclear Waste Fund (for example, activities at a geologic repository), from that Fund. The liability of all responsible parties is limited to the amount of coverage provided by the Price-Anderson system. State and local governments cannot be required to provide additional compensation. DOE has revised the EIS to include more details about indemnification under the Price-Anderson Act (see Appendix M).

Costs from accidents during transportation involving a radiological release or a precautionary evacuation would be covered under the Price-Anderson Act. Costs from accidents or incidents that did not involve a radiological release would be covered under the carrier's insurance. In addition to Price-Anderson indemnification, the Motor Carrier Act of 1980 and its implementing regulations (49 CFR Part 387) require motor vehicles carrying spent nuclear fuel or high level radioactive waste to maintain financial responsibility of at least $5 million, which would be available to cover public liability from a non-nuclear incident and for environmental restoration. Federal law does not require rail, barge, or air carriers of radioactive materials to maintain liability coverage, although these carriers often voluntarily carry such insurance. Regardless of whether they had insurance, a radioactive materials incident involving these carriers would be subject to state law applicable for any other type of accident. See Appendix M of the EIS for more information.

As for mitigating accidents, the DOE Regional Servicing Contractors would be required to provide detailed written procedures for how they would respond to an incident and arrange for repair or replacement of equipment or recovery as appropriate. In accordance with ANSI N14-27 (DIRS 156289-ANSI 1987), the carrier is expected to provide appropriate resources for dealing with the consequences of an accident, isolating and cleaning up contamination, and maintaining working contact with the responsible governmental authority until the latter has declared the incident to be satisfactorily resolved and closed (see Appendix M of the EIS for more details).

8.9 (6885)
Comment - EIS001611 / 0001
Illinois may well be, I think, the only state in the country that has a cabinet level Department of Nuclear Safety. And in this instance I want to give them praise, because 15 years ago when they were formed, one of their members named John Cooper, who was formerly with NRC [Nuclear Regulatory Commission], was the one who insisted that all high level RAD [radioactive] shipments be escorted into, through and out of Illinois.

Now, those were in the days when shipments were one maybe every six to eight weeks for maybe a two- or three-month period. Now we are talking something quantitatively much greater. I just confirmed, five casks per day is orders of magnitude, almost, difference.

The concern, and this gets back to the EIS, though, is what is the cost and who bears the cost for these escort services that the Department of Nuclear Safety believes is essential to protect the public health and safety in Illinois? Well, if you take the numbers of projected shipments and over the 24-year period of the project, you have to take into account every one of those shipments will involve a minimum of seven state, federal and local agencies, including the governor's office.

I have repeatedly asked DNS if they could give me a ball park figure of what it would cost per shipment if you added all the costs. They haven't been able to come up with that yet. I hope someone will get that on the record at some point. But if you assume a $10,000 cost, which I believe is probably very low, given that seven major agencies are involved per shipment, you come out with a staggering figure of $312 million over the 24-year period of this project just for Illinois.

And if you decide that you want to give equal protection to the other 43 affected states, this gives you a maximum boundary of 13 and a half billion dollars just to escort these shipments around the country. I think this is something that the legislators, who will be taking up the Yucca Mountain Mobile Chernobyl bill tomorrow, really need to take a look at. But I do want to go on the record lauding the Department of Nuclear Safety for their escort efforts.

Response
DOE contractors would be responsible for acquiring, training, overseeing, and paying security and escort personnel. This means that DOE would ultimately bear the costs of escorts. The Department has identified this expense for those states currently requiring a permit (escort costs) for truck and rail shipments.

8.9 (8774)
Comment - EIS001816 / 0021
Cost Effectiveness: Truck transport can be more expensive than rail due to the greater number of shipments. The extent of combining rail and truck (intermodal) will affect the total cost of the program. The DEIS must define how a cost reduction to the YM [Yucca Mountain] program can be achieved with rail transport, and the projected cost to construct and operate an intermodal facility in Nevada.

Response
Section 2.1.5 of the EIS provides the estimated costs associated with the proposed action, including transportation costs in Nevada, estimated to be about $800 million. Two documents cited in the section describe transportation costs in detail:

- *Cost Estimate for the Heavy Haul Truck Transport Design* (DIRS 153442-Ahmer 1998)
- *Nevada Transportation Study Construction Cost Estimate* (for rail) (DIRS 118012-CRMWS M&O 1998)

The three mode options for transportation, mostly legal-weight truck, mostly rail to heavy-haul truck in Nevada, and mostly rail, have all been evaluated for estimated total cost. The cost comparison of mostly heavy-haul truck using an intermodal transfer in Nevada to that of a mostly rail scenario shows that the construction of an initial branch rail line to the proposed repository makes the mostly rail scenario more expensive in initial costs. However, the mostly heavy-haul truck scenario would be considerably more expensive than rail in the operations and maintenance areas. The result is that rail and heavy-haul truck transport system costs would be in the same rough order of magnitude, for similar transport lengths, over the life of the repository operation.

Construction and operations and maintenance costs for the intermodal transfer station associated with heavy-haul truck transport are included in the summaries shown in Item 1 above. The detailed cost estimate for construction and operation and maintenance of the intermodal transfer station is included in *Intermodal Transfer Station Preliminary Design* (DIRS 104849-CRWMS M&O 1997).

8.9 (8992)
Comment - EIS001040 / 0025
How will federal responsibility and funding be utilized by:

1. Carriers; on and off site during normal operations and accidents
2. State, tribal and local governments on and off site (for example 12 miles from an accident).

Response
Carriers of spent nuclear fuel and high-level radioactive waste would perform the transportation work under a contract with DOE. The carriers would have the responsibility for performing all transportation work in compliance with Federal, state, and local regulations, as applicable. As contractors to DOE, the carriers would be funded by DOE, and would be accountable to DOE for meeting all regulatory requirements (see Appendixes J and M of the EIS for more details).

Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training for public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel or high-level radioactive waste. Training would cover procedures required for safe routine transportation of these materials, as well as procedures for dealing with emergency response situations. The Nuclear Waste Fund would be the source of funds for work carried out under this subsection.

Office of Civilian Radioactive Waste Management; Safe Routine Transportation and Emergency Response Training; Technical Assistance and Funding, Notice of Revised Proposed Policy and Procedures (DIRS 104741-DOE 1998) describes the DOE policies for providing funding and technical assistance to eligible states and tribes for transportation training and emergency response planning.

8.9 (9489)
Comment - EIS001888 / 0152
[Summary of comments noted by Clark County Nuclear Waste Division staff at various citizens' meetings.]

Who will pay for the maintenance and/or upgrades to roads, bridges, etc. that will be impacted by the transportation?

Response
DOE assumed (DIRS 154675-Ahmer 1998) that road upgrades and maintenance would be funded by the Nuclear Waste Fund under the NWPA. If future road upgrades were required to install additional turnouts, because of increased traffic in areas where the heavy-haul trucks would be operating, DOE would work with the State of Nevada to ensure funding for that construction.

8.9 (9602)
Comment - EIS001888 / 0277
The Full Costs of Heavy Haul Transportation

The DEIS presents misleading cost data for heavy haul transportation. The engineering analysis presented to support the cost data ignores the costs of obtaining right-of-way to build an additional travel lane on each side of the northern and western beltways. This is a particularly serious problem due to the nature of the land uses adjacent to the beltways. It is likely that acquiring right of way for additional travel lanes through expensive residential, industrial and high-density commercial land uses will be extraordinarily high. The DOE has presented a fundamentally misleading estimate of the costs of the proposed heavy haul program by failing to include the right of way costs necessary to implement the program.

The last time similar heavy haul transporters traversed the State of Nevada was in 1993 when two autoclaves were moved to a mining site. The transporters themselves moved more slowly than anticipated and caused severe damage to many bridges and culverts en route. The DEIS should consider these effects and account for the likely costs of improving Clark County's infrastructure.

Response
The assumption stated in Section 2.1.3.3 of the EIS is that the planned Las Vegas Beltway (northern, western, and southern sections) would be completed before DOE could begin transporting high-level nuclear waste by 2010. To date, Clark County has acquired all the necessary land for this Beltway. DOE's intent was to utilize the full Beltway that lies within the present acquired land. Cost estimates used by the Department for completion of the Beltway were obtained from Clark County (DIRS 103710-Clark County, 1997 estimates) and amounted to approximately $130 million not including major interchanges. A recent report prepared for the City of North Las Vegas (DIRS 155112-Berger Group 2000) estimates the cost of completing the northern section of the Las Vegas Beltway to be $525 million including two major interchanges. Using the same assumptions used in the City of North Las Vegas estimate, completion of the entire Beltway would cost about $1,250 million.

Heavy-haul truck cost estimates include the cost of upgrading existing roads. These cost estimates are contained in Section 6.3.3.1 of the EIS for each of the five implementing alternatives and are: Caliente, $120 million; Caliente/Chalk Mountain, $63 million; Caliente/Las Vegas, $93 million; Sloan/Jean, $20 million; and Apex/Dry Lake, $20 million.

The autoclave loads are not directly comparable to the cask loads in that the autoclave weights are significantly higher than cask weights (2 to 3 times heavier).

8.9 (11877)
Comment - EIS001887 / 0393
The maximum cost estimate of $800 million for Nevada rail transportation, based on an estimate for the Caliente route, is completely unrealistic unless DOE plans to sacrifice safety by constructing a rail line that barely meets the minimum Federal Railroad Administration requirements. Nevada is particularly concerned that DOE contractor studies have recommended operating the line without a state of the art computerized train control system. DOE's cost saving measures include shipping loaded rail casks in general freight trains, which will require switching cars at the connection point. DOE's proposal to routinely park loaded rail cask cars on a side track for up to 48 hours is unprecedented and will result in a separate legal challenge.

Response
Section 2.1.5 of the EIS summarizes the estimated costs of the Proposed Action based on estimates developed in the referenced EIS cost summary report. The estimated cost of Nevada transportation would be $800 million. The five rail corridors have been developed to a conceptual design level of detail. The basis for this cost estimate is derived from rail alignment analysis which contains design inputs, such as the American Railway Engineering Association, and U.S. Department of Transportation regulations using the Federal Railway Administration Track Safety Standards. It is DOE's intent to meet or exceed applicable regulatory requirements concerning rail design, construction, and operations.

The conceptual design level of detail cost estimates have been reviewed by an independent architectural engineering company as part of the Total System Life-Cycle Cost process. The review team concluded that they had a high level of confidence in the estimates based on the thoroughness of the estimating work and the methodical approach used.

DOE has gone on record, in its Draft Request for Proposals, *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153487-DOE 1998), that the Regional Servicing Contractor would make maximum use of special train services wherever reasonably possible.

The U.S. Department of Transportation regulation (49 CFR 174.14) addresses rail shipments in yards, transfer stations, or interchange points, and permits a maximum time limit of 48 hours, except where weekly or biweekly service is available. This period of time does not include Saturdays, Sundays, and holidays. Should general freight be chosen as the method of shipment by rail, this regulation would come into play more so than if dedicated trains were used.

The position of DOE in its Draft Request for Proposals for transportation proposes the use of special trains and advanced rail technology for shipping spent nuclear fuel and high-level radioactive waste, as long as the operator can demonstrate this option is cost-effective and lessens the potential for adverse railroad incidents.

8.10 Transportation Accidents

8.10 (54)
Comment - 7 comments summarized
Several commenters expressed concern about the validity of the accident data and statistics used in the EIS analyses and questioned why state-specific data were not used. Another commenter suggested that local transportation agencies should have been contacted rather than just the State Departments of Transportation. One commenter asked about the number of accidents per year. A commenter from Georgia demonstrated that the Draft EIS provided very little state-specific data, which the commenter stated should have been included. Another commenter suggested that accident rates for hazardous material shipments should be used rather than overall accident rates and that costs of accidents should be provided.

Response
In estimating transportation impacts, the EIS used state-specific highway and railroad accident rates for 1994 through 1996. These data were obtained from the U.S. Department of Transportation Motor Carrier Safety Information System and the Federal Railroad Administration, respectively. To supplement these data, DOE requested that the 48 contiguous states provide truck and rail transportation accident data for use in the EIS. Five states responded with highway data – Nevada, California, Illinois, Nebraska, and South Carolina. No state submitted railroad data. DOE compared the data provided by the five states to the data from the Motor Carrier Safety Information System and found that the differences were small. A detailed discussion of this evaluation is provided in Section J.1.4.2.3 of the EIS. DOE did not use local data because the Motor Carrier Safety Information System and the Federal Railroad Administration data are aggregations of local data and, therefore, include these data.

DOE did not use data for hazardous materials incidents to estimate transportation impacts because many times the criteria used for reporting incidents are not relevant to incidents that could damage a spent nuclear fuel cask. For example, gasoline tanker truck spills, which are reported as incident, are not accidents that are comparable to those that might damage a spent nuclear fuel cask. In any case, the Motor Carrier Safety Information System would include these types of incidents in the accident rate if they resulted in a fatality or injury, or if the damage to the gasoline tanker truck was severe enough to result in the gasoline tanker truck being towed away.

Special requirements imposed on the transportation of spent nuclear fuel and high-level radioactive waste, as discussed in Section M.2 of the EIS, would be expected to reduce the accident rates for shipments to Yucca Mountain to below those assumed in the EIS and those experienced by routine hazardous waste shipment.
In response to public comments, DOE has added maps of the routes analyzed in the EIS, the state-by-state number of shipments and impacts, and a discussion on the range of potential costs of cleanup following a severe transportation accident to the EIS (see Section J.4).

8.10 (68)
Comment - 14 comments summarized
Commenters stated that the EIS does not provide a description of the maximum reasonably foreseeable accident. A commenter stated that a description of other accidents and incidents that are less than the maximum reasonably foreseeable accident should be provided to determine the impact of these on emergency response systems. A commenter requested DOE to analyze specific accident scenarios in Nevada. Another commenter indicated that the EIS generalizes that the likelihood of an accident in Nevada would be less than that for the rest of the Nation. Nevada commenters stated that the EIS must consider a spent nuclear fuel and high-level radioactive waste truck colliding head-on with another truck loaded with commercial or military explosives, with a truck or rail cask involved in a massive infrastructure failure (for example, bridge collapse) and a natural disaster (for example, a flood), and a rail or truck cask involved in an accident with a military aircraft. Another commenter stated that DOE has, in its accident analysis, given credence to the virtually impossible scenario and also stated that the chances that

such a worst case accident could occur essentially is zero. Another commenter stated that the Draft EIS “tweaks” the accident figures to understate the transportation risks to the actual people who will be affected.

Response

In response to public comments, DOE has substantially revised and expanded the transportation accident analyses in the EIS. Since DOE issued the Draft EIS, Sandia National Laboratories completed a study for the Nuclear Regulatory Commission, *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). The purpose of the study was to reexamine the risks associated with the transportation of spent nuclear fuel by truck and rail and compare the results to those published in NUREG-0170 (DIRS 101892-NRC 1977) and *Shipping Container Response to Severe Highway and Railway Accident Conditions* (DIRS 101828-Fischer et al. 1987; also called the Modal Study). The Draft EIS used the techniques, assumptions and data from the Modal Study. The new study concluded that earlier studies made a number of very conservative assumptions about spent nuclear fuel and cask responses to accident conditions, which caused their estimate of accident source terms, accident frequencies, and accident consequences to be very conservative (tended to overstate the risk) (Sprung et al. 2000).

DOE has revised Section J.1.4.2 of the EIS to include a description of the maximum reasonably foreseeable accident. As in *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000), accidents are not described in terms of specific circumstances, because various accidents could lead to the same combination of cask failure mechanism, impact velocity range, and temperature range. However, detailed “event trees” are presented for truck and rail accidents, as in Figures 7.3 and 7.4 of Sprung et al. (2000). These event trees illustrate the different combinations of events that occur during an accident. This approach to accident analysis precludes the necessity for analyzing numerous specific cases involving various collisions (such as airplanes and military trucks with explosives), various natural disasters, specific locations (such as mountain passes), or various infrastructure accidents. They are all covered by the considerations of impact velocities and temperatures on a cask. Some of these accidents would result in impact velocities and temperatures that exceed the Nuclear Regulatory Commission cask performance standards in 10 CFR Part 71.

The conditions of the maximum reasonably foreseeable accident analyzed in the EIS envelop conditions reported for the Baltimore Tunnel fire (a train derailment and fire that occurred in July 2001 in a tunnel in Baltimore, Maryland). Temperatures in that fire were reported to be as high as 820ºC (1,500ºF), and the fire was reported to have burned for up to 5 days.

The text box in Section 6.3.1.3.2 of the EIS discusses the likelihood of the maximum reasonably foreseeable accident occurring in Nevada. This is an extremely unlikely accident with a likelihood of occurrence of less than 2.8 in 10 million per year for the national transportation routes. The likelihood of this accident is directly related to the total number of shipment miles during the estimated 24-year duration of the shipment campaign. Total shipment miles outside Nevada greatly exceed the total shipment miles inside the State. Therefore, the EIS is correct in stating that it is more likely that this type of accident would occur outside Nevada than inside the State, and it is unlikely that a location in Nevada “will be the most likely setting in the nation for a worst-case accident.”

The shipping casks used to transport spent nuclear fuel and high-level radioactive waste would be massive and tough with design features that complied with strict regulatory requirements that would ensure the casks performed their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under severe accidents conditions. Based on the revised analyses in Sprung et al. (DIRS 152476-2000)., DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the more than 2,700 shipments of spent nuclear fuel over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

DOE could decide to use a dedicated train that carried only the material to be shipped to Yucca Mountain, or could elect to move the spent nuclear fuel and high-level radioactive waste in general freight. If the material was shipped as general freight, the position of the spent nuclear fuel or high-level radioactive waste car in the train would be regulated by 49 CFR 174.85. This regulation requires that railcars placarded "radioactive" must be separated from a locomotive, occupied caboose, or carload of undeveloped film by at least one nonplacarded car, and it cannot be placed next to other placarded railcars of other hazard classes.

<u>Comment</u> - 13 comments summarized

Commenters expressed concern about the impacts of contamination of surface water or groundwater from a transportation accident. Commenters expressed concern with impacts to surface-water bodies such as local rivers (for example, the Muddy and the Humboldt), major rivers (for example, the Mississippi and the Colorado), Lake Mead, and wellhead areas of public water supplies as well as groundwater systems. Other commenters expressed concern about comprehensive emergency planning and response capabilities, and their funding, and potential mitigation measures and who would implement them. Other commenters expressed concern about effects on food and natural resources affected by releases to surface- and groundwater bodies.

<u>Response</u>

The shipping casks used to transport spent nuclear fuel and high-level radioactive waste would be massive and tough with design features that complied with strict regulatory requirements that would ensure the casks performed their safety functions even when damaged. The casks would be designed to be watertight even after a severe accident. Furthermore, the high-level radioactive waste would be in a solid form that would not be easily dispersed (ceramics, metals, or glasses).

Numerous tests and extensive analyses, using the most advanced analytical methods available, have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

The EIS does not specifically analyze a transportation accident involving contamination of surface water or groundwater. Analyses performed in previous EISs (see Section 1.5.3 and Table 1-1 of this EIS) have consistently shown that the airborne pathway has the greatest potential for exposing large numbers of people in the event of a release of radioactive materials during a severe transportation accident. An analysis of the potential importance of water pathway contamination for spent nuclear fuel transportation accident risk using a worst-case water contamination scenario (DIRS 157052-Ostmeyer 1986) showed that the impacts of the water contamination scenario were about one-fiftieth of the impacts of a comparable accident in an urban area. Thus, it is extremely unlikely that an accident that resulted in a cask falling into any body of water would result in surface-water contamination, let alone groundwater contamination.

As discussed in Section J.1.1.4, the EIS does not specifically analyze a transportation accident involving contamination of surface-water or groundwater. While small particles generated by the impact forces and driven out of the cask by a severe fire (which would be extremely unlikely because there would be no fuel to sustain an engulfing fire of the type required to release radioactive material) could ultimately end up contaminating soils and surface waters outside the cask, this would not be the dominant pathway for radiological exposure and uptake after an accident.

A state is the primary authority responsible for the health and safety of its population and therefore, generally has the primary responsibility in responding to accidents that occur in its jurisdiction. However, a state can request assistance from Federal agencies as it judges what would be appropriate and needed to effectively respond to an accident. DOE, along with other Federal agencies, has the ability to respond quickly to radiological emergencies in any state, if requested. In addition, under U.S. Department of Transportation regulations, shippers and transporters have responsibilities for emergency response and cleanup. More information on emergency response is provided in

Appendix M of the EIS. In addition, Section M.8 discusses the broad indemnification for liability of all personal injury and property damage, including costs of emergency response, evacuation, and postaccident recovery and remediation activities, under provisions of the Price-Anderson Act and state law.

Comment - 17 comments summarized
Commenters stated that emergency management impacts are a critical component of the EIS and stated that the Draft EIS was inadequate because the economic impacts of cleaning up a radioactive release that could result in roads and businesses being shut down was not estimated. Other commenters stated that cleanup activities could cost hundreds of millions or billions of dollars. Others stated that no clear description of the maximum reasonably foreseeable accident was provided; nor were the costs to mitigate or to recover from that accident evaluated. Commenters stated that the 1986 Environmental Assessment for the Yucca Mountain site (DIRS 100136-DOE 1986) developed a worst-case accident scenario that resulted in the contamination of a 110-square-kilometer (42-square-mile) area, would require 462 days and cost $620 million to clean up in 1985 dollars, and stated that the Draft EIS should have provided the same information. Other commenters stated that if the RADTRAN code was run with updated dollar inflators to 2000, the costs could range from $2.5 billion to $9.4 billion. Commenters asked if such an accident was to occur, how large an area could be affected and stated that in an urban area such as Las Vegas, the impacts would be incredible. Commenters stated there are no known statistics as to the amount of damage that would occur in the area of the accident and questioned what it would mean for a community to experience such an accident and asked how long would people have to be evacuated, would it ever be safe for people to return, and what would the resulting health impacts be?

Response
In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments, and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $9.4 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive contamination. The studies address consequences for releases of radioactive materials in communities.

Although the studies project high costs for cleanup following severe accidents, the accidents evaluated would be very unlikely and, as a consequence, DOE believes the economic risks of transportation accidents would be very small. The shipping casks used to transport spent nuclear fuel and high-level radioactive waste would be massive and tough with design features that complied with strict regulatory requirements that would ensure the casks performed their safety functions even when damaged. Furthermore, the high-level radioactive waste would be in a solid form that would not be easily dispersed (ceramics, metals, or glasses).

Numerous tests and extensive analyses, using the most advanced analytical methods available, have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

DOE anticipates that the economic costs of accidents where there was no release of radioactive material would not be substantial. The health and safety consequences of a maximum reasonably foreseeable transportation accident are discussed in Section 6.2.4.2 of the EIS. The EIS analysis did not include the restorative effects of postaccident recovery, remediation, or cleanup in estimating the health and safety impacts, and would, therefore, tend to overestimate, rather than underestimate, actual radiological impacts.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was approved. See the introduction to Chapter 8 of this Comment-Response Document for more information.

Comment - 10 comments summarized
Commenters expressed concern about military aircraft crashes into spent nuclear fuel and high-level waste storage facilities and shipping casks during transportation. In addition, commenters expressed concern about accidents involving live military ordnance (for example, heat seeking missiles) or practice weapons on storage facilities and shipping casks during transportation. Commenters indicated that most transportation routes, rail and truck, cross or approach Nellis Air Force Base or Range, Fallon Naval Air Station, or other air training and practice ranges and, therefore, mitigative measures must be considered. Commenter concerns were for an understanding of potential impacts on cargo and on people, and impacts on military operations.

Response
An aircraft crash into a spent nuclear fuel or high-level radioactive waste cask would be extremely unlikely because the probability of a crash into such a relatively small object, whether stationary or moving, is extremely remote. Nonetheless, Section J.3.3.1 of the EIS analyzes consequences of an accident in which a large commercial aircraft or of a military aircraft is hypothesized to impact directly onto a cask. The analysis showed that the heavy shield wall of a cask could not be breached by the center shaft's penetrating force. With the exception of engines, the relatively light structures of an aircraft would be much less capable of causing damage to a cask. A resulting fire would not be sustainable or able to engulf a cask long enough to breach the integrity of the cask.

System malfunctions or material failures that could result in either an accidental release of ordnance or release of a practice weapon were discussed in the *Renewal of the Nellis Air Force Range Land Withdrawal: Legislative Environmental Impact Statement* (DIRS 103472-USAF 1999), and the *Final Environmental Impact Statement, Withdrawal of Public Lands for Range Safety and Training Purposes, Naval Air Station Fallon, Nevada* (DIRS 148199-USN 1998). The *Special Nevada Report* (DIRS 153277-SAIC 1991) states that the probability of dropped ordnance resulting in injury, death, or property damage ranges from about 1 in 1 billion to 1 in 1 trillion per dropped ordnance incident, with an average of about 1 in 10 billion per dropped ordnance incident. Less than one accidentally dropped ordnance incident is estimated per year for all flight operations over the Nellis Air Force Range (now called the Nevada Test and Training Range) and Naval Air Station Fallon. All of these analyses are incorporated in this EIS by reference. Spent nuclear fuel transportation would not affect the risk from dropped ordnance or aircraft crashes. The EIS does not evaluate radiological consequences of an impact of accidentally dropped ordnance on a shipping cask because the probability of such an event (about 1 in 10 billion per year) is so extremely low that it is not reasonably foreseeable. Accordingly, the Department believes there would be no need for associated mitigation measures and no impacts on military operations.

Comment - 14 comments summarized
Commenters stated that the Draft EIS is deficient in that it does not adequately address factors that could lead to human error and effects of organizational behavior (such as not following regulations or guidelines) on the spent nuclear fuel and high-level radioactive waste transportation system. That is, it is not adequate to state, as the Draft EIS does, that utilizing trained, qualified, and aware personnel would reduce accident risk. Several recent catastrophic accidents were offered as evidence of the human error factor (for example, Three Mile Island, Chernobyl, Bhopal, and *Challenger*). Commenters stated that a detailed description of the transportation system would be necessary for an analysis of the effect of human error on transportation risk and that such a description was not in the Draft EIS. Commenters stated that the focus of human error analyses should be on the interaction between human beings and the system of equipment, facilities, procedures, and environments. Clark County commenters described, in some detail, the various categories of human and organizational behavior that must be addressed along with examples from the DOE low-level radioactive waste transportation system. Specific issues identified included individual management behavior, institutional arrangements, organizational errors and factors, operator behavior, perceptual judgement, risk taking, accident rates and mitigation, design specifications, quality assurance, equipment manufacturing, system descriptions, inexperienced drivers, and rail and highway infrastructure.

Commenters wanted answers to several questions, including: what is the contribution of human factors (for example, errors) to truck and rail accident rates? How can this contribution be mitigated? Is the effect of human factors reflected in the accident rates used in the Draft EIS? Does the DOE transportation system have a positive or negative effect on these factors? Does the design of the rail and highway infrastructure exacerbate or mitigate these effects? How do human factors play in the privatization of the DOE spent nuclear fuel and high-level radioactive waste transportation system?

Response
Section J.1.4.2.1 of the EIS discusses potential effects of human error on accident probabilities and impacts. In addition, that section discusses how effects of human factors and errors are included in the risk. For example, the truck and rail accident rates used in the EIS include accidents involving all causes, including human error. Thus, human error is factored into accident rates and ultimately transportation risk. The accident rates used in the analysis are based on national transportation statistics, although use of highly trained and qualified personnel in transporting spent nuclear fuel and high-level radioactive waste, and preferred routes for highway shipments, would tend to mitigate the number and severity of transportation accidents. Use of preferred routes for highway shipments and expeditious routing for rail shipments (see Section J.1.2.2) would result in use of a transportation infrastructure that minimized radiological risk and time in transit. The analysis of transportation impacts did not take credit for these factors. In addition, the effects of emphasizing training and qualification of personnel who would be employed by DOE and contractors to transport spent nuclear fuel and high-level radioactive waste were not given credit in the assessment. Therefore, DOE believes that the accident rates used for analyses might tend to overstate the risk.

As discussed in Section 6.2 of the EIS, national transportation of spent nuclear fuel and high-level radioactive waste would use existing highways, railroads, and waterways. Section 6.3 describes transportation in Nevada that would use a combination of legal-weight trucks and heavy-haul trucks or railroads. Section 2.1.3 present conceptual descriptions of the vehicles that would transport the casks.

In response to public comments, DOE added Appendix M to the EIS to present information intended to assist readers in understanding transportation of spent nuclear fuel and high-level radioactive waste. Section M.3 presents DOE Transportation Practices, which were developed with input from states and other stakeholders. These practices, which would be applicable to contractors who would transport spent nuclear fuel and high-level radioactive waste, address concerns regarding compliance with transportation regulations and measures to reduce the frequency and severity of transportation accidents.

The Nuclear Regulatory Commission is considering including an assessment of the importance of human factors in cask design, manufacturing, and use in its planned Package Performance Study. The planned study, which is scheduled for completion in 2004, will provide an updated evaluation of the level of safety provided by spent nuclear fuel transport packages under a variety of railway and highway accident conditions.

Comment - 14 comments summarized
Commenters expressed concern about the use of the Nuclear Regulatory Commission's *Shipping Container Response to Severe Highway and Railway Accident Conditions* (Fischer et al. 1987; also called the Modal Study) in the EIS transportation accident analyses. Commenters stated that the assumptions, data, and models of the study are outdated and that the entire discussion of the Modal Study must be revised to address both the technical and procedural implications of the reassessment of the study currently being conducted by the Nuclear Regulatory Commission. Of particular concern was the design of current casks and the statistics concerning accidents and transportation system conditions. Other commenters expressed concern that only one model and one set of data were used, which did not allow comparison of results from alternative models or data sets. One commenter stated that changing the "reasonably foreseeable" criterion of 1 in 10 million, including proper accident distribution data, including real cask response to accident conditions, and using proper estimations of accident probabilities would make some circumstances in the Modal Study "reasonably foreseeable"; therefore, they must be considered in any acceptable consequence analysis.

Response
In March 2000, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). The purpose of the study was to reexamine the risks associated with

the transport of spent nuclear fuel by truck and rail and compare the results to those published in *Final Environmental Impact Statement on the Transportation of Radioactive Material by Air and Other Modes* (DIRS 101892-NRC 1977) and *Shipping Container Response to Severe Highway and Railway Accident Conditions* (DIRS 101828-Fischer et al. 1987). The new study concluded that both NRC (1977) and Fischer et al. (1987) made a number of very conservative assumptions about spent nuclear fuel and cask response to accident conditions, which caused their estimate of accident source terms, accident frequencies, and accident consequences to be very conservative (tending to overstate the risk). The new study also concluded:

"Based on this more detailed analysis, cask leakage is found to be even less likely than the estimates of the Modal Study, and retention of particles and condensable vapors by deposition onto cask interior surfaces is found to be substantial. Accordingly, both source term probabilities and magnitudes decrease further, and consequently accident population dose risks are reduced further by factors of 10 to 100" (DIRS 152476-Sprung et al. 2000).

DOE has updated the EIS transportation impact analysis to incorporate relevant findings of the updated Nuclear Regulatory Commission analysis. Sections 6.2.4 and J.1.4 of the EIS, concerning analysis of transportation accidents, have been revised to incorporate data from Spring et al. (DIRS 152476-2000). The EIS no longer relies on the data from the Modal Study. [However, data from the Modal Study are used in Spring et al. (2000).] This report contains revised estimates of probable releases from spent nuclear fuel casks during severe transportation accidents that involve long-duration fires accompanied by high impact forces. The effect of incorporating the new analyses was lower estimates for radiological risk than those presented in the Draft EIS.

The Nuclear Regulatory Commission is conducting the Package Performance Study to assess the performance of spent nuclear fuel packages during transportation accidents and to verify assumptions used in Sprung et al. (DIRS 152476-2000). The planned study, which is scheduled for completion in 2004, will provide an updated evaluation of the level of safety provided by spent nuclear fuel transport packages under a variety of railway and highway accident conditions.

Comment - 18 comments summarized
Commenters expressed concern about cancer and other detrimental health effects as a result of a transportation accident and about direct exposure to spent nuclear fuel or high-level radioactive waste due to an accident. Various potential short-term and long-term health effects were described to accentuate the concerns.

Response
The shipping casks used to transport spent nuclear fuel and high-level radioactive waste would be massive and tough with design features that complied with strict regulatory requirements that would ensure the casks performed their safety functions even when damaged. Numerous tests and extensive analyses have demonstrated that casks would provide containment and shielding even under the most severe kinds of accidents. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

The study concluded that in severe accidents cask leakage would be even less likely than previous estimates, such as *Shipping Container Response to Severe Highway and Railway Accident Conditions* (DIRS 101828-Fischer et al. 1987), and retention of particles and condensable vapors by deposition onto the cask interior surfaces would be substantial. The study concluded that: "Accordingly, both source term probabilities and magnitudes decrease further, and consequently accident population dose risks are reduced further by factors of 10 to 100" (DIRS 152476-Sprung et al. 2000).

In response to public comments, DOE has updated the transportation accident impact analyses in the EIS to incorporate the findings of the updated analysis. Sections 6.2.4.2 and J.1.4 of the EIS analyze the potential health impacts of transportation accidents. The EIS evaluates the maximum consequences of such an accident if it occurred. For example, Table 6-14 provides the estimated impacts of the maximum reasonably foreseeable accident for truck transportation. The highest consequences would occur in an urbanized area with a potential for (0.55) latent cancer fatalities. The likelihood of such an accident would be very small, about 2.3 in 10 million years. Table 6-15 presents the same data for the mostly rail scenario. The maximum reasonably foreseeable accident for rail transportation would occur in an urbanized area with a potential for 5 latent cancer fatalities. Similar to the truck accident, the likelihood of such a rail accident would be very small, about 2.8 in 10 million years.

8.10 (168)
Comment - 8 comments summarized
Commenters complained that the analyses in the EIS averaged the impacts of transporting spent nuclear fuel and high-level radioactive waste across the entire Nation for 30 years, and then concluded that these impacts would be insignificant. This was viewed as misleading because it diminishes the significance of impacts in specific cities or areas. One commenter does not believe it is acceptable to average the risks over 50 million people.

Response
The impacts reported in the EIS are the estimated impacts summed over the specific routes used for analysis in the EIS over the period necessary to ship the spent nuclear fuel and high-level radioactive waste, not the average impact across the Nation. The transportation impacts in the EIS were evaluated over the entire shipping period. The total impacts to exposed populations over that period were calculated. The techniques used best reflect the actual potential for radiological exposure from the proposed activities associated with each of the alternatives. In response to comments, Appendix J of the EIS has been expanded to include additional information on the state-specific accident data, route maps, and impact data (see Section J.4).

The transportation impacts in the EIS were not averaged over the entire population of the United States, hence the calculated exposed population would not be 50 million, as asserted. Rather, the transportation impacts were integrated over the exposed population along the transportation routes analyzed in the EIS and extrapolated to 2035. As discussed in Sections 6.2.3.1 and 6.2.3.2 of the EIS, the estimated exposed population ranged from 10 million for truck shipments to 16 million for rail shipments. For perspective, the population of the United States was about 250 million in 1990 and 280 million in 2000.

8.10 (299)
Comment - EIS002232 / 0002
The transport of high-level nuclear energy through Inyo and San Bernardino and neighboring California counties creates an unacceptable risk of accidental discharge.

Response
As discussed in Appendix J.1.4 of the EIS, the release of radioactive materials during an accident would be an extremely unlikely event (the estimated probability of even a small release would be 0.01 percent). Transportation safety related to potential release of radioactive materials is primarily based on the integrity of the shipping cask. The leaking of a transportation cask could only occur if mechanical forces (impact) and heat (fire) exceeded the design limits of the transportation cask structures and materials. Additional information on the safety and testing of transportation casks is provided in Section M.4. The accidents analyzed in the EIS is believed to cover accidents from all sources including heat, mechanical impacts, sabotage, impacts from airplanes and weapons, and mountain rollovers.

Section J of the EIS contains maps of each state in which transportation shipments would originate or through which they would pass. The maps have tables that list the number of shipments involved in the state and the impacts from these shipments within the state. The radiological health and safety impacts of transporting spent nuclear fuel and high-level radioactive waste in California are listed in Table J-74. The risks in Inyo County and San Bernardino would be lower than those presented in Table J-74 for the whole State.

Comment - EIS000159 / 0005
The transport accident analysis is unclear. It is impossible to assess the draft EIS basis for impacts of transportation accidents based on the vague descriptions in the reports and appendices.

Response
EIS Section 2.4.4 provides a summary discussion of the impacts of transportation accidents. More detailed discussion is provided in Chapter 6, and an in-depth description of the methodology, models, and sources of data used in the analysis is provided in Appendix J. A new Appendix M has been added to the EIS that contains additional information on topics such as transportation regulations, cask safety and testing, emergency response, and physical protection of spent nuclear fuel casks.

8.10 (738)
Comment - EIS000195 / 0002
In the second title Occupational and Public Health and Safety, page 6-95, you discuss traffic fatalities along the heavy haul routes.

What about traffic related injuries? That should also be addressed.

Response
The transportation analyses for Nevada provided in Section 6.3 of the EIS, presents the radiological and nonradiological impacts important to comparing the impacts of the Proposed Action and the No-Action Alternative. Traffic fatalities were used as the measure of impact because they can be combined with radiation-related latent cancer fatalities to yield an estimate of the total number of fatalities for the Proposed Action and the No-Action Alternative. In contrast, combining traffic related injuries with radiation-related latent cancer fatalities or radiation detriment would not yield an easily understandable estimate of total impacts.

8.10 (773)
Comment - EIS000096 / 0003
The Draft EIS largely ignores adverse environmental impacts of rail construction and operation on Tonopah, Goldfield, and Beatty. Under certain circumstances, these three communities would be close enough to the repository rail line to require evacuation in the event of a severe accident or terrorist attack. A rail accident or incident releasing radioactive materials would threaten public health and safety and harm the local economy.

Response
The analysis of human health and safety and environmental impacts for the rail transportation implementing alternatives affecting Tonopah, Goldfield, and Beatty can be found in Section 6.3.2 of the EIS. While a specific analysis of a severe accident or terrorist attack in the vicinity of these communities was not conducted, maximum reasonably foreseeable accidents were analyzed for national transportation. These results are reported in Section 6.2.4.2. The EIS analysis assumed that an accident determined to be reasonably foreseeable for national transportation could occur in Nevada with similar results.

8.10 (817)
Comment - EIS000144 / 0002
The Day Everything Went Wrong

It is a February day on Highway 93. Temperatures are hovering at roughly -50 degrees, considering the wind chill factor. A blizzard howls as the legal limit truck, carrying plutonium, negotiates the road. Visibility is severely limited. The driver is tired and knows he can't stop in Ely, for the government, as a sop to the people, has made it illegal for such shipments to halt within the populous areas of White Pine County. The truck has almost skidded off the ice-encrusted road on several occasions. The driver is tense.

Suddenly, a herd of mustangs appears out of the white-out; one, a white stallion, bewildered, races directly toward the truck. The driver can't swerve, he can't gear down--there's no time. The truck plows into the pale horse; the horse is thrown onto the truck's hood. Screaming. Its hooves and carcass smash through the windshield. The driver loses control; the truck hits a skid. The hardened trailer topples onto its side, propelling it and the cab off the road.

His seat belt has held the driver securely. He is shaken, glass covered, with several shallow cuts, but otherwise unhurt. After a moment, in which he composes himself, he swears at the horse bleeding furiously into the cab. He gets cautiously out, being careful not to tip the cab over. It feels like it might go; it's already up on two wheels with the weight of its load and the trailer's weird angle.

The driver checks himself for injuries, then walks around the wreck. "Thank God," he thinks. "The load seems fine." He gets on his cell phone and calls 911, reporting the accident to Ely's highway patrol. Then he digs flares out of the cab and proceeds to mark off the crash site.

It is eighty miles to Ely; the highway patrol instantly contacts the Yucca Mountain site, informing them of an accident and possible breach of environmental security. It is a six hour drive--a two hour flight from Yucca Mountain to the crash site. The snow continues as the patrolman rushes as fast as the deadly-slick road permits to pick up the driver.

What no one knows is if the plutonium is secure. In fact, a crack in the container is already emitting radioactivity into the air. Particles are carried by the snow to the ground, where they freeze into the already thick layer of ice; particles remain airborne.

Shortly a car carrying a family comes along. Despite the trucker's warning to stop and not near the crash, they are impatient, afraid that they will be in too much danger, so they plow through, taking particles with them. Of course, the trucker is generally armed, but by the time he slip-slides from where he has been setting flares, the car has driven out of range, and he can't see it well anyway.

With plutonium continuing to leak, an ecological disaster is in the making.

I could go on with this insane scenario; however, you people on this panel know more than I about why you have chosen to do absolutely nothing about putting White Pine County's concerns into the EIS.

Response
This Comment-Response Document addresses the concerns raised in all comments submitted on the Draft EIS, including those from White Pine County. In many cases, comments have resulted in changes to the EIS. For example, to analyze the potential for impacts that could affect environmental resources, DOE collected and considered large amounts of information including information provided by the State of Nevada and counties in the State. For the analyses, DOE used information that it judged to be relevant and reasonable. For example, based on comments submitted during scoping hearings for the EIS, DOE added consideration of the Caliente-Chalk Mountain Corridor and Caliente/Chalk Mountain heavy-haul truck route. In response to public comments on the Draft EIS DOE used projections of population growth in Nevada provided by Clark and Nye Counties and the Nevada State Demographer for updated information presented in the Final EIS. DOE reviewed many documents produced by Lincoln County and other county and State agencies. The transportation-related information contained in those documents was considered for inclusion in the EIS. Nevada highway traffic information was collected from the Nevada Department of Transportation (DIRS 103405-NDOT 1997). DOE obtained and used accident rates for Nevada highways from the Department of Motor Vehicles and Public Safety, State of Nevada (see Section J.1.4.2.3 of the EIS). DOE also used information contained in a report prepared for the City of North Las Vegas (DIRS 155112- Berger Group 2000). The information in this report provided DOE with an estimate of the cost of advancing completion of the Las Vegas Beltway for use by heavy-haul trucks, an estimate of the populations that might live along the Beltway, and a basis for estimating the dose to a maximally exposed individual in a Nevada community from transportation of spent nuclear fuel and high-level radioactive waste to Yucca Mountain. DOE used information contained in *The Statewide Radioactive Materials Transportation Plan, Phase II* to identify potential alternative highway routes for shipments of spent nuclear fuel and high-level radioactive waste that the State of Nevada has considered in the past (DIRS 103072-Ardila Coulson 1989).

Comment - EIS000173 / 0009
In one hour a legal, undamaged cask puts out gamma rays equivalent to 10 chest x-rays to those 6 feet away, and the surface of the cask puts out 10 times this much. Would you like to be in the car next to truck with such a shipment of casks stuck on the interstate for four to six hours like the vehicles on I-85 on October 19?

Response
As discussed in Section J.1.3 of the EIS, U.S. Department of Transportation Regulations (49 CFR 173.441) limit the dose rate from the side of a transport vehicle to 10 millirem per hour at 2 meters (6 feet). The radiation dose from standing 2 meters from a spent nuclear fuel cask for 1 hour is about equivalent to about one chest X-ray, not 10. The impacts to an individual in a traffic jam near a cask [assumed to be only 1.3 meters (4 feet) away] are listed in Table 6-9. The probability of a latent cancer fatality from this exposure is about 1 in 50,000. For perspective, the probability of a latent cancer fatality from all causes ranges from about 1 in 4 to 1 in 5.

8.10 (1069)
Comment - EIS000287 / 0002
Maintaining 77 sites is more hazardous than one. This is not taking into consideration that numerous communities along transport lines will have no protection against an accident. The DOE also asserts that this is cost efficient. Have they interpreted the costs of millions of additional cancer patients as a result of an accident or prolonged exposure due to routine shipping?

Response
Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel or high-level radioactive waste. The training of public safety officials would cover procedures required for safe routine transportation of these materials and for dealing with emergency response situations. Therefore, communities along transport routes would not be left unprotected. Section M.6 of the EIS provides more details on Section 180(c).

Neither the routine shipping or transportation accidents are expected to result in millions of additional latent cancer fatalities. For the Proposed Action, the analyses summarized in Table 2-9 of the EIS estimate that there could be about 3 latent cancer fatalities from the routine shipping of spent nuclear fuel and high-level radioactive waste over the 24-year campaign. For transportation accidents, the analyses in Section 6.2.4 estimate that there is a 2.3 to 2.8 in 10 million probability of a maximum reasonably foreseeable accident per year. Should the accident occur, the impact to the population would be about 5 latent cancer fatalities. For perspective, Section J.3.5.1 states that there would be about 220,000 cancer fatalities in a population of 1 million people along the transport routes from other causes besides the transport of spent nuclear fuel and high-level radioactive waste.

8.10 (1082)
Comment - EIS000232 / 0003
The impact on the national transportation system is further underestimated in the DEIS by the failure to include the fact that reusable shipping containers (casks) and the trucks or trains that deliver them to Yucca Mountain are going to have to return for another load. This means that Tables J-11, J-12, J-13 and much of the information extrapolated from them is going to have to be revised upwards. Table 2-7 indicates that normal traffic accident risks are very high, relative to the radiological risks (95%). Therefore, if the number of miles traveled doubles, the estimates of transportation risks will almost double without regard to the casks being empty or full.

Response
The EIS includes the mileage for empty return shipments in its calculation of traffic accident risks. For example, in Section 6.2.4.2.1 of the EIS, the subsection on Impacts from Traffic Accidents states that the fatalities would be primarily from traffic accidents; half would involve trucks transporting loaded casks to the repository and half would involve returning shipments of empty casks.

8.10 (1085)
Comment - EIS000232 / 0006
The risks listed in the DEIS throughout section J, list only fatalities as a consequence of transportation. A responsible risk assessment should also include maiming, permanent, partial and long-term disabilities, illness, lost workdays, etc., as they are surely part of the risk the nation will assume as you undertake this project.

Response
The transportation analyses for Nevada provided in Section 6.3 of the EIS presents the radiological and nonradiological impacts for comparing the Proposed Action and the No-Action Alternative. Traffic fatalities were

used as the measure of impact because they can be combined with radiation-related latent cancer fatalities to yield an estimate of the total number of fatalities for the Proposed Action and the No-Action Alternative. In contrast, combining traffic-related injuries with radiation-related latent cancer fatalities or radiation detriment would not yield an easily understandable estimate of total impacts.

8.10 (1123)
Comment - EIS000270 / 0004
DOE has inadequately characterized the impacts of transportation accidents and public health risks along designated nationwide routes. Using shipment numbers as listed in the DEIS and highway routing studies prepared by the UNLV Transportation Research Center, the State of Nevada has developed a preliminary estimate of potential legal-weight truck shipments through Colorado and Wyoming to Nevada.

Under the mostly truck scenario, there would be about 35,350 shipments through Denver over 39 years. To state this in another way, there would be an average of 2.5 truck shipments per day of highly radioactive material on I-70 through Denver every day, seven days a week, for as many as 39 years.

In 1995, Mr. Robert Halstead, a consultant for Nevada's Agency for Nuclear Projects, commented at the Scoping meeting held in Denver that "Colorado is an example of a state which would much more heavily affected by DOE's proposed multipurpose canister (MPC) base case." Mr. Halstead also stated during the 1995 hearing that Colorado reviewers of the EIS would have "No basis for evaluating the range of potential transportation impacts on unique local conditions." It was Sierra Club's concern then, as it is now, that high-level nuclear waste shipments traversing Denver and moving through the Eisenhower/Glenwood Tunnels is a dangerous, foolhardy enterprise as well as a significant public health hazard.

For this most recent hearing, Mr. Halstead has estimated that almost 9,100 rail shipments of highly radioactive material would move through Colorado and Wyoming over 39 years, an average of about 4.5 cask-shipments per week, and every week, for 39 years. Almost all of the rail shipments would follow the Union Pacific mainline from Gibbon, Nebraska to Salt Lake City through northeastern Colorado and southern Wyoming. Shipments from one reactor in Illinois would use the former Southern Pacific route through Grand Junction.

In addition, there would also be a considerable number of legal weight truck shipments through Colorado under the current capabilities scenario. Approximately 12,660 truck shipments would travel through Colorado on I-70, an average of 6.2 shipments per week, every week, for 39 years.

Sierra Club is not only concerned with radiation exposure to truckers, travelers, and those who live and work along the route, but accidents that will occur during shipment of this highly radioactive waste.

Response
Appendix J of the EIS has been revised to include maps of truck and rail routes used in the analysis, the number of shipments, and the impacts for each state through which spent nuclear fuel and high-level radioactive waste transport was analyzed. The estimated number of shipments and the radiological impacts are listed in Table J-75. These are estimates for analyzing transportation impacts in the EIS, and the actual routes, the number of shipments, and impacts for Colorado could be different depending on the actual routes chosen.

The shipping casks used to transport these materials would be massive, with design features that complied with strict regulatory requirements to ensure that the casks themselves were fault-tolerant; that is, the casks would perform their safety functions even when damaged. Numerous tests and extensive analyses, using the most advanced analytical methods available, have demonstrated that these types of shipping casks would provide containment and shielding even under the most severe kinds of accidents. Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there could be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

8.10 (1202)
Comment - EIS000306 / 0003
Also the plan to transport the waste an average of 2,000 miles from the reactors -- the average distance of the reactors to Yucca Mountain is 2,000 miles. And I didn't realize until tonight that they're taking a northern route along routes that are subject to snow and ice. I knew that Yucca Mountain was subject to snow and ice about eight months out of the year, a winding, narrow, mountain road where the trucks could easily fall off and the casks get opened or a diesel fire.

Response
As discussed in Section 3.1.2.2 of the EIS, the winter season in the Yucca Mountain region is mild, with mean temperatures ranging from 1.11ºC (34ºF) to 10.6ºC (51ºF) and precipitation ranging from 10 to 25 centimeters (4 to 10 inches) per year. Therefore, it is unlikely that Yucca Mountain would be subject to snow and ice for 8 months of the year.

Truck shipments to Yucca Mountain probably would take U.S. 95 and Lathrop Wells Road or Jackass Flats Road (see Figure J-10 in the EIS). These roads are not winding, narrow, mountain roads. Drivers would be required to maintain contact with the carrier dispatcher at regular intervals. In addition, DOE would use the TRANSCOM satellite system to track each shipment continuously, making it possible to adjust the routes or direct the driver to a safe haven if required. Section M.3 discusses protocols for dealing with adverse weather and road conditions. For example, the Regional Servicing Contractor would get information on weather and road conditions as part of preshipment planning. If weather conditions at the time of departure were not acceptable, the shipment would be delayed. While en route, the driver would receive reports of adverse conditions from the control center.

8.10 (1261)
Comment - EIS000228 / 0005
Section 1502.22 of the NEPA [National Environmental Policy Act] calls for agencies to disclose the unavailability of information in evaluating reasonably foreseeable significant adverse effects on the human environment. The absence of safety performance data for any component of the transportation system needed to move waste from generator sites to Yucca Mountain is a major gap in available information. Historic accident rates cannot necessarily be applied to the equipment used in the proposed action because the equipment has not yet been fabricated let alone tested and deployed operationally. The DEIS describes some areas where gaps in information exist, but does not make these gaps clear. Sections of the DEIS where there are gaps in information should be highlighted and the implications these gaps have on the validity of the conclusions of the DEIS thoroughly discussed.

Response
DOE does not lack safety performance data for the proposed transportation system. Spent nuclear fuel and high-level radioactive waste could be shipped in several configurations, all of which would require shipment in a shipping cask designed to existing standards established by the Nuclear Regulatory Commission. The Commission has developed an extensive body of empirical data on the performance of shipping casks designed for the safe transport of spent nuclear fuel and high-level radioactive waste. Casks have been placed on high-speed trains and smashed into solid concrete structures, immersed in high-temperature fires, and submerged underwater to verify empirically that they meet their rigorous design standards.

DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytic tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

8.10 (1316)
Comment - EIS000165 / 0001
I don't have the heart to tell my son that the trains he loves so much may be carrying things that could shorten his life or even kill him. A photo was taken a few years back of a cask sitting on the track right next to our house. It sat there for several hours. There was no security protecting it. A radiation reading taken nearby showed a level of 10 background. The levels of radiation that Tendal and I would be exposed to would have a significant impact on the total amount of radiation we would be exposed to over the course of our lives. Even if an accident weren't to happen, our lives would be shortened.

Response
As discussed in Section 6.2.3 of the EIS, over the 24 years of shipments associated with the Proposed Action, the collective radiation dose to members of the public was estimated to be about 2,400 person-rem or an average of 100 person-rem per year. For the average person along a transportation route, the radiation dose from the shipments would be about 3 millirem per year, while the individual radiation dose from background radiation is about 300 millirem per year. Therefore, the radiation dose from the shipment of spent nuclear fuel and high-level radioactive waste would not appreciably increase the total amount of radiation that a person would be exposed to over a lifetime and would not be likely to shorten a person's life.

8.10 (1798)
Comment - EIS000312 / 0002
We also have some broad concerns about public health impacts associated with an accident. And given the limited time here to comment, I want to raise a particular issue. We ask that the Department of Energy address findings that are available in a report done by Dr. Ed Lyman of the Nuclear Control Institute which, as we understand, compares releases from the proposed mixed oxide fuel program in the Department of Energy, compares that to releases from the uranium fuel. And it does it in the context of an accident, and I understand that his findings related to accidents show two times more latent cancers from the release of MOX, mixed oxide fuel particles, than from regular irradiated fuel. And we've got your Department and folks, certainly, from the Aiken and Augusta area that are working very hard; and some folks in that area are inviting this program to be started at Savannah River site. So we urge you to incorporate in your assumptions what this would do in terms of the public health impacts.

Response
The report referred to by the commenter discusses severe nuclear reactor accidents involving mixed-oxide fuel, not transportation accidents. Severe nuclear reactor accidents involving mixed-oxide fuel are beyond the scope of this EIS. In addition, less than 1 percent of the shipments to the repository would consist of mixed-oxide spent nuclear fuel, so shipping it to the repository would not appreciably increase the overall risk of shipping spent nuclear fuel to the repository.

8.10 (1928)
Comment - EIS000467 / 0003
I wanted to address the lack of realistic accident scenarios. Right here in Washington, D.C. we are on the transport route of 146 rail casks projected from the North Anna Nuclear Plant on the CSXT rail line that passes right through Union Station, along the Metro stations, through Silver Spring. This was the very same tracks where the Amtrak and MARC trains collided in 1996, the deadly and fiery crash. So accidents do happen. CSXT was found partly responsible for this accident because they had removed safety sensors on the rail lines.

Response
As discussed in Appendixes J and M, most real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask in a river, and similar extreme accident conditions, would not likely result in release of radioactive materials from the shipping casks. If a spent nuclear fuel rail cask had been on the CSXT train that collided with a commuter train in 1996, the accident conditions would not have been more severe than the design standards for the cask. No release of radioactive materials from the cask would have been expected. The performance standards for the casks prescribed by the Nuclear Regulatory Commission were selected to ensure that less than 1 percent of real-world accidents would result in loss of cask integrity and release of radioactivity from the cask. These standards ensure that the casks would be extremely robust.

As stated in Section J.1.4.2.2 of the EIS, accident rates used in the EIS are state-specific rail accident involvement and fatality rates based on statistics compiled by the Federal Railroad Administration for 1994 through 1996. Rail accident rates include both mainline accidents and those occurring in railyards. Therefore, realistic accidents such as the one described by the commenter were included in the analysis. More details on transportation accident data are provided in Section J.1.4.2.3.

8.10 (1992)
Comment - EIS000516 / 0004
What is the modeling that you used to come up with your transportation prediction for safety? And why weren't armed guards taken into account for transporting nuclear waste? Why wasn't human error taken into account for transporting this waste? Human error is the most dangerous of all, the most unforeseen, and any kind of safe systems modeling will take this into account. Why is there no inspection and maintenance required for this transportation?

Response
As discussed in Section 6.2.1 of the EIS, state-of-the-art transportation routing and dose assessment computer codes were used to estimate the impacts from transporting spent nuclear fuel and high-level radioactive waste.

The CALVIN computer program was used to estimate the numbers of shipments of spent nuclear fuel from commercial sites. This program uses information on spent nuclear fuel stored at each site and an assumed scenario for picking up the spent nuclear fuel from each site. The program also uses information on the capacity of shipping casks that could be used.

The HIGHWAY computer program is a routing tool used to select existing highway routes that would satisfy U.S. Department of Transportation route selection regulations and that DOE could use to ship spent nuclear fuel and high-level radioactive waste from the 77 sites to the repository.

The INTERLINE computer program is a routing tool used to select existing rail routes that railroads would be likely to use to ship spent nuclear fuel and high-level radioactive waste from the 77 sites to the repository.

The RADTRAN 5 computer program is used to estimate the radiological dose risks to populations and transportation workers of incident-free transportation and to the general population from accident scenarios. For the analysis of incident-free transportation risks, the code uses scenarios for persons who would share transportation routes with shipments—called onlink populations, persons who live along the route of travel—offlink populations, and persons exposed at stops. For accident risks, the code evaluates the range of possible accident scenarios from high probability and low consequence to low probability and high consequence.

The RISKIND computer program is used to estimate radiological doses to maximally exposed individuals for incident-free transportation and to populations and maximally exposed individuals for accident scenarios. To estimate incident-free doses to maximally exposed individuals, RISKIND uses geometry to calculate the dose rate at specified locations that would arise from a source of radiation. RISKIND is used to calculate the radiation dose to a population and hypothetical maximally exposed individuals from releases of radioactive materials that are postulated to occur in maximum reasonably foreseeable accident scenarios.

Sections 6.2.2, 6.2.3, and 6.2.4 of the EIS discuss the impacts of loading operations, incident-free transport, and accidents, respectively, including workers, inspectors, and guards. Details of the impacts to armed guards (security escorts) were included in the transportation analysis. This is discussed in more detail in Section J.1.3.2.1.

Accidents of all causes, including accidents caused by human error, were used to estimate the impacts from transporting spent nuclear fuel and high-level radioactive waste. Therefore, human error was included in the analysis of transportation impacts. More details on transportation accident data are provided in Section J.1.4.2.3 of the EIS.

Inspections of spent nuclear fuel and high-level radioactive waste shipments would be performed. For example, trucks would have to pass the Commercial Vehicle Safety Alliance enhanced safety inspection, which includes a radiological survey and stringent examination of all driver, vehicle, and hazardous material requirements. More details on transportation regulations, including those that address inspection, can be found in Section M.2 of the EIS.

Maintenance would be required. For example, Section M.3.2.1.6 of the EIS describes a Carrier Management Plan, which includes a maintenance program.

8.10 (2266)
Comment - EIS000394 / 0003
As we have noted in the past, however, explicit treatment of post-accident protective measures, such as interdiction of contaminated properties and the embargo of contaminated crops, would make the document stronger, and would provide state and local officials and members of the public with a more complete picture of the radiological consequences of major transportation accidents. As we also have commented previously, we would like to see recovery issues, such as decontamination, re-entry, and return, explicitly addressed in the EIS.

Response
In response to public comments, DOE has included a discussion on the costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Eas (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its public comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities. Although the studies project high costs for clean up following severe accidents, the accidents evaluated are very unlikely and, as a consequence, DOE believes the economic risks of transportation accidents would be very small.

8.10 (2398)
Comment - EIS000674 / 0001
The Draft Environmental Impact Statement is deficient in its treatment of the safety aspects of heavy-haul trucks.

If you use, for example, Nevada average accident rates and the projected shipment miles for DOE's top Module 2 scenario and you look at the Caliente route, you come to the conclusion that you've got a projection using those historical numbers of about 24 accidents, 12 loaded, 12 unloaded over 39 years. There could be more, there could be less.

The point is when you start doing risk analysis, you do a baseline, and if the historical trends hold into the future, you can assume there will be accidents, and that's assuming that the heavy-haul trucks are as safe as other traffic.

So I don't see any basis in the DEIS. There's no empirical evidence to support their conclusion quote that the accident risks are low for all five route alternatives.

Response
The EIS acknowledges that transportation accidents could occur during the transport of radioactive materials to the proposed Yucca Mountain Repository. In Section J.1.4.2.3.2, the EIS estimates that there could be as many as 66 accidents under the mostly legal-weight truck shipping scenario and 2 accidents could occur under the mostly rail scenario. A study recently conducted by Sandia National Laboratories concluded that only a tiny fraction of all accidents, less than 1 in 10,000, would be severe enough to result in a failure of a spent nuclear fuel shipping cask (DIRS 152476-Sprung et al. 2000). The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. Based on these statistics, DOE does not expect an accident to occur that would involve radiological consequences. Similarly, DOE does not expect an accidental release to occur on any of the five heavy-haul truck routes.

To place these risks in perspective, DOE compared the risks of fatalities from traffic accidents involving shipments of spent nuclear fuel and high-level radioactive waste to the expected fatalities on U.S. highways over the 24 years of the Proposed Action (see Section 6.2.4.2.1 of the EIS). Although this comparison is based on the national transportation impacts, it is illustrative of Nevada transportation impacts. The EIS states that approximately four fatalities could occur under the mostly legal-weight truck scenario during the 24 years of the Proposed Action. This can be compared to the approximately 1 million traffic fatalities projected to occur over that same period from all traffic accidents on U.S. highways. Based on this comparison and comparisons of other transportation impacts to commonly accepted risks, DOE concluded that the transportation risks would be low.

DOE used available, heavy-combination, legal-weight truck traffic accident statistics for heavy-haul truck accident rates. While DOE agrees heavy-haul truck shipments could be obstacles to traffic due to their length and slow transit speeds, special precautions would be taken improve the safety of heavy-haul truck shipments. These special precautions include restricting movement to daylight hours and requiring escort vehicles to warn other drivers of the slow-moving vehicles. In addition, DOE proposes a number of improvements to the candidate heavy-haul truck routes to improve traffic flow and safety, such as providing truck passing lanes, improving road surfaces, and widening shoulders. Based on the special precautions and the proposed improvements to heavy-haul truck routes, DOE is confident that heavy-haul trucks carrying spent nuclear fuel and high-level radioactive waste shipping casks can be operated safely.

8.10 (2849)
Comment - EIS000871 / 0001
The most important thought that comes to mind when I hear that nuclear waste being transported over the railways is derailment which we just had a coal train derail in Belleville Illinois a few days ago. How good are the rails from coast to coast? Is it even safe to transport the waste over the interstate highway systems with the many road ragers out there? In a radius of 50 to 100 miles a million or more lives may be at stake.

Response
Safety is DOE's primary concern when shipping all types of radioactive material, including spent nuclear fuel and high-level radioactive waste. Section 2.1.3.2 of the EIS states that DOE would comply with applicable regulations of the U.S. Department of Transportation and Nuclear Regulatory Commission regulations. Both agencies strictly regulate all aspects of radioactive material transportation, including packaging (casks), transporting, and handling radioactive materials for all modes of transportation, and include standards for inspection, labeling, shipping papers, placarding, loading and unloading, allowable radiation levels, and limits for contamination of packages and vehicles, among other requirements. In addition, the regulations specify training for personnel who perform handling and transport of hazardous materials, liability insurance requirements for carriers, and safety requirements for vehicles and transport operations. DOE would implement all applicable regulations, including its own, through its Regional Servicing Contracts as described in the draft Request for Proposals for these services (DIRS 153487-DOE 1998). More details on DOE and other agency transportation regulations can be found in Section M.2 of the EIS.

8.10 (3311)
Comment - EIS001085 / 0001
The potential collective long term risk from direct exposure to ground contamination and from ingestion pathways through food and soil contamination should be included in RADTRAN4 transportation accident analyses. In agricultural areas the collective risk from ingestion pathways could be substantially greater than the inhalation pathway. The input parameters such as the food transfer factors (ACCDNT (6,k)), soil transfer factors (ACCDNT (6, k)) and cleanup level (CULVL) used in RADTRAN4 calculations should be provided. The value of cleanup level should be estimated based on a comprehensive pathway analysis including all pathways of exposure, all nuclides of radiological significance and all weather conditions (all 6 or 7 meteorological categories).

Response
Appendix J of the EIS describes the exposure pathway analysis used in the calculation of transportation accident risks. The analyses performed using RADTRAN 5 included inhalation, air immersion, direct exposure to ground contamination, and ingestion pathways. Input parameters such as dose conversion factors, food transfer factors, and soil transfer factors are available on the Yucca Mountain EIS Transportation Calculation Package, which is part of the EIS Administrative Record.

Comment - EIS000688 / 0002
You're sitting here just a few meters from the railroad tracks over which you propose to transport high-level nuclear waste.

Now, transport yourself back in time to New Year's Eve 1910. Flood waters would be twisting those railroad tracks into pretzels. Millions of tons of rock would be raining down from the hillsides on to the railroad, and you would be sitting up to your necks in mud the consistency of pancake batter.

Response
As discussed in Sections 6.2.4.2 and J.1.4.2.1 of the EIS, the accident analyses included a maximum reasonably foreseeable accident. This accident is more severe than would likely occur in real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask in a river, and similar extreme accident conditions. The performance standards for the casks prescribed by the Nuclear Regulatory Commission were selected to ensure that these real-world accidents would not likely result in release of radioactivity from the cask. These standards ensure that the casks would be extremely robust.

8.10 (3489)
Comment - EIS000719 / 0001
The Draft EIS falls shy of adequately considering the impacts of transporting the waste materials to Yucca Mountain. The DOE notes that the region of influence for public health and safety along existing transportation routes is a half mile from the center line of transportation rights-of-way for non-accident conditions, and 50 miles for accident conditions (p. 3-98).

However, the DEIS neither shows specific routes outside of Nevada to be used to transport waste materials, nor addresses the baseline conditions along those routes. In order to do a complete impact analysis, the DOE should map specific routes and establish baseline conditions along those routes, as well as clearly and honestly identify potential impacts along those routes.

One can look at a map of the current locations of radioactive waste to see that this highly irradiated waste will need to ravel through 43 states-past the homes, workplaces, and hospitals of 50 million Americans to get to Yucca Mountain. Those 50 million Americans have a right to be informed about the risk associated with transporting nuclear waste and the impacts on public health and the environment that will occur from the transportation.

The DEIS should clearly and accurately characterize the risks involved along the transportation routes, and it should use the most current information available to do so. Further, it should include site-specific data to show the effects of accidents in highly populated areas or areas where it would be difficult to retrieve a leaking cask (such as ravines and rivers).

Response
In response to public comments, DOE has included maps of the highway routes and rail lines it used for analysis in the EIS (see Section J.4). It also included potential health and safety impacts associated with shipments for each state through which shipments could pass.

Based on the results of the impact analyses presented in Chapter 6 and Appendix J of the EIS, as well as the results published in numerous other studies and environmental impact analyses cited in the EIS, DOE is confident spent nuclear fuel and high-level radioactive waste can be and would be safely transported to Yucca Mountain. DOE believes, as the EIS reports, that the potential impacts of this transportation would be so low for individuals who live and work along the routes that these individual impacts would not be discernible even if the corresponding doses could be measured. The analysis presented in the EIS factored in the characteristics of spent nuclear fuel and high-level radioactive waste, the integrity of shipping casks that would be used in transport, and the regulatory and programmatic controls that would be imposed on shipping operations (see Appendix M). The EIS analytical results are supported by numerous technical and scientific studies that have been compiled through decades of research and development by DOE and other Federal agencies of the United States, including the Nuclear Regulatory Commission and the U.S. Department of Transportation, as well as by the international community, including the International Atomic Energy Agency.

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site was approved. See the introduction to Chapter 8 of this Comment-Response Document for additional information.

DOE does not believe it necessary to consider population characteristics on a community-by-community basis to determine potential public health and safety impacts from the transportation of spent nuclear fuel and high-level radioactive waste. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions if there are uncertainties, offers the most appropriate means to arrive at conservative estimates of transportation-related impacts.

With respect to a shipping cask falling into a river, the EIS does not specifically analyze a transportation accident involving contamination of surface water or groundwater because previous EIS analyses have consistently shown that the airborne pathway has the greatest potential for exposing large numbers of people to radioactive material in the event of a severe transportation accident. Ostmeyer (DIRS 157052-1986) analyzed the potential importance of water pathway contamination for spent nuclear fuel transportation accident risk using a worst-case water contamination scenario. The analysis showed that the impacts of the water contamination scenario would be about one-fiftieth of the impacts of a comparable accident in an urban area. A water contamination scenario could affect groundwater resources, but to much lower levels of contamination than surface water because of the delay associated with the infiltration of meteoric water to groundwater. Therefore, the results of the analysis indicate that water pathway contamination would not be a significant contributor to the radiological risks of transporting spent nuclear fuel.

With respect to recovering a shipping cask that falls into a ravine or river, the transportation carrier involved in an accident would be responsible for planning, cost, and arrangements necessary to safely recover the shipment and clean up any radioactive contamination that could occur (see Section 6.2.4.2 of the EIS). Recovery of 23-metric-ton (25-ton) truck casks or rail casks weighing 110 metric tons (120 tons) is not an easy operation, especially in areas where deploying mobile carriers is difficult. However, capability to lift such weights does exist for rail and truck modes and would be deployed as required in the unlikely event of a cask leaving the conveyance or transport vehicle.

8.10 (3608)
Comment - EIS001031 / 0013
What are you going to do when a truck or train crashes? What funding is provided to local communities for equipment and training for a high level radioactive accident/emergency? If there is an accident, how large an area could be affected?

Response
In response to public comments, DOE has provided additional information on emergency response activities following transportation accidents (see Section M.5 of the EIS). Section 180(c) of the NWPA requires DOE to provide technical assistance and funds to states for training public safety officials of appropriate units of local government and tribes through whose jurisdictions it would transport spent nuclear fuel or high-level radioactive waste. The costs of providing this technical assistance and training have not yet been determined but the funds would come from the Nuclear Waste Fund. According to the Notice of Revised Proposed Policy and Procedures published in the *Federal Register* (63 *FR* 23753, April 30, 1998), a one-time planning grant of $150,000 would be provided to eligible states and tribal jurisdictions for the determination of training and funding needs and for preparation of the application for funds about 4 years before shipments began.

State and local governments deal with transportation accidents involving hazardous materials on a daily basis across the United States. According to the Notice of Revised Proposed Policy and Procedures (63 *FR* 23753, April 30, 1998), DOE would provide funding and technical assistance to eligible jurisdictions along transportation routes to address incremental training requirements resulting from shipments of spent nuclear fuel and high-level radioactive waste to the repository. DOE would allow a variety of activities an applicant state or tribal jurisdiction might consider appropriate for training under the Section 180(c) program. Along a specific transportation route, it would be the applicant's decision as to who received training.

The DOE Radiation Emergency Assistance Center/Training Site has been working with state and local groups, including hospitals, to provide medical emergency response training, as well as providing treatment and medical consultation for injuries resulting from radiation exposure and contamination. Among the training courses conducted are courses in the handling of radiation accidents by emergency staff, and medical planning and care in radiation accidents.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

8.10 (3782)
Comment - EIS001244 / 0004
The DEIS must consider the real impact of an accident along the route.

What will be the response of the local health and emergency personnel?

Are the relevant personnel trained for responding to an accident involving high level nuclear waste?

Is the medical establishment trained to treat patients exposed to high level nuclear waste?

What type of emergency preparedness is required to be in place to adequately respond to an accident involving high level nuclear waste?

Who will pay the cost of formulating such a plan and training all the emergency response and health professionals?

What are the economic impacts on the local economy if an accident occurs? This question applies to all communities along the transportation routes.

What are the direct economic impacts to families and businesses in the area of the accident during the emergency response?

What type of cleanup is required in the case of an accident involving the release of high level nuclear waste?
What are the stigma effects to property owners in the area of an accident?

What are the stigma effects to Las Vegas if we have an accident here? Our economy is based on tourism. Other destinations are available to individuals who would be reluctant to bring their families to a city which has experienced a nuclear accident. How long would the stigma of a nuclear accident impact the economy of our city? What happens to all non-tourist sectors of the economy if an accident involving nuclear waste in our city seriously undermines the tourist revenue of the region?

Response
Several of the questions in this comment requested more information on emergency preparedness. Two regulations address the commenter's concern. First, Section 180(c) of the NWPA requires DOE to provide funds for training emergency response personnel in eligible jurisdictions along selected transportation routes. Sections M.5 and M.6 of the EIS discuss these requirements in detail. Second, there is a Federal Radiological Program outlined in the Federal Radiological Emergency Response Plan and the Federal Radiological Monitoring and Assessment Plan. These plans outline the policies, procedures, roles, and responsibilities of Federal, state, local, and Native American tribal agencies in planning for and responding to emergencies involving releases or suspected releases of radiological materials from government and commercial facilities or operations. Under Section 180(c), DOE will fund eligible jurisdiction planning activities to determine current capabilities and needs, and will fund training for emergency response activities.

The purpose of Section 180(c) is to ensure that first responders are sufficiently trained to respond safely to an incident involving the shipment of spent nuclear fuel and high-level radioactive waste. DOE has committed to provide technical and financial assistance for training as mandated by Section 180(c) approximately 4 years before shipments would begin. In addition, the Emergency Planning and Community Right-To-Know Act mandates the formation of emergency planning and response capability by the states. The *Federal Register* notices make it clear that the funding will go to states and tribes. Local governments would not be eligible to receive Section 180(c) grants directly. However, states and tribes would have to coordinate their planning with local jurisdictions, indicating in the application that the needs of local public safety officials have been considered and how the training assistance would be provided to local jurisdictions and their public safety officials.

DOE recognizes that emergency preparedness capabilities and needs vary from jurisdiction to jurisdiction. To assist states and tribes in determining what their needs are and where the Section 180(c) funds and assistance can best be applied, DOE will provide a one-time planning grant to aid in making this determination. Appendix M of the EIS discusses Section 180(c).

In the event of an incident or accident involving radioactive materials, states, tribes, and local governments can request assistance from the Federal Government under the Federal Radiological Emergency Response Plan. Assistance is available from 17 different agencies. In addition, DOE maintains eight Regional Coordinating Offices across the country that are ready to provide assistance. Appendix M contains information about these resources.

The Regional Servicing Contractor would have to provide specific written procedures to drivers and crews that clearly defined detailed actions in the event of an emergency or incident. The draft Request for Proposals, *Acquisition of Waste Acceptance and Transportation Services for the Office of Civilian Radioactive Waste Management* (DIRS 153487-DOE 1998), focused on these and related responsibilities. Appendix M of the EIS discusses carrier and shipper responsibilities for emergency situations.

With regard to cleanup after a transportation accident, the Price-Anderson Act establishes a system of financial protection for the public in a nuclear accident (compensation for damages, loss, or injury suffered), regardless of who causes the damage. Section M.8 of the EIS discusses the Price-Anderson Act.

DOE would not make routing decisions for some years; such decisions would in accordance with U.S. Department of Transportation routing guidelines. According to the report *Identification of Factors for Selecting Modes and Routes for Shipping High-Level Radioactive Waste and Spent Nuclear Fuel* (DIRS 103718-DOT 1998), routing evaluations should consider such parameters as emergency response capabilities; local terrain, road design, and climate characteristics as they affect accident rates; economic effects of accidents; sensitive environments exposed; and locations of special facilities such as hospitals and schools.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 of the EIS included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

For perspective, the current insured limit of responsibility for an accident involving releases of radioactive materials to the environment is $9.43 billion. The annual cost of transporting spent nuclear fuel and high-level radioactive waste to Yucca Mountain would be about $200 million.

With respect to comments on perceived risk and stigma associated with potential transportation accidents, while stigmatization of southern Nevada can be envisioned under some scenarios, it is not inevitable or numerically predictable. Any such stigmatization would likely be an aftereffect of unpredictable future events, such as accidents, which would not be expected to occur. As a consequence, DOE addressed but did not attempt to quantify any potential for impacts from risk perceptions or stigma in this Final EIS.

Comment - EIS001287 / 0004
A single accident could have major ramifications for much of Ohio. The potential risk of a significant release of radiation, though statistically small, could be incalculably catastrophic. There are too many uncertainties with rail or highway transportation. Too many potential hazards exist: accidents, other drivers, weather problems, road or track problems, which could ultimately compromise safety.

The costs of any leaks or accidents will effect the environment we live in for thousands of years. A major accident would pose obvious risks in terms of cancer but it would also poison farmland, effect watersheds, and flora and fauna in the vicinity. And it appears that studies minimize the health effects on humans by only identifying the cancer risk, while ignoring other effects of radiation exposure. It is unconscionable to take such genetic, teratogenic, and environmental risks.

Response
The EIS contains a discussion of potential impacts from accidents in both the mostly legal-weight truck scenario and the mostly rail scenario (see Section 6.2.4.2). The accident analysis includes a description of the consequences of a severe accident that would result in a leak in a transportation cask, although that is an extremely unlikely event [an annual probability of 2.8 (rail) to 2.3 (truck) in 10 million]. The leaking of a transportation cask could only occur if mechanical forces (impact) and heat (fire) exceeded the design limits of the transportation cask structures and materials. Section M.4 contains more information on the safety and testing of transportation casks. The accident analyzed in the EIS is believed to cover accidents from all sources including heat, mechanical impacts, sabotage, impacts from airplanes and weapons, and mountain rollovers.

DOE, the U.S. Department of Transportation, and the Nuclear Regulatory Commission recognize that there are many uncertainties with rail or highway transportation. Many hazards–accidents, other drivers, weather problems, road or track problems—could compromise safety. To mitigate the potential for a release of radioactive materials caused by these uncertainties, the Federal agencies listed above have a myriad of regulation, if adequately implemented, to preclude any release of radioactive materials. These agencies take human behavior seriously and consider these factors in all that they do from selection and training of personnel to post transport evaluations (see Section J.1.4.2.1 of the EIS).

The location of the maximally exposed individual was assumed to be at the downwind distance that yielded the highest radiation dose. For analysis of the consequences of severe truck and rail accidents and acts of sabotage, the distance used was estimated using the RISKIND computer program (see Sections 6.2.4.2.1, 6.2.4.2.2, and 6.2.4.2.3 of the EIS). RISKIND calculates the atmospheric dispersion of radioactive materials downwind from the point of release and is used to estimate the downwind location where the dose would be greatest.

The risks of transportation accidents are discussed in Sections 6.2.4.2 and J.1.4.2 of the EIS. Table J-81 lists estimates of transportation risks for Ohio for the mostly truck and mostly rail transport scenarios. In estimating these risks, accidents caused by all sources, such as other drivers, weather problems, and road or track problems, were included. The analysis addressed a variety of exposure pathways for air submersion, to food consumption, to direct radiation from materials deposited on the ground. Federal agencies have concluded that the protection of humans provide sufficient protection for flora and fauna. Therefore, latent cancer fatalities is a clear measure for comparing implementing alternatives.

The EIS uses the risk of a latent cancer fatality as its primary measure of radiological impact. However, other radiation-related impacts such as the incidence of nonfatal cancers and severe genetic effects are discussed in Section F.1.1.5 of the EIS. All radiation effects are linear with latent cancer fatalities and including these other radiation-related impacts would increase the total detriment from radiation exposures by about 50 percent.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report (DIRS 154814-Sandquist et al. 1985) used in the 1986 Environmental Assessments, and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

8.10 (4057)
Comment - EIS001474 / 0006
Just a couple weeks ago a low-level waste shipment in Ohio was involved in a head-on collision and there was a big fire involved. And I'll be interested to see what kind of releases were involved in that.

Response
Greater-than Class C low-level radioactive waste could be shipped to the repository in Module 2. However, the impacts for spent nuclear fuel accidents would generally be larger than accidents involving greater-than-Class-C waste, because the amount of radioactivity contained in a spent nuclear fuel cask would be much larger.

As discussed in Appendixes J and M, most real-world accidents that have been postulated for spent nuclear fuel and high-level radioactive waste shipments, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask in a river, and similar extreme accident conditions, would not be likely to result in release of radioactive materials from the shipping casks. The performance standards for the casks prescribed by the Nuclear Regulatory Commission were selected to ensure that less than 1 percent of real-world accidents would result in loss of cask integrity and release of radioactivity from the cask. These standards ensure that the casks would be extremely robust.

8.10 (4082)
Comment - EIS001482 / 0004
And then I look in the DEIS, and this -- what do you call it -- a region of influence is only 50 miles on this thing. If you would have an accident on the highway, you would only consider it 50 miles. You know, that's ridiculous.

Response
The EIS estimates impacts from transportation accidents to the population living within 80 kilometers (50 miles) of the transportation route. Air modeling studies have shown that, in the event of a radioactive material release from a transportation accident, most of the radiation dose would go to the population within 80 kilometers. Although there could be small effects beyond 80 kilometers, the statistical uncertainty in the analytical models is too high at such distances to provide meaningful results.

8.10 (4296)
Comment - EIS001160 / 0105
Page 6-27: The assumptions underlying this section and related table are suspect. First, the assumption appears to be that the cask cannot be breached in any way, either by heat or physical forces. While the data presented here and in the supporting texts indicate the improbability of cask breach, they cannot rule it out. Rail casks, speared by a rail during accident would cause cask breach, extreme heat might damage seats, a terrorist act could breach the container, etc. Collective doses in these scenarios would be considerably higher than the data presented here. DOE should thoroughly rethink these hypotheses and present data that includes the potential for containment breach, along with the statistical probability of such an accident occurring. Second, distances from containers either during an accident or in subsequent clean up are not presented, either here or in Appendix J. It would be possible to skew data either up or down by adjusting the distance from radiation source. In other parts of this document (6.2.4.2.3 1 6, line 4-5) the assumed distance from source is 150 Meters (about 500 feet). Here again the data presented (if I understand the writer correctly) appears to disagree with data presented later on in the document on maximum exposure risks. Without knowing how this data was calculated, we cannot confirm or dispute the findings, and on the face of it, these exposure risks, associated with an accident appear artificially low.

Response
The EIS contains a discussion of potential impacts from accidents in both the mostly legal-weight truck scenario and the mostly rail scenario (see Section 6.2.4.2). The accident analysis includes a description of the consequences of a severe accident that would result in a leak in a transportation cask, although that is an extremely unlikely event [an annual probability of 1.4 (rail) to 1.9 (truck) in 10 million]. The leaking of a transportation cask could only occur if mechanical forces (impact) and heat (fire) exceeded the design limits of the transportation cask structures and materials. Additional information on the safety and test of transportation casks is provided in Section M.4. The

accident analyzed in the EIS is believed to cover accidents from all sources including heat, mechanical impacts, sabotage, impacts from airplanes and weapons, and mountain rollovers.

The location of the maximally exposed individual was assumed to be at the downwind distance that yielded the highest radiation dose. For severe truck and rail accidents, the distance used was 360 meters (1,200 feet) (see Sections 6.2.4.2.1 and 6.2.4.2.2 of the EIS). For sabotage events, the distance was 140 meters (460 feet) (see Section 6.2.4.2.3). The distances are different because different dispersion conditions would exist during severe accidents and sabotage events.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

8.10 (4302)
Comment - EIS001160 / 0111
Page 8-79, Section 8.4.1. Inventory module 1 or 2 impacts, and Table 8-59. Some of the data reflected in this table does not seem to compute correctly. Specifically, a 58 percent increase in time spent shipping material reflects nearly 90 percent increase in kilometers traveled (580 million kilometers traveled vs. 1 billion kilometers traveled) with only a 50 percent increase in fatalities (8.6 to 12.9). The fatality rate per kilometer driven actually drops in the inventory module I or 2 scenario from the proposed action by about 20 percent. This doesn't seem logical. An argument that the kind of waste being transported is a consideration is not meritorious in as much as trucks must still travel the same highways and therefore would incur the same risks as other commercial trucking and have roughly the same number of accidents.

Response
The comment compared kilometers traveled and fatalities on the Totals line of Table 8-59 of the Draft EIS and noted a 90-percent increase in kilometers traveled resulted in only a 50-percent increase in fatalities. The data in the table actually compute correctly. Comparing each category in Table 8-59 separately, there is a consistent relationship between kilometers traveled and fatalities. For example, with the Materials category, there would be a 73-percent increase in kilometers traveled [130 million versus 225 million (80 million versus 140 million miles)] and a 68-percent increase in fatalities (2.5 versus 4.2). Taking rounding error into account, these percent increases are consistent. The same consistent relationship occurs for each category listed in Table 8-59. The apparent error appears only when attempting the same comparison on the Totals line. The same comparison cannot be made on the Totals line because the percent differences for each category are not additive; each category involves transportation along a specific set of routes with their own route-specific accident and fatality rates. If the route-specific accident and fatality rates happened to be identical for each category, the percent differences in data on the Totals line would be additive.

8.10 (4384)
Comment - EIS001523 / 0003
The EIS proposes either rail truck options for transportation of waste (Moore, 1). However, the DOE does not accurately assess the potential risk or probability of environmental damage or serious accidents resulting from either option. The EIS cited that the frequency of accidents on national interstate highways is not likely to change, despite a recent speed limit increase on these highways and gives no supporting evidence for its conclusion (Resnikoff, 3). The probability of accidents was also incorrectly calculated to be less than what is actually likely. The DOE does not include the effects of increased highway use in the Las Vegas and surrounding areas as a result of projected population growth. In assessing the potential danger of rail accidents, the DOE uses incomplete data by only assessing the risk resulting from a nuclear fuel falling from a low bridge and does not consider the consequences, which could result from an accident from a tall bridge (Resnikoff, 5).

Resnikoff, Martin. Cask Safety and related issues in the draft Yucca Mountain EIS. http://www.state.nv.us/nucwaste/eis/yucca/rwmaymeis.pdf. Jan 26, 2000.

Moore, Rick. Rail Issues in the Draft EIS. http://www.state.nv.us/nucwaste/eis/yucca/moore1a.pdf. http://www.state.nv.us/nucwaste/eis/yucca/moore1b.pdf. Jan 26, 2000.

Response
DOE believes that the EIS adequately analyzes the environmental impacts that could result from the Proposed Action. This belief is based on the level of information and analysis, the analytical methods and approaches used to represent conservatively the reasonably foreseeable impacts, and the use of bounding assumptions where information is incomplete or unavailable, or where uncertainties exist. The use of widely accepted analytical tools, latest reasonably available information, and cautious but reasonable assumptions offer the most appropriate means to arrive at conservative estimates of transportation-related impacts.

For the reasons discussed above, DOE believes that the EIS provides the environmental impact information necessary to make certain broad transportation-related decisions, namely the choice of a national mode of transportation outside Nevada (mostly rail or mostly legal-weight truck), the choice among alternative transportation modes in Nevada (mostly rail, mostly legal-weight truck, or heavy-haul truck with use of an associated intermodal transfer station), and the choice among alternative rail corridors or heavy-haul truck routes with use of an associated intermodal transfer station in Nevada.

8.10 (4781)
Comment - EIS001519 / 0007
Transportation of the spent fuel is an extremely dangerous undertaking because of the cataclysmic destruction it would cause to the surrounding area of the crash site and the high probability of there being an accident. There were 382,030 accidents involving heavy load trucks in 1997, an average of about 1,047 per day. When taken together with the fact that it would take over 23 years to move all the spent fuel to the repository, it is difficult to accept the idea that over that long time span, there will be no accidents involving a nuclear waste Carrying truck.

Response
About 53,000 shipments are estimated for the mostly legal-weight truck scenario. Given the number of shipments, traffic accidents probably would occur, although DOE does not believe that any of the accidents would be severe enough to result in the release of radioactive material, primarily because of the structural integrity of the casks in which the material would be transported.

8.10 (4888)
Comment - EIS000337 / 0028
Pg. 6-17,18, Section 6.2, National Transportation: I understand the probability and if one goes back and examines the train wreck that spilled thousands of gallons of toxic material into the Sacramento River it probably is outside the limits for the model used by DOE. It only takes one to do significant damage. The difference between all the past accidents and one that could occur transporting nuclear waste is that past accidents were cured in one life time but the nuclear accident time to cure could extend over many life times. The reference section is again laced with adjectives that do not belong in an engineering document. If you can state it is not "likely" or "unlikely" or "very unlikely" state the probability. No place in this document did I find any comment on the nuclear waste that is imported with respect to quantity and route. Please provide the data to me.

Response
Probabilities of severe spent nuclear fuel accidents are presented in Section J.1.4.2.1 of the EIS. Over 24 years of truck shipments to Yucca Mountain there would be less than a 1-percent chance of an accident that could result in a release of radioactive material from a cask. The chance of a rail accident that would cause release from a cask would be even lower. The chance that such an accident would occur in any locale would be much less than 1 percent. Therefore, an accident such as the train derailment near the Sacramento River would not be likely to release radioactive materials from the casks into the river.

DOE would not import spent nuclear fuel or high-level radioactive waste from foreign countries for disposal in the proposed repository. However, the Department has agreed to accept certain shipments of spent nuclear fuel from foreign research reactors as discussed in *Final Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel* (DIRS 101812-DOE 1996). Such fuel would be shipped to an existing DOE site for interim storage before ultimate shipment to a repository. The description of DOE spent nuclear fuel in Appendix A of the EIS includes the characteristics of the foreign research reactor fuel. Figure A-1 shows the locations of the commercial and DOE sites from which materials would travel to the repository. Tables J-10 and J-11 list the highway and rail routes, respectively, that DOE analyzed for this EIS.

8.10 (4891)

Comment - EIS000337 / 0031

Pg. 6-28, block at the bottom of the page: DOE uses the argument that if the accident is not reasonable it is not analyzed. This is defined by conditions that occur more often 1 in 10 million times a year. They eliminate any conditions that occur less than that number. The public should be told of what can happen because if it can it will in the years that material is being transported.

Response

Environmental impact statements are not required to analyze worst-case accidents but they are required to analyze reasonably foreseeable accidents. DOE guidelines (DIRS 104601-DOE 1993) suggest that these include accidents with probabilities in the range of 1 in a million to 1 in 10 million per year. As discussed in Section 6.2.4.2 and J.1.4.2.1 of the EIS, the accident analyses in the EIS include these "maximum reasonably foreseeable accidents." In addition to accidents with a probability greater than 1×10^{-7} per year, the EIS presents the consequences from all accident severity categories presented in Sprung et al. (DIRS 152476-2000).

8.10 (5036)

Comment - EIS001520 / 0004

The analyses of the impacts of transportation accident should include estimates of the environmental impacts associated with cleaning up after any accidents that release radioactive materials to the environment.

The analyses of transportation accidents that result in releases of radioactive materials to the environment assume that the released materials are not cleaned up. While this assumption may provide a bounding estimate of the radiation doses that nearby residents could receive, it is unrealistic because it fails to estimate the environmental impacts of clean up (e.g., worker radiation exposure; condemnation of roads, land, or water supplies; disposal of contaminated soil and building materials). A methodology for make such estimates was presented in Transportation of Radionuclides in Urban Environs: Draft Environmental Assessment, NUREG/CR-0743; SAND 79-0369, July 1980. While somewhat dated, the cost estimates and perhaps the methodology could be updated for today's use. The Board recommends that the final EIS include estimates of the environmental impacts of clean-up after transportation accidents.

Response

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

Comment - EIS001520 / 0011

The draft EIS uses the "Modal Study" (discussed on page 6/29 of the draft EIS) in its analyses of transportation accidents. It is our understanding that this study will be updated by the U.S. Nuclear Regulatory Commission, but not in time for inclusion in the final Yucca Mountain EIS. The Board recommends that the final EIS note any efforts to update the study and discuss the DOE's plans for reviewing the results of any update to determine whether a supplement to the final EIS may be needed.

Response
Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). DOE has concluded that the models used for analysis in the Draft EIS relied on assumptions about spent nuclear fuel and cask response to accident conditions that caused an overestimation of the resulting impacts. Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there could be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 presents consequences for accidents that could release radioactive materials.

8.10 (5294)
Comment - EIS000968 / 0011
By not identifying specific routes for shipment, key issues were not addressed in the DEIS. For example, the Cal-Nev Fuel Pipeline runs parallel to the Union Pacific Railroad from the San Bernardino area into the Las Vegas Valley. These 14" and 9" fuel lines could cause significant impact in the event of a rail accident, and they are the main supply of all motor vehicle and aircraft fuels into Southern Nevada.

Response
"Real-life conditions" that would involve various types of collisions (such as airplanes and military trucks carrying explosives), various natural disasters, specific locations (such as mountain passes or near pipelines), or various infrastructure accidents (such as track failure) in effect constitute a combination of cask failure mechanisms, impact velocities, and temperature ranges, which the EIS does evaluate. Shipping casks used to transport spent nuclear fuel and high-level radioactive waste would be massive, with design features that complied with strict regulatory requirements to ensure that the casks were fault-tolerant; that is, the casks would perform their safety functions even when damaged. Numerous tests and extensive anlyses, using the most advanced analytical methods available, have demonstrated that these types of shipping casks would provide containment and shielding even in the most severe kinds of accidents.

Since the publication of the Draft EIS, the Nuclear Regulatory Commission published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000). Based on the revised analyses in this report, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in 99.99 percent of all accidents (of the thousands of shipments over the past 30 years, none has resulted in an injury due to release of radioactive materials). The analysis in the EIS used data presented by Sprung et al. (2000) and state-specific accident rates (DIRS 103455-Saricks and Tompkins 1999) to estimate the likelihood and severity of transportation accidents. The data from these studies are based on national data collected from actual accidents. The national data include accidents in which road hazards and other local conditions (such as pipeline failures) were contributing factors.

The analysis in the EIS estimated that during the approximately 53,000 truck shipments for the mostly legal-weight truck scenario there could be 66 accidents. Each of these would have less than a 0.1-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release would be even less. The corresponding chance that such an accident would occur in any particular locale would be extremely low. Section J.1.4.2.1 of the EIS presents consequences for accidents that could release radioactive materials.

Comment - EIS001887 / 0323
Page 6-30; Box - Transportation Accidents

The Draft EIS incorrectly assumes that simply requiring contractors to comply with ANSI N14.27-1986-1993) will guarantee timely availability of the trained personnel and special equipment necessary for recovery and reshipment of casks damaged in severe accidents. In particular, DOE must demonstrate the economic and technical feasibility of recovering and re-shipping large (125 tons or greater loaded weight) rail casks such as those proposed for transport of civilian and naval reactor SNF [spent nuclear fuel]. The analysis must consider the possibility of significant loss of shielding and/or containment as a result of a severe accident or terrorist attack. The analysis must further consider the possibility of such incidents occurring in difficult terrain comparable to that found along potential rail routes identified in the Draft EIS, such as the Union Pacific railroad between Uvada and Elgin, and along potential HHT [heavy-haul truck] routes identified in the EIS, such as SR375 through Hancock Summit.

Response
DOE considers compliance with ANSI N14.27-1986 (DIRS 156289-ANSI 1987) to be only one element of effective emergency preparedness. There are many other elements of DOE's emergency preparedness program that help to ensure timely response to potential transportation accidents. The other elements include the accident response capabilities of DOE's eight Regional Coordinating Offices, preshipment planning, emergency response training for local first responders, satellite tracking and communications, driver training and awareness, and shipment prenotification. However, DOE is aware that risk minimization is best accomplished by preventing accidental releases in transit. The Type B accident-resistant packages that would be used to transport spent nuclear fuel and high-level radioactive waste are the key to prevention. However, should an accident occur, DOE, its contractors and carriers, and other Federal agencies would be prepared to respond. Section M.5 of the EIS provides more information about emergency preparedness for transportation accidents.

The EIS notes that the transportation carrier involved in an accident is responsible for planning, cost, and arrangements necessary to safely recover the shipment and clean up any radioactive contamination that occurred (see Section 6.2.4.2). Recovery of 23-metric-ton (25-ton) truck casks or rail casks weighing 110 metric tons (120 tons) is not an easy operation, especially in areas where deploying mobile carriers is difficult. However, capability to lift such weights does exist for rail and truck modes and would be deployed as required in the unlikely event of a cask leaving the conveyance or transport vehicle.

The Draft Request for Proposals for Waste Acceptance and Transportation Services (DIRS 153847-DOE 1998) describes Operational Protocols that the contractors would follow. These protocols are summarized in Section M.3 of the EIS. The Request for Proposals requires the transportation contractors to be responsible for providing DOE with specific written procedures that clearly define detailed actions to be taken in the event of an off-normal event. These procedures will address repair or replacement of equipment, or recovery, as appropriate. These requirements are applicable to transport by both truck and rail.

The EIS includes analyses of the public and worker health impacts of severe accidents that could result in failure of the shipping cask (see Sections 6.2.4.2 and 6.3.2). However, the specific locations of potential accidents cannot be predicted so bounding assumptions were made about the locations, such as conservative population distributions and weather conditions. An accident in difficult terrain, such as suggested by the commenter, would be unlikely to have greater health impacts than those analyzed in the EIS. This is because areas with difficult terrain would be sparsely populated in relation to the urban areas in which the maximum reasonably foreseeable accidents were assumed to occur.

8.10 (5713)
Comment - EIS001887 / 0326
Page 6-32 to 6-33; Section 6.2.4.2 .2– Impacts from Accidents – National Mostly Rail Scenario

The Draft EIS underestimates the radiological consequences of a maximum reasonably foreseeable rail accident by a least a factor 15, and by up to a factor of 40 or more. The number of latent cancer fatalities could be 1,380 or more.

Under contract with the State of Nevada, Radioactive Waste Management Associates (RWMA) prepared a bounding scenario analysis of the a accident reported in Table 6-12, using the RADTRAN and RISKIND models and a range of credible alternative assumptions about SNF [spent nuclear fuel] age and radiological characteristics, atmospheric dispersion, and population densities. Nevada is submitting the RWMA analysis as Attachment AA.

Response
The National Environmental Policy Act requires assessment of reasonably foreseeable impacts from proposed agency actions. In its various EISs, DOE has defined a reasonably foreseeable accident as one that has a frequency

of occurrence of at least once in 10 million years (1×10^{-7} per year). The concept of a maximum reasonably foreseeable accident is sometimes misinterpreted as being a “worst-case” accident. The analysis referred to by the commenter would be considered a worst-case analysis.

An example of a worst-case transportation accident would involve a shipment containing the highest possible quantity of spent nuclear fuel or high-level radioactive waste, in a highly populated area, with catastrophic failure of the shipping container, an engulfing fire lasting many hours, and stable weather conditions (very low atmospheric dispersion of plume). However, this worst-case accident scenario would not be reasonably foreseeable because it requires the simultaneous occurrence of a series of unlikely events, which, compounded, result in a likelihood of occurrence that is less than once in 10 million years. This is clearly the case with respect to the analysis referred to by the commenter, which assumed 10-year cooled spent nuclear fuel, the highest possible loading of crud on the external surfaces of fuel assemblies, population distribution equivalent to Manhattan, the highest possible release fractions, low wind speed, and stable atmospheric conditions. The analysis referred to by the commenter did not account for the probabilities of these conditions. The frequency of this specific accident scenario would be the combined frequency of any accident, the conditional probability of a severity category 6 event (as assumed by the commenter), and the probabilities of encountering the conditions discussed above (for example, low wind speed, 10-year cooled spent nuclear fuel, maximum crud source term). The frequency of this specific accident scenario would be well below the definition of maximum reasonably foreseeable. Council on Environmental Quality regulations (40 CFR 1502.22) state that analysis of accidents should avoid scenarios that are based on pure conjecture and avoid compounding conservatisms.

DOE is aware that there are uncertainties associated with the transportation impact results presented in the EIS. There are uncertainties associated with route characteristics, demographics, weather, atmospheric dispersion models, spent nuclear fuel characteristics, accident rates, release fractions, and many other elements of the risk assessments. Because one of DOE’s goals is to choose between alternatives, the consistent consideration of uncertainty among alternatives means that the relative differences in impact estimates among alternatives should not be affected. To account for uncertainties in the data, conservative assumptions were made so the impacts reported in the EIS would bound the potential impacts (that is, would produce results that are higher than the true risk). However, DOE has chosen not to use conservative assumptions in all cases, as this practice tends to produce unrealistic and improbable results. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing environmental impacts. Such practices mask the real differences and would not produce suitable results to support choices among the alternatives. Thus, for example, DOE has chosen to use realistic waste characteristics information, accident rates, highway and rail distances between waste generators and the proposed repository, the number and distribution of people along the routes, and shipping cask capacities. DOE believes that the impacts presented in the EIS are bounding, yet not so conservative that the true differences among alternatives are masked. DOE does not believe it has understated the true risks of transporting spent nuclear fuel and high-level radioactive waste to the proposed Yucca Mountain Repository.

The analysis referred to by the commenter pointed out that the assumptions used in the EIS for the age and radiological characteristics of spent nuclear fuel in the maximum reasonably foreseeable accident scenarios could understate the transportation risks. It is true that DOE could ship some spent nuclear fuel that is more radioactive than the 26 year-old pressurized water reactor spent nuclear fuel analyzed in the scenario. Based on comments received and DOE’s additional review of technical documents and conduct of hazard analyses, the basis for the transportation impact analysis has been revised to consider commercial spent nuclear fuel that has median hazard. Spent nuclear fuel having median hazard would be discharged from a reactor approximately 14 years before shipment to Yucca Mountain. If any 5-year old or 10-year old spent nuclear fuel were to be shipped to the repository, it would be a small fraction of the total shipments. This is a case in which “average” data is used in the EIS as opposed to bounding assumptions. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing accident scenarios. Other elements of the impact analyses (for example, radiation dose rates, atmospheric dispersion modeling, release fractions) are bounding such that the transportation impact results presented in the EIS are bounding.

Comment - EIS001887 / 0339
Page 6-96; Section 6.3.3.1

Accidents

The Draft EIS discussion of HHT [heavy-haul truck] accidents is deficient. Because of the lack of actual experience with long distance HHT shipments, no meaningful empirical data is available to support the Draft EIS assertion that accident risks “are low for all five [route] alternatives.”(p. 6-96) HHT operations on the routes identified in the Draft EIS may experience substantially higher accident frequencies and consequences. For example, using Nevada average accident rates and projected shipment-miles for DOE’s Module 2 scenario, the expected number of HHT accidents on the Caliente route would be about 24 (12 loaded, 12 empty) over 39 years. The severity and consequences of accidents could be greater because of unique local hazards. Steep upgrades and downgrades (especially in combination with horizontal curves less than 800 feet radius) and critical side slopes and steep drop-offs (common near the summits of mountain passes) could subject casks to extreme accident impact forces and make emergency response, cask recovery, and post-accident cleanup difficult. Such conditions appear to exist near Oak Springs Summit on U.S. 93, near Hancock Summit on SR 375, and at several other locations along the Caliente HHT route.

Response
DOE recognizes the special considerations associated with heavy-haul truck shipments along the five candidate routes identified in the EIS. Road upgrades would be needed along these routes before their use to ship casks containing spent nuclear fuel and high-level radioactive waste. Tables J-36 through J-40 of the EIS summarize the road upgrades needed for the five routes. Heavy-haul truck shipments would be subject to permit conditions established by the State of Nevada, which would establish escort requirements and speed limit and other restrictions to reduce the risk of accidents associated with such shipments. Based on the restrictions placed on heavy-haul truck shipments, DOE believes that the use of Nevada average accident rates overestimates accident risks.

8.10 (5882)
Comment - EIS001900 / 0003
The DEIS does not examine the potential impact of transportation accidents in Connecticut or elsewhere. Yet, the Department of Energy has estimated that a severe accident in the transport of such waste would contaminate 42 square miles for well over one year. The State of Connecticut lacks an infrastructure to deal with such a disaster.

Response
In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist at al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

Comment - EIS001560 / 0005
One of which was the estimate of the chances of an accident being one to two in 10 million, I believe that’s what was said. That sounds like a statistic and statistics are usually based on experience. Now does this mean that there have been one or two accidents already in 10 million tries, I doubt it. I think they have, somehow, come up with an estimate and made it sound like a valid statistic. Which concerns me greatly, especially because the difference between one and two in 10 million is a hundred percent difference in a statistic. So where is this estimate from?

Response
The EIS contains a discussion of potential impacts from accidents in both the mostly legal-weight truck scenario and the mostly rail scenario (see Section 6.2.4.2). The accident analysis included a description of the consequences of a severe accident that resulted in a leak in a transportation cask, although that is an extremely unlikely event [an

annual probability of 1.4 (rail) to 1.9 (truck) in 10 million]. A transportation cask could only leak if mechanical forces (impact) and heat (fire) exceeded the design limits of the transportation cask structures and materials. Section M.4 provides additional information on the safety and test of transportation casks. DOE believes the accident analyzed in the EIS covers accidents from all sources including heat, mechanical impacts, sabotage, impacts from airplanes and weapons, and mountain rollovers.

DOE, the U.S. Department of Transportation, and the Nuclear Regulatory Commission recognize that there are many uncertainties with rail or highway transportation. Many hazards exist—accidents, other drivers, weather problems, road or track problems—that could ultimately compromise safety. To mitigate the potential for a release of radioactive materials caused by these uncertainties, the Federal agencies listed above have a myriad of regulations, if adequately implemented, to preclude any release of radioactive materials. The Departments of Energy and Transportation and the Nuclear Regulatory Commission take human behavior seriously and consider this factor in all that they do, from selection and training of personnel to post transport evaluations (see Section J.1.4.2.1 of the EIS).

Factors that affect accident probability include state-specific accident rates; accidents per kilometer; the fraction of accidents that occur in rural, suburban, and urban population zones; the probability that an accident would be of a certain severity; and the annual shipping mileage in rural, suburban, and urban population zones. Weather conditions affect the probability of accident consequences because stable, worst-case, weather conditions are only about one-tenth as likely as neutral, average weather conditions.

8.10 (6332)
Comment - EIS001613 / 0002
I am not a scientist and I do not have enough information to completely dismiss the analysis and tests performed by the DOE to ensure the safe transportation of this hazardous material, but I do understand that these trucks will be driving through communities across America, and that one small release of radioactive material in a rural area would contaminate 42 square miles, require 460 days to clean and cost up to $620 million.

From your comments earlier tonight, I think we can all agree that human error is possible and, therefore, catastrophe could not be completely ruled out. I hope that your analysis is honest and not skewed to make it seem that the Department of Energy is taking responsibility for their actions.

On my way over here tonight, I was imagining the visual terror of thousands of trucks bearing the nuclear energy emblem driving through our communities as a reminder to our children that they will have to bear the burden of our actions.

Response
The EIS acknowledges that transportation accidents could occur during the transport of radioactive materials to the proposed Yucca Mountain Repository. In Section J.1.4.2.3.2, the EIS estimates that there could be as many as 66 accidents under the mostly legal-weight truck shipping scenario and 8 accidents could occur under the mostly rail scenario. A study recently conducted by the Nuclear Regulatory Commission (DIRS 152476-Sprung et al., 2000) concluded that only a tiny fraction of all accidents, less than one in 10,000, would be severe enough to result in a release of radioactivity from a spent nuclear fuel shipping cask. The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. Based on these statistics, DOE does not expect an accident to occur that would result in a radiological release and subsequent environmental cleanup.

Human error was considered in the EIS transportation analyses. For example, the truck and rail accident rates used in the EIS included accidents involving all causes, including those with human error as a cause. Human error in design, manufacturing, or use of transportation casks would be minimized through an aggressive quality assurance program and oversight by the Nuclear Regulatory Commission. Detailed written procedures would cover handling and loading of shipping casks at the commercial and DOE generator facilities and the proposed repository. Dry runs would familiarize operators with the shipping cask, cask handling equipment, and site-specific cask handling procedures. The transportation contractors, in addition to driver training and certification programs, would conduct detailed preshipment planning. All of these activities, and others, are designed to minimize the impacts of human errors. However, the greatest protection against human error during transportation would be the accident-resistant

Type B shipping casks used to transport spent nuclear fuel and high-level radioactive waste. A properly designed, fabricated, loaded, and maintained shipping cask would reduce vulnerabilities to all accidents, including human error, to levels that provided adequate protection to the public, workers, and environment.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

8.10 (6476)
Comment - EIS001632 / 0033
Page 3-142, Sections 3.3.2 and 3.3.3: The draft EIS briefly discusses ground and surface water impacts, but we were unable to find an assessment of ground water contamination from a surface spill. The transportation impacts analysis should consider ground water recharge zones and the proximity of transportation corridors to ground water supplies and community water systems.

Response
The EIS sections cited by this comment identify potentially affected waterways and groundwater characteristics pertaining to the 77 commercial and DOE generator sites. Sections 7.2.1.3 and 7.2.2.3 discuss the potential hydrologic impacts associated with the No-Action scenarios.

With regard to transportation, Sections 3.2.2.1.3 and 3.2.2.2.3 of the EIS provides information on hydrology related to transportation corridors within Nevada. Table 3-37 and 3-39 present surface-water resources and groundwater basins, respectively, along the candidate rail corridors. Table 3-58 and 3-59 do the same for candidate heavy-haul truck routes. For Nevada transportation, potential impacts to hydrology from construction and operations are presented throughout Chapter 6. For example, see Section 6.3.2.2.1. The analyses are based on an identification of surface-water resources within the 400-meter (0.25-mile) corridor for each alternative and outside the corridor, but within 1 kilometer (0.6 mile). Designated groundwater basins are identified.

DOE does not specifically analyze a transportation accident, such as a spill, involving contamination of surface water or groundwater because the casks are designed to be watertight and spent nuclear fuel and high-level radioactive waste are not easily dispersed in water. While small particles could be generated by the impact forces of an accident, and driven out of a shipping cask by a severe fire, the amount of contamination that could ultimately enter groundwater would be much lower than that which would initially enter surface waters. Factors such as soil sorption of radionuclides, rate of flow into recharge areas, dilution by rain water and surface water, dilution by the large volume of groundwater, and delay associated with infiltration would mitigate and greatly reduce any contamination that could occur. Therefore, water pathway contamination, including subsequent contamination of food and natural resources, would not be a significant contributor to the radiological risks of transporting spent nuclear fuel. DOE has, however, identified potential mitigation measures for surface water and groundwater from the construction and operation of transportation systems. See Sections 9.3.3.1 and 9.3.3.2 of the EIS.

8.10 (6622)
Comment - EIS000938 / 0013
The analysis that was conducted to evaluate the dust cloud created by an accident is fatally flawed. Volume 2, Page J-8, 4th paragraph states that the average meteorological conditions are the national averages for wind speed and atmospheric stability. This assumption is assured for the State of California where North winds cause natural wind tunnels. An accident in one of the passes could spread the toxic dust cloud over the entire LA [Los Angeles] basin. DOE must utilize the wind and atmospheric conditions for the area being studied for the impact of a terrorist attack.

Response
The precise location, timing, prevailing weather conditions, and other circumstances surrounding a transportation accident cannot be predicted. In addition, it would not be practical for the EIS to attempt to analyze accident

consequences for every location along the shipping route. Instead, maximum consequences were analyzed for three types of population zones: urban, suburban, and rural. For example, an accident in the Las Vegas area would be characterized by the analysis for an urban area. In addition, the analysis of maximum reasonably foreseeable accidents considered conservative 95-percent meteorological conditions (conditions that are exceeded less than 5 percent of the time). These meteorological conditions result in larger impacts than the "average" conditions referred to by the commenter. Tables 6-14 and 6-15 of the EIS provide the estimated impacts of the maximum reasonably foreseeable accident in an urbanized area for truck and rail, respectively. Table J-24 shows consequences of maximum reasonably foreseeable accidents in urbanized and rural areas.

Section 6.2.4.2.3 of the EIS discusses potential sabotage. The use of average wind speeds and neutral atmospheric conditions does not greatly affect the estimated consequence of the event, should it occur. In fact, higher wind speeds and less stable atmospheric conditions would be expected to decrease the potential dose received by individuals in the path of any the release. The analyses in the EIS estimate as many as 48 latent cancer fatalities could result from a successful sabotage attack on a spent nuclear fuel shipping cask.

8.10 (6693)
Comment - EIS001632 / 0087
Page J-8, second full paragraph: This paragraph discussed the methodology used to estimate, the radiation impact resulting from accidents. The spectrum of possible accident severity was divided into categories. Then "each category of severity received a conditional probability of occurrence." A release fraction was assigned to each category. Please provide a brief discussion of how values were assigned and a table listing the values.

Response
Section J.1.4.2.1 of the EIS contains a discussion of accident severity categories, conditional probabilities, and release fractions. Figure J-9 shows the values for pressurized-water and boiling-water reactor spent nuclear fuel, respectively.

8.10 (6700)
Comment - EIS001878 / 0064
Incidents and accidents involving military aircraft and ground transportation have occurred in Nevada in the past, and may also occur in the future. The DEIS does not specifically evaluate this risk. The FEIS for Withdrawal of Public Lands for Range Safety and Public Purposes, NAS Fallon, NV (Department of the Navy, May 1998) and the FEIS, Proposed Fallon Range Training Complex Requirements, NAS Fallon, NV (Department of the Navy and Bureau of Land Management, January 2000) address the public safety impacts and other impacts of military aircraft operations in areas that would be affected by the transportation elements of the proposed action. However, the Yucca Mountain DEIS does not adequately consider: (1) potential cumulative public safety impacts, (2) whether the transportation elements of the proposed action would adversely affect the Navy's and the BLM's [Bureau of Land Management's] risk assessments, or (3) threats from military training flights associated with the Fallon NAS to trucks and trains carrying SNF [spent nuclear fuel] and HLW [high-level radioactive waste]. See Exhibit K for a map depicting current military flight patterns, which include many thousands of annual operations according to the Navy and the BLM.

Response
System malfunctions or material failures that could result in either an accidental release of ordnance or release of a practice weapon were discussed in the Renewal of the *Nellis Air Force Range Land Withdrawal Legislative Environmental Impact Statement*, the *Final Environmental Impact Statement, Withdrawal of Public Lands for Range Safety and Training Purposes, Naval Air Station Fallon, Nevada*, and the *Final Environmental Impact Statement, Proposed Fallon Range Training Complex Requirements, Naval Air Station Fallon, Nevada*. The *Special Nevada Report* (DIRS 153277-SAIC 1991) states that the probability of dropped ordnance resulting in injury, death, or property damage ranges from about 1 in 1 billion to 1 in 1 trillion per dropped ordnance incident, with an average of about 1 in 10 billion per dropped ordnance incident. Less than one dropped ordnance incident is estimated per year for Nellis Air Force Range and Naval Air Station Fallon. Because the probability of such an accident is so low and, should an aircraft accident occur, the potential for release from such an accident is unlikely, no further analysis is presented in this EIS. In addition, considering the risk assessments presented in the Nellis Air Force Range, Naval Air Station Fallon, and this EIS, military training flights would not pose a safety threat to trucks or trains carrying

spent nuclear fuel or high-level radioactive waste nor a health risk to populations in the area. It is the Department's opinion that the EIS adequately analyzes impacts to transportation from military activities.

Bechtel-SAIC Company (DIRS 157210-BSC 2001) estimated the potential releases of radioactive materials that could result from the crash of a commercial jet airliner into a shipping cask containing spent nuclear fuel. According to the analysis, the release from a rail cask struck by a jet engine traveling 640 kilometers (400 miles) per hour and exposed to the ensuring jet-fuel fire would be no greater than the releases in a severe rail transportation accident in which the cask impacted a hard rock surface at between 48 and 97 kilometers (30 and 60 miles) per hour and was engulfed by fire for 0.5 hour. The consequences of this accident–1,300 person-rem or 0.67 latent cancer fatality–are presented in Section J.1.4.2 of the EIS. The consequences for an event in which the commercial airliner impacted a legal-weight truck cask would be about the same–1,100 person rem or 0.57 latent cancer fatality. A truck cask event that would have similar consequences would involve impact into a hard rock surface at a speed greater than 190 kilometers (120 miles) per hour followed by an engulfing fire for up to 0.5 hour.

8.10 (6769)
Comment - EIS001522 / 0010
It is even more question-begging, and even more incredible, when DOE knows neither the canister that will eventually be designed, nor the routes, nor the modes of transport, to claim that "the overall radiological accident risk ... from all accident scenarios over the 24 years of transportation activities ... would be about 0.07 latent cancer fatalities" at most (DEIS, 1999, 6-7). Obviously such fatalities depend strongly on the mode and routes of transport, so these figures appear to be mere guesses, and surely they are not science. Besides, as the state of Nevada pointed out, the DOE simplified cask design and accident scenarios, "created" data to fill the gaps, ignored human error in transport, and so on (DEIS, 1999, 6-29). Given all these problems with the DOE's using subjective data, there is no way that a reliable probability about cancer fatalities, induced by transport, could be given by the DOE. And if not, then the DEIS is not an example of science but an example of mere opinion, rhetoric, and begging the question.

Response
The transportation analysis in the EIS provides a reliable estimate of risks and impacts from shipments of spent nuclear fuel and high-level radioactive waste to the repository at a national level. At present, DOE cannot predict the actual mix of rail and legal-weight truck shipments that could occur. Therefore, the EIS analyzes two scenarios, mostly legal-weight truck and mostly train (rail), as bases for the transportation risk assessment. Using these scenarios, the analysis in the EIS describes the range of legal-weight truck and rail shipments that could occur. As a consequence, the transportation impacts that result from the actual mix of rail and legal-weight truck shipments when the repository was operational would be within the range of impacts estimated in the EIS.

The EIS contains a discussion of potential impacts from accidents in both the mostly legal-weight truck scenario and the mostly rail scenario (see Section 6.2.4.2 of the EIS). The accident analysis includes a description of the consequences of a severe accident that resulted in a leak in a transportation cask, although that is an extremely unlikely event [an annual probability of 1.4 (rail) to 1.9 (truck) in 10 million]. A transportation cask could only leak if mechanical forces (impact) and heat (fire) exceeded the design limits of the transportation cask structures and materials. Section M.4 provides additional information on the safety and test of transportation casks. DOE believes the accident analyzed in the EIS covers accidents from all sources including heat, mechanical impacts, sabotage, impacts from airplanes and weapons, and mountain rollovers.

DOE, the U.S. Department of Transportation, and the Nuclear Regulatory Commission recognize that there are many uncertainties with rail or highway transportation. Many hazards exist—accidents, other drivers, weather problems, road or track problems—that could ultimately compromise safety. To mitigate the potential for a release of radioactive materials caused by these uncertainties, the Federal agencies listed above have a myriad of regulations, if adequately implemented, to preclude any release of radioactive materials. The Departments of Energy and Transportation and the Nuclear Regulatory Commission take human behavior seriously and consider this factor in all that they do from selection and training of personnel to post-transport evaluations (see Section J.1.4.2.1 of the EIS).

The choice of canister type would not affect the transportation risk analysis because canistered and uncanistered fuel would be shipped inside Type B containers that met Nuclear Regulatory Commissions regulations for shipment of spent nuclear fuel and high-level radioactive waste.

DOE has not determined the specific routes it would use to ship spent nuclear fuel and high-level radioactive waste to the proposed repository. Nevertheless, the analysis in the EIS used current regulations governing highway shipments and historic rail industry practices to select existing highway and rail routes. This approach is consistent with previous DOE environmental impact statements that have evaluated national transportation impacts and provides a reasonable estimate of the potential environmental impacts of transportation of spent nuclear fuel and high-level radioactive waste to the proposed repository.

Comment - EIS001784 / 0005
We need a lot more information on nuclear transport accidents that have occurred in the 2,500 “successful” shipments of similar high-level radioactive wastes that I have read have already taken place in the U.S. Where can I get this information? Will it be available to the public if the effort to upload Yucca Mountain with mega-rads goes into effect?

Response
The EIS does not refer to 2,500 successful shipments. It does use recognized analytical methods that incorporate accident experience data to estimate the likely impacts of the transportation of spent nuclear fuel and high-level radioactive waste. Besides the descriptions of transportation in this EIS (Chapter 6 and Appendix J), the *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs: Final Environmental Impact Statement* (DIRS 101802-DOE 1995) contains more information. In addition, the *Idaho High-Level Waste and Facilities Disposition Draft Environmental Impact Statement* (DIRS 155100-DOE 1999) contains information on waste shipments.

The Yucca Mountain Project provides technical and project information on its Internet site (*http://www.ymp.gov*) and other media. The EIS contains revised information on the transportation of spent nuclear fuel and high-level radioactive waste.

8.10 (7083)
Comment - EIS001873 / 0032
P. 2-53. DEIS should state the maximum amount of radioactive waste that could be held at an intermodal facility and the maximum time that it could be held. These figures should be the basis for normal and accident scenario impacts including sabotage and terrorism. Security facilities connected with the intermodal sites should be identified.

Response
At this time, the heavy-haul truck alternatives for transporting spent nuclear fuel and high-level radioactive waste to the proposed repository are in conceptual stages of development. A concept for an intermodal transfer station is shown in Figure 2-28 and for a heavy-haul truck system is shown in Figure 2-29. A determination of the amount of the radioactive material and the amount of time a shipping cask would be held at the intermodal transfer station is unknown. However, if DOE decided to use heavy-haul truck transport and construct an intermodal transfer station within Nevada, it would conduct additional field surveys, state and local government consultations, environmental and engineering analyses, and appropriate National Environmental Policy Act reviews. The detailed information requested by the commenter would be developed as part of more detailed design and engineering studies, should DOE decide to use heavy-haul truck. In addition, detailed safety analyses of the intermodal transfer station would be conducted to evaluate more fully the final design and provide the basis for the identification of systems, structures, and components important to safety, technical specifications, safety-related controls, and safe operating procedures. For the purposes of the EIS, DOE believes it has adequately demonstrated the feasibility of the heavy-haul truck implementing alternatives, including the intermodal transfer station, and developed them sufficiently to support comparisons of alternatives and decisionmaking about transportation alternatives.

With respect to identification of security facilities, much of the security information about the intermodal transfer station would be protected as safeguards information. This would include such things as the designs and capabilities of physical protection systems, number and deployment of the protective force, locations and capabilities of intruder detection systems, etc. Information of this type is protected to prevent its disclosure to potential terrorists or saboteurs. As discussed above, additional engineering and design studies would be conducted, including development of physical security systems, if DOE decided to construct an intermodal transfer station.

8.10 (7099)

Comment - EIS000995 / 0011

During the Three Mile Island shipments, there was an accident on the very same, highly inspected and maintained train tracks, luckily not involving the TMI shipments. This accident sticks in my mind because it was in a very hard to reach area that was, also, close to highly populated communities. The accident involved train cars hanging, suspended, off of a train trestle over a river. For many hours they hung there while a high-intensity, long-duration fire blazed beneath them. It was a struggle for the emergency personnel to get to the accident site, severely delaying their response. What dangers would this type of accident present if the train cars were carrying the casks containing high-level radioactive waste from radioactive reactors nationwide?

Response

In the severe transportation accidents analyzed in the EIS, fully engulfing fires were analyzed. This means that the cask was assumed to be at the center of the fire, were the amount of heat transferred to the cask would be the greatest. At other locations, such as the cask dangling above the fire, the amount of heat transferred to the cask would be less and therefore, the amount of damage to the cask would also be less. Therefore, the consequences of the type of accident described by the commenter would be less than the consequences of the severe transportation accidents presented in the EIS.

The consequences of these severe accidents are presented in Sections 6.2.4.2.1 and 6.2.4.2.2 of the EIS for truck and rail transportation, respectively. For a severe truck accident, the probability is about 2.3 in 10 million per year. The consequences of this severe truck accident were estimated to be 0.55 latent cancer fatality. For a severe rail accident, the probability is about 2.8 in 10 million per year. The consequences of this severe rail accident were estimated to be 5 latent cancer fatalities.

8.10 (7265)

Comment - EIS001832 / 0013

DOE NEPA [National Environmental Policy Act] guidance to consider 1 in 10 million events is inconsistent with public policy elsewhere. Considering that used fuel will be transported for a relatively short period of time, the chances that such a “worst case accident” might occur is essentially zero. The chances of such a fatal accident are far less than those of loss of life due to meteor impact, which has a probability of occurrence of 1 in 100,000 years.* To find such an improbable accident to analyze, DOE had to go farther into the realm of the incredible than they will be required to do by the responsible regulatory authorities.** The extreme conservatism of going beyond what is reasonable, in postulating worst case accidents, forces DOE to consider severe transportation accident scenarios that are not credible thereby increasing the calculated environmental impacts and effects to non credible levels.

DOE’s analysis of these highly improbable severe transportation accidents also assumes no mitigation, which is misleading. In reality, a swift and comprehensive emergency response would follow any severe transportation accident. While DOE must consider the full impacts of a postulated severe transportation accident, DOE should also include the results of mitigation measures related to emergency response.

If DOE believes it is required to leave analyses in the FEIS that consider 1 in 10 million events, the FEIS should, at a minimum, also describe the effects at higher, more realistic probabilities.

*United States Atomic Energy Commission, Reactor Safety Study, WASH-1400, August 1974

**For example, NRC [Nuclear Regulatory Commission] has proposed, in updating its Reactor Safety Goal Policy Statement, requiring licensees to evaluate large early release events having a probability of 1 in 10,000 or greater.

Response

The *Recommendations for the Preparation of Environmental Assessments and Environmental Impact Statements* (DIRS 104601-DOE 1993) requires evaluation of high-consequence, low-probability accidents. This requirement is interpreted to mean accidents with at least a 1-in-10-million-per-year probability. These accidents are known as maximum reasonably foreseeable accidents. In order to provide an upper bound on potential consequences, DOE has chosen to not include the effects of mitigation, although interdiction of foodstuffs is assumed in evaluating the consequences of the maximum reasonably foreseeable accident. In the transportation risk assessment, a complete spectrum of accidents was evaluated, including accidents with higher probabilities than the maximum reasonably foreseeable accident. The radiological risks from transportation accidents were found to be very low. The analysis of accidents for national transportation of spent nuclear fuel and high-level radioactive waste to a Yucca Mountain Repository is presented in Section 6.2.4.2 of the EIS.

8.10 (7273)
Comment - EIS001832 / 0021
Because the transportation of spent nuclear fuel is a subject of considerable public concern, DOE should put the transportation risk into perspective (as suggested in Comment I) with other non-voluntary risks that might be better understood by the general public. It should be evident, and clearly identified, that the risk associated with the transport of spent fuel as part of the proposed action is small. It may also be useful to put into perspective the less than 1 in 10 million probability of the severe transportation accident evaluated in the analysis (such as comparing it to the chance of a meteor striking a person.

Response
Based on the revised analyses, DOE has concluded in the EIS that casks would continue to contain spent nuclear fuel fully in more than 99.99 percent of all accidents (of the thousands of shipments over the last 30 years, none has resulted in an injury due to release of radioactive materials). This means that of the approximately 53,000 truck shipments, there would be an estimated 66 accidents, each having less than a 0.01-percent chance that radioactive materials would be released. The chance of a rail accident that would cause a release from a cask would be even less.

8.10 (7383)
Comment - EIS001887 / 0325
Impacts of Maximum Reasonably Foreseeable Accident

The Draft EIS underestimates the consequences of a maximum reasonably foreseeable accident. The consequence assessment reported in Table 6-11 considered a cask loaded with 26 year-old PWR SNF [pressurized-water reactor spent nuclear fuel]. The Draft EIS should have evaluated a range of accident scenarios, including a cask loaded with 10 year-old PWR SNF and a range of other critical assumptions, including release height, atmospheric dispersion models, and downwind population densities. Nevada believes that RADTRAN and RISKIND analyses of the same accident involving 10 year-old fuel and other credible alternative assumptions would result in latent cancer fatalities higher by a factor of 2 to a factor of 40 or more, that is, 10 to 200 latent cancer fatalities.

Further, the NRC [Nuclear Regulatory Commission] recently authorized utilities to plan for truck shipments of 5 year Cooled, high enrichment (5 percent), high-burnup (62,000 MWR/MTHM) fuel to Yucca Mountain (Addendum 1 to NUREG-1437), and the discussion at page 6-12 indicates that DOE is not only aware of, but concurs in, the NRC assessment. Therefore, a legally sufficient evaluation of the maximum reasonably foreseeable accident should include a RADTRAN and RISKIND analysis of the same accident involving a GA 4 cask loaded with SNF having the same maximum radiological characteristics approved by the NRC. The human health effects of the same accident could be hundreds of times greater than those reported in Table 6-11.

Response
Based on comments the characteristics of the spent nuclear fuel used in the transportation analyses have been revised. As discussed in Section A.2.1.5 of the EIS, the revised spent nuclear fuel characteristics are

- Pressurized-water reactor -- 15 years old, 50 gigawatt-days per metric ton of heavy metal (MTHM) of burnup, 4.5 percent enrichment

- Boiling-water reactor -- 14 years old, 40 gigawatt-days per MTHM of burnup, 3.5 percent enrichment

These characteristics were derived through a dose-based hazard index analysis using the radionuclide inventory of the assemblies and the screening models in *Screening Models for Releases of Radionuclides to Atmosphere, Surface Water, and Ground* (DIRS 101822-NCRP 1996). These screening models account for all exposure pathways.

The choice of these spent nuclear fuel assembly characteristics was based on a detailed hazards analysis that is discussed in Appendix A of the EIS. A spent nuclear fuel assembly with these characteristics has potentially higher accident consequences than more than 70 percent of the total number of spent nuclear fuel assemblies.

8.10 (7496)
Comment - EIS001576 / 0002
There is an analysis going on at the present time looking at interstates throughout the continental United States and looking at what kinds of obstacles are along the interstates. For instance, bridge abutments. On the interstate highway system a bridge abutment cannot be at 90 degrees from the roadway. It must be sloped away from the roadway and it must be tilted away from the roadway. So those kinds of things would cause glancing accidents, we've looked at those events but what is along that right of way that you could run into that might challenge the cask. So far and they haven't finished this, but they've done those stretches of roadway which were recommended as being the most likely to have these kinds of obstacles. They've come up to the conclusion that given what's alongside the highway that you could run in to, the cask would have to be traveling sideways, because it's got impact limiters on the end, which would abrogate the impact, but it had to be traveling sideways, at a speed of about 120 miles an hour in order to cause the cask to fail in some way. Not to break open, they're not egg shells, but to cause a leakage in some other part of the cask, usually the seals. I don't know about you, I've seen a lot of 18 wheelers going very fast, but I've never seen one going 120.

Response
DOE agrees that cask failure during a truck accident would be unlikely.

8.10 (7831)
Comment - EIS001595 / 0002
America's roads and rails are not reliable enough to bear this lethal load. We in Illinois remember the recent ghastly rail wreck in Bourbonnais where two steel cars compacted to a few feet thick.

Two weeks ago I was on I-80 going out to Omaha and it was littered with overturned semi's from an ice storm that had killed four professional drivers and scattered their loads onto the highway. The system proposed requires perfection and we do not have it. There is weather, there is human error and there is technical error.

Response
As discussed in Appendixes J and M, most real-world accidents that have been postulated, including truck crashes into bridges, train derailments followed by fires, derailments followed by immersion of a cask into a river, and similar extreme accident conditions, would not likely result in release of radioactive materials from the shipping casks. The performance standards for the casks prescribed by the Nuclear Regulatory Commission ensure that less than 0.01 percent of real-world accidents would result in loss of cask integrity and release of radioactivity from the cask. These standards ensure that the casks would be extremely robust.

Adequate roads, highways, rail lines, crossings, bridges, and tunnels exist to support spent nuclear fuel and high-level radioactive waste transportation, which requires no special transportation infrastructure that is not necessary for the safe transportation of commodities in the United States.

As discussed in Section M.3.2.1.4 of the EIS, highway route determination would consider weather. The accident rates used in the EIS to analyze transportation impacts included accidents of all causes, including human errors and technical errors. More details on these accident rates are contained in Section J.1.4.2.3. Risks associated with transportation of radioactive material through Illinois are presented in Table J-82 of the EIS.

8.10 (7955)
Comment - EIS001903 / 0016
Pp. J-60 to J-63. The EIS should include a qualitative discussion of the nature of the maximum reasonably foreseeable accident scenarios. The EIS should also identify the composition and amount of material at risk (i.e., what kind of fuel and how much?) and what release fractions (from Table J-21 to Table J-22) were used.

Response
Section J.1.4.2 of the EIS has been revised to include a description of the maximum reasonably foreseeable accident. As in the U.S. Nuclear Regulatory Commission report *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 152476-Sprung et al. 2000), the description is in terms of cask failure mechanism, impact velocity range, and temperature range for the accident. Other accidents are described in a similar manner in Section 7.2.6 of Sprung et al. (2000). Some of these accidents result in impact velocities and temperatures that exceed the U.S. Nuclear Regulatory Commission cask performance standards in 10 CFR Part 71.

The qualitative description of the accident has been expanded and clarified.

8.10 (7966)
Comment - EIS001791 / 0002
Where I live I've heard the train whistle. I know the patterns of the train whistles as they go past my house and there have been times in the recent past where those train whistles blow constantly and constantly, and I have run up to the track to see what was wrong. The signals are off and there's people crossing the tracks without knowing there's a train approaching, so that kind of potential is possible.

Response
The rail accident data used in the EIS included accidents of all causes, including grade crossing incidents, as discussed by the commenter. More details on the rail accident data are provided in Section J.1.4.2.3 of the EIS.

8.10 (8050)
Comment - EIS002001 / 0003
What will happen to us if a truck gets into a wreck and an explosion occurs? Think of the people in it will hurt or even kill.

Response
The EIS acknowledges that transportation accidents could occur during the transport of radioactive materials to the proposed Yucca Mountain Repository. In Section J.1.4.2.3.2, the EIS estimates that there could be as many as 66 accidents under the mostly legal-weight truck shipping scenario and 8 accidents could occur under the mostly rail scenario. A study recently conducted by the Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000) concluded that only a tiny fraction of all accidents, less than one in 10,000, would be severe enough to result in a release from a spent nuclear fuel shipping cask. The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. Based on these statistics, DOE does not expect an accident to occur that would result in a radiological release and subsequent environmental cleanup.

Although it is extremely unlikely that an accident would occur resulting in functional damage to the cask and a release of radioactivity, the EIS evaluates the consequences of such an accident if it occurred. For example, Table 6-14 provides the estimated impacts of the maximum reasonably foreseeable accident for truck transportation. The highest consequences would occur in an urbanized area resulting in about 0.55 latent cancer fatality. The likelihood of such an accident is very small, about 2.3 in 10 million years. Table 6-15 presents this same data for the mostly rail scenario. The maximum reasonably foreseeable accident for rail transportation would occur in an urbanized area resulting in about 5 latent cancer fatalities. Similar to the truck accident, the likelihood of such a rail accident is very small, about 2.8 in 10 million years.

8.10 (8109)
Comment - EIS001873 / 0006
One worst-case accident scenario for a transportation accident involving highly radioactive waste indicates a 40-square mile area would be contaminated. Nuclear waste accidents have a potential for extremely bad consequences, which must be weighed against their probability of occurrence. In Caliente, the probability of occurrence would appear to be much higher if a transfer depot were located near the city than if train shipments were just passing through.

Response

The EIS acknowledges that transportation accidents could occur during the transport of radioactive materials to the proposed Yucca Mountain repository. In Section J.1.4.2.3.2, the EIS estimates that there could be as many as 40 accidents under the mostly legal-weight truck shipping scenario and 2 accidents could occur under the mostly rail scenario. A study recently conducted by the Nuclear Regulatory Commission (DIRS 152476-Sprung et al. 2000) concluded that only a tiny fraction of all accidents, less than one in 10,000, would be severe enough to fail a spent nuclear fuel shipping cask. The reason for this is the rigorous design, performance, and testing requirements (see 10 CFR Part 71) for spent nuclear fuel and high-level radioactive waste shipping casks. Based on these statistics, DOE does not expect an accident to occur that would result in a radiological release and subsequent environmental cleanup.

However, in response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

Potential accidents at an intermodal transfer station were analyzed in Section J.3.3.1. Because the spent nuclear fuel and high-level radioactive waste would remain within the sealed transportation casks while at the intermodal transfer station, they are not very vulnerable to release from the casks. This analysis found no credible accidents with the potential for release of radioactive materials from the transportation casks being handled at the facility.

8.10 (8154)

Comment - EIS001653 / 0093

Pg 6-41 Maximum Accident-should be based upon shipment miles.

Response

DOE based the probabilities, or frequencies, of the maximum reasonably foreseeable accidents calculated in the EIS on the total shipment miles, as suggested by this comment. With the exception of Nevada, which would host the proposed repository, DOE chose to describe transportation impacts on a national rather than a regional level. The EIS indicates that because transportation impacts on the national level would be low, impacts for individual regions would be lower.

8.10 (8255)

Comment - EIS000817 / 0100

P. 4-59. No matter how you look at it, hauling waste across the country and storing it at Nevada has to bring an increase to cancer and radiation doses. Why risk this? Too many accidents are possible. Some will happen. Human error will be a big concern. This is not a perfect world.

Response

Transporting spent nuclear fuel and high-level radioactive waste across the country could result in a slight increase in radiation doses and cancer rates for people along the transport routes. In Section 6.2.3 of the EIS, DOE has estimated that there could be up to 1.6 to 2.5 latent cancer fatalities from the routine shipping of spent nuclear fuel and high-level radioactive waste by legal-weight trucks and by rail. Transportation accidents, including those caused by human error, were examined in the EIS. In Section 6.2.4, DOE estimated that there is a 2.3 in 10 million probability per year of a maximum foreseeable truck accident. Should the accident occur, there could be about 0.55 latent cancer fatality in the exposed population. For perspective, there would be about 220,000 cancer fatalities in a population on 1 million along the transport routes from other causes besides the transport of spent nuclear fuel and high-level radioactive waste.

8.10 (8291)

Comment - EIS001575 / 0001

As we try to do this plan of taking nuclear waste and moving it all across the country, it's like a standardized McDonald operation, every truck will be the same, every driver will be the same, I'm sure there won't be any variables. Well, I just wrote down a few variables. Who makes the trucks? Are they always exactly the same?

60 minutes or 20/20 just had a program that said about licensing of drivers. It said that they have no information about drivers, they don't have anything about their records, they don't have anything about their mental states, there's 10,000 variables. We see bus drivers go off the road because they have a heart condition. We see two basketball players going 100 miles an hour and one of them doesn't even have a license and one of them does. There's so many variables in this thing. What happens if weather comes, black ice? What if two kids in Lakewood, playing around with a crowbar on one of those rail tracks decide just to move one a little bit? It's just a little bit of vandalism, it isn't gonna matter at all. Poor people here in Lakewood, they thought they had it so well because Mayor White is going to eliminate the sirens through their town. It's going to be awful quiet as it goes through Lakewood in a tough density place with nuclear waste going through there. So then once the sirens are quiet, who knows what can happen.

Response

As stated in Section 2.1.3.2 of the EIS, DOE would comply with all applicable regulations of the U.S. Department of Transportation and the Nuclear Regulatory Commission. At this time, many years before shipments could begin, DOE does not know who would make the trucks used to transport spent nuclear fuel. However, all trucks would have to pass the Commercial Vehicle Safety Alliance enhanced safety inspection, which includes a radiological survey and stringent examination of all driver, vehicle, and hazardous material requirements. DOE knows how it would acquire Regional Servicing Contractors, and the protocols and processes to which these contractors would be held (see Section M.3). These protocols are based on Department of Transportation and Nuclear Regulatory Commission regulations and the successful experience achieved during the Waste Isolation Pilot Plant transportation activities.

The accident analysis includes a description of the consequences of a severe accident that would result in a leak in a transportation cask, although that is an extremely unlikely event [an annual probability of 1.4 (rail) to 1.9 (truck) in 10 million]. Transportation safety related to potential release of radioactive materials is primarily based on the integrity of shipping cask. The leaking of a transportation cask could only occur if mechanical forces (impact) and heat (fire) exceeded the design limits of the transportation cask structures and materials. Additional information on the safety and test of transportation casks is provided in Section M.4 of the EIS. The accident analyzed in the EIS is believed to cover accidents from all sources including heat, mechanical impacts, sabotage, impacts from airplanes and weapons, and mountain rollovers.

Truck drivers would have to meet physical standards, have a commercial driver's license, and successfully complete a road test. Drivers would be trained on the properties and hazards of spent nuclear fuel and high-level radioactive waste as well as on the procedures to follow in the event of an emergency. Drivers would also have training in the use of radiation detection instruments, use of communications and satellite tracking equipment, inspection procedures, and adverse weather procedures. The Nuclear Regulatory Commission regulations also address human behavior as discussed in Section J.1.4.2.1 of the EIS.

8.10 (8321)

Comment - EIS001963 / 0003

The DEIS should clearly and accurately explain the risks involved along the transportation routes. It should also use the most current information to do so. It should also include site-specific data to show the effects of accidents in populated areas.

Response

DOE believes that the EIS adequately analyzes transportation-related impacts that could result from the Proposed Action. DOE also believes that the EIS provides the information necessary to make decisions on the basic approaches to transporting spent nuclear fuel and high-level radioactive waste (either rail or truck shipments), as well as the choice among alternative rail corridors in Nevada, if the site is approved. The reader is referred to the introduction to Chapter 8 of the CRD for additional information.

At this time, many years before shipments could begin, it is impossible to predict with a reasonable degree of accuracy which highway or rail lines would be used. For example, in the interim, state or Native American tribal governments may designate alternate preferred highway routes and new highways and rail lines could be constructed or modified. Therefore, for purposes of analysis in the EIS, DOE identified representative highway routes in accordance with U.S. Department of Transportation regulations, which require the use of preferred routes (Interstate System highway, beltway or bypass, and state or tribal designated alternate route). DOE identified rail lines based on current rail practices, as there are no comparable Federal regulations applicable to the selection of rail lines for the shipment of radioactive materials. In response to public comments, DOE has included in the EIS maps of representative highway routes and rail lines that were used for the EIS analysis (see Figures 6-11 and 6-12).

The analysis is route-specific to the extent needed to support the decisions to be made on the basis of the information contained in this EIS. For example, the analysis considered route-specific shipping distances and population data as well as state-specific truck accident rates. The most recent publicly available data was used in the analysis. The use of additional location-specific data such as the commenter suggests would not materially affect the comparisons of alternatives and decisions to be made with regard to construction and operation of the proposed repository. The requested analysis could provide useful information for identifying and quantifying differences between alternative routes; however, DOE does not intend to designate preferred routes based on the EIS. Rather, this would occur in the future, and would be conducted in accordance with U.S. Department of Transportation routing guidelines. The preferred routes would be submitted to the Nuclear Regulatory Commission for approval. DOE would consider location-specific data during the route selection process.

8.10 (8325)
Comment - EIS001572 / 0002
Living close beside an interstate in Toledo on the emergency vehicle entry route, I've noticed an increasing frequency of accidents on that interstate. I suggest a review of the -- and greater definition of the projections of future accident frequencies going into the calculation.

Response
Recent state-specific accident rates were used in the accident analyses for the EIS. In addition, accident rates were one of the primary route selection factors identified in the U.S. Department of Transportation report *Identification of Factors for Selecting Modes and Routes for Shipping High-Level Radioactive Waste and Spent Nuclear Fuel* (DIRS 103718-DOT 1998).

8.10 (8383)
Comment - EIS001873 / 0066
P. 6-96. Accident risks are not the same for the different routes, which should be obvious. Accident risks should be higher in the intermodal transfer area.

Response
The comment correctly points out that a statement in Section 6.3.3.1 of the Draft EIS that "…accident risks … would be the same among the Nevada heavy-haul truck transportation implementing alternatives…" is incorrect and not consistent with the data listed in Table 6-55. DOE has corrected this in the Final EIS.

There are no data to support the statement that "Accident risks should be higher in the intermodal transfer area." Accident risks, however, would be proportional to the number of operations and shipment miles.

8.10 (8414)
Comment - EIS001873 / 0077
P. 9-17. Having identified the potential for contamination of surface water, DOE must explain how they would clean up the Meadow Valley Wash after a worst case accident near the Caliente intermodal site and what that would cost.

Response
An accident that resulted in contamination of the Meadow Valley Wash near the Caliente intermodal site would be extremely unlikely. Spent nuclear fuel and high-level radioactive waste would be transported in very robust casks, designed to withstand the impact forces and fires that could be associated with very unlikely transportation

accidents. The forces associated with handling accidents at the intermodal site would be far less severe than the design and performance standards for the casks. Potential accidents at an intermodal transfer station are evaluated in Section J.3.3.1 of the EIS. No credible scenarios were identified that would likely result in a release from the casks.

Environmental Impact Statements are not required to analyze "worst-case" accidents. Rather, EISs analyze those accidents that are reasonably foreseeable. According to Section 6.4 of *Recommendations for the Preparation of Environmental Assessments and Environmental Impact Statements* (DIRS 104601-DOE 1993), these are accidents with probabilities in the range of 1 in a million to 1 in 10 million per year. The consequences of severe accidents are presented in Sections 6.2.4.2.1 and 6.2.4.2.2 of the EIS. For the maximum reasonably foreseeable truck accident, the probability would be about 2.3 in 10 million per year, and for a maximum reasonably foreseeable rail accident, the probability would be about 2.8 in 10 million per year. A transportation accident near Meadow Valley Wash, such as the maximum reasonably foreseeable accident accidents analyzed in Chapter 6, would not be reasonably foreseeable because its probability would be less than 1 in 10 million per year.

In response to public comments, DOE has included a discussion on the range of potential costs of cleanup following a severe transportation accident in Appendix J of the EIS. This discussion reviews calculations of land area contaminated and costs for cleanup presented in past studies, including a report used in the 1986 Environmental Assessments (DIRS 154814-Sandquist et al. 1985), and information submitted by the State of Nevada in its comments on the Draft EIS. The information submitted by the State included estimates of cleanup costs as high as $270 billion. Cost data used in the studies reviewed in Section J.1.4.2.5 included data compiled from case studies involving actual cleanup of radioactive materials contamination. The studies address consequences for releases of radioactive materials in communities.

Comment - EIS001887 / 0435
Use of data from the Modal Study to estimate accident severities and probabilities of severe accidents

1.1. Use of "mid-lead" temperature as parameter determining accident severity

1.1.1 Lead (MP 621 degrees F) will stabilize the inner core temperature in the event of a fire until it is completely melted. This has the affect of insulating the inner core from temperature increases for an extended period of time. Uranium, with a much higher melting point, will not melt, resulting in an inner core temperature that will rise constantly with heat input; therefore, inner cores of newer casks are expected to have higher temperatures during a fire of a given intensity.

1.1.2. The use of mid-lead temperature results in grouping of all fires with temperature greater than 1050 degrees F into one consequence category, since lead-nickel alloying occurs here, weakening the integrity of the older casks. Since uranium and/or stainless steel will behave differently under temperature duress, new classifications based on its properties must be used for categorizing fire intensities.

1.2. Use of "reference cask" containing a water jacket neutron shield

The Modal Study models the dead air space resulting from the evaporation of the water jacket neutron shield to reduce the heat transfer rate from a fire to the cask by over 70%. Modern casks use polypropylene, not water jackets; hence the estimated heat transfer rate in fire events is a significant underestimate of the behavior or modern casks (Audin states this may result in a reduction in the time it takes to melt the lead cask from 1.09 hours to 20 minutes).

1.3. "Lead cask bias" used to select most appropriate measurement parameter

The decision to use strain on the inner cask wall as the primary measure of cask response is based on lead's tendency to "slump" when subjected to high loading, resulting in high strains on inner cask wall. However, uranium and/or stainless steel, is strong and rigid and thus will not slump. Rather, the force from impacts will be transferred to the joints and welds of the cask, likely resulting in a greater force being applied to them that those in a lead cask. The choice of strain as the sole measurement parameter for physical duress will likely lead to an underestimation of the damage caused to newer casks through picture of welds and seals in the event of an accident. Therefore, new experiments must be performed to model this behavior.

1.4. Incorrect use of “distribution” and “frequency” of velocities

The EIS states that, even though the average speed limit on national interstates has increased since the Modal Study, the distribution of accidents, and the frequency distribution of accidents, on the highways is not likely to change. However, no evidence is cited to support this statement. The National Highway Safety Traffic Administration (NHTSA 1998), along with numerous other agencies, have provided evidence that increases in speed limit lead to more accidents, more fatalities, and a greater proportion vehicles traveling at higher speeds. All of these suggest that the DOE is incorrect in claiming that increased speed limits will not affect accident severity distributions. In one study assessing the change in Interstate fatalities in states which raised the speed limit in 1995, the NHSTA discovered that “Interstate fatalities experienced a statistically significant increase in those states that raised their posted speed limits late in 1995 or early in 1996.” (NHTSA 1998) Further, the Insurance Institute for Highway Safety reported that distributions of travel velocities do indeed change with increased speed limits. For example, the Institute cited traffic statistics in New Mexico, finding that “the proportion of motorists exceeding 70 mph grew from 5 percent shortly after speed limits were raised [from 55 to 65 mph] to 36 percent.” (Institute). This shows that the EIS’s statement that traffic velocity distributions will not be affected is incorrect, which leads to the conclusion that the probabilities of severe accidents used by the EIS are also incorrect and likely to be underestimates. This provides another reason why the Modal Study is not useful or relevant to current transportation conditions.

1.5. Improper assumptions regarding the location of severe accidents

The Modal Study correlated severe accidents with high velocities, concluding that the most severe accidents will take place, both for rail and truck, in rural environments. However, most severe rail accidents take place at downgrades, which are as likely to be located in suburban areas as rural ones. Further, the probability of a severe truck fire is greater in urban and suburban environments then it is in rural ones. Refer to Resnikoff, 1993.

In determining severe accident scenarios, the EIS assumed that severe accidents had an equal probability of occurring anywhere, with the probability in each population zone being determined by the length of time each truck or train passes through it. Since trucks and trains spend less time in urban zones, some of the most severe accident scenarios are considered “not reasonably foreseeable” in urban areas. Accident data does not support the assumption that severe accidents are randomly distributed (Resnikoff, 1993). Therefore, the DOE needs to assess the consequences of these most severe accidents as occurring in urban zones.

1.6. Improper Exclusion of most severe accident scenarios

1.6.1. The Modal Study used as its “average highway conditions” a stretch of Interstate 5 in Los Angeles and Orange counties. For example, it tallied the number, height, and geographic conditions of the bridges on this stretch and used these to estimate the number of bridges of a certain height. This was then used to estimate how many tall bridges existed in the entire nation for spent fuel trucks to cross. Using this, it was determined that an accident involving a truck falling off a high bridge was not “reasonably foreseeable” and its consequences were not determined. Since this stretch of highway is dominated by urban areas, the distribution of bridge types is biased in favor of small, short bridges, like the ones that cross over other roads. This is not representative of national conditions and leads to the unnecessary exclusion of a potentially disastrous consequence.

1.6.2. The Modal Study assumes that the probability of train accidents involving the falling off of a bridge is the same as that for the highway scenario, with the geographic conditions also taken from the highway estimations. More clearly, the Study used data taken from Interstate 5 to estimate the geographic conditions of national train routes, including bridge heights. Thus, the same argument given for the highway scenario (point 1.5.1) holds here, but more so since there is no proof that highway and rail conditions are similar.

1.6.3. The method of rejecting accidents having a yearly probability less than one in 10 million is arbitrary and incorrect when performing a probabilistic risk assessment. The product of the probability and the likely consequences are what determine significance in a risk assessment.

1.6.4. DOE consistently offers estimations of health effects due to transportation without giving a range of likely effects in the event of an accident. This is based on the assumption that the effects given are “conservative.” However, the points raised here show that the studies are not conservative: unless new studies are performed, a range of possible health effects should be given.

1.6.5. If the DOE insist on using the “reasonably foreseeable” criteria of 1 in 10 million mentioned above, improper accident distribution data, unknown cask response to accident conditions, and improper estimation of accident probabilities (all mentioned above) will make some circumstances not deemed “reasonably foreseeable” in the Modal Study “reasonably foreseeable.” These events must be considered in any acceptable consequence analysis.

Response

General: At the time the Draft EIS was published, DOE considered *Shipping Container Response to Severe Highway and Railway Accident Conditions* (DIRS 101828-Fischer et al. 1987; also called the Modal Study) to contain the best available information regarding spent nuclear fuel shipping cask performance under severe accident conditions. However, the Nuclear Regulatory Commission recently published *Reexamination of Spent Fuel Shipment Risk Estimates* (DIRS 154276-Sprung et al. 2000), which contains additional information regarding spent nuclear fuel transportation accidents, including the use of different shipping cask designs than the representative steel-lead-steel cask used in Fischer et al. (DIRS 101828-1987). This study addresses, in part, the criticisms of the Modal Study that are summarized by the commenter. Because Sprung et al. (2000) provides more recent information and is based on the most recent shipping cask designs (including steel/lead/steel, steel/depleted uranium/steel, and solid monolithic steel designs), DOE has conducted an analysis using the information from Sprung et al. (2000). The results of this analysis are presented in Appendix J of the EIS and show that the impacts estimated in the EIS using Fischer et al. (1987) exceed the impacts estimated using Sprung et al. (2000). As a consequence, the Draft EIS overestimated the impacts of spent nuclear fuel transportation accidents and the Final EIS contains more realistic estimates.

Comments 1.1.1 and 1.1.2. These comments have been addressed by Sprung et al. (DIRS 152476-2000), which considers the performance of depleted uranium shielded and monolithic steel shipping cask designs subjected to severe fire conditions.

Comment 1.2. This comment, which is about the neutron shield material assumptions in the thermal analysis, is addressed specifically in Sprung et al. (DIRS 152476-2000). Section 6.5 of that document states that the neutron shield region was set to change instantaneously at the start of the fire from water to air in the transient thermal analysis. This causes the inner surface of the neutron shield to reach fire temperature very rapidly. If water or solid hydrogenous materials were present in the neutron shield region, it would absorb thermal energy and slow the heatup of the inner regions of the shipping cask. Thus, the assumption of an air-filled neutron shield region is conservative in relation to assuming water or solid hydrogenous materials are present in this region.

Comment 1.3. This comment has been addressed by Sprung et al. (DIRS 152476-2000), which considers the performance of depleted uranium shielded and solid monolithic steel shipping cask designs subjected to severe impact conditions.

Comment 1.4. DOE was unable to identify recent studies that could be used to quantify the effects of increased Interstate System highway speeds on traffic accident rates or severities. However, on a national basis, the fatality rate in 1999 for all motor vehicle accidents remained at historically low levels, the same as 1997 and 1998 fatality rates, and lower than the rates from 1989 to 1996. Fatality rates in 1999 were lower for all vehicles and for large trucks than they were in the early 1990s, before the Interstate Highway System speed limits were increased. This information was obtained from BTS (DIRS 148081-1999). Although there are other factors that contribute to the trends in fatality rates, such as increased use of seat belts, increased legal drinking age, and reduced blood alcohol content restrictions, the increased Interstate System highway speed limits have not had a dramatic effect on national fatality rates for all vehicles or for large trucks alone. In addition, a significant change in highway fatality rates could affect the magnitude of the impacts calculated but would not have a significant effect on the comparisons among alternatives or on identification of the preferred national or Nevada transportation alternatives.

The Nuclear Regulatory Commission is currently designing a program to further evaluate spent nuclear fuel shipping cask integrity in the "Package Performance Study." The planned study, which is scheduled for completion in 2004, will provide an updated evaluation of the level of safety provided by spent nuclear fuel transport packages under a variety of railway and highway accident conditions.

Comment 1.5. The analysis of the likelihood and consequences of maximum reasonably foreseeable accidents is presented in Section J.1.4.2.1 of the EIS. The National Environmental Policy Act requires assessment of reasonably foreseeable impacts from proposed agency actions. In its various EISs, DOE has defined a reasonably foreseeable accident as one that has a frequency of occurrence of at least once in 10 million years (1×10^{-7} per year). The concept of a maximum reasonable foreseeable accident is sometimes misinterpreted as being a "worst-case" accident. A worst-case accident would be one in which conservative assumptions were used to maximize the consequences, such as worst-case weather, 100-percent release of shipping cask contents, highest population density, etc. Such "compounded" conservatisms yield unrealistic results for an accident scenario that is not credible. Consistent with Council on Environmental Quality regulations (40 CFR 1502.22), DOE is attempting to avoid compounding conservatisms, yielding unrealistic results, in analyzing environmental impacts. Such practices mask the real differences and would not produce suitable results to support choices among the alternatives. DOE believes that the impacts presented in the EIS are bounding, yet not so conservative that the true differences among alternatives are masked.

The commenter is incorrect in asserting that the EIS did not evaluate the consequences of maximum reasonably foreseeable accidents in urban areas. In Section J.1.4.2.1 of the EIS, the consequences of maximum reasonably foreseeable accidents are listed for both urban and rural areas.
