AVAILABILITY OF REFERENCE MATERIALS IN NRC PUBLICATIONS

NRC Reference Material

As of November 1999, you may electronically access NUREG-series publications and other NRC records at NRC's Public Electronic Reading Room at http://www.nrc.gov/reading-rm.html. Publicly released records include, to name a few, NUREG-series publications; *Federal Register* notices; applicant, licensee, and vendor documents and correspondence; NRC correspondence and internal memoranda; bulletins and information notices; inspection and investigative reports; licensee event reports; and Commission papers and their attachments.

NRC publications in the NUREG series, NRC regulations, and *Title 10, Energy*, in the Code of *Federal Regulations* may also be purchased from one of these two sources.

1. The Superintendent of Documents
   U.S. Government Printing Office

Abstract

Characteristics of tornadoes reported in the contiguous United States from January 1950 through August 2003 have been used to determine tornado strike probabilities and maximum wind speeds for use in nuclear power plant design. Maps have been prepared that show the distribution of tornado events and design wind speeds. Appendices contain the number of tornadoes and estimates of strike probabilities and maximum wind speeds by 1°, 2°, and 4° latitude and longitude boxes.

The methods used in this analysis are identical to those used in the analysis leading to publication of the tornado climatology in NUREG/CR-4461, Rev. 1. The primary difference between the climatology presented here and the climatology in Rev. 1 is that wind speed estimates in this climatology are based on the Enhanced Fujita Scale that correlates wind speeds with damage caused by tornadoes. These wind speeds are significantly lower than the wind speeds in the original Fujita Scale. A second difference is that the wind speeds in the Enhanced Fujita Scale are nominally 3-second average wind speeds, whereas the wind speeds in the original Fujita Scale were nominally the fastest quarter-mile wind speeds. The National Weather Service intends to implement the Enhanced Fujita Scale by February 2007.

The results of this analysis indicate that a maximum wind speed of about 230 mph is appropriate for tornadoes with a best estimate probability of 10^{-7} per year for the central portion of the United States; a maximum wind speed of 200 mph is appropriate for a region of the United States along the east coast, and the western great plains; and a maximum wind speed of 160 mph is appropriate for the western United States. Corresponding wind speeds in NUREG/CR-4461, Rev. 1, were 300 mph, 260 mph, and 200 mph, respectively.

FOREWORD

The Nuclear Regulatory Commission is revising Regulatory Guide 1.76, "Design Basis Tornado for Nuclear Power Plants." (The revision also includes information about tornado missiles and is entitled "Design-basis Tornado and Tornado Missiles for Nuclear Power Plants.") The present report, NUREG/CR-4461, Rev. 2, was written to support this effort, and is based on much more tornado data than the data used in support of the original version of Regulatory Guide 1.76, which was published in 1974. The present report uses data on tornadoes which were reported in the contiguous United States from January 1950 through August 2003, 50.67 years of data. Moreover, the methodology was changed by including a term to account for the finite dimensions of structures, and by accounting for the variation of wind speeds along and across the tornado footprint. In these respects, the present report is similar to Revision 1 of this report, published in April 2005. The major difference between the present report and NUREG/CR-4461, Rev. 1, is that wind speed estimates in the present report are based on the Enhanced Fujita Scale that correlates wind speeds with damage caused by tornadoes, while the wind speed estimates in NUREG/CR-4461, Rev. 1, were based on the original Fujita Scale. The Enhanced Fujita Scale was approved for use in February 2006, and it is scheduled for implementation in February 2007. The wind speed estimates based on the Enhanced Fujita Scale are considerably lower than those based on the Fujita scale.

One of the defining characteristics of the design-basis tornado is that its frequency of exceedance is 1×10^{-7} per year. The contiguous United States is divided into three regions. Using the results of the present report, the maximum wind speed of the design-basis tornado in Region I is 230 mph, in Region II is 200 mph, and in Region III is 160 mph. The original version of Regulatory Guide 1.76 also used three regions, but these regions did not coincide with the regions now used. The region of the original version of this guide with the highest design-basis tornado wind speed had a design-basis wind speed of 360 mph. This is to be contrasted with the current highest design-basis tornado wind speed of 230 mph.

Executive Summary

A revised tornado climatology for the contiguous United States (NUREG/CR-4461, Rev. 1) published in April 2005 summarized tornado information reported for the contiguous United States based on information for more than 46,800 tornado segments occurring from January 1, 1950, through August 2003. More than 39,600 of these segments had sufficient information on location, intensity, length, and width to be used in the analysis presented in the report.

Subsequently, the National Weather Service announced that in February 2007 it intends to switch from using the Fujita Scale, which relates damage caused by tornadoes to tornado wind speeds, to using the Enhanced Fujita Scale. Included in this switch are 1) changing the averaging interval for wind speed estimates from the fastest quarter-mile wind speed to a maximum 3-second average wind speed, 2) changing the minimum tornado wind speed from 40 mph to 65 mph, and 3) changing the wind speed intervals associated with each F Scale class.

This report examines the implications of switching from the Fujita Scale to the Enhanced Fujita Scale on design wind speed estimates for tornadoes. The first two of the changes tend to increase design wind speeds; however, the increases in wind speeds associated with these changes are small compared with the decreases in wind speed associated with the changes in wind speed intervals. The net effect of the changes is a reduction of design wind speed of 50 to 70 mph in large portions of the United States.

Specifically, Chapter 5 of this report has been revised to show 10^{-5}, 10^{-6}, and 10^{-7} yr^{-1} probability design wind speeds for the contiguous United States estimated using the January 1950 through August 2003 database and the Enhanced Fujita Scale. Chapter 6 has been revised to show the potential changes in design wind speed for nuclear power plant sites and for various cities throughout the country.

Characteristics of tornadoes that are not related to wind speed are not affected by switching to the Enhanced Fujita Scale. Consequently, the characteristics summarized in Chapter 2 of this report are not changed from the previous report. The summary for the contiguous United States is followed by separate summaries for western, central, and eastern regions of the United States. Each summary includes the number of events, and the median, average, and expected values for length, width, and area. In addition, the summaries include the lower and upper limits for the 90 percent confidence intervals for the expected values. Lognormal distributions were assumed for tornado event lengths, widths, and areas in calculation of the expected values and the confidence intervals for the expected values.

Chapter 3 of the report evaluates two potential adjustments to the data. The average number of tornadoes reported each year has been increasing since at least 1950. The NCDC data confirm this trend but indicate that the increase is limited to the least intense tornadoes. Evaluation of the consequences of unreported tornadoes in Chapter 3 suggests that the unreported tornadoes may be neglected without a significant effect on estimates of strike probabilities or maximum wind speeds. As a result, no attempt is made to account for unreported tornadoes. Variation of the maximum wind speed along and across the tornado footprint is discussed, and the method used to account for this variation is described. Small numerical changes have

been made in the factors used to account for the variation of wind speed across the tornado footprint that are related to switching to the Enhanced Fujita Scale, but the method of accounting for the variation of wind speed along and across the footprint is otherwise unchanged.

Chapter 4 describes the methods of estimating the tornado strike probabilities and the conditional probability that the maximum wind speed will exceed a specified value assuming that a tornado strike occurs. Methods are described for point structures and for finite-sized structures. The methods used for point and finite structures are the same as in the analysis NUREG/CR-4461, Rev. 1.

Maximum wind speed estimates are presented in Chapter 5 and in Appendices A, B, and C. The distribution of maximum wind speed estimates are presented for large regions and by 1°, 2°, and 4° latitude and longitude boxes. The wind speed patterns shown in the figures in Chapter 5 are similar to the patterns presented in the initial version of NUREG/CR-4461, but the wind speeds are generally significantly lower.

Chapter 6 presents a comparison of tornado wind speeds estimated assuming the Enhanced Fujita Scale with those estimated assuming the original Fujita Scale. Two sets of comparisons are presented. The first is for United States nuclear power plant sites, and the other is for representative cities throughout the United States.

Chapter 7 discusses sources of uncertainty in the analysis. The first part of the chapter considers the uncertainty associated with the model used to characterize tornado footprints. Next, the chapter discusses uncertainty in the estimation of tornado characteristics. The length, width, and intensity of a tornado are estimated subjectively from damage caused by the tornado and are all subject to error. Two methods for adjustment of data to account for potential errors in classification of tornado intensity are discussed. They are shown to alter some of the basic tornado statistics, such as total area impacted by and total length of tornadoes, and are therefore rejected for this study. Four relationships between damage classification and maximum wind are discussed. Finally, the uncertainty associated with the statistical variation in tornado dimensions and intensity is discussed. The source of uncertainty is also dealt with in Chapter 2 and is considered in assigning confidence intervals to strike probabilities and maximum wind speeds.

Finally, Chapter 8 provides recommendations on design criteria for tornadoes should the NRC staff choose to implement the Enhanced Fujita Scale. These recommendations are based on the maximum wind speeds for the 2° boxes, but also consider the number of tornadoes and population density. For the 10^{-7} yr^{-1} probability level, a design wind speed of 230 mph is recommended for a large region in the central United States; a design wind speed of 200 mph is recommended for the western portion of the Great Plains and for the east coast; and a design wind speed of 160 mph is recommended for the western United States. The corresponding wind speeds recommended in NUREG/CR-4461, Rev. 1, based on the original Fujita Scale were 300 mph, 260 mph, and 200 mph, respectively.

Acronyms, Abbreviations, and Symbols

a_l	scale parameter for the Weibull distribution function for the conditional life-line strike probability
a_p	scale parameter for the Weibull distribution function for the conditional point strike probability
A_r	area of a region of interest, e.g., the contiguous United States, or the area of a 2° latitude and longitude box
A_t	total area impacted by tornadoes within a region of interest in N years
$A_{u \geq u_o}$	tornado impact area with wind speed, u, greater than some threshold speed, u_o
AEC	U.S. Atomic Energy Commission
b_l	shape parameter for the Weibull distribution function for the conditional life-line strike probability
b_p	shape parameter for the Weibull distribution function for the conditional point strike probability
EF	Enhanced Fujita Scale relating tornado damage and estimated maximum wind speed
E(x)	expected value of a variable x
Exp(x)	exponential of x, i.e., e^x
F	Fujita Scale relating tornado damage and estimated maximum wind speed
f(x)	probability density function for a variable x
ft	feet
$L_{u \geq u_o}$	total tornado path length in a region of interest with wind speed, u, greater than some threshold speed, u_o
L_t	total tornado path length in a region of interest regardless of wind speed

Lat.	latitude
Long.	longitude
LLNL	Lawrence Livermore National Laboratory
mi	miles
mph	miles per hour
N	number of years of tornado record used to determine A_t
NCDC	National Climatic Data Center
P_l	finite-structure strike probability for a tornado, regardless of wind speed
$P_l(u \geq u_o)$	finite-structure strike probability for a tornado with a wind speed, u, greater than some threshold speed, u_o
$P_l(u \geq u_o \mid s)$	conditional finite-structure strike probability for a tornado with a wind speed, u, greater than some threshold speed, u_o, assuming that a strike occurs
P_p	point-structure strike probability for a tornado, regardless of wind speed
$P_p(u \geq u_o)$	point-structure strike probability for a tornado with a wind speed, u, greater than some threshold speed, u_o
$P_p(u \geq u_o \mid s)$	conditional point-structure strike probability for a tornado with a wind speed, u, greater than some threshold speed, u_o, assuming that a strike occurs
TorBoxes	computer program used for regional tornado analyses
TorStrk	computer program used for site-specific tornado analyses
u_o	threshold wind speed or wind speed of interest
V[w]	variance of a variable w
w_s	characteristic horizontal dimension of a finite structure, assumed to be 200 ft for this analysis
yr	year

1.0 Introduction

Among the missions of the U.S. Nuclear Regulatory Commission (NRC) is the protection of public health and safety and the environment from the effects of radiation from nuclear reactors, materials, and waste facilities. In performing this mission, the NRC evaluates the consequences of events external to nuclear facilities that may lead to release of radioactive materials to the environment. Tornadoes are among the external events of interest.

Current NRC guidance on tornado characteristics for consideration in the design of nuclear power plants is found in Regulatory Guide 1.76 (AEC 1974). This guidance is based on a summary of information from a variety of sources called WASH-1300 (Markee et al. 1974). In the initial version of NUREG/CR-4461, Ramsdell and Andrews (1986) summarized data on tornadoes that occurred from January 1954 through December 1983 and were listed in a tornado database maintained by the National Severe Storms Forecast Center.

Revision 1 of NUREG/CR-4461 updates the 1986 report using tornado data collected from January 1, 1950, through August 2003. It contains statistics on tornado dimensions and wind speeds by region of the country, and estimates of strike probabilities and design wind speeds by boxes with sides of 1°, 2°, and 4° of latitude and longitude. Following completion of NUREG/CR-4461, Rev. 1, the NRC staff prepared a draft Regulatory Guide (DG-1143) to update Regulatory Guide 1.76 to reflect more recent tornado data and published it for comment on February 2, 2006. At about the same time, the National Weather Service decided to use the Enhanced Fujita Scale relating tornado damage to maximum wind speed beginning February 1, 2007. Significant public comment on DG-1143 suggested that the update to RG-1.76 be based on the Enhanced Fujita Scale rather than the original Fujita Scale (TTU 2006; NOAA 2006).

This report examines the effects on tornado characteristics of changing from the original Fujita Scale to the Enhanced Fujita Scale. Those characteristics that are not an explicit function of wind speed, such as the number of events, distribution within the United States, footprint length and width, and strike probability, are not affected by switching to the Enhanced Fujita Scale. On the other hand, those characteristics that are directly related to wind speed, such as the probability of exceeding a given wind speed at a point should the point be struck by a tornado, are significantly impacted by the switch. The report does not examine other implications of the switch that could result from reduction of tornado design wind speeds, such as the possible increase in importance of winds associated with hurricanes.

The characteristics of tornadoes in the contiguous United States are presented in Chapter 2, along with the particular characteristics of the western, central, and eastern regions. Chapters 3 and 4 discuss methodological issues: Chapter 3 focuses on possible adjustments to the available data, and Chapter 4

describes methods used here for estimating strike probabilities and maximum wind speeds for point structures and structures of finite dimensions. Chapter 5 gives results of the analysis, and Chapter 6 compares maximum wind speeds estimated using the Enhanced Fujita Scale with estimates made using the original Fujita Scale. Chapter 7 discusses uncertainty in the data and the analysis. Finally, Chapter 8 suggests structural design criteria by region, considering the numbers of tornadoes, maximum wind speed estimates, and population densities, should the NRC staff choose to implement the Enhanced Fujita Scale.

2.0 Tornado Data

The tornado database used to prepare the initial version of NUREG/CR-4461 was maintained by the National Severe Storms Forecast Center in Kansas City, Missouri, which is operated by the National Weather Service. Since then, the responsibility for maintaining the list of tornadoes has been transferred to the National Climatic Data Center (NCDC) in Asheville, North Carolina. The statistics for tornadoes striking the contiguous United States are now included in the storm events data base maintained by the NCDC.

In February 2004, a copy of the database was obtained from NCDC for use in updating NUREG/CR-4461. The database, which covers the period from January 1, 1950, through August 31, 2003, contains entries for 46,864 tornado segments. A tornado segment is a portion or all of a tornado. Prior to 1996, tornadoes were divided into segments when they entered or left a county in which there was an injury or fatality, or when they crossed a state boundary. Since 1996, tornadoes are now divided into segments when they cross a state or county line, when there are skips not exceeding 2 miles or 4 minutes travel, and when they have a sharp change in direction. Only about 10 percent of the tornadoes have more than one segment. Division of tornadoes into segments does not have a significant effect on the results of the analysis that follows.

Among the statistics included in the database for tornadoes are date, time, location, length, width, and maximum intensity (wind speed). Of these statistics, the most useful are the location, length, width, and maximum intensity. If these four elements are present, data for the event can be used in all aspects of the analysis. If the location and intensity are listed, the tornado will not be used in estimating tornado dimensions, but it will be counted and used in estimating strike probabilities.

The area of the tornado footprint used in the analysis is the product of the path width and length. The widths reported for tornado segments prior to 1994 were the mean path width. These widths are the appropriate widths for use in estimating the footprint area. Since 1994, the maximum path width has been reported. This change in definition of the width results in overestimates of the footprint area for the more recent tornadoes. No corrections have been applied to the widths reported since 1994 to account for the change in definition. As a result, widths of recent tornadoes provide a conservative bias to the estimates of strike probability in this analysis.

The data contained in the database are made available by the NCDC without warrantee, i.e., the information compiled in the database comes from several of sources with varying levels of reliability and much of the information about the tornadoes is based on subjective judgement. In the course of working with the data for this report, several inconsistencies (fewer than 20) were noted. For example, in several instances the reported lengths of tornado segments were inconsistent with the reported positions of the beginning and end points of the tornado segments. Elsewhere, the latitude and longitude of tornado segments were not consistent with the reported county and state. In these instances, the latitude and longitude of the starting point of the tornado were generally assumed be correct, unless they were unreasonable, e.g., in the middle of the Pacific Ocean. When the length of a tornado segment was

inconsistent with distance between the beginning and end points of the segment, the latitude and longitude of the beginning point, and the length were assumed to be correct. Overall, the database is in reasonably good condition and acceptable for use in this climatology.

2.1 Tornado Intensities

Most of the statistics in the database related to tornadoes are self-explanatory. The exception is the tornado intensity. The tornado database does not include estimates of the maximum wind speeds in tornadoes. However, it does include an estimate of tornado intensity in the form of an intensity scale that is based on the damage caused by the tornado. The most common tornado intensity scale developed by Fujita (1971, 1978) classifies tornado intensity in six F Scale classes, F0 to F5. Wind speeds are rarely measured by meteorological instruments. Instead, they are estimated from damage associated with the tornado. The range of wind speeds assigned to classes by Fujita is listed in Table 2-1. This range been extended from F5 through F12, which has the speed of sound as its upper limit (NCDC 2004). However, no tornado has been assigned an intensity of F6 or greater, and, because of the imprecision in estimating F-scale and wind speeds in tornadoes, there is some question whether an F6 or greater tornado would be identified if it did occur. According to NCDC (2004), the strongest tornadoes are in the F5 range.

Table 2-1. Fujita Tornado F Scale Intensity Wind Speed Relationships

Intensity	Description	Original Fujita Scale (Fastest quarter mile, mph)	Fujita Scale (3-s gust, mph)	Operational Enhanced Fujita Scale (3-s gust, mph)
F0	Light damage	40 to 72	45 to 78	65 to 85
F1	Moderate damage	73 to 112	79 to 117	86 to 110
F2	Considerable damage	113 to 157	118 to 161	111 to 135
F3	Severe damage	158 to 206	162 to 209	136 to 165
F4	Devastating damage	207 to 260	210 to 261	166 to 200
F5	Incredible damage	261 to 318	262 to 317	>200

It should be noted that the maximum wind speed associated with a tornado occurs for only a small fraction of the footprint and at any location for only a short period of time. Depending on the translational velocity of the tornado, a location might experience wind speeds near the maximum for 5 to 10 seconds.

The problems of tornado intensity from damage are well known. It is a subjective process. For example, damage estimates are limited by the nature of the area where the tornado strikes. If there is nothing to damage, there is no way to assign an F Scale. Similarly, where there are structures, the damage will depend on the nature of the construction.

In 2001, Texas Tech University Wind Science and Engineering Research Center organized a forum of scientists and engineers to consider alternatives to the Fujita Scale (TTU 2006). The Enhanced Fujita

Scale shown in Table 2-1 is the result of the forum's work. To determine the Enhanced Fujita Scale, 28 damage indicators with several degrees of damage for each indicator are used to estimate the wind speed impacting structures in the path of the tornado. The damage indicators are related to types of structure, while the degree of damage describes the type of damage observed. The Enhanced Fujita Scale is based on the highest wind speed estimated in the tornado path.

Tornado wind speeds are estimated, not measured. They are related to averaging periods corresponding to relevant wind data collected by the National Weather Service. The Fujita Scale winds are approximately fastest quarter-mile wind speeds. Presently, peak winds recorded by National Wind Service instruments are about 3-second averages. Thus, the Enhanced Fujita wind speeds are nominally 3-second averages. For fastest quarter-mile wind speeds less than 300 mph, the maximum 3-second gust will be higher than the fastest quarter-mile wind speed. Table 2-1 shows the equivalent 3-second gust wind speeds for the original Fujita Scale.

One of the constraints in development of the Enhanced Fujita Scale was to preserve the utility of the existing tornado database. As a result, there is a very high correlation between speeds associated with the Enhanced Fujita Scale and those of the original Fujita Scale. Several members of the forum used original Fujita Scale criteria to assign Fujita Scale categories to the degrees of damage of the Enhanced Fujita Scale. Linear regression of the wind speeds estimated by the two scales gave

$$S_{EF} = 0.6246 \cdot S_F + 36.393 \qquad (2\text{-}1)$$

where S_{EF} is the wind speed for the Enhanced Fujita Scale and SF is the wind speed (mph) for the original Fujita Scale adjusted to a 3-second average (TTU 2006).

The National Weather Service has announced it intention to adopt and implement the Enhanced Fujita Scale by February 20007 (NOAA 2006). Chapters 5, 6, and 8 of this report have been updated from the corresponding chapters in NUREG/CR-4461, Rev. 1, to reflect the change to the wind speeds associated with the Enhanced Fujita Scale. In general, the change results in decreases in tornado wind speeds ranging from about 30 mph in the western United States to about 70 mph in the central United States. Note that the damage classification is still based on criteria associated with the original Fujita Scale.

2.2 United States Tornado Characteristics

The initial step in estimation of tornado strike probabilities and characteristics for use in design of structures is the characterization of the reported tornadoes. Tornado dimensions tend to increase with tornado intensity, and weak tornadoes are more common than strong tornadoes. As a result, the distributions of tornado dimensions are skewed. The modes (most frequent) and medians (50th percentile values) of the distributions are smaller than the means (averages). Mean tornado characteristics are important because they are used in estimating the probability of a tornado strike, and, along with the tornado intensities, they are used to estimate design wind speeds.

Using simple arithmetic averages to estimate mean tornado characteristics from tornado tracks tends to result in underestimates of the true values because of the skewed nature of the distributions. This bias decreases as the number of tornadoes considered increases.

Underestimation of tornado dimensions leads to underestimation of tornado strike probabilities and other design characteristics. Consequently, another statistic is frequently used to estimate mean characteristics: the expected value of the distribution. The expected value is essentially a weighted average rather than an arithmetic average. The expected value of a random variable x (any tornado dimension) is defined as

$$E(x) = \int_{-\infty}^{\infty} xf(x)dx \tag{2-2}$$

where f(x) is the probability density function for x. For skewed distributions, the expected value is a better estimate of the true mean than an arithmetic average if the form of the distribution is known because information about the distribution is used in calculating the expected value. That is, the expected value converges to the true mean faster than the arithmetic average.

Following a suggestion by Thom (1963), the lognormal probability density function has been assumed to represent tornado characteristics (Markee et al. 1974; AEC 1974; Schreck and Sandusky 1982; Ramsdell and Andrews 1986). The data in the current tornado database suggest that this assumption is reasonable. Thus, the lognormal assumption is used for the analyses that follow.

Johnson et al. (1994) contains a detailed description of the properties of the lognormal distribution. To determine tornado characteristics, the reported values are transformed by taking logarithms of the values. Then, the mean and variance of the transformed values are computed using the usual statistical method. Finally, the desired statistics are calculated by reversing the transformation.

Given the average, u, of the transformed values and the variance, v, the following statistics of the distribution can be estimated directly:

Expected value	=	$\exp(u + v/2)$	(2-3)
Mode	=	$\exp(u - bv)$	(2-4)
Median	=	$\exp(u)$	(2-5)
Lower limit (5%)	=	$\exp(u - 1.645\ v^{1/2})$	(2-6)
Upper limit (95%)	=	$\exp(u + 1.645\ v^{1/2})$	(2-7)

In addition, treating (u + v/2) as a random variable, w, the variance of w, V[w] is approximately

$$V[w] \approx v/n + \frac{v^2}{2(n-1)} \tag{2-8}$$

where n is the number of tornado events used to estimate u and v. For sufficiently large n, perhaps as small as 20, the 90 percent confidence interval for the expected value is approximately

$$\exp\{w - 1.645(V[x])^{1/2}\} < E[x] < \exp\{w + 1.645(V[w])\} \tag{2-9}$$

Equations (2-2) through (2-9) provide the bases for estimation of strike probabilities and the 5th and 95th percentile limits on the 90 percent confidence interval for the expected values.

Table 2-2 lists the characteristics of tornado segments in the contiguous United States, derived from the NCDC tornado data. The table shows that the 90 percent confidence interval in the expected values increases as the intensity increases. This increase is associated with the decrease in the number of segments as the intensity increases. Tables 2-3 through 2-5 list the distributions of tornado dimensions for all tornadoes and for tornadoes by reported tornado intensity.

The geographical distribution of tornado events in the United States between the beginning of 1950 and the end of August 2003 is shown in Figure 2-1. A tornado event is defined as a tornado occurrence within a defined area. A tornado segment in the NCDC database may be counted as an event in more than one area. However, for the boxes shown in Figure 2-1, fewer than 5 percent of the tornadoes contribute to events in more than one box. For larger boxes, this percentage decreases. For the 2° and 4° boxes that form the basis for the analysis in Chapter 5, the percentages of segments contributing to events in more than one box decrease to about 2.3 percent and 1.1 percent, respectively.

Each number in Figure 2-1 represents the number of tornado events occurring in a box that covers 1° of latitude by 1° of longitude. The latitude and longitude labels shown in the figure represent the latitude and longitude of the southeast corners of the boxes. The area covered by each box is a function of latitude. Along the southern border of the country, the area is approximately 4,000 mi^2; in the middle of the country, it is about 3,600 mi^2; and along the northern border, it is about 3,200 mi^2. Figures 2-2 and 2-3 show the geographical distributions of more intense tornadoes, with Figure 2-3 showing only the most intense tornadoes, i.e., those having F Scales of F4 and F5.

Table 2-2. Tornado Segment Statistics for the Contiguous United States

2.3 Regional Tornado Characteristics

Previous studies have indicated that tornado characteristics vary across the country. Figures 2-1, 2-2, and 2-3 show the contiguous United States divided into three regions. The western region is the United States west of 102° west longitude. The central region covers most of the rest of the United States except for the eastern seaboard and a small area along the northern border of the United States just west of Lake Michigan. This remaining region is referred to as the eastern region. Tornado characteristics for each of the regions are listed in the tables presented in this section.

The characteristics of tornado segments in the western United States are listed in Tables 2-6 through 2-9. Tables 2-10 through 2-13 list the characteristics of tornado segments in the central United States, and Tables 2-14 through 2-17 list the characteristics of tornado segments in the eastern United States. Note that Table 2-6 lists three F5 tornado events in the western United States. These events are not included in calculations of design characteristics because there is no information on the tornado lengths.

Table 2-6. Tornado Segment Statistics for the Western United States

3.0 Adjustments to the Tornado Data

In the analysis in NUREG/CR-4461, tornado data were used as reported. No attempt was made to adjust or correct the data for potential errors in the subjective evaluation of characteristics of a specific tornado. However, there are two areas where potential adjustments to the data were considered. The first area is under-reporting of tornadoes, particularly the weaker tornadoes. The second area is the assumption that the tornado intensity is uniform over the entire area impacted by the tornado. Section 3.1 discusses the under-reported tornadoes, and Section 3.2 discusses the variation of tornado intensity within the footprint.

3.1 Unreported Tornadoes

Fujita (1978) discusses the history of tornado reports from 1912 through 1977. There was a gradual increase in the number of tornadoes reported annually until the early post-World War II era, when there was a large increase in the number of tornadoes reported. The increase in reported tornadoes has been attributed to increased efficiency in data collection and increased population density. Analysis of Fujita's data in the initial version of NUREG/CR-4461 (Ramsdell and Andrews 1986) indicated that most of the increase in the total number of tornadoes was due to increases in F0, F1, and F2 tornadoes. Any increase in the number of F3 through F5 tornadoes was statistically insignificant. Figure 3-1 shows that the trend in number of tornadoes each year has continued. However, statistical analysis of the number of tornadoes since January 1950 discloses that the only tornadoes with a statistically significant trend are the F0 tornadoes. Figure 3-2 shows the number of F0 tornadoes each year since January 1950 and the total number of more intense tornadoes. This figure shows that in 1950 there were almost no F0 tornadoes

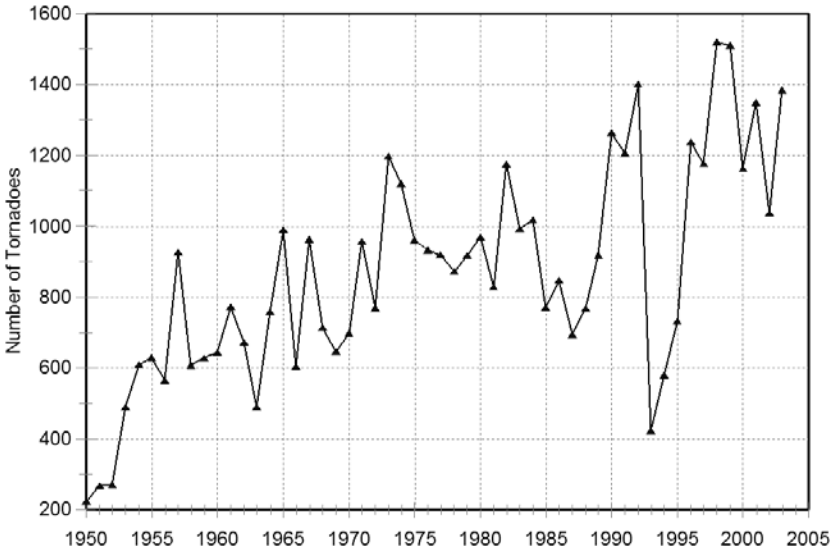

Figure 3-1. Annual Number of Reported Tornadoes (1950 through August 2003)

reported and that there has been a steady increase since then. In contrast, the figure shows that the number of F1 through F5 tornadoes, while highly variable, does not have an upward trend.

The potential impact of the F0 tornado trend has been evaluated by assuming that the trend is in the reporting of F0 tornadoes, not in the number of occurrences of F0 tornadoes, and that the average number of tornadoes per year over the last 8 years is representative of the true average for the full 53+ year period. Given these assumptions, there should have been about 43,400 F0 tornadoes during this period. Yet, there were only about 17,500 F0 tornadoes reported. The area impacted by the 17,500 reported F0 tornadoes is about 534 mi^2. Had all 43,600 F0 tornadoes been reported, it is estimated that the impacted area would increase to about 1,320 mi^2. This is an increase of about a factor of 2.5, which is significant. However, the increase in total area impacted by all tornadoes by accounting for unreported F0 tornadoes is much smaller. The total area would increase from about 30,400 mi^2 to 31,100 mi^2, an increase of less than 2.5 percent. Figure 3-3 shows that the addition of the missing F0 tornadoes has little impact on tornado strike probability for the more likely events and decreases the probability for low probability events. As a result, no adjustment was made to the data to account for unreported F0 tornadoes.

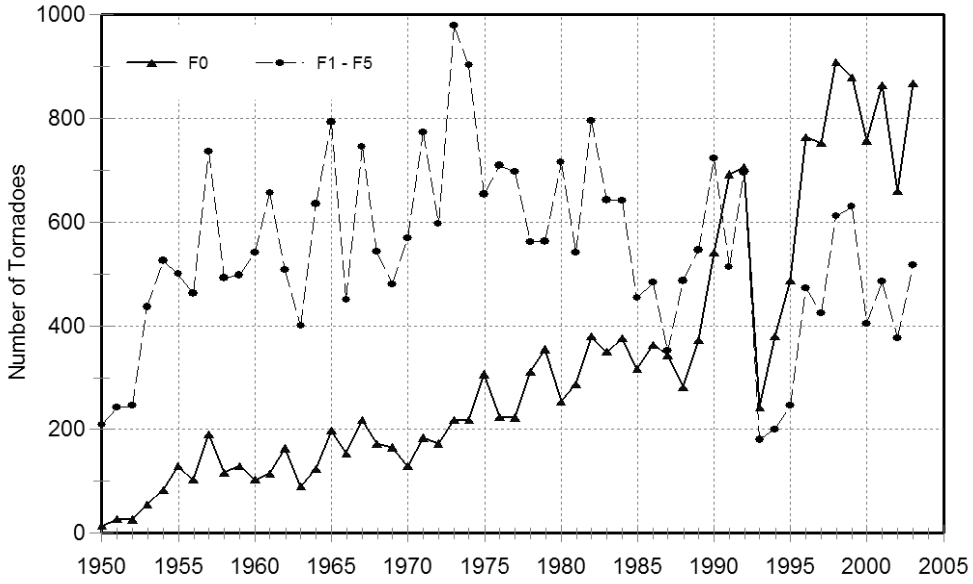

Figure 3-2. Number of F0 Tornadoes and Total Number of F1 through F5 Tornadoes by Year Since 1950

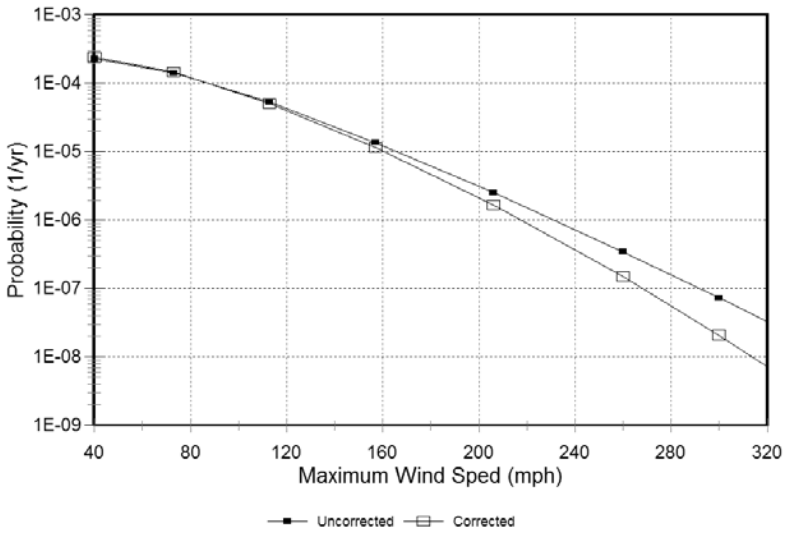

Figure 3-3. Wind Speed Probability With and Without Correction for Unreported F0 Tornadoes

3.2 Variation of Wind Speed Within the Impact Area

The analysis in the initial version of NUREG/CR-4461 (Ramsdell and Andrews 1986) assumed that intensity reported for each tornado represented the wind speed experienced by the entire area within the ground footprint of the tornado. This conservative assumption was consistent with assumptions made in previous analyses (Markee et al. 1974; Shreck and Sandusky 1982). Theoretical considerations and empirical evidence in tornado tracks indicate that the assumption is incorrect and that only a small fraction of the area of the footprint is impacted by the maximum wind speed in the tornado. Note that all segments of a tornado have the same intensity and the analyses presented in this report are based on total area and length. Therefore, segmentation of the tornadoes in the database does not affect either the adjustment or the results of the analysis.

Reinhold and Ellingwood (1982) present the results of several studies that have estimated the variation of maximum wind speeds along and across tornado paths. In addition, they have combined these results to estimate fractions of the impacted area associated with each wind speed class. Reinhold and Ellingwood (1982), Table 15d, lists the areal distribution of wind speeds used in the analysis in NUREG/CR-4461, Rev. 1, to estimate the area associated with wind speed ranges from the areas associated with reported F Scales. This table was based, in part, on a tornado model that used the wind speeds associated with the original Fujita Scale. As a result, the adjustments to the table were required to account for the wind speeds associated with the Enhanced Fujita Scale.

Specifically, Table 3-1 in NUREG/CR-4461, Rev. 1, was based on the product of two matrices, one that described the variation of wind speed across the tornado path, and another that described the variation of wind speed along the tornado path. The matrix that described the variation of wind speed across the tornado path was based on a tornado model the was linked to the Fujita Scale wind speeds. This matrix was replaced by a matrix developed by combining estimates from a conservative tornado model and data

from empirical evaluation of tornado damage. The tornado model was a stationary Rankine vortex with Enhanced Fujita Scale wind speeds, and the empirical data were from Table 7c of Reinhold and Ellingwood (1982). The probability estimates were combined as a weighted average with the data from Table 7c having a weight of 2/3 and the estimates from the Rankine model having a weight of 1/3. The results of this process were then combined with the information of variation of wind speed along the tornado path in Reinhold and Ellingwood, Table 6c, to estimate the fraction of the area associated with each Enhanced Fujita Scale wind speed class given the Fujita F Scale for the tornado. Table 3-1 presents these fractions. As before, the conversion of total impact areas by F Scale to areas associated with wind-speed classes is performed on tornado statistics rather than on individual tornadoes.

Table 3-1. Tornado Area Intensity Distribution for the Point Structure Design Wind Speed Estimates

Intensity F Scale	Wind-Speed Range (mph)	Recorded Tornado F Scale					
		F0	**F1**	**F2**	**F3**	**F4**	**F5**
EF0	65 - 85	1	0.772	0.616	0.529	0.543	0.538
EF1	86 - 110		0.228	0.268	0.271	0.238	0.223
EF2	111 - 135			0.115	0.133	0.131	0.119
EF3	136 - 165				0.067	0.056	0.07
EF4	165 - 200					0.032	0.033
EF5	>200						0.017

The interpretation of Table 3-1 is as follows: 100 percent of the area impacted by F0 tornadoes has a wind speed in the 65 to 85 mph range. For F1 tornadoes, 22.8 percent of the area has wind speeds in the 86 to 110 mph range, and 77.2 percent of the area has wind speeds in the 65 to 85 mph range. Similarly, 11.5 percent of the area impacted by F2 tornadoes has wind speeds in the 111 to 135 mph wind speed range, 26.8 percent has wind speeds in the 86 to 110 mph range, and the remaining 61.6 percent of the area has wind speeds in the 65 to 85 mph range.

Adjustment of areas based on tornado event dimensions to areas associated with intensity (wind speed) is illustrated in Table 3-2. The first column in the table lists the reported F Scale, and the last column lists the range of maximum wind speeds associated with the EF Scale. The total area impacted for tornadoes in each category is listed in the second column. The third column lists the area by wind-speed classes after adjustment to account for variation in wind speed within the impact area. For example, the total area impacted by winds from 65 through 85 mph is all of the area of F0 tornadoes, plus 77.2 percent of the area impacted by F1 tornadoes, plus 61.6 percent of the area impacted by F2 tornadoes, etc. Note that the areas in column 3 decrease monotonically with increasing wind speed, while the areas in column 2 do not. Note also that the total impact area for all tornadoes before and after the adjustment remains constant within limits of roundoff error; the adjustment does not affect the strike probability. The fourth column lists cumulative area based on wind speed. The F0 entry lists the total area for tornadoes of all classes. This is

the area to be used in calculating the strike probability. The F1 entry lists the total area with wind speeds of 86 mph or greater. In this analysis, impacted areas used in calculation of strike probabilities and design characteristics have been adjusted for the variation in speed along and across tornado paths.

The analysis in the initial version of NUREG-4461 (Ramsdell and Andrews 1986) estimated only tornado strike probabilities and design wind speeds for point structures. That analysis was based entirely on the tornado impact areas. The impact area adjustment just described is appropriate for estimating strike probabilities and design speeds for point structures. This report considers both point structures and finite structures.

Table 3-2. Area Impacted by Tornadoes in the Contiguous United States

F Scale	Total Area (mi^2) by F Scale	Total Area (mi^2) by Wind-Speed Range	Cumulative Area (mi^2)	Probability of Wind Speed Exceeding Threshold	Enhanced Fujita Scale Wind-Speed Range (mph)
F0	533.6	18420.6	30357.6	1.00×10^{0}	65 - 85
F1	4695.8	7652.0	11937.0	3.43×10^{-1}	86 - 111
F2	10184.8	3136.0	4285.0	1.41×10^{-1}	111 - 135
F3	9117.7	947.6	1149.0	3.78×10^{-2}	136 - 165
F4	5043.7	187.8	201.4	6.63×10^{-3}	166 - 200
F5	782	13.6	13.6	4.48×10^{-4}	>200

Estimation of strike probabilities and design speeds for finite structures involves both tornado impact areas and tornado lengths. Consequently, it is necessary to estimate the total length of tornado paths associated with wind speeds. Table 3-3 presents estimates of the distribution of wind speeds by length for each F Scale made by Twisdale and Dunn (1981). These estimates are used in the same way as the information in Table 3-1.

Tornado lengths used in the estimates of strike probability and design characteristics for finite-structures in this report have been adjusted to account for the variation of wind speed along tornado paths. This adjustment does not change the total path length for all tornadoes.

Note that all segments of a tornado have the same intensity, and the analyses presented in this report are based on total area and length. Therefore, segmentation of the tornadoes in the database does not affect either of the adjustments or the results of the analyses.

Table 3-3. Tornado Length Intensity Distribution for the Finite-Structure Design Wind Speed Estimates

Intensity F Scale	Wind-Speed Range (mph)	Recorded Tornado F Scale					
		F0	**F1**	**F2**	**F3**	**F4**	**F5**
EF0	65 - 85	1	0.572	0.28	0.116	0.142	0.133
EF1	86 - 110		0.428	0.352	0.245	0.158	0.102
EF2	111 - 135			0.368	0.318	0.278	0.189
EF3	136 - 165				0.321	0.21	0.242
EF4	166 - 200					0.212	0.185
EF5	>260						0.149

4.0 Tornado Model

The general approach used to evaluate tornado strike probabilities and design wind speeds in NUREG/CR-4461, Rev. 1, and in this revision follows the approach taken in the initial version of NUREG/CR-4461. However, two significant modifications have been made to that approach. The first modification is addition of a second term to the estimation of strike probabilities. In the initial version of NUREG/CR-4461, strike probabilities were estimated using a point strike calculation in which the structure dimensions were assumed to be negligible relative to tornado dimensions. The current analysis includes a "life line" term to account for finite building dimensions (Garson et al. 1975). The second modification to the approach used in the initial version of NUREG/CR-4461 is to account for the variation of tornado intensity along and across the tornado path. The previous analysis assumed that the entire tornado footprint experienced wind speeds equaling or exceeding the minimum wind speed for the reported tornado intensity (Fujita F Scale). Section 3.2 describes the change in basis for area and length from the F Scale to wind speed. The calculations described in the following sections assume that areas and lengths associated with wind-speed ranges are used. Thus, they account for the variation of wind speed along and across the path.

The specification of a design basis wind speed has two parts: specification of an exceedence probability and specification of the appropriate wind speed for the exceedence probability. The approach followed in the past (Markee et al. 1974; AEC 1974; Shreck and Sandusky 1982; Ramsdell and Andrews 1986) has been to define the exceedence probability, to estimate the probability of a tornado striking a site, and to determine the conditional probability of exceeding specified wind speeds, assuming that a tornado strike occurs. The design exceedence probability and the strike probability are used to establish a conditional probability, which is converted to the design wind speed. This same general procedure is used in this analysis.

4.1 Point Structures

Consider, first, the point structure probability, P_p. The probability of the wind speed, u, exceeding some value u_o at a site is defined as the product of the probability that a tornado will strike the point structure and the conditional probability that the wind speed u will exceed u_o, assuming that a tornado strike, s, occurs:

$$P_p(u \geq u_o) = P_p \times P_p(u \geq u_o | s) \qquad (4\text{-}1)$$

The strike probability can now be defined without regard to the tornado intensity:

$$P_p = \frac{A_t}{NA_r} \tag{4-2}$$

where A_t is the total area (mi^2) impacted by tornadoes in the region of interest, which has an area denoted by A_r (mi^2), and N is the number of years of record. For example, A_r, the area of the contiguous United States, is about 3,020,000 mi^2, and the N is 53.67 years. The total tornado area is the product of the expected area for tornado events and the total number of tornado events that impacted the region of interest in N years (~30,358 mi^2). Using these values, the expected strike probability is about 1.87×10^{-4} yr^{-1}. The same calculations can be made using the upper and lower limits of the 90 percent confidence interval for the expected area. The results of the calculations show that the limits are 1.72×10^{-4} yr^{-1} and 2.04×10^{-4} yr^{-1}, respectively. The number of events in these calculations include events that were not considered in the calculation of the expected values for the area because of missing information.

Equation (4-1) shows the probability of exceeding a given wind speed at a point as the product of two components. The first component is the probability of a tornado striking a point, and the second component is a conditional probability of exceeding a given wind speed assuming that a tornado strike occurs, $P_p(u \geq u_o|s)$. As indicated above, the strike probability can be estimated from the total area impacted by tornadoes without regard to F Scale. The conditional probability of exceeding u_o given that a tornado has occurred is estimated as

$$P_p(u \geq u_o|s) = \frac{A_{u \geq u_o}}{A_t} \tag{4-3}$$

where $A_{u \geq uo}$ is the total area impacted by wind speeds greater than u_o. The next-to-last column in Table 3-2 lists the results of applying Equation (4-3) to the areas in column 4 of Table 3-2. These values, with the lower bound wind speed in each range in the last column, provide up to six points on a curve that can be used to represent the conditional probability.

The probability of exceeding u_o may be represented by a Weibull distribution. In that distribution,

$$P_p(u \geq u_o|s) = \mathrm{Exp}\left[-\left(\frac{u_o - 65}{a_p} \right)^{b_p} \right] \tag{4-4}$$

where 65 is the minimum tornado wind speed, and a and b are parameters of the Weibull distribution. Estimation of these parameters requires good estimates of $A_{u \geq uo}$ which can only be obtained from considering a large number of tornadoes. An optimization procedure, for example, the Nelder-Mead Simplex algorithm (Nelder and Mead 1965), may be used to determine the parameter values that minimize the sum of squares of the errors between the probabilities estimated using the Weibull distribution and the observed probabilities.

The optimization algorithm requires impacted areas for at least three F Scales. Many areas of the west and some areas of the east do not have a reported F2 or stronger tornado. In addition, the confidence interval for the expected area and length of tornadoes increases rapidly as the number of tornadoes decreases. Therefore, the contiguous United States has been divided into three regions for the purpose of determining the conditional probability to ensure that there are sufficient tornadoes to adequately define the frequency of low probability events. Figures 2-1, 2-2, and 2-3 show the regions. The dividing line between the western and central regions was moved 3° east from the dividing line between the western and eastern United States in the initial version of NUREG/CR-4461 after considering the number of F2 or greater tornadoes (Figures 2-2 and 2-3). The dividing line between the central and eastern United State was based on the number of F4 tornadoes (Figure 2-3).

4.2 Large Structures

Consider now the probability represented by the life-line term. If a structure is large, the probability of being struck by a tornado is greater than that based only on tornado dimensions. The additional probability is determined by a characteristic dimension of the structure and the expected length for tornadoes. This additional probability is estimated by the life-line term.

The process for estimating the life-line term is nearly identical to the process for estimating the point-structure term. The initial step is to separate the desired probability into a strike probability that is independent of intensity and a conditional probability that considers intensity:

$$P_l(u \geq u_o) = P_l \times P(u \geq u_o|s) \tag{4-5}$$

The initial definition of the strike probability is also the same:

$$P_l = \frac{A_t}{NA_r} = \frac{w_s L_t}{NA_r} \tag{4-6}$$

However, in this case, the impacted area is estimated as the product of a characteristic building dimension, w_s, (mi), and the total length of tornado paths, L_t (mi). A characteristic dimension of 200 ft (0.0379 mi) has been assumed for this analysis. With this change, the conditional probability statement becomes:

$$P_l(u \geq u_o|s) = \frac{L_{u \geq u_o}}{L_t} \tag{4-7}$$

where $L_{u \geq u_o}$ is the total tornado path length with wind speeds equaling or exceeding u_o.

Continuing the analogy with the point-structure term, the conditional probability may be represented by a Weibull distribution, and the parameters of the distribution may be estimated using an optimization procedure:

$$P_l(u \geq u_o|s) = \mathrm{Exp}\left[-\left(\frac{u_o - 65}{a_l} \right)^{b_l} \right] \tag{4-8}$$

4.3 Total Strike Probability and Design Wind Speed

The total probability of a structure being struck by a tornado with winds exceeding some value u is the sum of the point structure and life-line probabilities:

$$\begin{aligned} P(u \geq u_o) &= P_p(u \geq u_o) + P_l(u \geq u_o) \\ &= \frac{A_t}{NA_r}\mathrm{Exp}\left[-\left(\frac{u_o - 65}{a_p} \right)^{b_p} \right] + \frac{w_s L_t}{NA_r}\mathrm{Exp}\left[-\left(\frac{u_o - 65}{a_l} \right)^{b_l} \right] \end{aligned} \tag{4-9}$$

Equation (4-9) provides the means to estimate the probability of a tornado strike with wind speeds exceeding u_o, but it cannot be inverted to estimate the wind speed, u_o, associated with a given probability. Estimation of the wind speed associated with a given probability involves two steps. In the first step, strike probabilities are estimated for a range of wind speeds that is sufficiently large that the strike probability of interest is included within the range of calculated strike probabilities. Then, in the second step, the wind speed of interest, u_o, associated with the given probability is determined by interpolation.

5.0 Analytical Results

Two computer programs were written to analyze NCDC tornado data. One of the programs, TorBoxes, was used to calculate the descriptive tornado statistics presented in Chapter 2.0 and tornado statistics for 1°, 2°, and 4° boxes. The other program, TorStrk, was written to calculate tornado statistics for specific locations.

The results of manual analysis of the descriptive tornado statistics are presented in Section 5.1. These results include estimates of the strike probabilities and Weibull parameter values for the contiguous United States and the three regions of the United States shown in Figures 2-1, 2-2, and 2-3. Design statistics for the 1°, 2°, and 4° boxes based on local strike probabilities and conditional wind speed probabilities calculated using the appropriate regional Weibull parameter values are presented in Section 5.2.

5.1 Contiguous United States and Regions

Chapter 2.0 presents descriptive statistics for tornadoes in the contiguous United States and for the western, central, and eastern regions. These statistics have been used to estimate strike probabilities for the contiguous United States and each of the regions. They have also been used to estimate parameter values, a and b, for the Weibull distributions that are assumed to describe the conditional probability of the wind exceeding a specified speed if a tornado does strike. Table 5-1 contains the results of these calculations. Probabilities of exceeding specified wind speeds in the contiguous United States and the three regions are compared in Figure 5-1.

Table 5-1. Calculated Tornado Model Parameters

		Point Structure			Finite Structure		
	Region	**Strike Probability**	**a**	**b**	**Strike Probability**	**a**	**b**

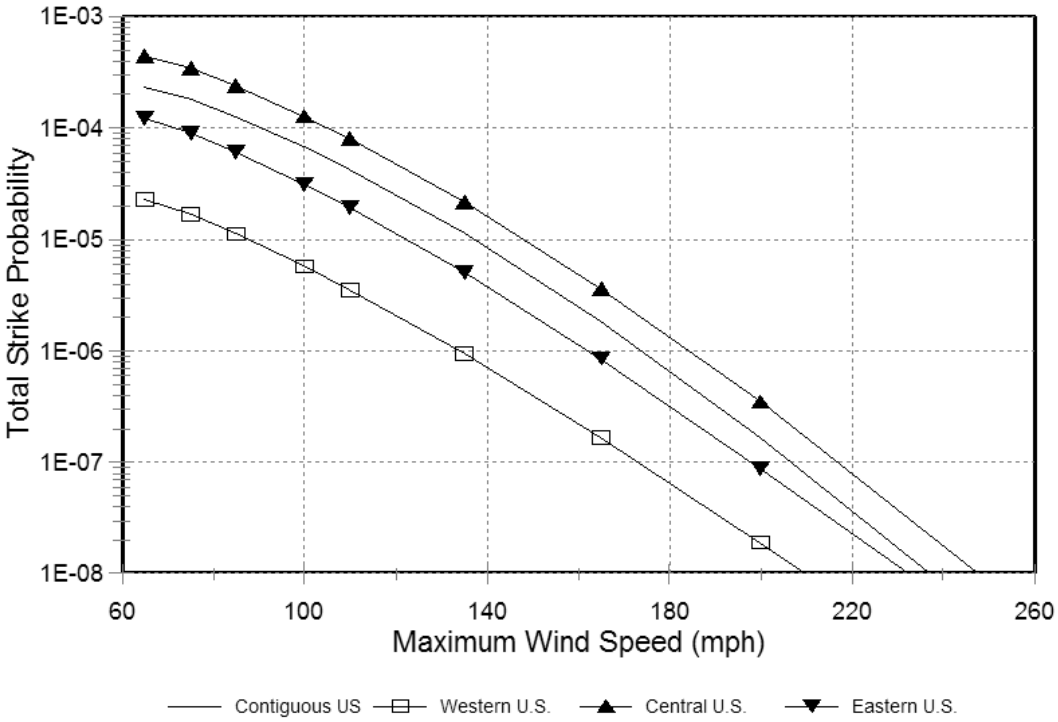

Figure 5-1. Comparison of Conditional Wind Speed Probabilities Calculated for the Contiguous United States and for the Western, Central, and Eastern Regions

Figures 5-2 and 5-3 compare the conditional probabilities associated with the point-structure and life-line terms, respectively. The curves in these figures show the effects of the differences in the Weibull parameters listed in Table 5-1. Remember that these figures do not include the probability that an event will occur. Figure 5-2 shows that there are no significant regional differences in the conditional probabilities associated with the point-structure term for the most likely events (events with greater than 1×10^{-2} probability of occurrence). For events with less than a 1×10^{-2} probability of occurrence, slightly higher wind speeds are more likely in the western region than in either the central or eastern region. Figure 5-3 shows that the regional differences in conditional probabilities associated with the life-line term are greater than those associated with the point-structure term. Even then, there is less than a factor-of-2 difference in probability of wind speeds as high as about 200 mph.

The effects of uncertainty of strike probabilities on the maximum tornado wind speed for the three regions are shown in Figures 5-4 through 5-6. The uncertainty associated with strike probability is small in the central United States where the tornado frequency is high and large in the western United States where the tornado frequency is low. The ranges of uncertainty shown in these figure are lower than the actual uncertainty ranges because they do not include uncertainties associated with the areal distribution of wind speeds within the tornado footprint or the uncertainties in estimates of the Weibull parameters.

5.2 Subregional Results

Tornado characteristics have been estimated for 1°, 2°, and 4° latitude and longitude boxes. These characteristics are listed in Appendices A, B, and C. Appendix A lists the characteristics for 2° boxes; Appendix B lists the characteristics for 4° boxes; and Appendix C lists the characteristics for 1° boxes. The characteristics for the 2° and 4° boxes are considered most reliable; those for 1° boxes should only be used if the number of events is large enough to ensure that the statistics are likely to be reliable. The appendices include the expected tornado impact area and length; the point-structure, finite-structure, and total strike probabilities; and design wind speeds at the 10^{-5}, 10^{-6}, and 10^{-7} yr^{-1} probability levels. The upper and lower limits for these characteristics are also included, as are the number of events and the land area within the box.

Figure 5-7 shows the distribution of tornadoes by 2° boxes. The design wind speeds for the 2° boxes are shown in Figures 5-8 through 5-13. Figures 5-8 and 5-9 show the expected and upper limit wind speeds, respectively, for the 10^{-5} yr^{-1} probability level. The upper limit speeds only account for uncertainty in the strike probability. They do not account for other sources of uncertainty. Figures 5-10 and 5-11 show the wind speeds for the 10^{-6} yr^{-1} probability level, and Figures 5-12 and 5-13 show the wind speeds for the 10^{-7} yr^{-1} probability level. In the figures showing design wind speeds, the number 0 indicates that there were no tornado events in the box or that the wind speed for the probability level is less than 65 mph.

6.0 Comparison of Results

Chapter 6 of NUREG/CR-4461, Rev. 1, compared the wind speed estimates generated by the methodology used in this study assuming the original Fujita Scale relating tornado damage to wind speeds with speeds estimated in the initial version of NUREG/CR-4461 (Ramsdell and Andrews 1986) and in a study for the U.S. Department of Energy (Boissonnade et al. 2000). The methods used in the analysis in NUREG/CR-4461, Rev. 1, gave maximum wind speed estimates that tended to be about 20 mph lower than the estimates of either of the other two analyses.

This chapter presents a comparison of wind speeds estimated using the methodology of NUREG/CR-4461, Rev. 1, assuming the Enhanced Fujita Scale with wind speeds estimated using the same methodology assuming the original Fujita Scale. Wind speed estimates for 10^{-5}, 10^{-6}, and 10^{-7} yr^{-1} probability striking a building with a 200-ft characteristic dimension are compared.

Table 6-1 lists the wind speeds estimated for 73 nuclear power plant site in the United States. The expected wind speeds for each of the locations have been extracted from the tables in Appendices A in NUREG/CR-4461, Rev. 1, and in this report. Blanks in the table indicate that the wind speed at the given probability level would have been less than 65 mph. Figure 6-1 compares the 10^{-7} yr^{-1} probability level wind speeds graphically. The numbers shown in the figure are the index number for the site listed in the first column of Table 6-1.

Table 6-2 lists wind speeds estimated for representative cities throughout the United States. The expected wind speeds for each of the locations have been extracted from the tables in Appendices A in NUREG/CR-4461, Rev. 1, and in this report. Blanks in the table indicate that the wind speed at the given probability level would have been less than 65 mph. Figure 6-2 compares the 10^{-7} yr^{-1} probability level wind speeds graphically. The numbers shown in the figure are the index number for the city listed in the first column of Table 6-2.

Both figures indicate the high correlation between wind speeds estimated using the Enhanced Fujita Scale and those estimated using the original Fujita Scale that would be expected.

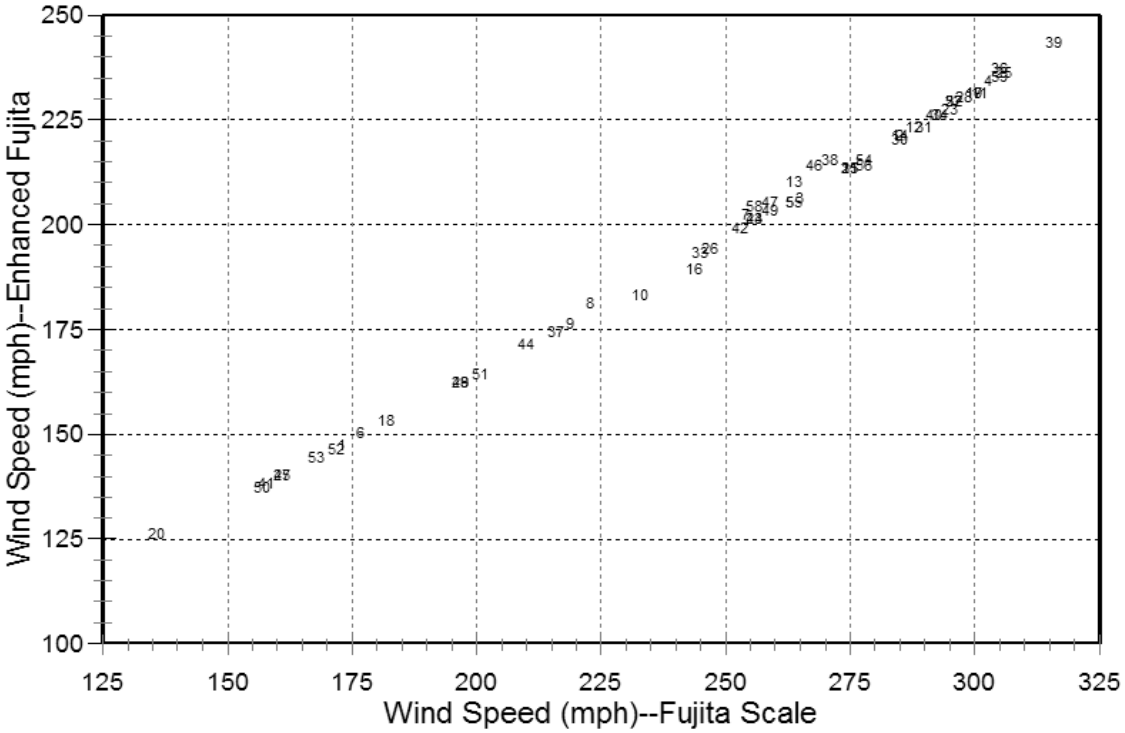

Figure 6-2. Comparison of 10^{-7} yr^{-1} Probability Level Wind Speeds Estimated for Representative Cities in United States

7.0 Uncertainty

This chapter addresses uncertainties associated with estimation of tornado strike probabilities and wind speeds. Many of the uncertainties arise from the subjective nature of determination of such fundamental characteristics as the length, width, and intensity of individual tornadoes. Other uncertainties arise from the models used to describe the tornado footprint and the probability distributions for the areas, lengths, and wind speeds of tornadoes.

7.1 Tornado Footprint Model

The basic model of a tornado footprint is a rectangle characterized by the width and length of the tornado path. Within the rectangle that defines the footprint, there are smaller rectangles associated with various wind speed thresholds. It is unlikely that any footprint is truly rectangular. However, the information in the NCDC tornado database does not support a more complex footprint model. Segmentation of tornadoes on the basis of changes in direction of motion since 1996 provides for improved representation of tornado footprints. Nevertheless, a rectangular footprint is still assumed for each segment.

The area of each segment is estimated by the product of the segment length and width. Most likely, the typical tornado footprint is narrow on the ends and widest at some point in the middle; the area of the footprint thus will be correct only if the average width of the tornado is used in calculation of the area. Average footprints were recorded for tornadoes prior to 1994. Since then, the maximum tornado width has been recorded. As a result, the tornado footprint model will lead to overestimates of the average tornado event area and, therefore, to overestimates of strike probabilities for point structures.

The analysis presented in this report accounts for the variation of wind speeds within the rectangle, but it does not account for possible deviations of actual tornado footprint shapes from the assumed rectangular shape. Accounting for the variation of wind speed within the footprint in the current analysis represents an advance over the assumptions used in the analysis in the initial version of NUREG/CR-4461.

7.2 Length, Width, and Area

The fundamental characteristics of tornadoes are generally assessed after the fact from damage caused by the tornado. The damage depends on the intensity of the tornado and the nature of the surface where the tornado occurs. General guidelines existed for assessing the damage, but, ultimately, the characterization is subjective. It is necessary to distinguish the area damaged by the tornado from the area covered by debris scattered by the tornado.

The Enhanced Fujita Scale (TTU 2006) includes far more comprehensive guidelines for evaluation of tornado intensities. However, those guidelines were not used to estimate the intensities of tornadoes listed in the tornado database used as a basis for the analysis in this report.

Resolution of reported tornado lengths and widths in the NCDC database is sufficient to ensure that resolution of the lengths and widths is not a significant source of uncertainty. Both tornado length and width tend to increase with increasing tornado intensity. It is likely that the more intense the tornado, the better the estimates of tornado dimensions. Less than 17 percent of the total footprint area in the contiguous United States during the study period was associated with F0 and F1 tornadoes. As a result, it seems unlikely that potential errors associated with estimation of the lengths and widths of these tornadoes would significantly affect the estimation of strike probabilities for point structures. The evaluation of the effect of the unreported F0 tornadoes discussed in Section 3.1 supports the conclusion that uncertainty in the lengths and widths (areas) of F0 and F1 tornadoes is unlikely to be a significant source of uncertainty in the strike probabilities for point structures. Given the typical dimensions of F2, F3, F4, and F5 tornadoes, it seems unlikely that uncertainties in reported lengths and widths would result in a factor-of-2 uncertainty in the total footprint area or point-structure strike probabilities.

The life-line term used to account for finite structure size on strike probabilities depends on tornado length and a characteristic dimension for the structure. Of the fundamental tornado characteristics, the tornado length is likely to be the characteristic that can be estimated most accurately if it assumed that absolute errors in the estimation of length and width are about equal. Consequently, the uncertainty in the life-line term associated with uncertainty in the expected tornado length is likely to be less than the uncertainty in the point-structure strike probability. The characteristic structure dimension assumed in this analysis is 200 ft. This assumption will lead to under- or overestimates of the life-line term for structures that have larger or smaller characteristic dimensions. For structures that have larger characteristic dimensions, finite-structure corrections should be larger than those presented in the appendices, and for structures that have smaller characteristic dimensions, the finite-structure corrections should be smaller.

No effort has been made to make more quantitative estimates of the uncertainties in the reported tornado lengths and widths than those presented above or to account for these uncertainties in assessing expected values or confidence intervals. The results of the analyses presented in the appendices contain sufficient information to adjust the finite-structure corrections for differences in characteristic structure dimensions. The finite-structure strike probabilities may be scaled up or down for larger or smaller structures by multiplying the strike probabilities by the ratio of the characteristic dimension for the new building to the assumed characteristic dimension (200 ft).

7.3 F Scale

Classification of tornado intensities is subjective. It depends on assessment of damage to vegetation and structures, and in turn, the extent of the damage depends on the types of vegetation present and the types of construction of structures. As a result, it is likely that there are errors in the F Scales assigned to tornadoes in the NCDC database. Twisdale et al. (1978) and Twisdale and Dunn (1981) present information that may be used to compensate for potential classification errors. This information is included in Reinhold and Ellingwood (1982).

Summarized tornado area and length statistics were adjusted to account for potential errors in assigned F Scales using the information presented by and Twisdale et al. (1978) and Twisdale and Dunn (1981). The total area and length of tornado footprints were calculated following adjustment and compared with the statistic calculated without the adjustment. Table 7-1 shows the changes in dimensions. The increase in area is significant; the change in length may not be. In any case, compensation for potential classification errors using tornado statistics does not conserve the total dimensions.

Table 7-1. Changes in Tornado Impact Statistics Associated with Compensation for Potential Classification Errors

		With Compensation for Potential Classification Errors	
	Unmodified NCDC Tornado Data	**Twisdale et al. (1978)**	**Twisdale and Dunn (1981)**
Total Area (mi^2)	30398	44806	36235
Total Length (mi)	198750	197013	199975

A second effect of adjustment to account for potential classification errors is a large increase in the total area and length of the portion of tornado paths associated with F4 and F5 intensities. The adjustment using information presented by Twisdale et al. (1978) results in an increase in area with F4 and F5 intensity by 20 percent and in length by 7 percent. Using the information from Twisdale and Dunn (1981), the increases in area and length were about 65 percent and 70 percent, respectively. When area and length associated with F5 tornadoes are considered, the increases are more pronounced. Using the information from Twisdale et al. increases the area by about 50 percent and the length by about 30 percent. The information from Twisdale and Dunn increases the area by more than a factor of 2 and the length by more than a factor of 3. Changing to the Enhanced Fujita Scale will not affect this conclusion.

Considering 1) that the compensation matrices do not conserve total area or length when applied to tornado statistics and 2) that the matrices significantly increase the area and length associated with the highest wind speeds, no adjustment of tornado statistics for potential classification errors has been made in this update.

7.4 Association of Wind Speeds with F Scales

Even prior to the forum convened by Texas Tech University, it was suggested that the wind speeds associated with the Fujita F Scales were too high (e.g., Twisdale et al. 1978). Although Reinhold and Ellingwood (1982) use the Fujita wind speeds, they indicate that the speeds, particularly for stronger tornadoes, are likely to be too high. Wind speed ranges suggested by Twisdale et al. (1978) for F0 through F5 tornadoes are listed in Table 7-2. Experts evaluating these relationships for a Monte-Carlo tornado model being prepared at the Lawrence Livermore National Laboratory (LLNL) (Boissonade et al. 2000) assigned weights to the Fujita, Twisdale-Uniform, Twisdale-Linear relationships of 0.6, 0.078, and 0.322, respectively. This indicates that experts in the field still tended to favor the Fujita relationships. The panel also proposed its own relationship, shown in the next-to-last column of Table 7-2. This was done to account for F Scale classification errors. The relationships were compared graphically in Figure 7-1 of NUREG/CR-4461, Rev. 1 using curves based for the entire contiguous United States.

Table 7-2 and Figure 7.1 of NUREG/CR-4461, Rev. 1, have been expanded to include the wind speeds of the Enhanced Fujita Scale (TTU 2006). The Enhanced Fujita Scale wind speed probability curve is similar to the curves for the Twisdale linear relationship and the relationship proposed by the LLNL panel of experts.

Table 7-2. Tornado F Scale Intensity Wind Speed Relationships

Intensity	Description	Fujita Scale (mph)	Twisdale-Uniform (mph)	Twisdale-Linear (mph)	Expert Panel (mph)	TTU Forum (mph)
F0	Light damage	40 to 72	40 to 65	40 to 73	40 to 75	65 to 85
F1	Moderate damage	73 to 112	65 to 96	73 to 103	75 to 105	86 to 110
F2	Considerable damage	113 to 157	96 to 114	103 to 135	105 to 135	111 to 135
F3	Severe damage	158 to 206	114 to 139	135 to 168	135 to 170	136 to 165
F4	Devastating damage	207 to 260	139 to 181	168 to 209	170 to 215	166 to 200
F5	Incredible damage	261 to 318	181 to 236	209 to 277	215 to 270	>200

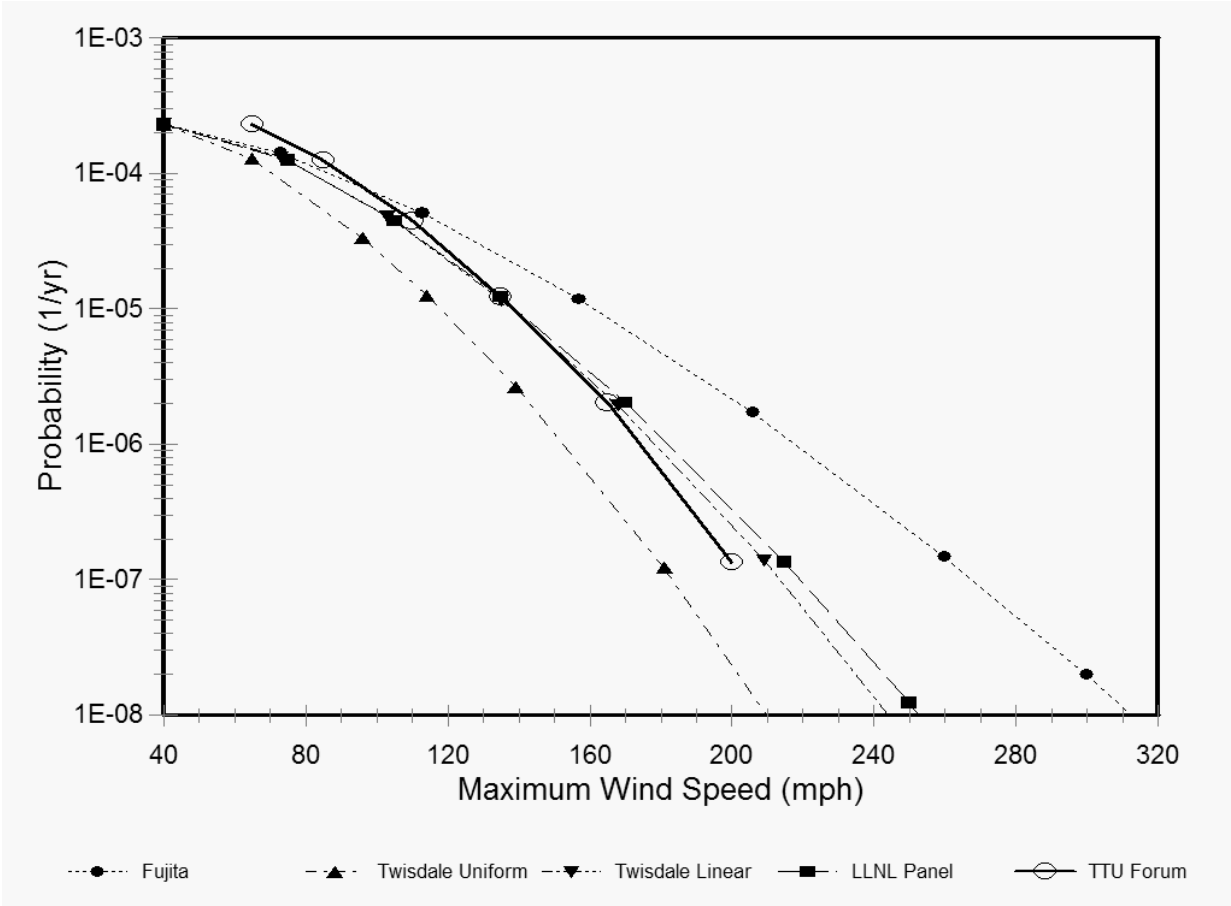

Figure 7-1. Comparison Tornado Maximum Wind Speed Probability Estimates Resulting from Use of Five Relationships Between F Scale and Wind Speed

7.5 Natural Variation in Tornado Dimensions

The previous sections in this chapter deal with uncertainty associated with estimates of tornado dimensions. This section deals with uncertainty in the estimates of the expected area and length of tornadoes associated with the natural variability of tornado dimensions and the finite sample size used to estimate the expected values. This uncertainty is treated explicitly in these analyses by assuming that tornado path length and area have lognormal distribution. The details of estimation of the confidence intervals for the expected values for lognormal distributions are described in Section 2.2.

8.0 Recommendations

Information presented in Chapters 2.0, 5.0, and 6.0 is based on analysis of the tornado data using procedures described in Chapters 3.0 and 4.0. This chapter presents recommended tornado design characteristics for use in those instances where detailed analysis is not warranted. The recommendations are based on the results of the 2° box calculations.

The 2° box design wind speeds based on expected values show a good deal of spatial variation, particularly in the western United States. A nine-point low-pass filter was used to smooth out some of this variation. In the filter, the wind speed in each box surrounded by boxes with calculated speeds was replaced by a weighted-average of the expected speeds for the box and eight adjacent boxes. The original speed for the box was given a weight of 8 and a weight of 1 was given to the speeds in each of the other boxes. The resulting speeds are shown in Figures 8-1 through 8-3. The speeds shown in boxes along the borders are the original speed estimates.

Each of the figures is divided into three regions, numbered 1 through 3, as indicated by shading, and a design wind speed is suggested for each region. The suggested speed is based on the spatially averaged speeds in the region. However, other factors, such as number of reported tornadoes and population densities, have been considered in selecting the speeds and drawing the boundaries between regions. Table 8-1 lists the tornado design wind speeds for each region.

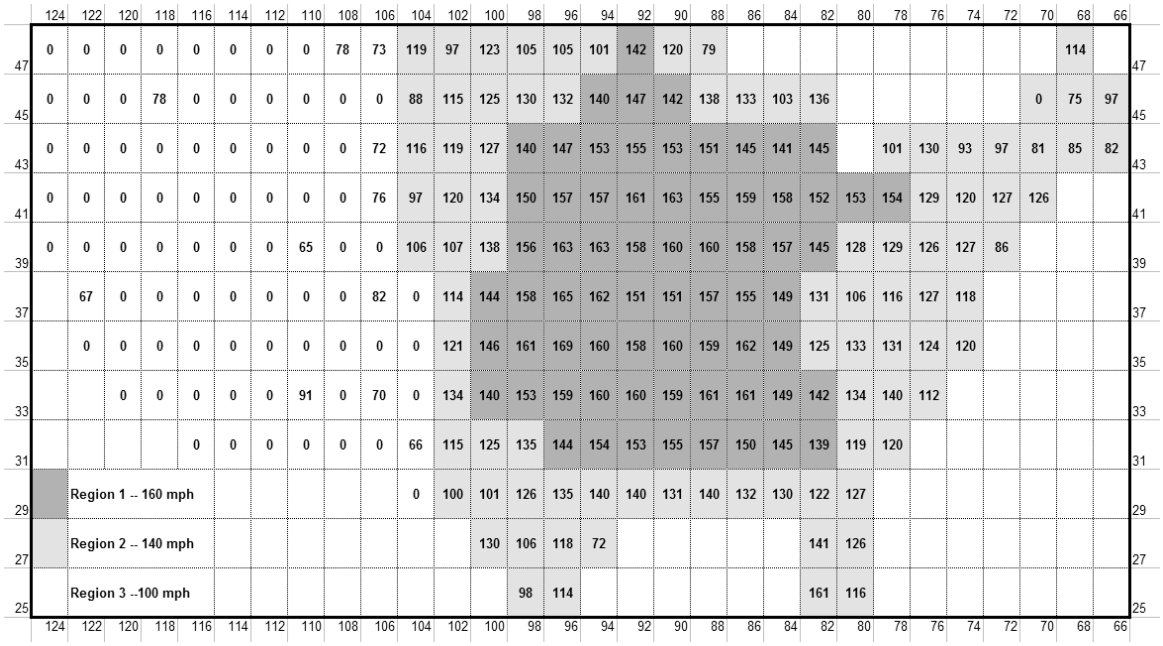

Figure 8-1. Recommended Tornado Design Wind Speeds for the 10^{-5} yr^{-1} Probability Level

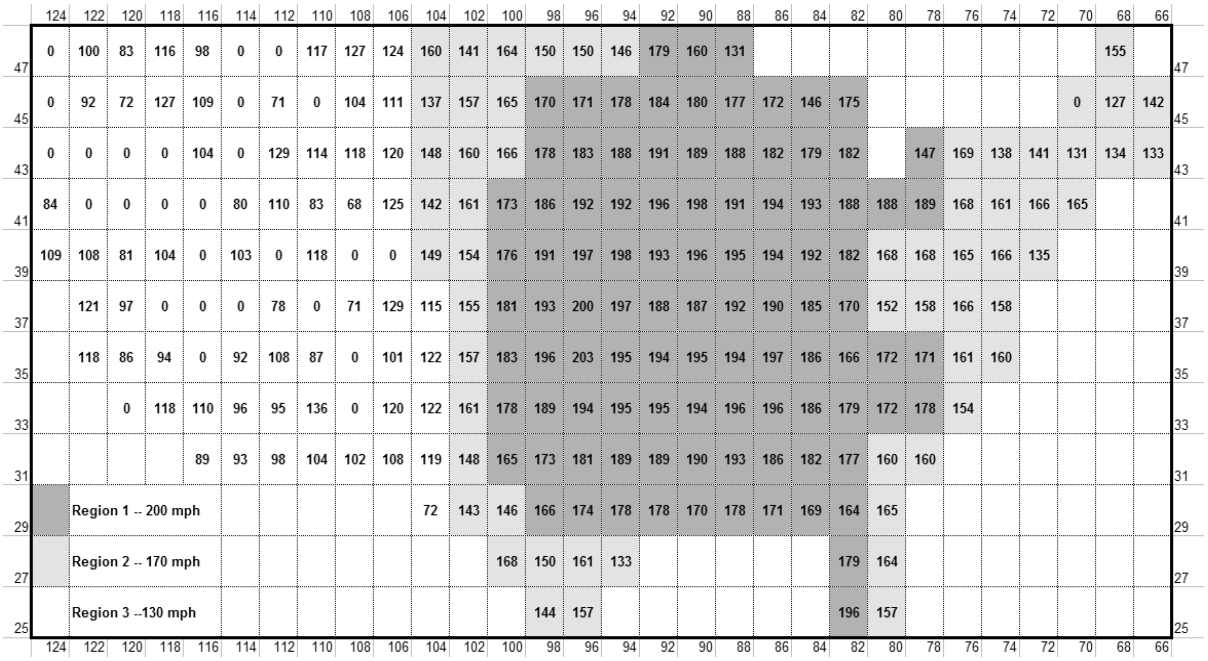

Figure 8-2. Recommended Tornado Design Wind Speeds for the 10^{-6} yr^{-1} Probability Level

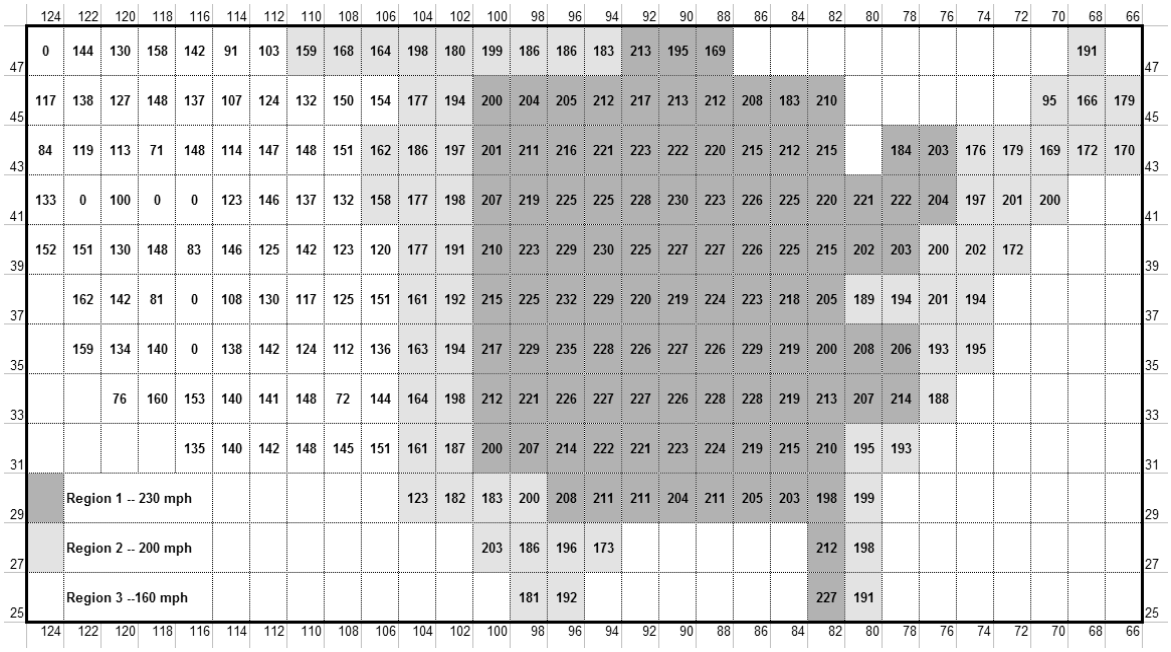

Figure 8-3. Recommended Tornado Design Wind Speeds for the 10^{-7} yr^{-1} Probability Level

Table 8-1. Recommended Tornado Design Wind Speeds

	Wind Speed (mph)		
Design Probability (yr^{-1})	**Region 1**	**Region 2**	**Region 3**
1.0×10^{-5}	160	140	100
1.0×10^{-6}	200	170	130
1.0×10^{-7}	230	200	160

Appendix A

Results for 2° Boxes

Appendix A

Results for 2° Boxes

This appendix contains the detailed results of the analysis for the 2° boxes. The output for each box generally consists seven lines. However, if there were no tornado events in the box or the information for the tornado events was insufficient to perform an analysis, then there is only one line of output. The first line of output starts with the latitude and longitude of the southeast corner of the box. The next two entries in the line are the land area for the box assumed in the analysis and the fraction of the total box area assumed to be covered by land. The last three items in the first line are the number of total events observed and the number of events included in the calculation of expected values of area and length for events. For some boxes, this is the only line. Care should be taken when using strike probability and wind speed data from this appendix to ensure that the number of tornado events is sufficient to give reasonable results. As a minimum, there should be 10 events, and 20 or more events are desirable.

The second through seventh lines include the results of the calculations. Lines two and three contain the results of the strike probability calculations for the point structure and life-line terms, respectively. In line two, the first number is the expected area, in square miles, for tornado events for the box; the second and third numbers are the lower and upper limits of the 90 percent confidence interval for the expected area. The last three numbers are the expected strike probability for a point structure and the lower and upper limits for the strike probability confidence interval. The format for the information in the third line is similar to that for the second line. The first three numbers are the expected length, in miles, for the life-line term and the lower and upper limits on the expected length. The last three numbers are the additional strike probability for finite structures, assuming a characteristic dimension of 200 ft for the structure.

The fourth line gives the expected total strike probability for the box and the lower and upper bounds of the 90 percent confidence interval. These values are the sums of the values direct above in lines two and three. Lines five through seven give the maximum wind speeds, in mile per hour, for 10^{-5} yr^{-1}, 10^{-6} yr^{-1}, and 10^{-7} yr^{-1} design criteria. As before, the first number is the expected value, and the second and third numbers are the lower and upper limits of the 90% confidence interval.

If a strike probability is desired for a different size structure, the values in line three should be adjusted by the ratio of the characteristic dimension for the structure to 200 ft. The new life-line terms should be added to the point structure terms to get the revised strike probabilities. The ratio of the new strike probability to the original strike probability may then be used to adjust the design criteria probability levels associated with the maximum wind speeds. For example, consider the box with its southeast corner at 25° N latitude, 80° W longitude. If the strike probability were desired for a larger structure, say one with a characteristic dimension of 400 ft, then the expected value of the life-line term (3.473×10^{-5} yr^{-1}) should be multiplied by two and added to the point structure term (3.643×10^{-5} yr^{-1}) to get the new expected strike probability (1.059×10^{-4} yr^{-1}). With this new expected strike probability, the 10^{-5} yr^{-1} design criterion associated with the 118 mph expected maximum wind speed should be increased to account for the change in strike probability. The new design criterion is the product of the old design criterion (10^{-5} yr^{-1}) and the ratio of

the new strike probability (1.059×10^{-4} yr^{-1}) to the original strike probability (7.116×10^{-5} yr^{-1}). Or, carrying out the arithmetic, the new design criterion is 1.488×10^{-5} yr^{-1}.

The lower limit for the maximum wind speed in a tornado is 65 mph. Two wind speeds less than 65 mph are used to provide information when the design wind speed would be less than 65 mph. A design wind speed of 50 mph indicates that the tornado strike probability for the box is less than 10^{-7} yr^{-1}. A design wind speed of 60 mph indicates that the design wind speed for the design probability specified at the beginning of the line is less than 65 mph, but that the design wind speed at the 10^{-7} yr^{-1} probability level exceeds 65 mph.

Appendix B

Results for 4° Boxes

Appendix B

Results for 4° Boxes

This appendix contains the detailed results of the analysis for the 4° boxes. The output for each box generally consists seven lines. However, if there were no tornado events in the box or the information for the tornado events was insufficient to perform an analysis, then there is only one line of output. The first line of output starts with the latitude and longitude of the southeast corner of the box. The next two entries in the line are the land area for the box assumed in the analysis and the fraction of the total box area assumed to be covered by land. The last three items in the first line are the number of total events observed and the number of events included in the calculation of expected values of area and length for events. For some boxes, this is the only line. Care should be taken when using strike probability and wind speed data from this appendix to ensure that the number of tornado events is sufficient to give reasonable results. As a minimum, there should be 10 events, and 20 or more events are desirable.

The second through seventh lines include the results of the calculations. Lines two and three contain the results of the strike probability calculations for the point structure and life-line terms, respectively. In line two, the first number is the expected area, in square miles, for tornado events for the box; the second and third numbers are the lower and upper limits of the 90 percent confidence interval for the expected area. The last three numbers are the expected strike probability for a point structure and the lower and upper limits for the strike probability confidence interval. The format for the information in the third line is similar to that for the second line. The first three numbers are the expected length, in miles, for the life-line term and the lower and upper limits on the expected length. The last three numbers are the additional strike probability for finite structures, assuming a characteristic dimension of 200 ft for the structure.

The fourth line gives the expected total strike probability for the box and the lower and upper bounds of the 90 percent confidence interval. These values are the sums of the values direct above in lines two and three. Lines five through seven give the maximum wind speeds, in mile per hour, for 10^{-5} yr^{-1}, 10^{-6} yr^{-1}, and 10^{-7} yr^{-1} design criteria. As before, the first number is the expected value, and the second and third numbers are the lower and upper limits of the 90% confidence interval.

The lower limit for the maximum wind speed in a tornado is 65 mph. Two wind speeds less than 65 mph are used to provide information when the design wind speed would be less than 65 mph. A design wind speed of 50 mph indicates that the tornado strike probability for the box is less than 10^{-7} yr^{-1}. A design wind speed of 60 mph indicates that the design wind speed for the design probability specified at the beginning of the line is less than 65 mph, but that the design wind speed at the 10^{-7} yr^{-1} probability level exceeds 65 mph.

Appendix C

Results for 1° Boxes

Appendix C

Results for 1° Boxes

This appendix contains the detailed results of the analysis for the 1° boxes. The output for each box generally consists seven lines. However, if there were no tornado events in the box or the information for the tornado events was insufficient to perform an analysis, then there is only one line of output. The first line of output starts with the latitude and longitude of the southeast corner of the box. The next two entries in the line are the land area for the box assumed in the analysis and the fraction of the total box area assumed to be covered by land. The last three items in the first line are the number of total events observed and the number of events included in the calculation of expected values of area and length for events. For some boxes, this is the only line. Care should be taken when using strike probability and wind speed data from this appendix to ensure that the number of tornado events is sufficient to give reasonable results. As a minimum, there should be 10 events, and 20 or more events are desirable.

The second through seventh lines include the results of the calculations. Lines two and three contain the results of the strike probability calculations for the point structure and life-line terms, respectively. In line two, the first number is the expected area, in square miles, for tornado events for the box; the second and third numbers are the lower and upper limits of the 90 percent confidence interval for the expected area. The last three numbers are the expected strike probability for a point structure and the lower and upper limits for the strike probability confidence interval. The format for the information in the third line is similar to that for the second line. The first three numbers are the expected length, in miles, for the life-line term and the lower and upper limits on the expected length. The last three numbers are the additional strike probability for finite structures, assuming a characteristic dimension of 200 ft for the structure.

The fourth line gives the expected total strike probability for the box and the lower and upper bounds of 90 percent confidence interval. These values are the sums of the values direct above in lines two and three. Lines five through seven give the maximum wind speeds, in mile per hour, for 10^{-5} yr^{-1}, 10^{-6} yr^{-1}, and 10^{-7} yr^{-1} design criteria. As before, the first number is the expected value, and the second and third numbers are the lower and upper limits of the 90% confidence interval.

The lower limit for the maximum wind speed in a tornado is 65 mph. Two wind speeds less than 40 mph are used to provide information when the design wind speed would be less than 40 mph. A design wind speed of 50 mph indicates that the tornado strike probability for the box is less than 10^{-7} yr^{-1}. A design wind speed of 60 mph indicates that the design wind speed for the design probability specified at the beginning of the line is less than 65 mph, but that the design wind speed at the 10^{-7} yr^{-1} probability level exceeds 65 mph.

NRC FORM 335 (9-2004) NRCMD 3.7

U.S. NUCLEAR REGULATORY COMMISSION

BIBLIOGRAPHIC DATA SHEET

(See instructions on the reverse)

1. REPORT NUMBER (Assigned by NRC, Add Vol., Supp., Rev., and Addendum Numbers, if any.)

NUREG/CR-4461, Rev 2

2. TITLE AND SUBTITLE

Tornado Climatology of the Contiguous United States

3. DATE REPORT PUBLISHED

MONTH	YEAR
February	2007

4. FIN OR GRANT NUMBER

JCN N6337

5. AUTHOR(S)

J.V. Ramsdell, Jr.
J.P. Rishel

6. TYPE OF REPORT

Technical

7. PERIOD COVERED *(Inclusive Dates)*

6/9/2006 to 12/31/2006

8. PERFORMING ORGANIZATION - NAME AND ADDRESS *(If NRC, provide Division, Office or Region, U.S. Nuclear Regulatory Commission, and mailing address; if contractor, provide name and mailing address.)*

Pacific Northwest National Laboratory
PO Box 999
Richland, WA 99352

9. SPONSORING ORGANIZATION - NAME AND ADDRESS *(If NRC, type "Same as above"; if contractor, provide NRC Division, Office or Region, U.S. Nuclear Regulatory Commission, and mailing address.)*

Division of Risk Assesment & Special Projects
Office of Nuclear Regulatory Research
US Nuclear Regulatory Commission
Washington, DC 20555-0001

10. SUPPLEMENTARY NOTES

A.J. Buslik, NRC Project Manager

11. ABSTRACT *(200 words or less)*

Characteristics of tornadoes reported from January 1950 through August 2003 have been used to estimate tornado strike probabilities and maximum wind speeds. Maps included in this report show the distribution of tornado events and design wind speeds. Appendices contain the number of tornadoes and estimates of strike probabilities and maximum wind speeds by 1°, 2°, and 4° latitutde and longitude boxes. The primary difference between the climatology presented here and the climatology in NUREG/CR-4461, Rev 1 is that wind speed estimates in this climatology are based on the Enhanced Fujita Scale rather than the original Fujita Scale. The National Weather Service intends to implement the Enhanced Fujita Scale by February 2007. For a best estimate probability of 1.0E-7 per year, a maximum wind speed of about 230 mph is appropriate for tornadoes in the central United States, and maximum wind speeds of 200 mph and 160 mph are appropriate for regions of the United States along the east coast and the western great plains, and for the western United States, respectively. Corresponding wind speeds in NUREG/CR-4461 Rev. 1 were 300 mph, 260 mph, and 200 mph, respectively.

12. KEY WORDS/DESCRIPTORS *(List words or phrases that will assist researchers in locating the report.)*

Tornadoes, Characteristics, Distributions, Enhanced Fujita Scale, Strike Probabilities, Design Wind Speeds
