This scientific analysis report also supports the resolutions of Key Technical Issues, including: ECRB moisture monitoring (Section 6.10); Alcove-8/Niche-3 (Niche 3107) testing (Section 6.11); flow through the Calico Hills nonwelded vitric (Section 6.13); and analogue radionuclide data from test blocks at Busted Butte (Section 6.13).

1.4 CONSTRAINTS AND LIMITATIONS

The field-testing activities and the associated analyses are subject to the constraints and limitations of spatial locations and temporal durations for tests conducted in the underground drifts. One niche in the ECRB, Niche 5 (Niche CD 1620), has been excavated in the Tptpl unit (see Figure 1-1). Most of the other existing testing alcoves and niches in the ESF (shown in Figure 1-2) are located at or above the horizon of the Tptpmn unit (see Figure 1-1). Test results and analyses from these sites provide data for the upper and middle tuff units. Some of the active flow tests were conducted within a few hours to a few days of each other because of limited accessibility to the test beds in the evenings and on weekends. Depending on system characteristics, the establishment of steady-state conditions can require longer tests. Some tests used automatic data acquisition systems for long-term monitoring and liquid releases, subject to power interruptions and equipment malfunctions. These constraints and limitations are addressed in the analyses of Section 6, if applicable.

GS980908312242.030 [DIRS 135224]	–	–	6-26	1 slant borehole core saturation.

^a Also used as input in Section 6.8 on niche water-potential measurement, as shown in Table 4-8.

^b Also used as input in Section 6.9 on construction-water migration, as shown in Table 4-9.

ESF = Exploratory Studies Facility; TDR = time domain reflectrometry.

- Section 6.13 presents the results of different phases of transport tests at Busted Butte.
- Section 6.14 summarizes geochemical and isotope data in pore water, rocks, and fracture in-fill minerals collected from test locations in different tuff units.

The list of data supporting these analyses can be found in the tables labeled “b” and “c” of Section 4.1.

The tests performed in niches and alcoves along the ESF are illustrated in Figure 6-1. Seepage into drifts at the repository level is related to water percolating down from the ground surface. Drift-seepage tests at niche sites quantify the seepage from liquid pulses released above the niches. Percolation flux has a fast fracture-flow component and a slow matrix-flow component. This partitioning of flow is evaluated at the fracture-matrix test bed in Alcove 6. The heterogeneous hydrogeologic setting (with alternating tuff layers) determines the percolation distribution throughout the UZ, with input from infiltration at the ground surface boundary. The mechanism of redistributing near-surface fracture flow by the porous PTn, especially the flow-damping process by the PTn unit, is studied in a test bed in Alcove 4. The PTn unit examined at Alcove 4 consists of layered, altered, and bedded tuffs transected by a fault. Wetter climate conditions increase the infiltration, as quantified in an artificial infiltration test in Alcove 1 and in moisture monitoring at depth in Alcove 7. The seepage threshold data from niches and from systematic hydrological characterization are inputs to the model report *Seepage Calibration Model and Seepage Testing Data* (BSC 2004 [DIRS 171764]).

Figure 6-1 illustrates general issues (DOE 1998 [DIRS 100550], Section 3.1; Figure 3-1) pertaining to UZ flow processes of seepage, percolation, and infiltration. The tests illustrated in Figure 6-1 focus on different issues to quantify the functional relationships among these processes. Seepage is smaller than percolation flux because of capillarity-induced drift diversion (BSC 2004 [DIRS 171764], Section 6), and percolation may be smaller than infiltration because of lateral diversion of percolating water along tuff interfaces to bounding faults. All tests use tracers to assist the characterization of plume migration.

Figure 6-2 illustrates the ECRB cross-drift to ESF main drift seepage collection system to study the migration of water and tracer flow from one drift to another. The crossover point is located in the northern part of the ESF, as illustrated in Figure 1-1 and Figure 1-3. In 1998, the seepage monitoring system was used to monitor the migration of construction water from the ECRB cross-drift. Niche 3 (Niche 3107), originally excavated and used for the drift seepage study, is part of the drift-to-drift study as a seepage collection site. The existing horizontal boreholes at Niche 3 (Niche 3107) are used for wetting-front monitoring for liquid released from Alcove 8, excavated from the ECRB cross-drift and directly above Niche 3 (Niche 3107).

Because neither the ESF main drift nor the ECRB cross-drift reaches the Calico Hills hydrogeologic tuff unit (CHn) below the repository block, a dedicated drift complex was excavated at Busted Butte, 8 km southeast of Yucca Mountain, to evaluate flow and transport processes in vitric CHn. Early results were first reported in the report *Unsaturated Zone and Saturated Zone Transport Properties* (CRWMS M&O 2001 [DIRS 154024]). The different field-testing phases and recent updates are presented in Section 6.13.

Table 6-25. Water-Potential Measurements in the Exploratory Studies Facility and in the Enhanced Characterization of the Repository Block Cross-Drift

^a Description taken from Automated Technical Data Tracking database.

ECRB = Enhanced Characterization of the Repository Block.

ESF = Exploratory Studies Facility.

barometric signals from the ground surface, less attenuation and phase lag were observed for signals from the ESF. For Borehole NRG-7a, which is within 30 m (in horizontal distance) from the ESF tunnel, the changes in water potential could also be related to the ESF dryout (see the last entry of Table 6-25 for DTNs of surface-based boreholes).

The main effects of ESF ventilation are the drying of rocks around the tunnel, the suppression of potential seepage into tunnels, and the perturbation of the gas flow field around the tunnel. Niche 1 (Niche 3566) and Alcove 7 in the ESF (Figure 1-2), and the last section of the ECRB Cross-Drift (Figure 1-1) have been closed for long periods (see Section 6.10.2 below), to minimize or eliminate the ventilation effects, and to gain additional information on the rewetting processes and potential seepage events under near-natural conditions (with drift entrances blocked off). Both the data collected during active ventilation phases and the data collected during passive nonventilation phases will contribute to the assessment of UZ responses to large-scale perturbations at Yucca Mountain.

6.10.1.2.2 Observation of Moisture Effects in Alcove 3 and Alcove 4

Alcove 3 and Alcove 4 were excavated in the vicinity of the TCw-PTn and PTn-TSw interfaces, respectively (Section 1.2). Corroborating studies have been performed between Alcove 3 and Alcove 4 that quantified in situ water-potential, moisture, and temperature fluctuations in the nonwelded units of the Paintbrush Group (PTn), to identify gradients between the PTn and adjacent Tiva Canyon tuff and Topopah Spring tuff (DTN: GS021008312242.003 [DIRS 162178]). The studies identified an effect of ventilation-induced drying to a depth of 4.9 m into the tuff from the ESF. As a result, water-potential values were more negative (lower moisture content) near the tunnel surface and greater (higher moisture content) beyond the zone influenced by ventilation. From surface to depth, water-potential values were:

- Tiva Canyon – 27.0 bars to -3.5 bars (ventilation effects),
- Paintbrush
nonwelded – 1.7 bars to -0.1 bars, and
- Topopah Spring – 1.4 bars to -0.6 bars.

The combined evidence of high moisture values at the Tpbt2/Tptrv3 contact (-0.1 and -0.3 bars), along with the 10° east dip of the beds, indicates a high potential for lateral water flow in the PTn (DTN: GS021008312242.003 [DIRS 162178]; LeCain et al. 2002 [DIRS 158511]). The PTn lateral flow has been evaluated in *UZ Flow Models and Submodels* (BSC 2004 [DIRS 169861]).
