- Section 5.0, “References,” of APP-GW-GLR-137 needs to be updated since the currently referenced topical report discusses the methodology used to determine certain uncertainties that factor into the calculation of the OPΔT and OTΔT setpoints. APP-GW-GLR-137 states that a revision to the topical report will be issued at a later date. This change was incorporated in Revision 1 to the TR.

The staff concludes that, based on the information provided in APP-GW-GLR-137 and the responses to RAIs, no significant change was made to the functional output and underlying methodology for the digital based OPΔT and OTΔT margin to trip functions and it is, therefore, concluded that SAFDLs will not be exceeded. Improvements to the measurement of core power for input to the margin to trip calculation were made by using actual core parameters versus using differential temperature. This change addresses a source of previous inaccuracy in the trip functions. To provide further assurance that the ΔT power signal used in the margin to trip calculation is valid, the signal is also compared to the plant calorimetric heat balance routinely performed in SR 3.3.1.3 as given in Chapter 16 of the DCD.

The setpoint calculated in the digital-based methodology for the OTΔT setpoint is based on allowable core power as a function of pressurizer pressure and core inlet temperature instead of allowable ΔT as a function of T_{AVG}. This is a simpler method and allows for direct translation of the appropriate DNB thermal design limits into the OTΔT trip function. The OPΔT setpoint calculation is unchanged in the digital methodology, except for the units. The OPΔT setpoint is manually fixed at a determined power level and only changes as a function of the adverse axial offset.

7.A.3 Conclusion

After reviewing APP-GW-GLR-137, the staff finds the proposed OPΔT and OTΔT reactor trip function calculational methodology to be acceptable and considers Open Item OI-SRP16-CTSB-42 resolved.

8. ELECTRIC POWER SYSTEMS

8.2 Offsite Power Systems

8.2.2 Offsite Circuits within the AP1000 Scope of Design

In the second paragraph of Section 8.2.2 of NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design," the Nuclear Regulatory Commission (NRC) staff stated that the main generator normally provides power to the main alternating current (ac) power system. When the main generator is not available, the generator output breaker is opened and the plant auxiliary power comes from the switchyard by back feeding through the main step-up transformers and the unit auxiliary transformers (UATs). There is also a maintenance source provided through a reserve auxiliary transformer (RAT). The maintenance source is site-specific, and bus transfer to the maintenance source is manual. In Section 8.2.3.4, "Specific Interface Requirements for Supporting Chapter 15 Analyses," of NUREG-1793, the NRC staff stated that the AP1000 design uses no automatic transfers of reactor coolant pump (RCP) buses to alternate power supply. In addition, in Section 8.3.1, "Onsite Power Systems," of NUREG-1793, the NRC stated that the 6.9 kilovolt (kV) buses are provided with access to the maintenance source through normally open circuit breakers connecting the bus to the RAT and that bus transfer to the maintenance source is manual.

In technical report (TR) (TR-79), "Electrical System Design Changes," Revision 1, the applicant added a fast bus transfer scheme, along with an operator-initiated maintenance transfer, to the AP1000 design. This change required installation of an additional RAT to allow complete bus transfer from UATs to RATs.

As a result of the above changes to Tier 2, the corresponding portions of the Tier 1 AP1000 design control document (DCD) Table 2.6.1-3 (untitled) and Figure 2.6.1-1, "Main ac Power System," were affected.

8.2.2.1 Evaluation

The proposed change will allow transfer of 6.9 kV RCP buses from the UATs to the RATs. The applicant stated that the addition of the fast bus transfer scheme will avoid a reactor trip resulting from component failure or spurious actuation of the protective relaying associated with any of the main step-up transformers, UATs, or isophase bus duct, which would cause an RCP trip and a reactor trip. Thus, when either normal or preferred power supply is unavailable because of an electrical fault at the main step-up transformer, UAT, isophase bus duct, or nonsegregated bus duct, fast bus transfer will be initiated to transfer the loads to the RATs. In addition to the above, the applicant has also added operator-initiated, sync-supervised, closed-transition transfers on a bus-by-bus basis to the AP1000 design.

The staff was concerned about a statement in Section 8.3.1.1.1 of the AP1000 DCD, which reads:

> …in the event of a loss of voltage on these buses, the diesel generators are automatically started and connected to the respective buses and in the event of a fast bus transfer, the diesel generator connection to the bus is delayed such that the fast bus transfer is allowed to initiate.

This statement implies that the diesel generator is already running during the fast bus transfer and its connection to the bus is delayed. In request for additional information (RAI) RAI-SRP8.3.1-EEB-02, the NRC requested that the applicant clarify when the diesel generator would start during fast bus transfer. In its response dated July 11, 2008, the applicant revised Section 8.3.1.1.1 of the DCD to clarify the statement as follows:

> In the event where a fast bus transfer initiates but fails to complete, the diesel generator will start on an undervoltage signal, but if a successful residual voltage transfer occurs, the diesel generator will not be connected to the bus, as the successful residual voltage transfer will provide power to the bus prior to the diesel connection time of 2 minutes.

The staff concluded that this revision to the AP1000 DCD satisfies its concern. The staff verified that Revision 19 to the AP1000 DCD includes the foregoing change.

8.2.2.2 Conclusion

The staff has reviewed these changes and concludes that the additions of a RAT and the bus transfer scheme to the AP1000 design provide additional plant availability and enhance the offsite power supply to the safety-related battery chargers, RCPs, and those priority loads provided for defense-in-depth functions.

8.3 Onsite Power System

8.3.1 AC Onsite Power System

8.3.1.1 Electric Circuit Protection

In this section of NUREG-1793, the NRC discussed the ratings and major types of protection systems employed for the AP1000 medium voltage switchgear. In TR-79, the applicant made the changes described in the sections below.

8.3.1.1.1 Rating of 6.9-kV Switchgear Buses

In TR-79, the applicant proposed to revise the short-circuit rating of 6.9-kV switchgear buses from the current 500 megavolt amps (MVA) (40 kilo-amperes (kA)) to 63 kA. The Tier 2 portions of the AP1000 DCD affected in the electrical area include Figure 8.3.1-1, “AC Power Station One Line Diagram,” and Table 8.3.1-3, “Component Data – Main Power System.”

8.3.1.1.1.1 Evaluation

Originally, the AP1000 DCD included the short-circuit rating of the 6.9-kV switchgear buses as 500 MVA (approximately 40 kA). The applicant proposed to revise the short-circuit rating from the current 40 kA to 63 kA. The applicant stated that the value change from 40 kA to 63 kA is based on revised short-circuit calculations that demonstrate that 63 kA is bounding, given the UAT/RAT size and the expected largest motor size driving the allowed impedance of the UAT/RAT transformers. In RAI-SRP8.3-EEB-01, the staff asked the applicant to justify this change in terms of the reason the interrupting rating changed from 40 kA to 63 kA and whether the proposed change affects the onsite distribution system analysis.

In its response dated October 17, 2008, the applicant stated that the onsite distribution system analysis supports the described engineering values. The value change from 40 kA to 63 kA is based on a computation of short-circuit current from an infinite source upstream of a UAT/RAT, neglecting the minimal contribution between the X-Y secondary windings of the transformer. In addition, the applicant considered a conservative assumption of a 100-percent motor load on a 100-percent loaded transformer winding using a 6.5 multiplier for motor short-circuit contribution. This value was computed while establishing a transformer impedance low enough to allow for starting the single largest motor. This computation demonstrates that 40 kA is inadequate and that 63 kA is bounding given the UAT/RAT size and the expected largest motor size driving the allowed impedance of the UATs/RATs.

8.3.1.1.1.2 Conclusion

The NRC reviewed this change and concludes that the proposed rating of 63 kA is acceptable because, in the current design, the starting current value of the largest motor is 58 kA, which is well in excess of 43 kA for the 6.9-kV switchgear bus rating. Therefore, a 63-kA rating for the 6.9-kV switchgear bus bounds the largest motor. Based on this discussion, the issue is resolved.

8.3.1.1.2 Air Cooled Chillers

In TR-79, the applicant proposed to revise AP1000 DCD Figure 8.3.1-1 to show the air-cooled chillers VWS-MS-02 and VWS-MS-03 being fed from the 6.9-kV buses ES-1 and ES-2, respectively.

The Tier 2 portions of the AP1000 DCD affected include Figure 8.3.1-1.

8.3.1.1.2.1 Evaluation

Figure 8.3.1-1 of the AP1000 DCD did not show the air-cooled chillers VWS-MS-02 and VWS-MS-03 being fed from the 6.9-kV buses ES-1 and ES-2, respectively. These loads were previously connected at the 480-volt (V) level. The applicant revised the DCD to reflect the connection of these loads directly to the 6.9-kV buses.

8.3.1.1.2.2 Conclusion

The staff reviewed this change and concludes that these loads were erroneously shown connected at the 480-V level and that the connection of the air chillers to the 6.9-kV buses is consistent with the design for this size of motor load. Therefore, the proposed change is acceptable.

8.3.1.1.3 Raw Water Feeder Breaker Change

In TR-79, the applicant proposed to revise AP1000 DCD Figure 8.3.1-1 to show the three raw water pumps and their auxiliaries. The Tier 2 portions of the AP1000 DCD affected include Figure 8.3.1-1.

8.3.1.1.3.1 Evaluation

AP1000 DCD Figure 8.3.1-1 in Revision 15 showed that three feeders for three raw water pumps were fed directly from 6.9-kV buses and their auxiliaries were powered from 480-V buses. The applicant has proposed to have each of these three feeders support the respective raw water pump and the associated auxiliaries of that pump. The proposed change allows a single feeder to the raw water pump house and distributes power within that structure.

8.3.1.1.3.2 Conclusion

The staff reviewed this change and concludes that it has no impact on the safety systems; therefore, it is acceptable.

8.3.1.2 Standby Diesel Generators

Section 8.3.1.2, “Standby Diesel Generators,” includes the staff’s review of generator exciter and voltage regulator systems as well as power sources.

8.3.1.2.1 Generator Exciter and Voltage Regulator Systems

In the sixth paragraph of Section 8.3.1.2 of NUREG-1793, the staff stated that the generator exciter and voltage regulator systems are capable of providing full voltage control during operating conditions, including postulated fault conditions.

In TR-79, the applicant proposed to delete the word “static” from the description of the exciter type so that a more readily available design may be used.

In addition, the applicant revised the nominal power ratings of various pieces of equipment and diesel generator loading in Table 8.3.1-2, “Onsite Standby Diesel Generator ZOS MG 02B Nominal Loads,” of the AP1000 DCD.

8.3.1.2.1.1 Evaluation

There are no regulatory criteria that require a specific diesel generator exciter type. Revision 15 of the AP1000 DCD specified that each onsite diesel generator has a “static” exciter. NUREG-1793 did not identify what type of exciter was used for standby diesel generators. The staff concludes that deleting the word “static” from the description of the exciter type will provide applicant flexibility in choosing what equipment is to be procured and there is no impact on performance requirements.

In Revisions 16 and 17 of the AP1000 DCD, the applicant revised the rating and operating load sizes of various pieces of equipment and updated the affected diesel loading tables. The staff reviewed the revised loads in Tables 8.3.1-1 and 8.3.1-2 and found that the total loads exceed the rating of diesel generators. The portions of the AP1000 DCD affected include Tables 8.3.1-1 and 8.3.1-2. In RAI-SRP8.3.1-EEB-01, the staff noted that the sum of the total loads (automatic and manual) listed in each revised table exceeds the continuous rating of each diesel generator and requested the applicant to justify why it is acceptable to exceed the continuous rating of the diesel generator at this stage of the design. Also, the applicant was requested to describe provisions included in the design that will prevent overloading of the diesel generators when manual loads are powered from the diesel generator.

In its response dated June 23, 2009, the applicant stated that onsite standby diesel generators have a nominal rating of 4000 kilowatt (kW); however, the units will accept loads up to the overload ratings of the diesel generators for the period of time specified for those ratings. The intent of the diesel generator loading is to accept all automatic loads followed by other loads to be manually added under operator control. In addition, the applicant stated that the abnormal operating procedures include diesel generator load management details to be followed after the automatic load sequencing. These procedures will identify that additional loads can be manually loaded at the operator's option. The operator will assess plant conditions and available diesel generator capacity to determine if these additional components should be started. The operator has main control room indication of the current power demand on each of the diesel generators upon which to base his decision. The staff finds the response to the RAI to be acceptable.

8.3.1.2.1.2 Conclusion

The staff concludes that removing the word "static" from the type of exciter would provide the applicant more flexibility in choosing other excitation systems; therefore, the proposed change is acceptable. The staff also finds the changes made to Tables 8.3.1-1 and 8.3.1-2 for auto-connected loads to be acceptable because: 1) the total auto-connected loads (2706 kW, 3126 kW) on each diesel generator is still within the continuous rating of 4000 kW; and 2) the procedures that will prevent overloading of the diesel generators when manual loads are powered from the diesel generator are included.

8.3.1.2.2 Power Sources

In the third paragraph of Section 8.3.1.2, "Standby Diesel Generators" of NUREG-1793, the staff stated that during plant startup, shutdown, and maintenance, the generator breaker is opened. Under this condition, the preferred power supply system provides the main ac power from the high-voltage switchyard through the main step-up transformers and two UATs. Each UAT supplies power to about 50 percent of the plant loads. The UATs have two identically rated 6.9 kV secondary windings.

In TR-114, "AP1000 Auxiliary Building Boiler Sizing and Design," the applicant added a third two-winding UAT sized to accommodate the electric auxiliary steam boiler and site-specific loads. In addition, in Revision 17 to the AP1000 DCD, the applicant revised Section 8.3.1.1.1, "Onsite AC Power System," to describe the neutral overcurrent protection for the RATs.

As a result of the above changes to Tier 2, the portions of the Tier 1 AP1000 DCD affected include Figure 2.6.1-1, "Main AC Power System," and Tables 2.6.1-3 and 2.6.1-5.

8.3.1.2.2.1 Evaluation

The applicant has proposed a design change from a diesel-fired auxiliary steam boiler to an electric auxiliary steam boiler for the AP1000 to alleviate issues in current plants related to operational problems caused by fuel fouling in diesel-fired boilers in standby service. This change reduces the size requirement on the auxiliary boiler by over 50 percent (from approximately 70 megawatts (MW) to 25 MW). As a result, the applicant added a third two-winding UAT sized to accommodate the electric boiler and site-specific loads. The third UAT would be located outside the turbine building in the transformer area. A 25-MW electric boiler would be installed in the boiler room of the turbine building along with its associated switchgear ES7, load center, and motor control center. This design change would not have any impact on the safety systems.

The staff was concerned that the applicant did not provide any neutral overcurrent protection for the RATs. In RAI-SRP8.2-EEB-03, dated March 13, 2008, the staff asked the applicant to justify its failure to provide neutral overcurrent protection for the RATs. In its response dated April 22, 2008, the applicant stated that it had inadvertently omitted the neutral overcurrent protection from page 8.3-2 of the AP1000 DCD. The applicant committed to modify DCD Section 8.3.1.1.1 to show neutral overcurrent protection for the RATs. The staff finds the above design to be consistent with the recommendations of Institute of Electrical and Electronics Engineers (IEEE) Standard 666, "IEEE Design Guide for Electric Power Service Systems for Generating Systems."

The staff confirmed that Revision 19 to the AP1000 DCD includes the neutral overcurrent protection for the RATs.

8.3.1.2.2.2 Conclusion

The staff reviewed this change and concludes that the addition of the third UAT and its associated switchgear ES7 has no impact on the safety systems and, therefore, the proposed change is acceptable. In addition, the staff finds the inclusion of the overcurrent protection for the RATs acceptable because it is consistent with expected engineering practice.

8.3.1.3 Ancillary AC Diesel Generators

In the first paragraph of Section 8.3.1.2 of NUREG-1793, the staff stated that the applicant has included two ancillary diesel generators located in the annex building to provide power to meet the post-72-hour power requirements following an extended loss of offsite power sources. Each ancillary diesel generator output is connected to a distribution panel.

In TR-79, the applicant proposed to revise Figure 8.3.1-3 of AP1000 DCD Tier 2 to reflect a four-wire 100 amp distribution panel from a three-wire 50 amp distribution panel, and a 100 amp breaker for both the diesel generator to the bus and for the test load tie to the bus from the 50 amp breaker.

8.3.1.3.1 Evaluation

There are no regulatory requirements concerning the number or rating of wires to or from a nonsafety-related ancillary diesel generator. The staff reviewed this change to determine whether it would adversely affect the design. Currently, AP1000 DCD Figure 8.3.1-3 shows the size of the ancillary diesel generator distribution panels as 50 amp with an incoming breaker of 30 amp from the generator. The applicant proposed to revise Figure 8.3.1-3 of the DCD to reflect a four-wire 100 amp distribution panel from a three-wire 50 amp distribution panel, and a 100 amp breaker for both the diesel generator to the bus and for the test load tie to the bus from the 50 amp breaker. The applicant stated that since the full load current of the generator is 53 amps, the main breaker of the distribution panel should be sized at the full capacity of the generator at a minimum. The diesel generator test load will also be changed to 100 amp to allow for this generator to be tested at full capacity. The applicant made its selection based on the 480 volts alternating current (Vac) standard-sized distribution panels available in the industry. In addition, to facilitate the use of this source as a feed to 277 Vac lighting circuits, these panels would be changed from three-wire system to four-wire system.

8.3.1.3.2 Conclusion

The staff reviewed these changes and concludes that the original rating of the bus and breakers of the panel was undersized and that the proposed revised rating of the diesel generator distribution panel is adequate because it exceeds the full load current of the diesel generator. Therefore, the proposed change is acceptable.

8.3.2 Direct Current Power and Uninterruptible Power Systems

8.3.2.1.1 Class 1E dc Distribution

In Section 8.3.2.1.1 of NUREG-1793, the staff stated that the Class 1E direct current (dc) power system consists of four independent 125 V Class 1E dc safety system divisions (Divisions A, B, C, and D). Divisions A and D are each comprised of one battery bank, one switchboard, and one battery charger. Divisions B and C are each comprised of two battery banks, two switchboards, and two battery chargers; however, in Revision 17 of the AP1000 DCD, the applicant changed the system voltage for the operation of Class 1E dc loads from 125 volts direct current (Vdc) to 250 Vdc.

The portions of the AP1000 DCD affected include pages 8.1-2, 8.1-3, 8.3-10, 8.3-14 through 8.3-17, 8.3-22 through 8.3-26, and Tables 8.3.2-1 through 8.3.2-7. The portions of the Tier 1 AP1000 DCD affected include Section 2.6.3, "Class 1E dc and Uninterruptable Power Supply System," Table 2.6.3-1 (untitled), Table 2.6.3-3, "Inspections, Tests, Analyses and Acceptance Criteria," and Table 2.6.3-4 (untitled).

As part of the staff's review of the proposed changes to the Class 1E dc system, the staff issued several RAIs. The staff's evaluation of the applicant's responses to the RAIs is as follows.

8.3.2.1.1.1 Evaluation

In RAI-SRP8.3.2-EEB-01, the staff requested that the applicant provide a discussion as to how this voltage change would impact motors, cables, protective devices, switchboard, and other equipment, as applicable. Also, the applicant was asked to describe how motor sizing and cable sizing would still be compatible with valve loads.

In its response dated May 7, 2009, the applicant stated that dc motor-operated valve motors would draw less current to accomplish the required power. Cable sizes would be reduced considerably. As the current drawn by the same size (kW) motor is halved and the total voltage drop allowed is doubled, the cable sizes would be reduced accordingly. Electrical distribution equipment would require, nominally, one half the current rating. The staff agrees with the applicant that by increasing the system voltage the current would be reduced, the cable sizes would be reduced, and the electrical distribution equipment would require less current. Therefore, the staff finds applicant's response to be acceptable and finds this issue resolved.

In RAI-SRP8.3.2-EEB-02, the staff noted that AP1000 DCD Section 8.3.2.1 indicates that the operating voltage range of the Class 1E batteries is 210 to 280 Vdc and the maximum equalizing charge voltage for the Class 1E batteries is 280 Vdc. The applicant was asked to confirm that the connected dc equipment is designed to operate up to the maximum voltage 280 Vdc.

In its response dated May 7, 2009, the applicant stated that all connected equipment design specifications would include the new voltage limit requirements. Based on the above, the staff finds that since specification of each piece of equipment would include the revised voltage specification, the applicant's response is acceptable and this issue is resolved.

In RAI-SRP8.3.2-EEB-03, the staff requested that the applicant provide the load profiles (duty cycle) from one minute to 24/72 hours for each of the 24-hour and the 72-hour Class 1E 250 Vdc batteries. The applicant was asked to discuss battery margins (aging margin, design margin, temperature correction factor, margin associated with float current for 100 percent state of charge) and the expected service life of these batteries.

In its response dated June 23, 2009, the applicant stated that for battery aging margin, a factor of 25 percent would be used for a 20 year qualified battery. Temperature correction would be based on minimum temperature of 16° Celsius (C) (60° F). With regard to float current margin, the applicant stated that this margin is described as a consideration for quick turnaround to service after discharge. Since the electrical design described in the AP1000 DCD utilizes a spare battery that can replace any safety-related battery, there is no immediate need to replace the discharged battery. The replacement interval/service life of the batteries will be in accordance with the testing program replacement requirements. Replacement intervals will be based on degraded performance in accordance with the required test program. However, the applicant did not provide the load profiles for 24-hour and 72-hour batteries as requested by the staff. The staff identified this as Open Item OI-SRP8.3.2-EEB-03 in the safety evaluation report (SER) with open items.

Subsequently, in a letter dated May 10, 2010, the applicant stated that the nominal loads on the batteries are identified in AP1000 DCD Tables 8.3.2-1, 8.3.2-2, 8.3.2-3, and 8.2.3-4 and that the design is based on intelligent assumptions on the loads. Also, as part of the response to the above open item, the applicant provided document, APP-IDS-EOC-001, Revision 0, “Class 1E 250 V DC Battery Sizing, Charger Sizing and Available Short Circuit Current,” for the staff’s review to assess the adequacy of the 24-hour and 72-hour batteries. The staff reviewed the applicant’s onsite documentation which included the load profiles for loss of offsite power and loss-of-coolant accident (LOCA) from one minute to 24/72 hours for each of the 24-hour and the 72-hour Class 1E 250 Vdc batteries in this report. Based on its review, the staff concluded that since the AP1000 Class 1E 250 Vdc batteries are sized in accordance with the recommendations of IEEE Standard 485, “IEEE Recommended Practice for Sizing Lead-Acid Batteries for Stationary Applications,” (which provides methods for defining the dc load and for sizing a battery to supply that load for stationary batteries), there is reasonable assurance that the batteries would be designed to have adequate capacity to meet their respective load profile. In addition, the staff determined that the battery qualification program and the applicable surveillance requirements in accordance with plant technical specifications would ensure that the batteries would envelop their designed load profiles throughout their designed life. On this basis, the staff considers Open Item OI-SRP8.3.2-EEB-03 resolved.

In RAI-SRP8.3.2-EEB-04, the staff requested that the applicant describe how the 24-hour and the 72-hour 250 Vdc batteries would be qualified for service life: If safety-related batteries would be qualified using the recommendations of IEEE Standard 535, “Standard for Qualification of Class 1E Lead Storage Batteries for Nuclear Power Generating Stations,” it is not clear how the standard applies since the standard was written under the assumption of an 8-hour duty cycle. Since AP1000 design duty cycles are significantly longer than 8-hour duty cycle and IEEE Standard 535 does not apply to duty cycles longer than 8 hours, the applicant was asked to describe how these batteries would be qualified for extended duty cycles of 24 hours and 72 hours. The applicant was also asked to discuss the failure mode(s) for both the 24-hour and 72-hour duty cycle batteries.

In its response dated May 7, 2009, the applicant stated that it intends to qualify the AP1000 safety-related batteries for 24-hour and 72-hour duty cycles through the implementation of industry standards IEEE Standard 323-1974, "IEEE Standard for Qualifying Class 1E Equipment for Nuclear Power Generating Stations"; IEEE Standard 344-1987, "IEEE Recommended Practice for Seismic Qualification of Class 1E Equipment for Nuclear Power Generating Stations"; and IEEE Standard 535-1986 as they apply to the equipment.

The qualification process for the AP1000 24-hour and 72-hour duty cycle batteries would be outlined in a test plan. Qualification of the batteries would be accomplished by type testing of both duty cycle designs to the AP1000 service conditions associated with their projected service life. In the qualification process, the batteries would be subjected to aging (thermal, wear/operational), abnormal environmental, and seismic conditions. There are no radiation and normal vibration conditions associated with the mounting locations of the batteries. Aging under normal and abnormal service conditions would be performed to degrade batteries to their end-of-life such that the safety function after the design basis event (DBE) (seismic) would be verified.

The aging conditions would include both electrical (chemical) cycling and thermal accelerated aging. Electrical (chemical) cycling would be performed in compliance with IEEE Standard 323. The proposed electrical (chemical) cycling is in line with Section 8.2.2 (6) of IEEE Standard 535-1986 for cases when the service conditions are more severe than those specified in the standard. The electrical (chemical) cycling of the batteries is based on the AP1000 maintenance/surveillance requirements with no less than 10 percent margin. During the testing process, the service and performance tests would be performed in conjunction with the thermal accelerated aging test of the batteries to place the batteries in an end-of-life condition. Upon completion of the battery aging, abnormal environmental testing to the AP1000 mild environment abnormal conditions would be performed. Following the abnormal environmental testing, seismic testing and a hard rock high frequency screening test would be performed.

At the completion of seismic testing, a post-seismic battery service test would be performed. The service test is used to demonstrate equipment functionality during and after the DBE (seismic), which is a requirement in accordance with IEEE Standard 344 and IEEE Standard 323. This is different from IEEE Standard 535, which only requires a performance test to be performed. In the process of performing the qualification testing of the AP1000 batteries, the program would identify any failure mechanisms that may surface during the projected service life in an AP1000 plant.

In a May 21, 2009 conference call, the staff requested that the applicant provide its step-by-step, detailed qualification test plan showing testing for desired qualified life of the batteries. However, the applicant did not provide its qualification test plan for the batteries prior to issuance of the SER with open items. This issue was tracked as Open Item OI-SRP8.3.2-EEB-04 in the SER with open items.

Subsequently, in a letter dated March 2, 2010, as part of the response to the above open item, the applicant provided document, EQ-TP-59-APP (APP-DB01-VPH-001), Revision 0, "AP1000 Test Plan for Safety Related 250 Vdc Batteries," for the staff's review. The staff reviewed the applicant's onsite documentation supporting the qualification methodology for the 24-hour and 72-hour extended duty cycle batteries. The applicant provided detailed steps that would be followed to qualify the batteries as requested by the staff. The qualification would be based on the requirements of IEEE Standard 323-1974, IEEE Standard 344-1987, and IEEE Standard 535-1986. Qualification of the Class 1E batteries would be performed by testing. Due to the difference in duty cycle, the test sequence would be performed on two groups of test cells. One group would be cycled and tested to the 24-hour duty cycle for AP1000 and the other group would be cycled and tested to the 72-hour duty cycle for AP1000. The test plan includes a series of modified performance tests at two year intervals that envelop the load profile of a service test throughout the installed 20-year life of the batteries.

In a public meeting held on May 27, 2010, to discuss the AP1000 Chapter 8 open items, the staff informed the applicant that its qualification test plan for the batteries is reasonable, but that the applicant must capture the qualification test plan as part of its licensing basis.

In a letter dated June 18, 2010, the applicant stated that it would revise its DCD to include the battery qualification test program. The applicant included the proposed revised Section 8.3.2.1.4, "Description," of the DCD as part of its response as follows:

> The qualification test program for AP1000 24-hour and 72-hour class 1E batteries meets or exceeds the requirements of IEEE Std 323, IEEE Std 344 and IEEE Std 535 including required and recommended margins and is in regulatory compliance with RGs 1.89, 1.100 and 1.158. The test program requires that the battery be subjected to accelerated thermal aging and discharge cycling (wear aging) in accordance with Institute of Electrical and Electronics Engineers (IEEE) Std 323 and IEEE Std 535 over its qualified life objective followed by the DBE seismic event performed in accordance with IEEE Std 344. In addition, following the aging process, the test specimens shall be subjected to environmental testing to verify the equipment's ability to operate in postulated abnormal environmental conditions during plant operation. Discharge cycling will be performed as a potential aging mechanism prior to seismic testing using Type 3 modified performance test method in accordance with IEEE Std 450-2002 at intervals representative of the AP1000 surveillance test requirements of the batteries with 10 percent margin in the number of discharge cycles which establishes margin for the expected life of the battery. Thus, magnitude / duration (modified performance test versus service and performance tests) and test interval envelop the AP1000 and industry cycling requirements. If new battery failure modes are detected during the qualification testing, these failure modes will be evaluated for any potential changes to the technical specification's surveillance requirements and revision to maintenance procedures required to ensure identification of degradation prior to reaching those failure modes during plant operation. Following the qualification process, a report that uniquely describes step-by-step the tests performed and results and addressing any deficiencies and repairs including photographs, drawings, and other materials will be maintained for records.

Based on the above, the staff concluded the applicant's test plan provided in EQ-TP-59-APP (APP-DB01-VPH-001) satisfies the recommendations of IEEE Standard 323-1974, IEEE Standard 344-1987, and IEEE Standard 535-1986 and provides reasonable assurance that its batteries and racks will perform their required functions throughout their qualified life. Therefore, Open Item OI-SRP8.3.2-EEB-04 is resolved subject to the verification that the AP1000 DCD is updated to include the revised paragraph. The staff confirmed that Revision 19 to the AP1000 DCD includes the revised paragraph.

In RAI-SRP8.3.2-EEB-05, the staff stated that in order to assess the adequacy of the dc power systems, it needed the results of 250 Vdc battery and battery charger sizing calculations, battery terminal voltage calculations, short circuit calculations, voltage drop calculations, and the associated assumptions used.

In its response dated May 7, 2009, the applicant stated that the results of 250 Vdc battery and battery charger sizing calculations, battery terminal voltage calculations, short circuit calculations, and voltage drop calculations would be available during a design review stage. This was tracked as Open Item OI-SRP8.3.2-EEB-05 in the SER with open items.

Subsequently, in a letter dated April 21, 2010, as part of the response to Open Item OI-SRP8.3.2-EEB-05, the applicant provided document, APP-IDS-EOC-001, for the staff's review. The document includes information to assess the adequacy of the battery banks and chargers for use in the Class 1E dc and uninterruptable power supply (UPS) for the AP1000 plant. The staff reviewed the applicant's onsite documentation that describes applicant's methodology for sizing batteries, chargers, and the available short circuit current from these sources. The staff verified that AP1000 Class 1E batteries are sized in accordance with the recommendations of IEEE Standard 485, and the battery chargers are sized in accordance with the recommendations of IEEE Standard 946, "IEEE Recommended Practice for the Design of DC Auxiliary Power Systems for Generating Stations." These standards provide guidance for sizing batteries and battery chargers. During its review of the document, the staff noticed that the required capacity of an IDSC-DB Division C, 72-hour battery is 2430 AH, while the batteries are rated for only 2400 AH in accordance with the AP1000 DCD. In a public meeting held on May 27, 2010, the staff asked the applicant to justify the apparent difference in the required capacity of the 72-hour battery per calculation versus the stated capacity of the 72-hour battery listed in Table 8.3.2-5 of the DCD.

In a letter dated June 18, 2010, the applicant stated that the required capacity of the IDSC-DB Division C, 72-hour battery in APP-IDS-EOC-001, Revision 0, would be revised to be made consistent with the AP1000 DCD. The staff finds the applicant's commitment acceptable because the revised calculations will ultimately be reviewed by the staff as part of the inspections, tests, analyses, and acceptance criteria (ITAAC) for the dc system, as described in AP1000 DCD Tier 1, Table 2.6.3-3, "Inspections, Tests, Analyses and Acceptance Criteria."

Based on its review, the staff concluded that the applicant's methodology for sizing batteries and battery chargers using these standards provides reasonable assurance that the batteries and battery chargers will be sized adequately and perform their safety functions as designed. The staff also verified that the dc switchboard rating exceeds the available short circuit current contributions from the batteries, battery chargers and regulating transformers. Further, ITAAC verifying that the batteries, chargers, and distribution systems are adequately designed are identified in AP1000 DCD Tier 1, Table 2.6.3-3. The staff will ultimately verify these ITAAC to ensure that the dc distribution system components, including the batteries and battery chargers, are adequately designed and the as-built design conforms to the approved plant design and applicable regulations. Therefore, Open Item OI-SRP8.3.2-EEB-05 is resolved.

In RAI-SRP8.3.2-EEB-06, the staff noted that AP1000 DCD Section 8.3.2.1.1.1, for 72-hour 250 Vdc batteries states, "Each switchboard connected with a 72-hour battery bank supplies power to an inverter. No load shedding or load management program is needed to maintain power during the required 24-hour safety actuation period." The staff requested that the applicant clarify if manual actions would be necessary to maintain power during the required 72 hours and to describe the loads that would be shed after 24 hours.

In its response dated May 7, 2009, the applicant confirmed that no operator action is necessary during the 72-hour period to maintain the adequacy of either the 24-hour or 72-hour portions of the dc power system. This satisfies the staff's concern and this item is resolved.

In RAI-SRP8.3.2-EEB-08, the staff noted that Figure 2.6.1-1, Tier 1 of the AP1000 DCD shows that the motor control centers that feed the safety-related 250 Vdc battery chargers are fed from 480 V load centers. The applicant was asked to provide a detailed drawing of the 480 V load centers, the motor control center (MCC) that feeds the battery chargers, and the dc MCC showing typical loads powered from these buses. The applicant was asked to describe how the 480 V load centers are protected from degraded voltage and frequency conditions and to provide the following information:

a. The results of an analysis of the onsite power distribution system to demonstrate that adequate voltages at terminals of the battery chargers are optimized for the maximum and minimum voltage variations of the offsite power for events such as a unit trip, LOCA, startup or shutdown.

b. A description of the analytical techniques, methodology, and assumptions used in performing the analyses. Also, provide the results of these analyses for each level of onsite electrical power distribution.

c. Identification of the analytical software (and its version) used for performing these studies and make available to the staff an electronic copy of the electrical distribution system model that forms the basis of the analytical studies.

In its response dated June 23, 2009, the applicant stated that the level of design detail requested would be available following the completion of the design review stage of the system. In general, the staff was seeking understanding of the applicant's approach to assuring consistency in the transfer to the combined license (COL) applicant: 1) analysis, calculations and assumptions made for maintaining adequate voltage regulation at safety-related equipment terminals; 2) the analysis and assumptions used to evaluate acceptable rating for equipment such as circuit breakers; and 3) the studies, acceptance criteria, and assumptions used to determine equipment sizing. This was tracked as Open Item OI-SRP8.3.2-EEB-08 in the SER with open items.

Subsequently, in letters dated February 1, 2010, and May 11, 2010, the applicant stated that to assure consistency in the transfer of design information to a COL applicant, it provides a COL applicant with a configuration-controlled model developed through the use of an Electrical Transient Analysis Program. The program includes the nonsafety-related ac design calculations, including design inputs, assumptions, methodologies, and acceptance criteria used in the development of the sizing basis, settings, load flow, short circuit, and voltage regulation. In addition, the applicant stated that it has performed an analysis of its onsite ac distribution system and that the results of the analysis of the onsite power distribution system demonstrate that adequate voltages at the terminal of the battery chargers are optimized for the maximum and minimum voltage variations of the offsite power for events, such as a unit trip, LOCA, startup or shutdown. The above will ensure that adequate voltages at terminals of the battery chargers are optimized for the maximum and minimum voltage variations of the offsite power to satisfy the requirements of 10 CFR Part 50, "Domestic licensing of production and utilization facilities," Appendix A, "General Design Criteria for Nuclear Power Plants," General Design Criteria (GDC) 17, "Electric Power Systems," with respect to their capacity and capability to perform their safety function. Although the applicant did not submit this information for staff review, the staff determined this response to be acceptable because ultimately all COL applicants would have to complete testing of the onsite (ac and dc) and offsite power systems, which are fully interconnected, to verify that the non-Class 1E ac power system will have an acceptable design to support the safety-related loads. Therefore, Open Item OI-SRP8.3.2-EEB-08 is resolved.

In RAI-SRP8.3.2-EEB-09, the staff noted that the AP1000 is designed to sustain a load rejection from 100 percent power with the turbine generator continuing stable operation while supplying the plant house loads. The staff is concerned about the transient conditions where a significant voltage spike during islanding could cause high dc voltage conditions on the output side of the battery chargers. Operating experience (see NRC Information Notice (IN) 2006-18, "Significant Loss of Safety-Related Electrical Power at Forsmark, Unit 1, in Sweden" dated August 17, 2006) has shown that the voltage spike due to malfunction of the main generator exciter or during islanding could go as high as 130 percent, which could go undetected by normally-provided relaying and could cause damage to the safety-related equipment or mis-operation. In this regard, the applicant was asked to describe how the protective features of the inverter and the new battery chargers would be coordinated so that any voltage transient would not result in inadvertent loss of the inverters or the batteries.

In a letter dated June 23, 2009, the applicant stated that the battery charger input circuit will conduct power to charge the batteries when ac power is available. The battery charger is specified to return to operation after voltage drifts outside of an acceptable input voltage range. The battery charger is also a qualified isolation device, isolating the battery and the inverter from the nonsafety-related ac system. During the period where the battery charger is not conducting, the battery will carry the load. In addition, the applicant stated that it has considered over-voltage events with the potential to have effects upon plant safety-related equipment as provided under the direction of IN 2006-18. However, the applicant did not provide the details of how to avoid this kind of event in AP1000 design or identification of potential vulnerabilities and actions that could reduce the challenges for the control room operators. This potential event is significant in that it can cause the common mode failure in all four trains and, therefore, could result in the loss of all four trains of safety-related ac and dc power. Transient voltages on the ac input to the battery chargers can result in high dc voltages that could lead to failures of critical electrical and electronic components including electrical inverters unless they are properly protected. During such a voltage transient, the inverter voltage surge protection could trip before actuation of the battery charger protection if the battery charger and inverter dc input voltage protection settings are very close to each other. Therefore, it is necessary that the safety-related battery chargers and inverter trips be coordinated such that the associated inverters do not trip on during voltage transients on the ac distribution system. This was tracked as Open Item OI-SRP8.3.2-EEB-09 in the SER with open items.

Subsequently, in letters dated January 26, 2010, and May 11, 2010, the applicant stated that as part of the component design specification, the battery charger/inverter would be designed specifically with consideration of the Forsmark incident identified in IN 2006-18. Industry evaluations of this incident identify the lack of coordination as a primary causative issue. In addition, the applicant stated that the protective devices will be set so that the battery charger will not trip on the over-voltage resulting from load rejection and will be set low enough to protect the equipment. The inverter dc input protection will be set at least 10 percent higher than the battery charger output dc protection to prevent the inverter tripping before the battery charger.

In a public meeting held on May 27, 2010, to discuss AP1000 Chapter 8 open items, the staff informed the applicant that its response to the above open item was inadequate. The staff stated that the safety-related inverter high dc input voltage trip set point and the associated battery charger high dc output voltage trip set point should be coordinated in both magnitude and time. The staff stated that the applicant should amend the DCD to include its response as modified.

In a letter dated June 18, 2010, the applicant provided a proposed revision to Section 8.3.2.1.4, "Maintenance and Testing," of the AP1000 DCD as part of its response to Open Item OI-SRP8.3.2-EEB-09 as follows:

> The inverter DC input protection will be set at least 10 percent higher than the battery charger trip setpoints to prevent the inverter tripping before the battery charger. The time delay for the inverter high dc input voltage trip will be set higher than the delay time delay for the battery charger to prevent the inverter tripping before the battery charger.

In addition, the applicant stated in its response dated May 11, 2010, that the battery charger function in the AP1000 design is to provide isolation between input ac and the dc system and to provide dc power when ac power is available. The staff noted that Section 8.3.2.2 of the AP1000 DCD states that Class 1E battery chargers and Class 1E voltage-regulating transformers are designed to limit the input (ac) current to an acceptable value under faulted conditions on the output side. Both have built-in circuit breakers at the input and output sides for protection and isolation. The circuit breakers are coordinated and periodically tested to verify their current-limiting characteristics. In the public meeting held on May 27, 2010, the staff requested the applicant explain how the requirement for periodic testing of the Class 1E battery chargers and Class 1E voltage-regulating transformers used as isolation devices would be satisfied by each COL applicant. The staff requested that the applicant indicate where this requirement would be located so that periodic testing of these devices was performed by each applicant to satisfy the recommendations of IEEE Standard 384, "IEEE Standard Criteria for Independence of Class 1E Equipment and Circuits," endorsed by Regulatory Guide (RG) 1.75, "Physical Independence of Electric Systems."

In the letter dated June 18, 2010, the applicant stated that a COL information item would be added to the AP1000 DCD to ensure that periodic testing was performed on the battery chargers and the regulating transformers. The applicant included the proposed revised Section 8.3.3, "Combined License Information for Onsite Electric Power," of the DCD as part of its response as follows:

> Combined License applicants referencing the AP1000 certified design will ensure that periodic testing is performed on the battery chargers and voltage regulating transformers.

Based on the above, the staff concluded that the applicant's modified response on battery charger and inverter trip setpoints satisfies the requirements of GDC 17 with respect to the capability of dc systems to perform their safety function. The staff determined that the addition of the above COL information item to the AP1000 DCD will ensure that periodic testing is performed on the battery chargers and the regulating transformers in accordance with the requirements of GDC 18, "Inspection and Testing of Electric Power Systems." The staff confirmed that Revision 19 to the AP1000 DCD includes the foregoing revised paragraph.

In RAI-SRP8.3.2-EEB-10, the staff remarked that Note 8 on Figure 8.3.1-4, "Inside Diesel Generator Building," (Sheets 1 and 2) of the AP1000 DCD indicates that the diesel generators include dc pre-lube oil pumps and keep-warm lube oil heaters and that these loads are not included on Table 8.3.2-2, "250 Vdc Class 1E Division B Battery Nominal Load Requirements," and Table 8.3.2-3, “250 Vdc Class 1E Division C Battery Nominal Load Requirements,” of the DCD. Additionally, the same tables do not include dc power requirements to close and recharge the springs of the circuit breakers, nor do they include the dc power requirements for diesel generator field flashing and starting. The staff asked the applicant to indicate whether the battery sizing will include these loads or provide a reference to where these loads are powered from.

In its response dated May 7, 2009, the applicant stated that the nonsafety-related diesel generator dc loads are not powered from the safety-related batteries. The required diesel generator dc loads will be powered from the nonsafety-related dc system. Nonsafety-related breakers will also have their spring charging motors powered from the nonsafety-related dc system.

The safety-related breakers, reactor trip and RCP trip will receive their control power from the safety-related dc system. Based on the above information, the staff finds this issue resolved.

8.3.2.1.1.2 Conclusion

The staff reviewed the proposed changes to the system voltage for the operation of Class 1E dc loads from 125 Vdc to 250 Vdc and concludes that the proposed changes are acceptable.

8.3.2.3 Non-Class 1E dc and UPS System

In this section of NUREG-1793, the staff stated that the non-Class 1E dc and UPS system consists of the dc electric power supply and distribution equipment that provides dc and uninterruptible ac power to the plant non-Class 1E dc and ac loads that are needed for plant operation and investment protection. Direct current Buses 1, 2, and 3 provide 125 Vdc power to the associated inverter units that supply the ac power to the non-Class 1E UPS system. Bus 4 supplies large dc motors and other dc power loads, but not inverter loads.

In Revision 17 to the AP1000 DCD, the applicant added another dc subsystem, which includes a battery, a battery charger, and the associated dc distribution equipment, and monitoring and protection devices to serve nonsafety-related loads.

The portions of the AP1000 DCD affected include pages 8.3-18 to 8.3-20, 8.3-24, Table 8.3.2-6 (Sheet 1) and a new Table 8.3.2-6 (Sheet 2). The portions of the Tier 1 AP1000 DCD affected include Table 2.6.1-2 (untitled), Section 2.6.2, “Non-Class 1E dc and Uninterruptible Power Supply System,” and Table 2.6.2-1, “Inspections, Tests, Analyses, and Acceptance Criteria,” Table 2.6.2-2 (untitled), and Figure 2.6.2-1, “Non-Class 1E dc and Uninterruptable Power Supply System” (Sheet 2 of 2).

8.3.2.3.1 Evaluation

The applicant added an additional dc subsystem (EDS5) in the non-Class 1E portion of the dc and UPS system in the AP1000 design, which includes a battery, a battery charger, and the associated dc distribution equipment, and monitoring and protection devices. As a result of the addition of the non-Class 1E dc subsystem EDS5, the large dc motors that were originally powered from EDS4 will now be powered from new EDS5.

8.3.2.3.2 Conclusion

The staff has reviewed the proposed change and concludes that the addition of subsystem EDS5 provides greater flexibility to service the non-Class 1E portion of the dc and UPS system for the AP1000 design. Since the proposed change has no impact on the safety-related systems, the proposed change is acceptable.

8.4 Other Electrical Features and Requirements for Safety

8.4.1 Containment Electrical Penetrations

In the first paragraph of Section 8.4.1 of NUREG-1793, the staff stated that for modular type penetrations (three penetration modules in one nozzle), the applicant has assigned the following:

- one module for low-voltage power
- one module for 120 Vac/125 Vdc control and signal
- one module for instrumentation signal

In TR-79, the applicant deleted the above assigned module separation criteria for cables of varying voltage service levels. In addition, the applicant revised Figure 8.3.1-1 of the AP1000 DCD to correct penetration numbers associated with each RCP.

As a result of the above changes to Tier 2, the portions of the Tier 1 AP1000 DCD affected include Figure 2.6.1-1 (Sheet 1 of 4 and Sheet 3 of 4).

In addition, in Tier 1, Section 2.2.1, “Containment System,” and Table 2.2.1-3, “Inspections, Tests, Analysis, and Acceptance Criteria,” the applicant added a new item “6d” to address environmental qualification requirements for non-Class 1E electrical penetrations to resolve the staff’s concern in RAI-TR93-ICE2-03.

8.4.1.1 Evaluation

The applicant stated that the electrical penetration conductor modules are in penetrations of the same service class. Modules for instrumentation signals will be in instrumentation penetrations; modules for power (e.g., 120/125 V) will be in control penetrations; and modules for low-voltage power will be in low-voltage power penetrations.

In addition to the above, the applicant stated that the penetration numbers shown in Figure 8.3.1-1 of Revision 15 of the AP1000 DCD were incorrect and were revised to reflect the correct penetrations associated with each RCP. The penetration numbers currently shown on the figure are E9, E10, E25, and E26. The correct penetration numbers are P10, P26, P9, and P25 for each of RCP 1B, 2B, 1A, and 2A, respectively.

With regard to qualification requirements for non-Class 1E electrical penetrations, in RAI-TR93-ICE2-03, the staff expressed its concern that non-Class 1E penetrations were not qualified for a harsh environment as were Class 1E penetrations. In its response, the applicant agreed with the staff that Class 1E and non-Class 1E penetrations must be qualified for maintaining their containment integrity to satisfy the requirements of GDC 50, “Containment Design Basis.”

8.4.1.2 Conclusion

The staff has reviewed these changes and concludes that the electrical penetration conductor modules are in penetrations of the same service class. This is consistent with the recommendations of RG 1.75, and is acceptable.

The staff also concludes that including environmental qualification requirements for non-Class 1E electrical penetrations satisfies the requirements of GDC 50 and is acceptable. In addition, the staff finds the proposed change to revise the penetration numbers associated with each RCP to be administrative in nature and acceptable.

8.4.2 Reactor Coolant Pump Breakers

In the first paragraph of Section 8.4.2 of NUREG-1793, the staff stated that the RCPs are powered from the four switchgear buses located in the turbine building. Each bus powers one RCP. Variable speed drives are provided for RCP startup. Two Class 1E circuit breakers connected in series power each RCP. These are the only Class 1E circuit breakers used in the main ac power system for the specific purpose of satisfying the safety-related tripping requirements of these pumps.

In TR-79, the applicant proposed to add input and output isolation breakers to each RCP variable frequency drive (VFD) unit. The proposed change would affect AP1000 DCD Tier 2, Table 8.3.1-3 and page 8.3-53 (untitled electrical drawing).

As a result of the above changes to Tier 2, the portions of the Tier 1 AP1000 DCD affected include Figure 2.6.1-1 (Sheet 1 of 4 and Sheet 3 of 4).

8.4.2.1 Evaluation

The applicant proposed to add input and output isolation breakers to each RCP VFD unit. The applicant stated that the addition of the input and output breakers allows for the VFD unit to be completely removed from service during normal plant operation by using the bypass breaker. Without the addition of these isolation breakers, the RCP pump would need to be offline in order to service the VFD unit.

There are no regulatory requirements concerning the ability to remove VFD units during normal plant operation.

8.4.2.2 Conclusion

The staff has reviewed this change and concludes that the addition of the input and output breakers will provide the applicant flexibility to service the VFD unit without removing the RCP offline and that this change has no impact on the safety systems. Therefore, the proposed change is acceptable.

9. AUXILIARY SYSTEMS

9.1 Fuel Storage and Handling

9.1.1 New Fuel Storage

9.1.1.1 Summary of Technical Information

Section 9.1.1, "New Fuel Storage" of the Westinghouse Electric Company, LLC (Westinghouse or the applicant) AP1000 design control document (DCD), Revision 15, was approved by the staff in the certified design. In the AP1000 DCD, Revision 17, the applicant has proposed to make the following changes to Section 9.1.1 of the certified design:

1. New fuel rack design change. The basis for this change is documented in technical report (TR)-44, "New Fuel Storage Rack Structural/Seismic Analysis," APP-GW-GLR-026, Revision 0 of May 2006, and TR-44, Revision 1 of July 2008. TR-44, Revisions 0 and 1 described the design details and design-basis analyses for the new fuel racks. To be consistent with the design of the new fuel racks and the analyses presented in these TR revisions, the applicant proposed several changes throughout Section 9.1.1 of DCD Revision 17.

2. Fuel handling crane change. The applicant proposed to replace references to the fuel handling jib crane for the new-fuel handling crane. The basis for this change is addressed in TR-106, "AP1000 Licensing Design Changes for Mechanical System and Component Design Updates," APP-GW-GLN-106, Revision 1 of September 2007.

3. The applicant proposed conforming changes to DCD Section 9.1.1 related to the new fuel storage rack criticality analysis. The basis for this change is documented in TR-67, "New Fuel Storage Rack Criticality Analysis," APP-GW-GLR-030, May 29, 2006.

9.1.1.2 Evaluation

The staff reviewed all changes identified in the proposed amendment to the AP1000 DCD. The staff did not re-review descriptions and evaluations of the new fuel storage in the AP1000 DCD, Revision 15, that were previously approved and that are not affected by the new changes. All technical changes in the DCD are supported by information presented in the applicant's TRs.

The regulatory basis for AP1000 DCD, Section 9.1.1, is documented in NUREG-1793, "Final Safety Evaluation Report Related to the Certification of the AP1000 Standard Design," of September 2004. The staff has reviewed the proposed changes to DCD Section 9.1.1 against the applicable acceptance criteria of NUREG-0800, "Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants," Sections 9.1.1, "Criticality Safety of Fresh and Spent Fuel Storage and Handling" and 9.1.2, "New and Spent Fuel Storage." The following evaluations discuss the results of the staff's review.

The specific criterion that applies to the changes evaluated in this section is Title 10 of the *Code of Federal Regulations* (10 CFR) 52.63(a)(1)(vii), "Finality of standard design certifications," which concerns contribution to increased standardization of the certification information.

9.1.1.2.1 New Fuel Rack Design Change

9.1.1.2.1.1 Summary of Technical Information

The applicant proposed the following changes for the new fuel racks:

1. In DCD Section 9.1.1.1, deleted "… to supporting grid structures at the top and bottom elevations." and replaced it with "… to a thick base plate at the bottom elevation."

2. In DCD Section 9.1.1.1, deleted "… but may be braced as required to the pit wall structure."

3. In DCD Section 9.1.1.1, added reference to DCD Figure 9.1-1 for rack layout.

4. In DCD Section 9.1.1.1, replaced "new fuel handling crane" with "fuel handling machine."

5. In DCD Section 9.1.1.1, added the sentence "The stress analysis of the new fuel rack satisfies all of the applicable provisions in NRC Regulatory Guide (RG) 1.124, Revision 1 for components design by the linear elastic method."

6. In DCD Section 9.1.1.2, deleted "and laterally supported as required at the rack top by the pit wall structures."

7. In DCD Section 9.1.1.2.1, added the sentence "The new fuel storage rack array center-to-center spacing of nominally 10.9 inches provides a minimum separation between adjacent fuel assemblies sufficient with neutron absorbing material to maintain a subcritical array."

8. In DCD Section 9.1.1.2.1, deleted "racks are purchased equipment. The purchase specification for the new fuel storage racks will require the vendor to perform confirmatory dynamic and stress analyses."

9. In DCD Section 9.1.1.2.1, changed future tense "will be done by the combined operating license (COL) applicant" to present perfect tense "has been done by DC applicant".

10. In DCD Section 9.1.1.2.1, deleted "and is braced as required to the pit wall structures."

11. In DCD Section 9.1.1.2.1 and Section 9.1.1.3, changed the maximum uplift load from 907 kilograms (kg) (2000 pounds (lb)) to 1814 kg (4000 lb).

12. In DCD Section 9.1.1.2.1, added the weight of the fuel handling tool and the control rod assembly to the weight of the fuel assembly in the fuel drop analysis. This changed the total drop weight from 850 kg (1875 lb) to 919 kg (2027 lb).

13. In DCD Section 9.1.1.2.1, replaced "The crane and the attachment to the building structure …" with "The fuel handling machine …"

14. In DCD Section 9.1.1.3, changed future tense "will be done by combined operating license (COL) applicant" to present perfect tense "has been done by DC applicant."

15. In DCD Section 9.1.1.3, deleted “The new fuel storage rack is purchased equipment. The purchase specification for the new fuel storage rack requires a criticality analysis of the new fuel storage racks.”

16. In DCD Section 9.1.1.3, identified that venting of the neutron absorbing material is “considered in the detailed design of the storage rack.”

The staff confirmed that the changes to DCD Revision 17, Section 9.1.1 were consistent with the design changes identified in TR-44, Revisions 0 and 1. TR-44, Revision 3, was issued in May 2010, to update both the design and the design basis, and to address unresolved issues. TR-44, Revision 4, was issued in July 2010, to clarify the analyses conducted to address sliding of the racks. TR-44, Revision 5, was issued in August 2010, to incorporate the applicant’s new position on accidental fuel assembly drops over the new fuel pit.

9.1.1.2.1.2 Evaluation

TR-44, Section 2.8.5, Revision 0, indicated that there were two postulated fuel drop scenarios over the new fuel pit, both from a height of 91.4 cm (36 in) above the top of the new fuel storage rack. In request for additional information (RAI)-TR44-01, the staff requested that the applicant describe the fuel handling operations that lead to the assumed 91.4 cm (36 in) drop height. The staff also issued RAI-TR44-02 through RAI-TR44-07, requesting specific information related to the accidental drop analysis.

In August 2010, the applicant submitted TR-44, Revision 5, in which the applicant deleted all reference to postulated new fuel assembly drop scenarios over the new fuel pit. The basis for this deletion was submitted in a revised response to RAI-TR44-01, dated August 13, 2010. This is further supported by the applicant’s revised response to RAI-TR44-06, dated September 13, 2010. The applicant stated that the new fuel is moved from the rail car bay to a cell in the new fuel storage rack by the single-failure proof hoist. The same hoist then moves the fuel assembly from the cell in the new fuel storage rack to the new fuel elevator. This sequence is repeated for each new fuel assembly, 67 per outage, on an 18-month schedule. The applicant stated that the single-failure-proof hoist is designed to meet the requirements of NUREG-0554, “Single-Failure-Proof Cranes for Nuclear Power Plants,” and is the only hoist capable of moving the new fuel above the operating floor. The applicant further stated that there are no safe shutdown systems or components currently housed in the new fuel pit or the resin transfer pump/valve room below it, and there are no criticality concerns for new fuel storage. The new fuel handling tool incorporates the same design features as the spent fuel handling tool (SFHT), which prevents inadvertent release of the new fuel assembly during handling operations. Based on the information in the revised RAI responses, the staff finds that the applicant has adequately justified that a new fuel assembly drop is unlikely and does not require analysis. RAI-TR44-02, RAI-TR44-03, RAI-TR44-04, RAI-TR44-05, and RAI-TR44-07 are no longer relevant, and are not discussed in this report.

As indicated in Table 2-3 of TR-44, one of the fuel handling accident loads that needs to be considered is uplift force on the rack caused by a postulated stuck fuel assembly. TR-44 Section 2.8.3 states: “An evaluation of a stuck fuel assembly, leading to an upward load of 2,000 lb has been performed. The results from the evaluation show that this is not a bounding condition as the local stresses do not exceed 2,500 psi.” The staff determined that the information provided was not sufficient for the staff to reach a conclusion that this load had been adequately considered. In RAI-TR44-08, the staff requested the applicant to provide a detailed description of the assumptions, the analyses conducted, the results obtained, and the basis for the conclusion that this is not a bounding condition.

In a letter dated June 7, 2007, the applicant stated that a nearly empty rack with one corner cell occupied is subject to an upward load of 907 kg (2000 lb), which is assumed to be caused by the fuel sticking while being removed. The ramification of the loading is two-fold:

1) The upward load creates a force and a moment at the base of the rack;
2) The loading induces a local tension in the cell wall.

The applicant attached a calculation documenting the maximum stress in the rack cell structure due to a postulated stuck fuel assembly. This local stress is well below the yield stress of the cell wall material (i.e., 207 MPa (30,000 psi)).

The basis for resolution of this RAI is similar to that of RAI-TR54-14, which is discussed in Section 9.1.2 of this report. The applicant re-defined the uplift force to be 1814 kg (4,000 lb), and showed that the induced stress is still well below the material yield stress. The applicant made appropriate changes in TR-44, Revision 1, and identified proposed changes to DCD Revision 17. The staff found this acceptable. However, the applicant’s proposed changes to DCD Revision 17 were not completely implemented. During the June 2-3, 2010, regulatory audit, the staff asked the applicant to submit a supplemental RAI response, addressing the omission. In a letter dated July 20, 2010, the applicant submitted a supplemental response, explaining that the paragraph omitted from the DCD revision discussed the new fuel handling crane, which has been superseded. Therefore, it is no longer relevant. The staff finds this explanation acceptable. Therefore RAI-TR44-08 is resolved.

The staff noted that insufficient descriptive information was included in TR-44, Revision 0, to permit an adequate review of the structural/seismic analysis of the new fuel rack. In RAI-TR44-09, the staff requested the applicant to provide descriptive information, including plans and sections showing the new fuel rack and vault walls. All of the major features of the rack, including the cell walls, baseplate, pedestals, bearing pads, neutron absorber sheathing, any impact bars, welds connecting these parts, and any other elements in the load path of the rack should be shown on one or several sketches.

In a letter dated July 17, 2007, the applicant stated that TR-44 Figures TR-44-9.1 through TR-44-9.5 provide additional descriptive information on the new fuel rack and new fuel storage pit floor and walls. The staff confirmed that appropriate additions were made in TR-44, Revision 1. In a letter dated July 20, 2010, the applicant submitted a revised response to RAI-TR44-9, because several dimensions on drawings had been updated. The applicant stated that the most recent change to DCD Figure 9.1-1 (Sheet 1 of 2) is included in the response to RAI-TR44-17 Revision 3, which was also submitted in a letter dated July 20, 2010. The staff reviewed the change to DCD Figure 9.1-1 and found it acceptable. RAI-TR44-09 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text.

The staff noted that TR-44, Revision 0, did not provide sufficient data regarding the input loads used for the seismic analysis of the new fuel rack. The staff issued RAI-TR44-11, which reads as follows:

a. Floor response spectra (X, Y, and Z - vertical directions) at or near the elevation of the top of the fuel rack and near the bottom of the fuel rack or vault floor corresponding to the damping value used for the analysis.

b. An explanation of why the envelope of these two sets of spectra were not used.

c. An explanation of the range of soil and rock properties used in enveloping the seismic floor spectra. Given that the certified DCD is applicable to a hard rock site and the location of e are these range of soil/rock properties specified for confirmation by a future COL applicant?

d. For the synthetic time histories, plots of the three time histories, the cross correlation coefficients, the comparisons of the spectra from the synthetic time histories to the enveloped target response spectra, and the comparisons of the power spectral density plots to the target power spectral density function associated with the target response spectra.

e. Which time history was used (displacement, velocity, or acceleration)? Were all three directions input simultaneously? Was gravity included in the time history analysis?

In a letter dated May 3, 2007, the applicant provided the following response:

a) Floor response spectra (X, Y, and Z - vertical directions) near the elevation of the bottom of the new fuel storage vault corresponding to the damping value used for the analysis are provided in the attachment to this response. No floor response spectra are provided near or at the elevation of the top of the new fuel rack.

   The ASB99 floor response spectra (FRS) represent the enveloping response spectra for the auxiliary and shield building (ASB) at elevation 99 feet (ft) for a range of soil/rock condition. FRS of various soil/rock analyses were first enveloped for various locations of the ASB. All of the ASB locations at elevation 99 ft were then grouped and enveloped to develop the ASB99 floor response spectra.

b) It is probable that the floor response spectra will be revised for various reasons and that a revision to the new fuel storage rack structural/seismic analysis report (TR-44) will be required. The methodology for developing the spectra is described in TR-44-11 a, d and e responses.

c) The range of soil and rock conditions for which the seismic floor spectra applies is described in Westinghouse technical report (TR)-03, APP-GW-S2R-010, Revision 0, “Extension of NI Structures Seismic Analysis to Soil Sites.”

d) The synthetic time histories, the response spectrum curves, and the power spectral density plots for the Auxiliary and Shielding Building (ASB) at Elevation 99 feet are provided, with this response. The cross correlation coefficients for the three orthogonal components (East-West, North-South, and Vertical) of the ASB99 synthetic time histories are summarized in the table below.

Description	Cross Correlation Coefficient
East-West to North-South	-0.0414
East-West to Vertical	0.0088
North-South to Vertical	0.0536

e) Acceleration time histories are used as the input motion for the seismic analysis of the spent fuel racks. The acceleration input is defined by three orthogonal components, which are input and solved simultaneously. Gravity is also included in the time history analysis.

The staff found this RAI response acceptable because it adequately addressed all of the staff's questions. RAI-TR44-11 was initially resolved. However, subsequent to the initial resolution of this RAI, the applicant revised the seismic design loads twice. Therefore, during the June 2010 audit, the staff requested that the applicant update this RAI response to reflect the current seismic design loads for the new fuel rack. In a letter dated July 9, 2010, the applicant submitted a revised response to RAI-TR44-11, updating the seismic design loads. The staff finds that the revised RAI response adequately describes the current seismic design loads for the new fuel rack. TR-44, Revision 3, includes the numerical results for the current design loads. Therefore, RAI-TR44-11 is resolved.

In RAI-TR44-12, the staff requested the applicant to address how the different impact stiffness values are determined for the fuel assembly-to-cell wall, rack-to-wall, and pedestal-to-bearing pad. In addition, since the impact forces can be greatly affected by the impact spring constant, the staff asked the applicant to address the sensitivity of the impact forces and rack responses to variations in these spring constants and whatever impact forces are imparted directly onto the cell walls or impact bars that are used?

In a letter dated July 5, 2007, the applicant stated that the impact stiffness values for the rack-to-wall and pedestal-to-bearing pad (concrete floor) are calculated as shown in Attachment 1 to the response. The fuel-to-cell wall impact stiffness is determined based on the solution for a simply supported circular plate under a concentrated load applied at its center, where the plate diameter is equal to the cell inner dimension and the plate thickness is equal to the cell wall thickness. The stiffness of the annular plate is then multiplied by the number of loaded storage cells for the new fuel storage rack, since the stored fuel assemblies are assumed to rattle in unison. A sensitivity study has not been performed specifically for the AP1000 new fuel rack to quantify the effect of variations in the impact stiffness values. However, sensitivity studies have been performed in the past for similar spent fuel rack applications submitted by HOLTEC, which employed the same method of computing the impact stiffness values, and the impact forces were found to be insensitive to small variations in the stiffness values provided that the integration time step was sufficiently small. There are no impact bars at the top of the new fuel storage rack. However, the new fuel storage rack is braced against the north and south walls of the new fuel storage pit by inserting stainless steel wedges in the interstitial space between the top of the new fuel storage rack and the pit opening.

The applicant subsequently changed the design of the new fuel rack to be free-standing in the new fuel pit. The steel wedges are no longer used. This is documented in TR-44, Revision 1. During the August 6-7, 2009 regulatory audit, the staff reviewed the updated calculations for the free-standing new fuel rack. The calculations support the applicant's conclusion in TR-44, Revision 1, that there are no credible impacts between the new fuel rack and the fuel pit walls, for the free-standing configuration.

Therefore, RAI-TR44-12 was resolved. A new issue arose related to new fuel rack sliding and potential wall impact, after the resolution of RAI-TR44-12. This is addressed in the discussion of RAI-SRP9.1.2-SEB1-02 in this report.

Section 2.2.2.2 of TR-44 describes the modeling of a single rack. It indicates that the rack cellular structure elasticity is modeled by a 3-D beam having three translational and three rotational degrees-of-freedom (DOFs) at each end so that two-plane bending, tension/compression, and twist of the rack are accommodated. In RAI-TR44-14, the staff requested the applicant to explain why shear stiffness/deformation is not also included and to provide more detailed information about how the beam model of the rack was developed, considering that it is an assembly of many square-celled structures welded at discrete locations.

In a letter dated April 13, 2007, the applicant stated that shear deformation is included in the rack dynamic model. The beam model of the rack was developed based on the applicable codes, standards and specifications given in Section IV(2) of the Nuclear Regulatory Commission (NRC) guidance on spent fuel pool (SFP) modifications entitled, "Review and Acceptance of Spent Fuel Storage and Handling Applications," dated April 14, 1978, which states that "Design ... may be performed based upon the AISC specification or Subsection NF requirements of Section III of the ASME Code for Class 3 component supports." The rack modeling technique is consistent with the linear support beam-element type members covered by these codes.

The basis for resolution of this RAI is similar to that of RAI-TR54-23, which is discussed in Section 9.1.2 of this report. The staff confirmed that appropriate changes were made in TR-44, Revision 1. Therefore, RAI-TR44-14 was resolved.

Section 2.2.2.2 of TR-44 refers to Figure 2-2 for the dynamic beam model of a single rack. The text and figure do not adequately describe the model. The staff issued RAI-TR44-15, which reads as follows:

a. Define what each series of nodal degrees-of-freedom (DOFs) correspond to (i.e., nodes 1, 2; P1, P2, ...; q4, q5, ..., 1*, 2*, ...). While some of these may be deduced by judgment, the report should clearly define all of these.

b. Explain whether there are five (5) nodes and four (4) beams along the rack beam model to coincide with the five (5) nodes and four (4) elements of the fuel assemblies.

In a letter dated June 7, 2007, the applicant provided the following response:

a. The attached table defines the nodal DOFs for the dynamic beam model of a single rack as depicted in Figure 2-2 of the technical report.

b. The rack cell structure is modeled as a single beam between two nodes, which are located at the top of the rack and at the baseplate elevation. This is consistent with HOLTEC's standard model for seismic analysis of spent fuel racks, which has been reviewed and approved by the NRC on numerous dockets. Although there is not a one-to-one correspondence between beam nodes and fuel assembly nodes, fuel-to-cell

> wall impact loads, which can occur at elevation 0, 0.25H, 0.5H, 0.75H, and H (where H is the height of the cell structure), are properly transmitted to the rack beam in accordance with the methodology outlined in Reference 12 in COLA technical report APP-GW-GLR-026 Revision 0.

The basis for resolution of this RAI is similar to that of RAI-TR54-24, which is discussed in Section 9.1.2 of this report. The staff confirmed that appropriate changes were made in TR-44, Revision 1. Therefore, RAI-TR44-15 was resolved.

In RAI-TR44-16, the staff requested the applicant to explain whether only a full new fuel rack is considered in the simulation, or if several scenarios are considered; i.e., different fill ratios, from empty to full; and provide the technical justification if only a full rack is considered.

In a letter dated June 7, 2007, the applicant stated that the new fuel rack is assumed to be fully loaded with maximum weight fuel assemblies in all three simulations. This scenario bounds any partially loaded configuration since it: (1) maximizes the vertical compression and lateral friction loads on the support pedestals; and (2) produces the maximum rack displacements and fuel-to-cell wall impacts. The displacements are larger for a fully loaded rack, as opposed to a partially filled rack, because the dynamic model conservatively assumes that all stored fuel assemblies rattle in unison. Hence, the momentum transferred between the rattling fuel mass and the new fuel rack is the maximum for a fully loaded rack. For a partially filled rack, the decrease in rattling fuel mass outstrips the destabilizing effect of an eccentric fuel loading pattern.

The staff determined that a quantitative evaluation of this issue would most likely be required. During the August 2009 audit, the staff reviewed Draft Revision 3 to HOLTEC Calculation HI-2063492, which includes analysis of a partial loading case. The staff requested that the applicant revise its RAI response to reflect this additional loading case, and also to include these results in the next revision of TR-44.

The applicant formally submitted Revision 3 to TR-44 in May 2010, which includes the results of the partial loading case. At the June 2010 audit, the staff and applicant discussed these results, which indicate that partial loading generates the limiting conditions for certain loading cases. The staff noted that the applicant’s current RAI response indicates that the partial loading case is not controlling, and that the DCD does not identify that a partial loading was considered. In a letter dated July 20, 2010, the applicant submitted a revised response to RAI-TR44-16, correcting the statement about the partial loading case, and also proposing a DCD change. The staff finds the response acceptable because it adequately addresses the inconsistency identified by the staff. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The staff issued RAI-TR44-17 which reads as follows:

> What are the gaps and tolerances for the gaps between the fuel assembly and cell wall, and between the rack and vault wall? What are the assumed initial locations of the various components (fuel assemblies and rack) and what is the technical basis for this assumption? Were any studies done for different initial conditions (considering tolerances); if not, explain why it was not necessary. Are there requirements in the DCD to ensure that the assumed gaps (considering tolerances) are maintained throughout the operating license period?

In a letter dated July 17, 2007, the applicant stated that all gaps between fuel assemblies and cell walls and between the rack and vault walls are set to match the nominal gaps provided on the layout drawing. The applicant attached a table summarizing the gap information used in the dynamic analyses. The applicant also stated that the new fuel storage rack is braced against the north and south walls of the new fuel storage pit by inserting stainless steel wedges in the interstitial space between the top of the new fuel storage rack and the new fuel storage pit opening. Fuel is assumed centrally located in the cell. This is conservative, since minimizing the gap on one or two walls will generally produce a larger hydrodynamic coupling effect. Some numerical studies were done on other rack projects; the results generally showed a small influence on results. A larger influence occurs if the gaps are assumed to be displacement dependent, rather than always being held constant at their initial value. The neglect of this effect is conservative.

The applicant further stated that, once the new fuel rack is installed, the "as-built" gaps are reconciled with the gaps initially used for analysis by evaluation of the numerical results and the predicted motions. The new fuel rack will be positioned in the new fuel storage pit in accordance with the gap information provided in the table attached to the July 17, 2007, letter. The only way the gaps would change over time would be by the action of a seismic event. COL applicants will have a procedure in place to address measurement of the post design-basis seismic event gaps, and to evaluate the acceptability of the configuration or to take appropriate corrective actions. The applicant proposed that the following statement be added to TR-44:

> Per DCD Subsection 3.7.5.2, Combined License applicants will prepare site-specific procedures for activities following an earthquake. These procedures will be used to accurately determine both the response spectrum and cumulative absolute velocity of the recorded earthquake ground motion from the seismic instrumentation system. An activity will be to address measurement of the post-seismic event gaps between the new fuel rack and walls of the new fuel storage pit and to take appropriate corrective actions.

During the August 2009 audit, the staff discussed the need to revise the HOLTEC drawing depicting the design gaps and tolerances, to reflect the change in the new fuel rack design to be free-standing.

During the June 2010 audit, the staff confirmed the HOLTEC drawings have been updated; and also requested the applicant to clarify the dimension and gap information for the new fuel racks in three related RAIs (RAI-TR44-09, RAI-TR44-017, and RAI-TR44-25), to be consistent with the current design basis. The staff noted that DCD Figure 9.1-1 needed to be updated. In a letter dated July 20, 2010, the applicant submitted a revised response to RAI-TR44-17, updating dimension and gap information. The applicant also proposed a change to DCD Figure 9.1-1. The staff finds the response acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Section 2.3.4.3 of TR-44, fourth bullet, develops the faulted (Level D) allowable maximum weld stress for the weld material. In RAI-TR44-22, the staff asked the applicant whether an allowable maximum weld stress based on the base metal was also developed. The staff noted that normally welds are checked for both weld material and base metal, as was done for Levels A and B in TR-44 Section 2.3.4.1.

In a letter dated June 7, 2007, the applicant provided a response that is essentially the same as its response to RAI-TR54-33 on the same topic. The detailed review is discussed in

Section 9.1.2 of this report. Based on that discussion, the staff found this RAI response acceptable. Therefore, RAI-TR44-22 was resolved.

Section 2.3.5 of TR-44 discusses dimensionless stress factors. It states that “R1 is the ratio of direct tensile or compressive stress on a net section to its allowable value (note pedestals only resist compression).” In RAI-TR44-23, the staff requested the applicant to explain why the pedestals only resist compression, since horizontal forces are also generated due to friction during a seismic event. These forces could be quite high and also would introduce shear and moments into the pedestal and rack structure.

In a letter dated July 17, 2007, the applicant stated that Section 2.3.5 of TR-44 defines seven stress factors (R1 through R7), which correspond to the American Society of Mechanical Engineers (ASME) Code Section III, Subsection NF stress limits for Class 3 components. R1 is defined as the ratio of direct tensile or compressive stress on a net section to its allowable value. Since the new fuel rack is freestanding, the net cross section of the support pedestals can only be subjected to direct compressive stress. The applicant further stated that horizontal forces are generated due to friction between the support pedestals and the floor and that these forces produce shear and bending stresses in the pedestals. The shear and bending stresses in the support pedestals, as well as the combined compression and bending stress, are measured by the other six stress factors (i.e., R2 through R7), which are defined in Section 2.3.5 of TR-44. The staff reviewed the RAI response and found it acceptable, because the applicant clarified that shear force and moment due to friction have been calculated and evaluated against applicable code limits. Therefore, RAI-TR44-23 was resolved.

Some of the information provided in Section 2.8.2 (Rack Structural Evaluation) and Tables 2-6 through 2-14 (stress results) of TR-44 is not clear. The staff issued RAI-TR44-24, which reads as follows:

a. Section 2.8.2.1, 2nd paragraph, indicates that the tables also report the stress factors for the AP1000 new fuel storage rack cellular cross section just above and below the baseplate. This implies that the fuel cells continue below the baseplate. Explain.

b. The same paragraph refers to “pedestal five in the first sheet of the summary tables for each simulation (that is, 9.M.0 where M stands for run number).” Explain what this means since the tables do not reflect this terminology.

c. The same paragraph refers to “ensures that the overall structural criteria set forth in Subsection 2.2.3 are met.” Structural criteria are not presented in Subsection 2.2.3.

d. Section 2.8.2.2 a. refers to a stress factor of 2.1516, which it states is given in the tables. However, no such stress factor is given, please explain. Also, are all cells welded to the baseplate on all four sides?

e. Section 2.8.2.2 b. indicates that a separate finite element model is used to check the baseplate to pedestal welds. Provide a short description of the model, computer code, loading, and location of the maximum tabulated stress in the weld referred to in Table 2-12.

f. Section 2.8.2.2 c. indicates that for calculation of cell welds, the fuel assemblies in adjacent cells are conservatively calculated by assuming that the fuel assemblies in adjacent cells are moving out of phase with one another. It then states that cell to cell weld calculations are based on the maximum stress factor from all runs. However, elsewhere in the report, it was stated that all of the fuel assemblies in the simulation are assumed to vibrate in phase. Provide more information to explain this.

g. Section 2.8.2.3 refers to Tables 2-6 through 2-13 for limiting thread stresses under faulted conditions for every pedestal. These tables do not seem to apply to pedestal thread shear stress. Therefore, clarify or correct this information.

h. For Table 2-6, Results Summary, please identify what rack component/element applies to each of the column headings (i.e., Max Stress Factor, Max. Shear Load, Max Fuel to Cell Wall Impact). Similarly, for Tables 2-11, 2-13, and 2-14, identify what rack component/element the table applies to.

i. Why is Table 2-14 labeled "Allowable Shear Stress for Level D"? This is inconsistent with the other tables. Explain.

In a letter dated July 17, 2007, the applicant provided the following response:

(a) The fuel cells do not continue below the baseplate. Stress factors are computed just above the baseplate, where the fuel cells are welded to the baseplate, and just below the baseplate where the support pedestals are welded.
Section 2.8.2.1 (2^{nd} paragraph, 2^{nd} sentence) will be revised as follows:

> "The tables also report the stress factors for the AP1000 new fuel storage rack cellular cross section just above the baseplate."

(b) The computer code DYNAPOST, which is listed in Table 2-15, computes the stress factors for the four support pedestals and for the cellular structure just above the baseplate based on the time history analysis results. For convenience, these five locations are identified as pedestal numbers 1 through 5 in the DYNAPOST output tables, which are not included in TR-44. Therefore, the sentence, "The locations above the base plate … are referred to as pedestal five in the first sheet of the summary tables for each simulation (that is, 9.M.0 where M stands for run number)" is not relevant to the report and will be deleted.

(c) The reference to Subsection 2.2.3 is a typographical error. The correct reference is Subsection 2.3.3.

(d) The factor of 2.1516 is not provided in the tables as stated in text.
Section 2.8.2.2 a. (2^{nd} paragraph) will be revised as follows:

> "Weld stresses are determined through the use of a simple conversion (ratio) factor (based on area ratios) applied to the corresponding stress factor in the adjacent rack material. This conversion factor is developed from the differences in base material thickness and length versus weld throat dimension and length." All fuel cells are welded to the baseplate on all four sides.

(e) The finite element code ANSYS is used to resolve the tension and compression stresses in the pedestal weld due to the combined effects of a vertical compressive load in the pedestal and a bending moment caused by pedestal friction. The compression interface between the baseplate and the pedestal is modeled using contact elements. The perimeter nodes on the pedestal are connected to the baseplate by spring elements in order to simulate tension in the weld. The maximum instantaneous friction force on a single pedestal from the rack seismic analysis is conservatively applied to the finite element model in the horizontal x- and y-directions simultaneously, along with the concurrent vertical load, at the appropriate offset location. The perimeter nodes on the pedestal are restrained to move only in the vertical direction so that the spring elements only resist bending. The limiting ANSYS results are combined with the maximum horizontal shear loads to obtain the maximum weld stress. The maximum weld stress reported in Table 2-12 occurs at the corner of the pedestal where the tensile stress in the weld due to bending is maximum.

(f) All stored fuel assemblies within a rack are assumed to rattle in phase for the seismic analysis of the new fuel rack using the HOLTEC proprietary computer code MR216 (a.k.a. DYNARACK). This analysis yields the maximum impact force between a single fuel assembly and the surrounding cell walls. When evaluating the weld connection between adjacent storage cells, the maximum fuel-to-cell impact force from the dynamic analysis is conservatively multiplied by a factor of 2 to consider out-of-phase fuel rattling.

(g) The reference to “Tables 2-6 through 2-13” in Section 2.8.2.3 is incorrect. The first sentence in Section 2.8.2.3 should be revised as follows: “Table 2-14 provides the limiting thread stress under faulted conditions.”

(h) In Table 2-6, the “Max. Stress Factor” column applies to the rack cell structure. The “Max. Vertical Load” and “Max. Shear Load” columns apply to a single rack pedestal. The “Max. Fuel-to-Cell Wall Impact” column provides the maximum impact force between a single fuel assembly and the surrounding cell wall at any of the five rattling fuel mass elevations (refer to Figure 2-5 of the report). Table 2-11 applies to the base metal adjacent to the baseplate to cell welds. Table 2-13 provides the shear stress in the cell to cell welds as well as the adjacent base metal. Table 2-14 applies to the pedestal internal threads.

(i) Table 2-14 should be labeled “Pedestal Thread Shear Stress” instead of “Allowable Shear Stress for Level D.” The allowable stresses reported in Tables 2-10 through 2-14 are Level D stress limits since the design basis ASB99 earthquake is a faulted condition (Level D).

The basis for resolution of this RAI is similar to that of RAI-TR54-36, which is discussed in Section 9.1.2 of this report. Based on that discussion and confirmation that the proposed changes were made in TR-44, Revision 1, the staff found this RAI response acceptable. Therefore, RAI-TR44-24 was resolved.

In the markup of the DCD, provided in Section 5 of TR-44, Revision 0, DCD Figure 9.1-1, new fuel storage rack, is identified for deletion. In RAI-TR44-25, the staff requested the applicant to explain why this figure was marked for deletion.

In a letter dated April 13, 2007, the applicant stated, “We are in agreement Revision 16 of the DCD will have a revised Figure 9.1-1 New Fuel Rack Layout. This figure will show the new fuel rack configuration in plan and elevation views identifying significant features and dimensions”.

The staff reviewed the RAI response and concluded that review of DCD Revision 16 would be necessary to determine if sufficient information is included in the revised Figure 9.1-1.

In TR-44, Revision 1, the applicant changed the new fuel rack design to be free-standing, which affects DCD Figure 9.1-1. This was discussed with the applicant and HOLTEC at the August 2009 audit. The applicant agreed to revise the figure as necessary to reflect the design change.

In a letter dated July 20, 2010, the applicant submitted a revised response to RAI-TR44-25, referencing its revised response to RAI-TR44-17, also submitted by letter dated July 20, 2010, for the updated dimension and gap information. RAI-TR44-25 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The staff noted that computer code MR216 (a.k.a. DYNARACK), as well as the other computer analysis codes used for the rack analyses, should have complete validation documentation, available for review during an audit. To streamline such an audit, in RAI-TR44-26, the staff inquired whether any of the computer codes have been previously reviewed and approved by the staff in other licensing reviews.

In a letter dated June 7, 2007, the applicant stated that computer analysis codes used to perform the seismic analysis of the new and spent fuel racks have been validated in accordance with HOLTEC's 10 CFR Part 50, "Domestic licensing of production and utilization facilities," Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants," quality assurance program. The validation documentation will be available for review during the audit. The validation documentation for the computer code MR216 has been previously submitted by HOLTEC International to the NRC staff for review and approval several times. Most recently it was reviewed by the NRC in 1998 in Docket 50-382 for the Waterford 3 Steam Electric Station.

The basis for resolution of this RAI is similar to that of RAI-TR54-39, which is discussed in Section 9.1.2 of this report. Based on that discussion, the staff found this RAI response acceptable. Therefore, RAI-TR44-26 was resolved.

In its review of TR-44, the staff did not identify any information related to inservice inspection of the new fuel rack. In RAI-TR44-27, the staff requested the applicant explain what provisions are provided for performance of inservice inspection of the rack, in accordance with 10 CFR 50.55a, "Codes and standards" and/or 10 CFR 50.65, "Requirements for monitoring the effectiveness of maintenance at nuclear power plants," as applicable.

In a letter dated June 7, 2007, the applicant stated that the new fuel rack is passive in nature. There are no moving parts on the new fuel rack, and it does not require any instrumentation. Therefore, there is no compelling need to perform inservice examination of the new fuel rack. Nonetheless, the new fuel rack can be accessed from above by way of an empty storage cell location(s) to enable the performance of inservice examination, as mandated by 10 CFR 50.55a(g)(3) for ASME Code Class 3 component supports. At the base of each storage cell (except at the four designated lifting locations), there is a 15.24 cm (6 in) diameter thru-hole in the baseplate, which provides access below the baseplate. The new fuel rack contains new fuel only during a short period prior to refueling. When it does not have new fuel, it could be lifted from the new fuel storage pit for inspection.

In summary, the new fuel rack is designed to provide access to surfaces that may come in contact with new fuel assemblies and to the support pedestals beneath the baseplate to support inservice examinations as needed.

From the information provided by the applicant, the staff concluded that there is ample access to the new fuel rack for inservice inspection. Therefore, RAI-TR44-27 was resolved.

The treatment of the new fuel storage rack as a safety class/seismic Category I component appears to represent a departure from past practice in the nuclear power industry. The draft update to RG 1.29, “Seismic Design Classification,” (DG-1156) does not identify new fuel storage racks as seismic Category I. In RAI-TR44-28, the staff requested the applicant to: (1) describe the technical basis for treating the new fuel storage rack as a safety class/seismic Category I component; and (2) explain how the safety significance of the AP1000 new fuel storage rack differs from prior nuclear power plant designs.

In a letter dated June 7, 2007, the applicant provided the following response:

1) We understand that both Regulatory Guide 1.29, Revision 3 and draft update to RG 1.29 (DG-1 156) do not identify new fuel storage racks as seismic Category I. However, the Westinghouse decided that all racks in the AP1000 plant would be seismic Category I. Holtec has designed and fabricated new fuel storage racks to seismic Category I. There is no additional analysis or fabrication cost to have the new fuel storage rack as seismic Category I.

2) The safety significance of the AP1000 new fuel storage rack does not differ from prior nuclear power plant designs. It is both the applicant's and HOLTEC's position that the form, fit and function of the AP1000 new fuel storage rack is the same as new fuel racks in operating PWRs.

On the basis that the applicant has invoked more stringent seismic design requirements than RG 1.29, the staff found that its technical approach is acceptable. Therefore, RAI-TR44-28 was resolved.

Section I, “Introduction,” was revised in TR-44, Revision 1 to add: “Per DCD Subsection 3.7.5.2, COL applicants will prepare site-specific procedures for activities following an earthquake. These procedures will be used to accurately determine both the response spectrum and cumulative absolute velocity of the recorded earthquake ground motion from the seismic instrumentation system. An activity will be to address measurement of the post-seismic event gaps between the new fuel rack and walls of the new fuel storage pit and to take appropriate corrective actions.”

The staff noted that DCD Section 3.7.5.2 does not discuss the need for COL applicants to prepare site-specific procedures for checking the gaps between the new fuel rack and walls of the new fuel storage pit following an earthquake. In RAI-SRP9.1.2-SEB1-01, the staff requested the applicant to explain how this requirement is conveyed to the COL applicants.

In its response dated February 24, 2009, the applicant proposed a revision to Section 3.7.5.2 of the DCD, requiring COL applications to include in their post-earthquake procedure a requirement to check the gaps between the new fuel rack and the new fuel pit walls and to take appropriate actions to restore the design gaps. Following the staff’s August 2009 audit, the applicant submitted a revised response on August 31, 2009. The staff found this revised RAI response acceptable, because it more clearly specifies the actions to be taken following an earthquake. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

In its review of TR-44, Revision 1, the staff noted that Section 2.8.1.4 “Impact Loads” was not revised, even though shims between the new fuel rack and the fuel pit wall have been deleted from the design. Quoting from TR-44, Revision 1, Section 2.8.1.4, “The maximum impact load from the set of shims that close the north-south gaps at the top of the rack is summarized in Table 2-8.” The staff also noted that the maximum rack-to-wall impact load in Table 2-8 increased from 50,802 kg (112,000 lb) in TR-44, Revision 0, to 69,853 kg (154,000 lb) in TR-44, Revision 1.

In RAI-SRP9.1.2-SEB1-02, the staff requested the applicant explain why the impact load increased, and describe how the design of the new fuel rack and the new fuel pit wall were evaluated for the significant increase (35 percent) in the impact load, in addition to other concurrent loadings.

In a letter dated April 1, 2009, the applicant submitted its response to RAI-SRP9.1.2-SEB1-02. The applicant stated that all references to shims will be deleted from TR-44. The applicant described the basis for the increased impact force, and clarified that the impact is the base plate against the wall, not the top of the rack against the wall. The applicant also stated that this impact only occurs for an unrealistically low coefficient of friction (COF) (0.2) between two dry steel surfaces. At realistic values (>0.5), the new fuel rack does not slide, and there is no rack-to-wall impact. The staff concluded that the detailed calculation(s) leading to the conclusion that there are no credible impacts between the new fuel rack and the fuel pit walls needed to be audited. At the August 2009 audit, the staff reviewed the detailed calculation, and found it acceptable to support the conclusion of no impact. The applicant agreed to revise TR-44 and Calculation APP-FS01-S3C-001 (HOLTEC Calculation HI-2063492), to clarify that there are no credible impacts between the new fuel rack and the new fuel pit walls, and to define the technical basis for this conclusion.

In May 2010, the applicant informed the staff that the COF could be as low as 0.24 because the actual surface condition is now steel on concrete, not steel on steel as it was previously. The applicant performed new calculations and evaluation of sliding and impact using a COF of 0.24. At the June 2010 audit, the applicant presented the results of the analysis for a 0.24 coefficient to the staff. TR-44, Revision 3, submitted just prior to the audit, includes the results of the new calculations. The staff reviewed the presentation material and related section of TR-44, Revision 3. The staff pointed out several apparent inconsistencies in the results presented, possibly indicative of an incorrect COF. Upon examination, HOLTEC confirmed that an incorrect COF had been used in one of the cases analyzed. During the audit, HOLTEC corrected the input file, re-executed the analysis, and presented the corrected results. The staff reviewed the corrected results, and found them acceptable.

The new results, for a 0.24 COF, show considerable sliding of the new fuel rack, but impact is avoided by increasing the minimum gap between the new fuel rack and the new fuel pit walls. The applicant agreed to revise the response to RAI-SRP9.1.2-SEB1-02 to describe the updated evaluation of sliding and impact, and also to identify necessary changes to TR-44.

In a letter dated July 30, 2010, the applicant submitted a revised response to RAI-SRP9.1.2-SEB1-02. The applicant stated that it had re-evaluated the range of appropriate friction values, to ensure that the interface between the new fuel storage rack and the new fuel pit floor is accurately and conservatively represented. The applicant concluded that the appropriate credible lower-bound COF is presented in Run Number 5 (COF=0.24). Additionally, Run Number 1 (COF=0.2) has been demonstrated to be non-credible, as noted above. It will be maintained in the supporting calculations, but for clarity it will be eliminated from the tables in the next revision of TR-44.

The applicant also attached TR-44, Revision 4 (July 2010) to the RAI response. Revision 4 clarifies what run numbers apply to the design basis and provides the detailed results for the credible lower-bound COF (COF=0.24). The report eliminates reference to the non-credible case for Run Number 1 (COF=0.2).

The staff reviewed TR-44, Revision 4, and confirmed that it includes appropriate new information related to Run Number 5 and that Run Number 1 has been deleted. The staff finds this acceptable to properly document the design basis for the new fuel rack. Therefore, RAI-SRP9.1.2-SEB1-02 is resolved.

Section 2.8.4.1, “Cell Wall Buckling Evaluation,” was revised in TR-44 Revision 1. The buckling equation and assumed rectangular plate boundary conditions were changed. The rectangular flat plate model representing the lower cell wall region was changed to clamped on all four edges. In the Revision 0 calculation, simple support was assumed. The staff determined that only one edge can truly be treated as clamped, and the other three edges can rotate somewhat due to the flexibility of the adjacent sections.

The staff issued RAI-SRP9.1.2-SEB1-03, which reads as follows:

> Section 2.8.4.1, "Cell Wall Buckling Evaluation" was revised in TR-44 Revision 1. A different buckling equation and different boundary conditions are indicated. The rectangular flat plate model representing the lower cell wall region is now assumed to be clamped on all 4 edges, Considering that only 1 edge can truly be treated as clamped, and the other 3 edges can rotate somewhat due to the flexibility of the adjacent sections, the staff requests Westinghouse to provide the technical basis for changing the boundary conditions to clamped on all 4 edges. Also, identify the minimum acceptable factor of safety and the technical basis for its selection.
>
> The staff notes that for K = 7.23, the revised σ_{cr} should be 15,600 psi, not 13,100 psi. Also, there is a typographical error: "31,100" should have been "13,100." The staff requests Westinghouse to correct the text of Section 2.8.4.1 accordingly.
>
> The staff also requests Westinghouse to identify the factor of safety based on the Rev 0 estimate of σ_{cr} = 7,090 psi.

In a letter dated April 14, 2009, the applicant submitted its response to RAI-SRP9.1.2-SEB1-03, in which it provided its technical basis for the revised calculation of buckling for the cell wall. The staff reviewed the response and determined that the information provided was insufficient, and that a significantly expanded technical basis would be needed before the staff could accept the cell wall buckling calculation. At the August 2009 audit, HOLTEC informed the staff that it was conducting a detailed nonlinear analysis of the bottom of the rack for vertical compressive load, and presented the ANSYS computer model and preliminary results. The staff found this to be a considerable analytical improvement. During the June 2010 audit, the staff reviewed

HOLTEC's final results of the ANSYS buckling evaluation of the cell walls, at the base of the new fuel rack. The calculation shows that a 1.5 factor of safety, in accordance with the acceptance criterion in ASME Code Section III, Subsection NF, has been achieved. The staff finds the analytical method used and the results obtained to be acceptable, based on its detailed review of HOLTEC's calculation. Therefore, RAI-SRP9.1.2-SEB1-03 is resolved.

9.1.1.2.1.3 Conclusion

The staff has conducted a detailed review of TR-44, which addresses DCD Revision 15 COL Information Item 9.1-1: "Perform a confirmatory structural dynamic and stress analysis for the new fuel rack, as described in AP1000 DCD Subsection 9.1.1.2.1. This includes the structural adequacy of the proposed AP1000 new fuel storage rack under postulated loading conditions and effects on the structure described in Subsection 3.8.4." The staff finds the new fuel rack design, as described in TR-44, Revision 5, to be acceptable. On the basis of its review, the staff concludes that the substance of the COL information item is completely addressed by TR-44, and that this COL information item is no longer needed.

In its previous evaluations of AP1000 DCD Section 9.1.1, the staff identified acceptance criteria based on the design's meeting relevant requirements in 10 CFR Part 50, Appendix A, General Design Criteria (GDC) 2, "Design Bases for Protection Against Natural Phenomena," and in GDC 4, "Environmental and Dynamic Effects Design Bases." The above evaluation concludes that the new fuel rack design meets these 10 CFR Part 50 requirements.

9.1.1.2.2 Fuel Handling Crane Change

The applicant proposed the following changes for the fuel handling crane:

1. Deleted references to the fuel handling jib crane and replaced them with references to the new-fuel handling crane in DCD Sections 9.1.1.1; 9.1.1.2; 9.1.1.2.1; and 9.1.1.3.

2. The capacity of the fuel handling crane was limited to 907 kg (2000 lb), the applicant is now proposing that the capacity of the fuel handling crane be limited to lifting a fuel assembly, control rod assembly, and handling tool.

3. The uplift capability of the new-fuel handling crane was increased from 907 kg (2000 lb) to 919 kg (2027 lb) in DCD Section 9.1.1.3.

However, in response to RAI-SRP9.1.4-SBPB-01, the applicant stated in a letter dated June 26, 2008, that the function of moving new fuel will be transferred to the fuel handling machine (FHM) and that the new-fuel handling crane will be eliminated.

The evaluation of this change is reviewed in Section 9.1.4 of this report. The staff determined that the changes made to DCD Section 9.1.1 are conforming changes that do not impact the staff's safety evaluation of DCD Section 9.1.1. Therefore, the staff finds the proposed change acceptable.

9.1.1.2.3 New Fuel Criticality Analysis

9.1.1.2.3.1 Summary of Technical Information

In the certified DCD Revision 15, Section 9.1.1, "New Fuel Storage," it is stated in Section 9.1.6.2 that the COL applicant is responsible for a confirmatory criticality analysis for the new fuel rack, as described in Section 9.1.1.3. This is COL Information Item 9.1-2. In DCD Revision 17, the applicant proposed to perform the confirmatory criticality analysis so that COL action is no longer necessary. DCD Section 9.1.1.3 is revised to reflect that the criticality analysis is now complete and Section 9.1.6.2 is revised to state that the COL information requested in this section has been completely addressed in TR-67, and the applicable changes are incorporated into the DCD. The applicant stated that no additional work is required by the COL applicant. The technical details of the criticality analysis for the AP1000 new fuel storage design is presented in TR-67. This report provides the technical support for the changes found in Section 9.1.1 of the DCD. The staff's review of the criticality analysis of AP1000 new fuel storage includes DCD Revision 17 Section 9.1.1 and TR-67.

The staff based its review of the AP1000 new fuel storage on the information in the DCD and the TRs referenced by the applicant. The review was limited in scope to the changes to the new fuel storage criticality analysis of DCD Revision 15 (NUREG-1793) as presented in Revision 17. The staff conducted its review of the criticality analysis of the new fuel storage in accordance with the guidelines provided in Section 9.1.1 of NUREG-0800.

10 CFR Part 50, Appendix A, provides a list of the minimum design requirements for nuclear power plants. According to GDC 62, "Prevention of Criticality in Fuel Storage and Handling," the licensee must limit the potential for criticality in the fuel handling and storage system by physical systems or processes.

The regulations regarding criticality for the AP1000 new fuel storage rack are as follows:

- 10 CFR 50.68(B)(2), "Criticality accident requirements," states the maximum K_{eff} value, including all biases and uncertainties, must not exceed 0.95, at a 95 percent probability and a 95 percent confidence level, with full density unborated water.

- 10 CFR 50.68(B)(3) states the maximum K_{eff} value, including all biases and uncertainties, must not exceed 0.98, at a 95 percent probability and a 95 percent confidence level, with optimum moderation and full reflection conditions.

- 10 CFR 50.68(B)(7) states the maximum enrichment of fresh fuel assemblies must be less than or equal to 5.0 weight-percent (w%) U-235.

9.1.1.2.3.2 Evaluation

The criticality analysis of new fuel storage racks for the AP1000 design is presented in TR-67.

Methodology

The analysis methodology uses SCALE-PC, a personal computer version of the SCALE-4.4a code system with the updated SCALE-4.4a version of the 44 group Evaluated Nuclear Data File, Version 5 (ENDF/B-V) neutron cross-section library.

SCALE-PC, used in both the benchmarking and the fuel assembly storage configurations, includes the control module CSA25 and the following functional modules: BONAMI, NITAWL-II, and KENO V.a. The SCALE system was developed for the NRC to satisfy the need for a standardized method of analysis for evaluation of nuclear fuel facilities and shipping package designs. SCALE-PC is a version of the SCALE code system that runs on personal computers.

Validation of SCALE-PC for fuel storage rack analyses is based on the analysis of representative critical experiments from two experimental programs: the Babcock & Wilcox (B&W) experiments in support of Close Proximity Storage of Power Reactor Fuel and the Pacific Northwest Laboratory Program in support of the design of Fuel Shipping and Storage Configurations. DCD Revision 15 and "Criticality Safety Criteria" (TANS Volume 35, page 278 dated 1980) were useful in updating pertinent experimental data for the Pacific Northwest Laboratory experiments. The validation of SCALE-PC was limited to the 44 group library provided with the SCALE-PC version 4.4a package (Westinghouse calculation CN-CRIT-206).

The approach used for the determination of the mean calculational bias and the mean calculational variance is based on Criterion 2 of "Criticality Safety Criteria (TANS Volume 35, page 278 dated 1980) and DCD Revision 17. For a given KENO-calculated value of K_{eff} and associated one sigma uncertainty, the magnitude of $k_{95/95}$ is computed. By this definition, there is a 95 percent confidence level that in 95 percent of similar analyses the validated calculational model will yield a multiplication factor less than $k_{95/95}$.

Assumptions

The assumptions used for the AP1000 new fuel storage rack are as follows:

- The Westinghouse AP1000 17x17 fuel assembly was modeled as the design basis fuel assembly with an enrichment equal to 5.0 w% U-235.

- Storage cell material and Metamic® poison material were modeled with a length of 426 cm (168 in). The storage cell material and Metamic® poison above and below the active fuel length were conservatively omitted.

- Fresh fuel assemblies were conservatively modeled with a UO_2 density of 10.686 gram per cubic centimeters (g/cm^3) (97.5 percent of theoretical density). This translates into a pellet density equal to 98.6 percent of theoretical density with a 1.1 percent dishing (void) fraction.

- All fresh fuel assemblies were conservatively modeled as containing solid right cylindrical pellets and uniformly enriched over the entire length of the fuel stack height. This conservative assumption bounds fuel assembly designs that incorporate lower enrichment blanket or annular pellets.

- All fuel assemblies were conservatively modeled as containing no burnable absorber material.

Design Input

The fuel assembly modeled in this analysis is the Westinghouse AP1000 17xl7 fuel assembly present in Figure 2-1 of TR-67. The bottom elevation of the Metamic® poison panel (436.9 cm (172 in) long) conservatively covers the active fuel length (427 cm (168 in)) with a 10.16 cm (4 in) overlap (5.08 cm (2 in) overlap on each end of the active fuel). Design data related to the AP1000 new fuel storage rack were obtained from HOLTEC. In addition, HOLTEC supplied Westinghouse a pressurized-water reactor (PWR) rack data sheet, which provides detailed new fuel storage rack design information (HOLTEC International Letter Number 1540001.doc, "PWR Rack Data Sheet," Revision 4, April 27, 2006).

Westinghouse general arrangement and concrete outline drawings were used to determine the new fuel storage vault geometry. A plan view of the AP1000 new fuel storage rack is shown in Figure 2-2 of TR-67. The AP1000 new fuel storage rack is located inside a concrete room (vault) in the AP1000 Auxiliary Building. The AP1000 new fuel storage rack is centered inside the vault and is an 8x9 array of storage cells, which provides 72 total storage locations. A hatch lid is provided for the vault for security, and for foreign material exclusion (FME).

The individual storage cells of the AP1000 new fuel storage rack are centered on a nominal pitch of 27.7 cm (10.9 in). Each storage cell consists of an inner stainless steel box, which has a nominal inside dimension of 22.4 cm (8.8 in) and is 0.19 cm (0.075 in) thick. Metamic® panels are attached to the outside surfaces of all storage cells except for the outside cell walls directly facing the North and South walls of the vault. No poison is required on these outside cell faces since there is just a small amount of space between the rack and storage vault concrete. However, poison is required on the outside cell faces in the East and West directions (see Figure 2-2 in TR-67) to mitigate the effects of an inadvertent placement of a fuel assembly outside of the rack, but within the vault on these two sides. Each Metamic® poison panel is held in place and is centered on the surface of the stainless steel box by an outer stainless steel sheathing panel. There is a small void space between the sheathing and the Metamic® panel. The dimensions of the Metamic® poison panel are 19.06 cm (7.5 in) in width by 0.27 cm (0.106 in) in thickness. The sheathing panels are 0.089 cm (0.035 in) in thickness.

Each storage cell is nominally 506.7 cm (199.5 in) long, and it rests on top of a base plate whose top is 12.7 cm (5 in) above the concrete floor. As stated above, each Metamic® poison panel is 436.9 cm (172 in) long overlapping the 426.7 cm (168 in) active fuel length. The Metamic® poison material is nominally a mixture of 31 w% B_4C and 69 w% aluminum.

KENO Model and Assumptions

The KENO V.a model is a three-dimensional representation of the AP1000 new fuel storage rack and vault. The 17x17 fuel assemblies are explicitly modeled as shown in Figure 2-1 of TR-67, and each assembly is fully enriched with 5 w% U-235 over the entire length of the active fuel (426.7 cm (168 in).

The 8x9 array of storage cells is modeled with the active fuel of a 17x17 fuel assembly in each location. The 8x9 array of storage cells is centered with the four walls of the concrete vault. The top of the vault is conservatively modeled without a lid. This is a conservative omission because a metal lid would absorb neutrons. Also included in the criticality model is the reflection provided by a postulated 30.48 cm (12 in) of full density water.

The fuel rod, guide tube, and instrumentation tube claddings are modeled with Zircaloy. This is conservative with respect to the Westinghouse ZIRLO product, which is a Zirconium alloy containing additional elements including Niobium. Niobium has a small absorption cross section, which causes more neutron capture in the cladding regions resulting in a lower reactivity. Therefore, this criticality analysis is conservative with respect to fuel assemblies containing ZIRLO cladding in fuel rods, guide tubes, and the instrumentation tube.

There are no burnable absorbers modeled in any of the fuel assemblies. The Zirconium grid straps are conservatively omitted. The 8x9 array of storage cells and vault are modeled at room temperature conditions (20 °C), and the system reactivity is evaluated at 11 moderator densities ranging from 1.0 g/ cm^3 down to 0.001 g/cm^3. A total of 1.2 million neutron histories are modeled in 1003 generations with 1200 neutrons per generation. It is noted that all KENO V.a results for the first three neutron generations are skipped to eliminate preliminary estimates of the system reactivity.

The methodology bias and uncertainty are discussed and evaluated in “Criticality Safety Criteria,” TANS Volume 35, page 278, dated 1980. The results of these KENO calculations showing final K_{eff} values (including bias and uncertainties) versus water density are given in Table 2-2 of TR-67. During a Regulatory Audit on November 16, 2006, the staff reviewed the applicant’s calculation, “AP1000 New Fuel Storage Rack Criticality Analysis,” which includes the uncertainty calculations as well as the final summation of uncertainties to be applied when calculating K_{eff} values.

Hypothetical Fuel Assembly Drop and Impact on Criticality Analysis

It is possible to drop a fresh fuel assembly into or on top of a storage cell in the AP1000 new fuel storage rack as described in Section 9.1.1.2.1 C of DCD Revision 17. In the event that the dropped fuel assembly hits the top of a storage cell, the applicant’s analyses indicate that neither the Metamic® nor the active fuel is adversely impacted. The applicant states there is no degradation of the criticality safety margin as a result of dropping a fuel assembly on top of a storage cell. The staff reviewed the applicant’s analyses and agrees with the approach and conclusions.

To conservatively bound the resulting deformation on the base plate following a drop of fuel assembly straight through an empty cell impacting the rack baseplate, the bottom elevations of 25 fuel assemblies were lowered by 12.7 cm (5 in). Even with the bottom elevation of the active fuel in 25 fuel assemblies lowered by 12.7 cm (5 in), the criticality design criteria given in Section 2.0 are still met. This conclusion is based upon the observation that the AP1000 new fuel storage rack is normally dry and not flooded with water. The applicant notes that for this hypothetical dropped fuel assembly accident the AP1000 new fuel storage rack would need to contain at least several feet of water in the bottom of the AP1000 new fuel storage rack before the criticality design basis limits would be exceeded. The accident scenario analyzed is beyond the design basis. Based on its review of the analysis, the staff finds the applicant’s design meets the criticality design basis limits for a hypothetical dropped fuel assembly.

Evaluation Results

Figure 2-2 of TR-67 displays the final K_{eff} values (including all biases and uncertainties) versus water density for the AP1000 new fuel storage rack. The maximum fresh fuel enrichment limit for the AP1000 new fuel storage racks is determined to be 5.0 w% U-235 since the final K_{eff} values at this enrichment are less than 0.98 at optimum moderation conditions and less than 0.95 at fully flooded conditions, assuming no soluble boron.

The staff has reviewed the changes submitted in TR-67, Revision 0. Given that: (1) the maximum K_{eff} value, including all biases and uncertainties, is less than 0.95 with full density unborated water; (2) the maximum K_{eff} value, including all biases and uncertainties, is less than 0.98 with optimum moderation and full reflection conditions; and (3) the maximum enrichment of fresh fuel assemblies is less than or equal to 5.0 w/o U-235, the AP1000 new fuel storage rack fully loaded with Westinghouse AP1000 17x17 fuel assemblies with an enrichment less than or equal to 5.0 w/o U-235 satisfies the criticality safety criteria specified in 10 CFR Part 50.68 and GDC 62 and, therefore, is acceptable.

9.1.1.2.3.3 Conclusion

The staff has reviewed the DCD Section 9.1.1 changes provided by DCD Revision 17 and supported by TR-67 submitted by the applicant, describing the new fuel storage racks, the criticality analyses performed, and the methods used. Based on this review, the staff concludes that the appropriate documentation was submitted and that the criticality aspects of the new fuel storage racks meet the requirements of GDC 62 related to the prevention of criticality.

9.1.1.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the applicant's application for design certification (DC) met the requirements of Subpart B to 10 CFR Part 52, "License, certifications, and approvals for nuclear power plants" that are applicable and technically relevant to the AP1000 standard plant design.

In its previous evaluations of AP1000 DCD, Section 9.1.1, the staff identified acceptance criteria based on the design meeting relevant requirements in GDC 2, GDC 4, GDC 5, "Sharing of Structures, Systems and Components," GDC 61, "Fuel Storage and Handling and Radioactivity Control," in GDC 62, and in GDC 63, "Monitoring Fuel and Waste Storage." The staff found that the AP1000 new fuel storage design was in compliance with these requirements, as referenced in NUREG-0800 Section 9.1.2 and determined that the design of the AP1000 new fuel storage, as documented in AP1000 DCD, Revision 15, was acceptable because the design conformed to all applicable acceptance criteria.

The staff reviewed the applicant's proposed changes to the AP1000 new fuel storage as documented in AP1000 DCD against the relevant acceptance criteria as listed above and in SRP, Sections 9.1.1, and 9.1.2. The staff finds that the applicant's proposed changes do not affect the ability of the new fuel storage to meet the applicable acceptance criteria. The staff also finds that the design changes have been properly incorporated into the appropriate sections of AP1000 DCD. The staff concludes that the AP1000 new fuel storage design continues to meet all applicable acceptance criteria. These DCD changes are generic and are expected for all COL applications referencing the AP1000 certified design. At this time, the NRC has not issued a COL for any AP1000 plant. Thus, the proposed changes incorporated into Revision 17 contribute to the increased standardization of the certification information in the AP1000 DCD and, thus, meet the requirements of 10 CFR 52.63(a)(1)(vii). Therefore, the staff finds that the proposed changes to AP1000 Section 9.1.1 are acceptable.

9.1.2 Spent Fuel Storage

9.1.2.1 Summary of Technical Information

Section 9.1.2, "Spent Fuel Storage" of the AP1000 DCD, Revision 15, was approved by the staff in the certified design. In AP1000 DCD, Revision 17 the applicant has proposed to make the following changes to Section 9.1.2 of the certified design:

1. Spent fuel rack design change. The basis for this change is documented in TR-54, "Spent Fuel Storage Racks Structure and Seismic Analysis," APP-GW-GLR-033, Revision 4 of June 2010. The applicant added detailed design information for the spent fuel racks and proposed several changes throughout DCD Section 9.1.2 to reflect the changes addressed in TR-54.

2. SFP water level increase. The basis for this change is documented in TR-121, "Spent Fuel Pool Water Level and Dose," APP-GW-GLN-121, of May 2007. The applicant proposed several changes throughout DCD Section 9.1.2 to reflect the changes addressed in TR-121.

3. Fuel handling crane change. The applicant proposed to replace references to the fuel handling jib crane for the new-fuel handling crane. The basis for this change is addressed in TR-106.

4. The applicant proposed several changes throughout DCD Section 9.1.2 to reflect the spent fuel rack criticality analysis change addressed in TR-65, "Spent Fuel Storage Racks Criticality Analysis," APP-GW-GLR-029, Revision 3 of March 3, 2011 including resolving COL Information Item 9.1-4 by performing a confirmatory criticality analysis for the spent fuel racks.

9.1.2.2 Evaluation

The staff reviewed all changes identified in Section 9.1.2 of the AP1000 DCD. The staff did not re-review descriptions and evaluations of the spent fuel storage in AP1000 DCD, Revision 15, that were previously approved and that are not affected by the new changes. All technical changes in the DCD are supported by information presented in the applicant's TRs.

The regulatory basis for AP1000 DCD, Section 9.1.2, is documented in NUREG-1793. The staff has reviewed the proposed changes to DCD Section 9.1.2 against the applicable acceptance criteria of NUREG-0800 Sections 9.1.1, "Criticality Safety of Fresh and Spent Fuel Storage and Handling" and 9.1.2, "New and Spent Fuel Storage." The following evaluations discuss the results of the staff's review.

The specific criterion that applies to the changes evaluated in this section is 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

9.1.2.2.1 Spent Fuel Rack Design Change

TR-54, Revisions 0 and 1, described the design details and design-basis analyses for the spent fuel racks. To be consistent with the design of the spent fuel racks and the analyses presented in TR-54, Revisions 0 and 1, the following changes were proposed in DCD Revision 17, Section 9.1.2:

1. Delete references "to supporting grid structures at the top and bottom elevations" and replaced them with "a thick base plate at the bottom elevation" in DCD Section 9.1.2.1.

2. Increase SFP capacity from 619 fuel assembly locations to 889 fuel assembly locations.

3. Replace Figures 9.1-2 and 9.1-3, which show the rack array center-to-center spacing, with new Figures 9.1-2, 9.1-3, and 9.1-4, which show the SFP rack layout in Region 1, Region 2, and overall SFP rack layout, respectively.

4. Add the following statement in DCD Section 9.1.2.1: "All spent fuel racks will be in place whenever fuel is stored in the spent fuel racks. See DCD Section 3.7.5.2, for discussion

of site-specific procedures for activities following an earthquake. An activity will be to address measurement of the post-seismic event gaps between spent fuel racks and to take appropriate corrective actions."

5. Add the following statement in DCD Section 9.1.2.1: "The stress analysis of the spent fuel racks satisfies all of the applicable provisions in NRC RG 1.124, Revision 1 for components designed by the linear elastic analysis method."

6. Add design scope, in addition to SFP, the fuel transfer canal, and the cask loading pit, the FHM traverses the new fuel storage pit and the rail car bay in DCD Section 9.1.2.1.

7. Delete the following statement in DCD Section 9.1.2.2.1: "The purchase specification for the spent fuel storage racks requires the vendor to perform confirmatory dynamic and stress analyses."

8. Add the additional design information on the spent fuel racks center-to-center spacing; and material characteristics and recommended monitoring schedule of the neutron absorbing material (Metamic) coupons used in the fuel storage racks in DCD Section 9.1.2.2.1.

9. Add the following statement in DCD Section 9.1.2.2.1: "Both of these rack module configurations provide adequate separation between adjacent fuel assemblies with neutron absorbing material to maintain a subcritical array."

10. Change design activities: Reference to seismic and stress analyses of the spent fuel racks are changed to present tense (e.g., are performed) from future tense (e.g., will be performed by the vendor) in DCD Section 9.1.2.2.1.

11. Add item F in DCD Section 9.1.2.2.1, addressing loads due to "Internally Generated Missiles."

12. Changed Equipment Classification: In DCD Section 9.1.2.3, the racks are changed from Equipment Class 3 to Equipment Class D.

13. Delete the following statement in DCD Section 9.1.2.3: "because of the close spacing of the cells, it is impossible to insert a fuel assembly in other than design locations."

9.1.2.2.1.1 Spent Fuel Rack Structural

9.1.2.2.1.1.1 Summary of Technical Information

The staff confirmed that the proposed changes to DCD Revision 17, Section 9.1.2 are consistent with the design changes identified in TR-54, Revisions 0 and 1. In order to resolve the outstanding issues, and also to evaluate subsequent changes to the spent fuel rack design and changes to the spent fuel rack design basis, submitted to the staff in TR-54, Revisions 2 and 3. TR-54, Revision 4, was issued in June 2010, to update both the design and the design basis, and to address the unresolved RAIs.

In total, the staff issued 44 RAIs for TR-54. The significant RAIs are discussed below. Any RAIs not specifically discussed herein were for clarification only, and did not require a detailed technical response by the applicant.

9.1.2.2.1.1.2 Evaluation

Section 2.8.5 of TR-54 indicates that the three drop scenarios all assume a 91.44 cm (36 in) drop height above the top of the spent fuel storage rack. In RAI-TR54-01, the staff requested that the applicant describe the fuel handling operation that determines this drop height.

In a letter dated April 9, 2007, the applicant stated that the fuel handling operations for the Section 2.8.5 scenarios are the normal fuel handling operations such as those performed during refueling outages, i.e., core fuel offloaded and reloaded from/to the Reactor Building via the fuel transfer system into and out of the SFP storage racks. There are also instances where fuel inspection and/or fuel repair will require the fuel to be removed from the spent fuel storage racks and moved to the designated fuel inspection or fuel repair workstation. These fuel handling operations include the transfer of fuel from the rack cells and into the cask area during dry cask storage operations.

The applicant also stated that the current fuel transfer system in the spent fuel building, which lifts and lowers the fuel during normal fuel handling operations, consists of the FHM and the SFHT. The FHM is a fixed mast manipulator-type bridge crane similar in design to the manipulator crane bridges used in numerous existing Westinghouse operating plants' Reactor Buildings. The SFHT is a long handled tool which latches onto the fuel assembly top nozzle via a manually actuated gripper. Lifting of the SFHT and attached fuel assembly is performed using an auxiliary hoist on the FHM bridge. The design of the SFHT is very similar in design to the fuel handling tool currently in use at numerous existing Westinghouse operating plants.

The applicant indicated that the current designs of the AP1000 SFP, spent fuel storage racks, FHM, and SFHT limit the height that the fuel assembly can be lifted above the spent fuel racks to 22.86 cm (9 in) maximum. This height is limited by the water coverage above the fuel assembly and is limited by the physical design of the FHM and SPHT via mechanical stops and/or tool length. The maximum fuel drop height will be approximately 22.86 cm (9 in); which is bounded by the Section 2.8.5 scenarios of 91.44 cm (36 in).

At the June 2010 audit, the staff inquired about the operational controls on spent fuel handling that will ensure no exceedance of the analyzed 91.44 cm (36 in) drop height. In a letter dated July 13, 2010, the applicant submitted a supplemental response to RAI-TR54-01, describing how this will be accomplished. The staff reviewed the RAI response and concluded that there are sufficient hardware, software, and administrative controls in place to ensure that the design basis fuel assembly drop height of 91.44 cm (36 in) will not be exceeded. Therefore, RAI-TR54-01 is resolved.

As described in Section 2.8.5, the objective of the LSDYNA impact analyses is to assess the extent of the permanent damage to the rack and the structural integrity of the SFP liner. In RAI-TR54-02, the staff inquired whether the analyses are also intended to address the structural condition of the dropped fuel assemblies. If the analyses are also intended to address damage to the fuel assemblies, the staff would need additional fuel assembly design details and LSDYNA analysis details. If not, the applicant was asked to identify where this is addressed in the DCD or other technical report(s).

In a letter dated April 9, 2007, the applicant provided the following response:

> The LSDYNA impact analyses are not intended to address the structural condition of a dropped fuel assembly. The analysis addresses the structural condition of the rack and its ability to maintain subcriticality. A fuel handling accident and its radiological consequence is addressed in DCD Subsection 15.7.4 Fuel Handing Accident. The fuel handling accident described in Subsection 15.7.4 is defined as the dropping of a spent fuel assembly such that every rod in the dropped assembly has its cladding breached so that the activity in the fuel/cladding gap is released.

The applicant referenced report, APP-FS02-Z0C-001, Revision 0, “Analysis of AP1000 Fuel Storage Racks Subjected to Fuel Drop Accidents,” for the requested LSDYNA analysis details.

The staff confirmed that TR-54, Revision 1, removed any information describing the fuel assembly capacity and margins, since this is not the purpose of the TR-54. The staff also confirmed that TR-54, Revision 2, Section 2.8.1.4, and related sections in DCD Revision 17 were revised to include the maximum calculated fuel impact load on the racks (demand), and show it is less than the allowable impact load (capacity). Therefore, RAI-TR54-02 was resolved.

Section 2.8.5 of TR-54 indicates that a quarter of the spent fuel rack and a single fuel assembly were modeled appropriately using LSDYNA's shell and solid elements. The rack is submerged under the water when an impact occurs. In RAI-TR54-04, the staff requested the applicant confirm whether the water-structure interaction has been accounted for or to provide an explanation why this effect is not important.

In a letter dated April 9, 2007, the applicant stated that the fuel assembly drop analyses conservatively neglect the water structure interaction in the wake of an impact. By assuming that the impact occurs in air, as opposed to water, none of the impact energy is diverted to fluid kinetic energy (i.e., fluid damping), which would attenuate the deformation to the fuel rack. The applicant referenced report APP-FS02-Z0C-001, Revision 0.

The staff reviewed the applicant’s response and concluded that neglecting the mitigating effects of the water is conservative; therefore, the response is acceptable, and RAI-TR54-04 was resolved.

Section 2.8.5 of TR-54 states that appropriate non-linear material properties have been applied to the rack components to permit yielding and permanent deformation. TR-54 Table 2-6 provides Young's modulus, yield strength, and ultimate strength. LSDYNA requires a true stress-strain relation for nonlinear materials. In RAI-TR54-05, the staff requested the applicant to provide the following: (1) a complete description of the material stress-strain curve and confirmation that a true stress-strain curve was used in these impact analyses; and (2) a description of the fuel assembly model, including the element properties and material properties for the dropped fuel assembly.

In a letter dated April 9, 2007, the applicant provided the following response:

> The spent fuel racks are fabricated from SA240-304 and SA564-630 stainless steel. For the impact analyses, a true stress-strain curve, which is obtained from <u>Atlas of Stress Strain Curves</u> (2nd Edition, ASM International) and [included] as

> Figure TR-54-5.1 [in the RAI response], is used to define the strength properties of SA240-304 stainless steel.
>
> The properties of SA564-630, which is used to fabricate the adjustable support pedestals, are input in terms of engineering stress-strain, based on material data taken from the ASME Code. Also, the welds that connect the rack components are modeled as a bi-linear elasto-plastic material having the engineering stress-strain properties of the adjoining base metal (i.e., SA240-304). The material property values, which are used to define the engineering stress-strain curves for SA564-630 stainless steel and for the structural welds, are [summarized in the table included in the RAI response].
>
> The fuel assembly is modeled by a rigid bottom end fitting and a mass at the top (representing the weight of lifting tool) connected by an elastic beam (with a Young's modulus of 1.04 x 10^7 psi and a Poisson's ratio of 0.3 for typical rod material) that has an equivalent mass and total cross sectional area of all fuel rods in an AP1000 fuel assembly. In addition, a very thin rigid shell is attached to the bottom end fitting to represent the side surfaces of the fuel assembly that might be in contact with rack cell walls in a shallow drop event. To maximize the damage in the rack, the fuel assembly is only allowed to move in the vertical direction.

The staff reviewed the applicant's response, and determined that additional clarifications were needed, related to representation of nonlinear material properties and modeling of the fuel assembly for the drop analysis. During April 2007 and October 2007 regulatory audits, the staff discussed the needed clarifications with the applicant.

Since curves are only provided at 21.11 °Celsius (C) (70 °Fahrenheit (F)) and 430 °C (806 °F), the staff was not sure how the stress-strain curve at the required temperature (65.55 °C (150 °F)) was obtained from Figure TR- 54-5.1. The applicant indicated that the true stress-strain curve for the stainless steel material at the appropriate temperature (65.55 °C (150 °F)) is derived by manual interpolation of the true stress-strain curves at 21.11 °C (70 °F) and 430 °C (806 °F), which are provided in Atlas of Stress Strain Curves (2nd Edition, ASM International) for Type 304 stainless. The properties were linearly interpolated to obtain the values at 65.55 °C (150 °F). However, the staff requested the applicant to demonstrate whether using a linear interpolation approach is conservative. Using data from the ASME Code Section II, Part D, the applicant showed that the temperature versus yield stress and ultimate stress for stainless steel materials is not linear; the applicant's linear interpolation resulted in a slight overestimation of these values in the LSDYNA drop analyses. The overestimation was less than 4 percent for the ultimate strength and less than 10 percent for the yield. The applicant concluded that the results would not change significantly. The staff reviewed the differences in the two interpolated stress-strain curves, and concluded that the applicant's assessment that the results would not change significantly is acceptable.

The staff was uncertain of the effect that modeling the welds using bi-linear elasto-plastic material having engineering stress/strain properties, rather than the true stress-strain curve, has on the results of the analysis. For the weld, the applicant indicated that the use of the engineering stress strain curve is conservative because it is lower than the true stress strain curve and the failure strain is less. The staff found this acceptable.

From the response dated April 9, 2007, it was not clear to the staff whether using the given Young's modulus and total cross-sectional area of all the fuel rods provides an equivalent axial stiffness of the fuel pellet material and fuel cladding material. The applicant indicated that the axial stiffness of the dropped fuel assembly is based on the cladding material only, rather than the cladding and fuel pellets. The mass of the lifting tool is placed on top of this elastic beam. The mass of the cladding is included within the density of the beam. The fuel mass is lumped at the bottom of the fuel assembly model. The thin rigid shell surrounds the entire fuel assembly to position the single line beam representation within the storage cell.

The applicant agreed to expand the existing information for the fuel assembly model, in the next revision to TR-54. The staff verified that Section 2.8.5 of the TR-54, Revision 1, included sufficient information describing the fuel assembly model. Therefore, RAI-TR54-05 was resolved. The staff confirmed that TR-54, Revision 4, includes the same descriptive information.

The fuel rack baseplate shown in Figures 2-7 and 2-8 of TR-54 appears to have only one layer of 8 node brick element through its thickness. It is not clear if a solid or a thick shell element is used. In RAI-TR54-06, the staff requested the applicant to clarify the type of element used for the baseplate.

In a letter dated April 9, 2007, the applicant stated that the baseplate is modeled using 8-noded solid elements arranged in a single layer. The staff determined that the applicant would need to provide justification, demonstrating that modeling the baseplate using an 8-node solid element can adequately capture the behavior of the plate, including bending through the thickness. The staff noted that the model is used for the drop analyses and the seismic analyses of the racks.

During the April 2007 audit, the staff discussed this concern with the applicant. The applicant agreed to provide a supplemental response to address the staff's concern.

During the October 2007 audit, the applicant indicated that the rack baseplate model was revised to utilize thick shell elements in HOLTEC Report No. HI-2063519, Revision 1. The applicant also indicated that they revised their model to use strain rate effects for the material properties. The net effect of both improvements resulted in lower deformations. The staff found the use of the thick shell element representation of the baseplate to be appropriate because it more closely simulates the true behavior under dynamic impact loadings.

During the May 2008 regulatory audit, the staff verified that HOLTEC Report No. HI-2063519, Revision 2, shows the rack baseplate modeled with thick shell elements, which can capture the bending behavior of the plates. In addition, strain rate effects were also included in the spent fuel rack analysis. These new analyses demonstrate that the maximum downward deformation of the rack baseplate is 7.98 cm (3.14 in), which is less than the 8.89 cm (3.5 in) used in the criticality analysis. Also, the criticality analysis was conservatively performed assuming a total of nine fuel assemblies deform the maximum value of 8.89 cm (3.5 in) rather than the single drop at 7.98 cm (3.14 in). Therefore, RAI-TR54-06 was resolved.

Section 2.8.5 of TR-54 indicates that the baseplate of the rack is connected to the cells by appropriate welding. However, the cells are described in Sections 2.1.1.1 and 2.1.1.2 as resting on top of the baseplate. Welded connections between the cells and the baseplate would greatly increase the strength of the whole rack system. The staff issued RAI-TR54-07, which reads as follows:

a) Confirm there is a welded connection between the baseplate and the cells.
b) Describe the design details of this connection.
c) Describe how this connection is modeled in LS-DYNA.

In a letter dated April 9, 2007, the applicant provided the following response:

a) The base of every storage cell is welded to the rack baseplate.

b) Each cell is welded to the baseplate on four sides by 1/16 in fillet welds having a minimum length of 7 ".

c) The cell to baseplate weld connection is modeled in LSDYNA by shell elements, which join the bottom of the cell and the baseplate top surface, with a thickness equal to the corresponding throat dimension of the weld.

The staff determined that the applicant provided sufficient information to clarify the cell-to-baseplate attachment, and found the response acceptable. Therefore, RAI-TR54-07 was resolved.

For the drop case in which the impact occurs directly above a rack pedestal, Section 2.8.5 of TR-54 provides the concrete strength of the pool floor and the thickness of the stainless steel liner, but does not provide the thickness of the pool floor. There is a possibility that the impact could also cause damage to the concrete floor, and pose a more severe consequence than causing the liner to yield. The maximum Von Mises stress in the SFP liner is reported as 161.3 MPa (23.4 kips per square inch (ksi)), which is much larger than the concrete strength of 27.6 MPa (4 ksi); the concrete may crush and crack locally at this level of stress. In RAI-TR54-08, the staff requested the applicant to provide additional details on the modeling of the concrete floor (including a figure of the concrete model, element type, boundary conditions, material properties, etc.) and the analysis results for the concrete floor (in addition to Figure 2-11).

In a letter dated April 10, 2007, the applicant stated:

> The spent fuel pool concrete floor is modeled only in the vicinity of the impacted rack pedestal with an assumed thickness of two ft and compressive strength of 4,000 psi. The pool liner and rack pedestal bearing pad are also modeled as shown in Figure TR54-8.1 [attached to the RAI response]. The periphery surface nodes of the SFP pool liner and the underlying concrete slab in the LSDYNA model are restrained from moving in the vertical direction and in the horizontal direction normal to the periphery surface to simulate the confining effect of the surrounding structure.
>
> The maximum compressive stress in the concrete floor, resulting from the fuel assembly deep drop event in which the impact occurs directly above a rack pedestal, is predicted to be 4,557 psi as shown in the Figure TR-54-8.2 [attached to the RAI response]. This maximum compressive stress slightly exceeds the assumed concrete compressive strength and is limited to the top surface of the concrete near the bearing pad edge. The very limited local damage to the concrete floor surface is acceptable since the acceptance criterion for the fuel deep drop accident is no gross failure of the SFP floor leading to an uncontrolled loss of SFP water.

The staff determined that the response is acceptable because the bearing capacity of confined concrete is greater than the compressive strength of 27.6 MPa (4,000 psi). As follow-up, the staff requested the applicant to describe the concrete material model used in LSDYNA. During the April 2007 audit, the applicant indicated that concrete nonlinear material model “Material 16" was used in the LSDYNA analysis. The staff requested the applicant to explain how the input parameters for Material 16 were developed and verified, since they do not appear to be derivable from commonly known material properties of concrete.

During the October 2007 audit, the applicant indicated that the properties of Material 16 in LS-DYNA were obtained from NUREG/CR-6608, “Summary and Evaluation of Low Velocity Impact Tests of Solid Steel Billet into Concrete Pads,” (February 1998). This concrete model was used by HOLTEC in the generic license for HI-STORM 100 storage casks, which received approval by the NRC. The staff requested the applicant confirm that the 27.6 MPa (4,000 psi) concrete compressive strength for the AP1000 fuel pool structure is consistent with the concrete strength used in the referenced NUREG/CR-6608 report. The applicant stated that the concrete pad modeled in NUREG/CR-6608 has a compressive strength of 29.0 MPa (4,200 psi), which is slightly greater than the compressive strength of the AP1000 SFP slab (27,6 MPa (4,000 psi)). In order to account for the difference in strength, the input parameters specified in Appendix C of NUREG/CR-6608, for use with LS DYNA Material Model 16, have been modified in accordance with HOLTEC Position Paper DS-240 for a compressive strength of 27.6 MPa (4,000 psi).

Since the concrete input parameters were adjusted to account for the differences in compressive strength between the concrete used in NUREG/CR-6608 and the concrete used in the AP1000 design, and considering the small difference in compressive strengths, the staff found this acceptable. Therefore, RAI-TR54-08 was resolved.

Section 2.8.5 of TR-54 does not indicate whether other fuel assemblies are in place when a fuel assembly drops through an empty cell and impacts the baseplate at its center. Depending on how the baseplate is designed, a full load of fuel assemblies may introduce progressive deformation after a fuel assembly impacts at the center of the baseplate. The maximum downward deformation of the baseplate is about 10.92 cm (4.3 in), as shown in TR-54 Figure 2-10. This may be significant enough to initiate a progressive deformation. Therefore, in RAI-TR54-09, the staff requested the applicant to provide: (1) the assumption for in-place fuel assemblies when the impact occurs; (2) the design basis for the baseplate; and (3) a figure similar to Figure 2-10 that shows the cells together with the severely deformed baseplate.

In a letter dated April 10, 2007, the applicant provided the following response:

(1) The spent fuel storage rack is assumed to be empty (i.e., no fuel assemblies in place) when a fuel assembly drops through an empty cell and impacts the baseplate at its center. This is a simplifying assumption, which is reasonable considering that the buoyant weight of a fuel assembly is approximately 1,525 lb whereas the impact load transmitted by the dropped fuel assembly is roughly 268,000 lb based on the LSDYNA solution.

(2) The design basis for the baseplate is to provide vertical support for the stored fuel assemblies and to protect the Spent Fuel Pool liner from a fuel assembly strike. In other words, a dropped fuel assembly should not pierce the baseplate and result in a direct impact with the liner.

During the April 2007 audit, the staff discussed the response with the applicant and requested a supplemental response for items (1) and (3). For item (1) the applicant indicated they would provide a supplement to the response, to address the effects of the additional fuel assemblies during the vertical drop accidents. For item (3) the applicant agreed to provide another detail showing the bottom plate and cell walls in the surrounding region where the maximum deformation and stresses occur.

In a letter dated May 17, 2007, the applicant submitted the revised RAI response. The applicant's response to items (1) and (2) was unchanged. For item (3), the applicant attached a figure to the response, showing the cells together with the severely deformed baseplate, for the same LS DYNA solution as shown in Figure 2-10 of TR-54. The applicant noted that the deformation of the cells is not significant compared to the baseplate, because the cell to baseplate weld connections broke as a result of the postulated fuel impact load before the cell walls were permanently deformed. The staff reviewed the applicant's revised response, and found the response to item (3) acceptable.

During the October 2007 audit, in response to item (1), the applicant indicated that the rack model, represented in HOLTEC Report No. HI-2063519, Revision 1, had been revised to consider the effects of all of the stored fuel assemblies in the rack, by modifying the density of the rack baseplate. The modeling of the baseplate was also changed to thick shell elements, and strain rate effects were included. The staff reviewed the HOLTEC calculation and confirmed that it includes the mass effect of all of the fuel assemblies by increasing the baseplate density. The staff concluded that the consideration of the rest of the fuel assemblies by increasing the mass of the baseplate is an acceptable approach to simulate the dynamic effects. The staff requested the applicant to finalize the HOLTEC calculation and revise TR-54, to describe the modeling approach used. The staff noted that its concern about the large vertical deformation (10.92 cm (4.3 in)) is addressed under RAI-TR54-10.

During the May 2008 audit, the staff verified that HOLTEC Report No. HI-2063519, Revision 2, shows that the rack is conservatively assumed to be fully loaded with fuel assemblies, except at the center cell where the dropped fuel hits the rack baseplate. Therefore, RAI-TR54-09 was resolved.

In Section 2.8.5 of TR-54, a vertical movement of 5.08 cm (2 in) of a fuel assembly is defined as the criticality limit, and the impact analysis shows that quite a number of fuel assemblies will have more than 5.08 cm (2 in) displacement. It appears that a rack design with only a 5.08 cm (2 in) space between the bottom of the baseplate and the top of the floor would eliminate this risk. In RAI-TR54-10, the staff requested the applicant to explain why the design has a space larger than 5.08 cm (2 in).

In a letter dated April 9, 2007, the applicant stated that each spent fuel rack storage cell is 506.73 ± 0.159 cm (199.5 ?± 0.0625) in) in length and rests on top of a base plate whose top is 5 in above the SFP liner. Each Metamic poison panel is 436.9 cm (172 in) long and has a bottom elevation that is 15.8 cm (6.23 in) above the top of the base plate. The active fuel region of each fuel assembly begins at an elevation 20.9 cm (8.23 in) above the top of the base plate. Therefore, the bottom elevation of the Metamic poison panel is positioned to be 5.08 cm (2 in) lower than the bottom elevation of the active fuel.

Therefore, the results of the criticality analyses are bounding even if the fuel assembly is vertically displaced downward by up to 5.08 cm (2 in) as a result of the hypothetical fuel assembly drop. The 5.08 cm (2 in) vertical displacement of the fuel assemblies, mentioned above in RAI-TR54-10, is not a criticality limit. The criticality analyses summarized in TR-65, Revision 0, addressed the hypothetical fuel assembly drop in Section 2.4.6.3 as follows:

> A fuel assembly (with a control rod and attached to the fuel assembly handling tool) is dropped and impahcts the baseplate as discussed in Subsection 2.8.5 of Reference 4. The analysis in Subsection 2.8.5 of Reference 4 indicates that the base plate will be defomed as a result of this drop. For conservatism, the fuel assemblies in nine storage cell locations will be modeled as vertically dropped by 3.5 inches to bound the consequences of the base plate deformation.

Since the criticality analysis demonstrates that the stored fuel assemblies remain subcritical following a hypothetical fuel assembly drop, the space between the bottom of the baseplate and the top of the floor is not designed to control criticality, but to protect the SFP liner from an impact strike. In other words, the rack baseplate is raised high enough above the floor (10.8 cm (4.25 in)) to prevent the baseplate from contacting the SFP liner when the baseplate deforms under impact.

The staff reviewed the above response and concluded that the response is acceptable. However, it should be noted that the maximum displacement of 8.89 cm (3.5 in) reported here does not agree with the 10.9 cm (4.3 in) indicated in Figure 2-10 of TR-54. During the April 2007 audit, the staff noted that the applicant needed to address the higher base plate deformation (10.9 cm (4.3 in)) in the vertical direction and how this may affect the criticality analysis.

During the October 2007 audit, the applicant indicated that the hypothetical drop, wherein a fuel assembly travels downward through an empty storage cell and impacts the baseplate, has been re-analyzed in HOLTEC Report No. HI-2063519, Revision 1, for both the Region 1 and Region 2 spent fuel racks. The new analysis model incorporates the following changes (as discussed in the RAI responses to RAI-TR54-06, RAI-TR54-09, and RAI-TR54-11): (1) the baseplate is modeled with thick shell elements; (2) the effect of the stored fuel assemblies is accounted for by increasing the mass density of the baseplate; and (3) strain rate effects are considered for the welds only. Based on the new analyses for the Region 1 and Region 2 spent fuel racks, the maximum vertical displacement of the rack baseplate is 7.98 cm (3.14 in), which is less than the 8.89 cm (3.5 in) displacement considered in the criticality analysis. Therefore, the existing criticality analysis remains bounding.

The improvements made to the fuel rack models were reviewed by the staff and found to be technically acceptable. The staff requested the applicant to finalize the HOLTEC calculation and to revise TR-54 to describe the modeling approach used.

During the May 2008 audit, the staff verified that HOLTEC Report No. HI-2063519, Revision 2, shows that: (1) the baseplate is modeled with thick shell elements; (2) the effect of the stored fuel assemblies is accounted for by increasing the mass density of the baseplate; and (3) strain rate effects are considered for the welds. The resulting vertical deformation due to the drop is 7.98 cm (3.14 in). Therefore, RAI-TR54-10 was resolved.

Figure 2-9 of TR-54 shows the permanent deformation at the top of a cell wall at Region 2. The permanent deformation is measured as 50.8 cm (20 in), which is just slightly smaller than the limit of 52.07 cm (20.5 in). Since the deformation at the impact location is so close to the limit (i.e., very little margin exists), the mesh should be locally refined, to ensure convergence with mesh size. Therefore, in RAI-TR54-11, the staff requested the applicant to perform an additional analysis with a finer mesh at the impact region to confirm that the LSDYNA model is suitable.

In a letter dated April 9, 2007, the applicant stated that the general acceptance criterion for the 91.44 cm (36 in) fuel assembly drop onto the top of a Region 2 rack is to maintain the stored fuel assemblies in a subcritical configuration. In measurable terms, the permanent deformation of the rack (measured downward from the top of rack) is limited to 52.07 cm (20.5 in), which is equal to the distance from the top of the rack to the top of the neutron absorber panel. This limit is conservative because the active fuel region begins 5.08 cm (2 in) below the top of the neutron absorber panels. Therefore, more margins exist than TR-54 indicates, and a mesh convergence study is not required.

The staff noted that, although the distance from the top of the rack to the top of the fuel is 57.15 cm (22.5 in), which gives a margin of 6.35 cm (2.5 in), this is still a relatively small margin. Because of the small margin, the staff requested the applicant to demonstrate whether the finite element model is sufficiently refined in the impact region.

During the April 2007 audit, the staff discussed this with the applicant. The applicant noted that the neutron absorber panels, beyond the 50.8 cm (20 in) deformation, respond in the elastic range and would not be damaged. The applicant also noted that the criticality analysis was performed for 9 fuel assemblies having the active fuel region exposed 8.89 cm (3.5 in) (see response to RAI-TR54-10).

During the October 2007 audit, the applicant indicated that the 91.44 cm (36 in) fuel assembly drop onto the top of a Region 2 rack has been re-analyzed in HOLTEC Report No.HI-2063519, Revision 1, with consideration of strain rate effects for the welds. The new analysis shows that the maximum permanent deformation of the rack cell wall is only 35.7 cm (14.06 in) (measured from the top of rack) versus the allowable limit of 53.71 cm (21.145 in) as defined in the analysis report. Since the margin between the calculated deformation and the allowable limit is greater than 17.78 cm (7 in), the applicant stated that there is no longer a need to demonstrate that the refinement of the model is adequate in the localized region of the impact zone.

The staff, however, requested the applicant to confirm the adequacy of the rack model in the crushed zone region by providing curves that compare the hourglass energy to the kinetic, internal, and/or total energy. The applicant provided these curves, which showed that the hourglass energy was essentially negligible in comparison to the internal energy of the cell structure and impact bar that were being plastically deformed during these drop accident cases. In view of the now much larger margins in the extent of plastic deformation in the new revised model, and the comparison of the hour glass energy, the staff found the response technically acceptable, pending the finalization of the HOLTEC calculation and revision of TR-54 to describe the new results.

During May, 2008 audit, the staff verified that HOLTEC Report No. HI-2063519, Revision 2, shows the results of the drop analyses onto the top of the fuel racks considering the strain rate effects for the welds. In view of the now much larger margins in the extent of plastic deformation in the new revised model, and the comparison of the hour glass energy, the staff found the response technically acceptable. The TR does not go to this level of detail; however, the staff confirmed the HOLTEC calculation incorporated the above modeling change. Therefore, RAI-TR54-11 was resolved.

There are a total of six impact analyses for the Region 1 and Region 2 racks (3 drop cases for each rack region). TR-54 only presents the results for three analyses, on the basis that these are the bounding conditions. In RAI-TR54-13, the staff requested the applicant to explain the technical basis for concluding that these are the bounding conditions, or provide the results for the three analyses not presented in the report.

In a letter dated May 17, 2007, the applicant stated that the analysis was performed for both the Region 1 and Region 2 racks. The bounding analysis was reported. The shallow drop event involving a Region 1 rack was analyzed and found to yield a plastic deformation of 38.1 cm (15.0 in) measured vertically from the rack top, which is bounded by the reported Region 2 rack shallow drop analysis with a predicted rack top plastic deformation of 50.8 cm (20 in). Similarly, Region 2 rack baseplate was found to deform less than 8.38 cm (3.3 in), which is smaller than the reported bounding baseplate deformation of 10.83 cm (4.264 in) for the Region 1 rack. Finally, because the Region 1 rack is lighter than the Region 2 rack, more impact energy can be transferred into the SFP floor and therefore results in bounding SFP floor damage in an event where the fuel assembly drops directly over a Region 1 rack pedestal; this bounding case was analyzed and reported.

The staff evaluated the RAI response and determined that the response provided an adequate explanation of why the three accident drop cases that were analyzed bound the other three drop cases. Therefore, the staff found the response acceptable and RAI-TR54-13 was resolved.

In accordance with NUREG-0800 Section 3.8.4, Appendix D, one of the fuel handling accident loads that need to be considered is uplift force on the rack caused by a postulated stuck fuel assembly. Section 2.8.3 of TR-54, Revision 0, states: "An evaluation of a stuck fuel assembly, leading to an upward load of 2,000 lb has been performed. The results from the evaluation show that this is not a bounding condition because the local stresses do not exceed 2,500 psi." The staff determined that additional information was needed in order to assess whether this load has been adequately considered. In RAI-TR54-14, the staff requested that the applicant provide a detailed description of the assumptions, the analyses conducted, the results obtained, and the basis for the conclusion that this is not a bounding condition.

In a letter dated May 17, 2007, the applicant stated: “A nearly empty rack with one corner cell occupied is subject to an upward load of 2000 lbf, which is assumed to be caused by the fuel sticking while being removed." The applicant attached a calculation, and stated that the local stress is well below the yield stress of the cell wall material (i.e., 147 MPa (21,300 psi) pursuant to Table 2-6). The applicant also noted that the value of 17.2 MPa (2,500 psi) will be changed in Section 2.8.3 to 20.7 MPa (3,000 psi) for the local stresses resulting from a stuck fuel assembly.

In a letter dated April 18, 2008, the applicant augmented its initial RAI response, stating that the calculation provided in the RAI response is excerpted from HOLTEC Report No. HI-2063523, (APP-FS02-S3C-001, Revision 0). The staff evaluated the supplemental RAI response, including the calculation that demonstrates the adequacy of the vertical welds along the height between adjoining cells and the horizontal welds at the base (cell walls to baseplate). The staff found all responses to staff’s concerns are satisfactory, pending revision to the HOLTEC calculation and the TR.

In December 2008, the staff reviewed TR-54, Revision 2, and related sections in DCD Revision 17. The staff noted that a new Section 2.8.6 has been added to TR-54, Revision 2, to describe the stuck fuel assembly evaluation. Section 2.8.6 states, “A nearly empty rack with one corner cell occupied is subject to an upward load of 5,000 lbf, which is assumed to be caused by the fuel sticking while being removed." This increase in uplift force was necessitated by changes in the spent fuel handling operations. The staff found the re-analysis to be acceptable. The predicted stresses are still below allowable stresses. Therefore, RAI-TR54-14 was resolved.

The staff noted that the descriptive information included in TR-54 was not sufficient to permit an adequate review of the structural/seismic analysis of the spent fuel racks, in accordance with NUREG-0800 Section 3.8.4, Appendix D. In RAI-TR54-15, the staff requested the applicant provide descriptive information, including plans and sections showing the spent fuel racks, pool walls, liner, and concrete walls. All of the major features of the racks including the cell walls, baseplate, pedestals, bearing pads, neutron absorber sheathing, any impact bars, welds connecting these parts, and any other elements in the load path of the racks should be shown on one or several sketches. These sketches should also indicate related information which includes key: cutouts, dimensions, material thicknesses, and gaps (fuel to cell, rack to rack, rack to walls, and rack to equipment area). In addition to the above, for review of postulated fuel handling drop accident and quantification of the drop parameters, sketches with sufficient details for the fuel handling system should be provided to facilitate the review as indicated in NUREG-0800 Section 3.8.4, Appendix D.

In a letter dated June 8, 2007, the applicant provided sketches in the attachment to the RAI-TR54-15 response, showing the major features of the racks and SFP. The applicant stated that these sketches would be incorporated in TR-54. The detailed design of fuel handling equipment and detailed sketches are not available. However, the quantification of the drop parameters has been established in the DCD (both maximum drop weights and heights). The DCD drop heights are much greater than what is being designed for the fuel handling equipment, which is stated in the RAI-TR54-01 response.

During the April 2007 audit, the complete design drawings of the spent and new fuel racks were available to the NRC for review. In addition, HOLTEC explained how the rack features were incorporated into the seismic/structural models.

During the October 2007 audit, the staff discussed five specific items with the applicant: key dimensions of the male and female pedestal components and bearing plates; welds connecting the pedestals to the baseplate; welds connecting the baseplate to the fuel cell walls; leak chase channels; and gaps between the racks. The applicant provided additional information to the staff, describing these details.

During the May 2008 audit, the staff reviewed all the pending revisions to TR-54 and the DCD. The staff identified the need for additional changes to certain figures in TR-54 and the need to include them in the DCD for consistency.

In a letter dated June 20, 2008, the applicant provided its supplemental response to this RAI. The staff reviewed the response and found that TR-54, Revision 2, and related sections in DCD Revision 17 had been appropriately revised. Therefore, RAI-TR54-15 was resolved.

The staff noted that TR-54 is a summary report. However, to adequately perform a technical review of the analysis and design of the spent fuel racks, a more detailed report should have been submitted, similar to those provided in past technical reviews of spent fuel racks for specific nuclear power plants. Therefore, in RAI-TR54-16, the staff requested the applicant provide the detailed spent fuel storage rack report/calculation for review.

In a letter dated April 9, 2007, the applicant stated that TR-54 is a summary report; and two calculations [HOLTEC Report No. HI-2063523, “Spent Fuel Rack Structural/Seismic Analysis for Westinghouse AP1000,” Revision 0, 08/15/2006 (APP-FS02-S3C-001); and HOLTEC Report No. HI-2063519, “Analyses of AP1000 Fuel Storage Racks Subjected to Fuel Drop Accidents,” Revision 0, 08/15/2006 (APP-FS02-Z0C-001)] form the basis for TR-54.

During the April 2007 audit, the staff reviewed both HOLTEC calculations. Based on this review, the staff requested the applicant to address nine specific questions related to gaps between racks, modeling assumptions, and solution convergence in the seismic analysis. Two significant issues required the applicant to conduct additional analysis. The staff requested that the applicant provide a justification for the assumptions used in developing the various spring stiffnesses, including how variations in the spring stiffnesses affect the results (e.g., sensitivity studies). The staff also requested the applicant to address the sensitivity of the numerical results to the integration time step used in the analysis. The remaining seven questions were requests for clarifications, not requiring additional analysis. The staff also requested the applicant to address 11 specific questions related to design parameters (e.g., weight, temperature, flow) and to analysis methods used for the drop accident analysis. These questions were requests for clarifications, not requiring additional analysis. The applicant agreed to address all of the staff’s questions by making appropriate changes and/or additions to the calculations.

During the October 2007 audit, the applicant indicated that, in order to address possible variations in the spring constants, a sensitivity study was performed in which the calculated impact spring constants were uniformly increased and decreased by 20 percent in two separate computer runs. The COF used for all three computer runs (i.e., 80 percent, 100 percent, and 120 percent of the calculated spring constants) is 0.8. The applicant also indicated that the time integration step used for the computer runs is 1×10^{-5} sec. In order to verify that the runs are converged, an additional computer run (Run 6) was performed using a time integration step of 5×10^{-6} sec (i.e., half of the original time step). The differences in results are minimal. HOLTEC Calculation HI-2063523 was updated to include the results of these sensitivity studies, and the final safety conclusions are based on the maximum results from all computer runs, including the sensitivity studies. The staff reviewed HOLTEC Calculation HI-2063523, Revision 1, and noted that the calculation had been revised to include the numerical results for the sensitivity studies, and that these results were considered with all the other runs in the structural assessments.

During the August 2009 audit, the staff confirmed that all 20 of the staff’s questions had been appropriately addressed in updates to the HOLTEC calculations and corresponding Westinghouse reports. Therefore, RAI-TR54-16 was resolved.

The staff noted that insufficient data were provided in TR-54 describing the seismic input loads used for analysis of the spent fuel racks. The staff issued RAI-TR54-17, which reads as follows:

a. Floor response spectra (X, Y, and Z - vertical directions) at or the near the elevation of the top of the fuel racks and near the bottom of the fuel rack or pool floor corresponding to the damping value used for the analysis.

b. Explain why the envelope of these two sets of spectra was not used.

c. The current DCD is applicable for the hard rock site. Therefore, provide further explanation for the range of soil and rock properties used in enveloping the seismic floor spectra. Where are these ranges of soil/rock properties specified for confirmation by a future COL applicant?

d. For the synthetic time histories, provide plots of the three time histories, the cross correlation coefficients, the comparisons of the spectra from the synthetic time histories to the enveloped target response spectra, and the comparisons of the power spectral density plots to the target power spectral density function associated with the target response spectra.

e. Which time history was used (displacement, velocity, or acceleration)? Were all three directions input simultaneously? Was gravity included in the time history analysis?

In a letter dated April 9, 2007, the applicant provided the following response:

a. Floor response spectra (X, Y, and Z vertical directions) near the elevation of the bottom of the spent fuel pool floor corresponding to the damping value used for the analysis are provided in the PDF attachment RAI-TR54-17a. No Floor response spectra are provided near or at the elevation of the top of the spent fuel racks (See response to RAI-TR54-17b).

   The ASB99 floor response spectra represent the enveloping response spectra for the auxiliary shield building at elevation 99 ft for a range of soil/rock condition. FRS of various soil/rock analyses were first enveloped for various locations of the ASB. All of the ASB locations at elevation 99 ft were then grouped and enveloped to develop the ASB99 floor response spectra. The spent fuel pool is at a lower elevation but the dynamic response is essentially the same as at elevation 99 ft.

b. The spent fuel racks are free-standing in the spent fuel pool. They are not anchored to the spent fuel pool walls. The spent fuel racks are excited in a seismic event by the floor response spectra representing the spent fuel pool floor (ASB99). There is no need to envelope multiple sets of floor response spectra.

c. The range of soil and rock conditions for which the seismic floor spectra applies is described in Westinghouse technical report “Extension of NI Structures Seismic Analysis to Soil Sites.”

d. The synthetic time histories, the response spectrum curves, and the power spectral density plots for the Auxiliary Shield Building at Elevation 99 ft are provided in Figures TR54-17.1 through TR54-17.9 (attached to RAI response). The cross correlation coefficients for the three orthogonal components (East West, North South, and Vertical) of the ASB99 synthetic time histories are summarized in the table [submitted as part of this response].

e. Acceleration time histories are used as the input motion for the seismic analysis of the spent fuel racks. The acceleration input is defined by three orthogonal components, which are input and solved simultaneously. Gravity is also included in the time history analysis.

The staff found this RAI response to be acceptable because it adequately addressed all of the staff's questions. RAI-TR54-17 was initially resolved. However, subsequent to the initial resolution of this RAI, the applicant revised the seismic design loads twice. Therefore, during the June 2010 audit, the staff requested that the applicant update this RAI response to reflect the current seismic design loads for the spent fuel racks. In a letter dated July 9, 2010, the applicant submitted a revised response to RAI-TR54-17, updating the seismic design loads. The staff finds that the revised RAI response adequately describes the current seismic design loads for the spent fuel racks. TR-54, Revision 4, includes the numerical results for the current design loads. Therefore, RAI-TR54-17 is resolved.

The staff noted that the seismic analyses only considered the bounding values (0.2 and 0.8) for the COF between the pedestal and the pool liner. In RAI-TR54-18, the staff requested the applicant to provide the technical basis for only considering these two bounding values and not other intermediate values. The staff also requested clarifications about sliding. What is assumed to slide, the pedestal to bearing plate or bearing plate to pool liner? If it is the surface between the bearing plate and pool liner, how is damage to the pool liner due to horizontal forces avoided? Are there any physical provisions to prevent the bearing plate and pedestal from sliding to the point that the pedestal centerline would be at or beyond the edge of the bearing plate?

In a letter dated April 10, 2007, the applicant stated that the coefficients of friction used in the seismic analyses, namely 0.2 and 0.8, are consistent with previous spent fuel rack license applications, and they are based on the experiments performed by E. Rabinowicz (TR-54, Reference 21: "Friction Coefficients of Water Lubricated Stainless Steels for a Spent Fuel Rack Facility," MIT, a report for Boston Edison Company, 1976). The lower value of 0.2 produces the maximum sliding displacement between the rack pedestals and the bearing plates. The higher value of 0.8 increases the rocking motion of the spent fuel racks and produces the maximum stress in the rack pedestals. Sliding occurs between the rack pedestal and the bearing plate since these two items are made of different materials (SA564-630 vs. SA240-304), whereas the pool liner and the bearing plate are made of the same material (SA240-304) and are more likely to gall. There are no physical provisions to prevent the rack pedestal from sliding beyond the edge of the bearing plate. The seismic analyses, however, demonstrate that the maximum sliding displacement at the base of the rack is less than the distance between the pedestal outside diameter and the edge of the bearing plate.

The staff reviewed the applicant's response and noted that three COF values (0.2, 0.5, and 0.8) are used for the new fuel rack analysis. The applicant needed to justify why all three values are not utilized for the spent fuel rack analysis. Consideration of an intermediate value is appropriate because the analyses are highly nonlinear and it is not evident which value(s) would govern. The need to consider other values is also discussed in Section 6.4.2 of NUREG/CR-5912, "Review of the Technical Basis and Verification of Current Analysis Methods Used to Predict Seismic Response of Spent Fuel Storage Racks." The staff also requested the applicant to provide the maximum horizontal displacement from the analyses and compare that against the distance between the pedestal centerline and the edge of the bearing plate.

During the October 2007 audit, the applicant indicated that an additional computer run had been performed for an intermediate COF of 0.5. During the May 2008 audit, the staff reviewed HOLTEC Calculation HI-2063523, Revision 1, and confirmed that the report describes the analysis and results for the additional case of a 0.5 COF. In addition, the staff reviewed TR-54, Revision 1, and confirmed that the 0.5 COF case was included. Therefore, RAI-TR54-18 was resolved.

The staff noted that the SFP is divided into 2 regions, with different rack designs. In RAI-TR54-20, the staff requested the applicant to explain the reason for the different type racks (i.e., Region 1 and Region 2). If it is because of different fuel assembly types, explain how the analysis considers the various types and combinations of fuel assemblies (e.g., mass, sizes, gaps, fluid coupling, etc.).

In a letter dated April 9, 2007, the applicant stated that the AP1000 uses only one fuel assembly type. The purpose of the Region 1 racks is to provide storage for up to 243 fresh fuel assemblies with a maximum initial enrichment up to 5.0 w% U-235. This is accomplished by spacing these storage cells on a pitch equal to 27.67 cm (10.9 in.) and employing a “flux trap” poison configuration between consecutive storage cells.

The purpose of the Region 2 storage racks is to provide storage for up to 646 fuel assemblies in a high density configuration. These storage cells employ a pitch equal to 22.93 cm (9.028 in.) and a single poison panel separates consecutive fuel assemblies.

The response clarified that all of the fuel assemblies are the same; only the rack configuration is different between Region 1 and Region 2. Since all of the racks are included in the 3-dimensional pool rack model, the staff found the response acceptable. Therefore, RAI-TR54-20 was resolved.

In RAI-TR54-21, the staff requested the applicant to explain how the different impact stiffness values are determined for the fuel to cell wall, rack to rack, rack to wall, and pedestal to floor. Since the impact forces are affected by the impact spring constants, how is the sensitivity of the impact forces and rack responses to variation in these spring constants addressed? Are impact forces imparted directly onto the cell walls or are there impact bars?

In a letter dated May 17, 2007, the applicant stated that the impact stiffness values for the rack to rack, rack to wall, and pedestal to floor are calculated as shown in the attachment to the RAI response. The fuel to cell wall impact stiffness is determined based on the solution for a simply supported circular plate under a concentrated load applied at its center, where the plate diameter is equal to the cell inner dimension and the plate thickness is equal to the cell wall thickness. The stiffness of the annular plate is then multiplied by the number of loaded storage cells for each rack, since the stored fuel assemblies are assumed to rattle in unison. A sensitivity study has not been performed specifically for the AP1000 spent fuel racks to quantify the effect of variations in the impact stiffness values. However, sensitivity studies have been performed in the past for similar spent fuel rack applications submitted by HOLTEC, which employed the same method of computing the impact stiffness values, and the impact forces were found to be insensitive to small variations in the stiffness values provided that the integration time step was sufficiently small. There are impact bars around the entire perimeter of each Region 2 spent fuel rack at the top of the rack. These bars prevent impact forces from being imparted directly onto the cell walls, and they reinforce the rack cell structure at the point of impact.

During the October 2007 audit, the staff discussed with the applicant the development of the spring constant for impact loads between the stored fuel assemblies and the cell walls, which is based on the solution for a circular plate with simply supported edges subjected to a uniform pressure load. This approach has been used consistently by HOLTEC since the mid 1980’s, when the computer code DYNARACK was first developed. As a result, numerous spent fuel rack licensing applications over the past 20 years have relied on this approach. The applicant also noted that, in response to RAI-TR54-16, a sensitivity analysis was performed in which all spring constants used in the DYNARACK model were uniformly increased and decreased by 20 percent. The stiffer springs resulted in only a 0.4 percent increase in the fuel-to-cell impact load.

The staff concluded that the applicant adequately addressed the sensitivity of the response to variations in the spring constants. Therefore, RAI-TR54-21 was resolved.

Section 2.2.2.2 of TR-54 describes some modeling information for a single rack. It indicates that the rack cellular structure is modeled by a 3-D beam having 3 translational and 3 rotational DOFs at each end, so that two-plane bending, tension/compression, and twist of the rack are accommodated. In RAI-TR54-23, the staff requested the applicant to explain why shear stiffness/deformation is not also included, and to provide more detailed information about how the beam model of the rack was developed, considering that it is an assembly of many square-celled structures welded at discrete locations.

In a letter dated April 9, 2007, the applicant stated that the shear deformation is included in the rack dynamic model. The beam model of the rack was developed based on the applicable Codes, Standards and Specifications given in Section IV(2) of the NRC guidance on SFP modifications entitled, “Review and Acceptance of Spent Fuel Storage and Handling Applications,” dated April 14, 1978, which states that “Design … may be performed based upon the AISC specification or Subsection NF requirements of Section III of the ASME Code for Class 3 component supports.” The rack modeling technique is consistent with the linear support beam element type members covered by these codes.

The staff verified that Section 2.2.2.2 of the TR-54, Revision 1, was revised to clarify that shear stiffness/deformation is also included in the rack model. Therefore, RAI-TR54-23 was resolved.

Section 2.2.2.2 of TR-54 refers to Figure 2-2 for the dynamic beam model of a single rack. The text and figure do not adequately describe the model. The staff issued RAI-TR54-24 which reads as follows:

a. Define what each series of nodal degrees-of-freedom (DOFs) correspond to (i.e., nodes 1,2; P1, P2, ...; q4, q5, ..., 1*, 2*, ...). While some of these may be deduced by judgment, the report should clearly define all of these.

b. Explain whether there are 5 nodes and 4 beams along the rack beam model to coincide with the 5 nodes and 4 elements of the fuel assemblies?

In a letter dated April 10, 2007, the applicant provided the following response:

a. Table 54-24.1 defines the nodal DOFs for the dynamic beam model of a single rack as depicted in Figure 2-2 of the technical report.

b. The rack cell structure is modeled as a single beam between two nodes, which are located at the top of the rack and at the baseplate elevation. This is consistent with HOLTEC’s standard model for seismic analysis of spent fuel racks, which has reviewed and approved by the NRC on numerous dockets. Although there is not a one to one correspondence between beam nodes and fuel assembly nodes, fuel to cell wall impact loads, which can occur at Elevation 0, 0.25H, 0.5H, 0.75H, and H (where H is the height of the cell structure), are properly transmitted to the rack beam in accordance with the methodology outlined in TR-54 Reference 11.

The staff found part (a) of the response acceptable, and determined that part (b) would require a review of Reference 11. During the April 2007 audit, the applicant indicated that to satisfy part (a) of the response it will include the information provided in the response in the TR. For part (b,) the applicant provided an explanation of how the fuel-to-cell impact terms at each fuel mass elevation are related to the single beam shape function at the same elevation.

During the October 2007 audit, the applicant indicated that Table 2-18 would be added to TR-54. This table defines the nodal DOFs for a single rack dynamic model. The staff reviewed the proposed revisions to Section 2.2.2.2 and Table 2-18. The staff found this technically acceptable. The staff also reviewed the approach described in Reference 11 of technical report APP-GW-GLR-033, Revision 0, for the use of the coupling terms to relate the internal deformations of the fuel nodes to the external deformations of the fuel rack beam nodes at the two ends. Based on this review and the use of this method in prior licensing submittals to the NRC, the staff found this approach to be acceptable.

The staff determined that the applicant made appropriate changes in TR-54, Revision 1. Therefore, RAI-TR54-24 was resolved.

In RAI-TR54-25, the staff requested the applicant to explain whether only full fuel racks are included in the two simulations, or if several scenarios are considered (i. e., different fill ratios, from partially full to full within a given rack; varying fuel locations within the partially filled rack; varying fill and locations in adjacent racks); and to provide the technical justification if only full racks are considered. The staff also asked whether it would be possible to have less than all fuel racks (8) in the pool. If so, then additional simulations would be needed. If not, is there a requirement in the DCD that specifies all fuel racks must always be in place whenever fuel is stored in any of the racks?

In a letter dated May 17, 2007, the applicant stated that all spent fuel racks, in both simulations, are assumed to be fully loaded with maximum weight fuel assemblies. This scenario bounds any partially loaded configuration since it (1) maximizes the vertical compression and lateral friction loads on the support pedestals and (2) produces the maximum rack displacements and fuel to cell wall impacts. The displacements are larger for a fully loaded rack, as opposed to a partially filled rack, because the dynamic model conservatively assumes that all stored fuel assemblies rattle in unison. Hence, the momentum transferred between the rattling fuel mass and the spent fuel rack is at a maximum for a fully loaded rack. For a partially filled rack, the decrease in rattling fuel mass outstrips the destabilizing effect of an eccentric fuel loading pattern.

The applicant further stated that the SFP rack analysis was performed with all eight fuel racks installed during operation of the SFP, which is consistent with the design intent of the AP1000 Spent Fuel Storage Racks. DCD Section 9.1 will include the statement that all spent fuel racks will be in place in the SFP whenever fuel is stored in the spent fuel racks.

The staff reviewed the response and concluded that the explanation provided in the response appears to support the conclusion that fully loaded racks would be expected to maximize impact forces and displacements. In addition, the use of the maximum weight for the fuel assemblies, the analysis assumption that all stored fuel assemblies rattle in unison, and consideration of the upper and lower bound COF at all support legs provide added conservatism to bound the results.

However, the staff noted that Section 9.1.2.2.1 of DCD Revision 16, states “The purchase specification for the spent fuel storage racks requires the vendor to perform confirmatory dynamic and stress analyses. The seismic and stress analyses of the spent fuel racks consider the various conditions of full, partially filled, and empty fuel assembly loadings.” Therefore, the applicant needed to explain this inconsistency between the DCD and the analyses actually performed. The staff noted that this statement occurs in two locations in DCD Section 9.1.

During the October 2007 audit, the applicant indicated that HOLTEC would perform additional analyses considering partially filled racks (from empty to full condition of various racks) in order to address the requirements in the DCD.

During the May 2008 audit, the staff reviewed HOLTEC Report No. HI-2063523, Revision 2, and draft TR-54, Revision 2, which show that additional cases were analyzed, which considered different racks in the pool having varying fill of fuel assemblies ranging from 0 percent, 25 percent, 33 percent, 66 percent, 75 percent, and 100 percent fill. These results, along with the other variations were presented in the report, and subsequent stress evaluations for the racks were based on the worst-case results from all nine cases considered.

TR-54, Revision 2, and related sections in DCD Revision 17 indicated that additional analysis for mixed loading of spent fuel racks was considered. Table 2-4 in TR-54, Revision 2, was revised to add three more simulations consisting of “fully loaded with modified gaps,” “mixed loadings,” and “empty” rack cases. Based on its review of these additional analyses, the staff requested the applicant to address the following items:

1. The report does not describe these additional cases, as discussed during the May 2008 audit. The staff’s understanding from the audit was that in the mixed loading case: (1) different racks had varying fill from 0 percent through 100 percent; and (2) the partially filled racks had the fill offset (i.e., center of mass was offset from the centerline of the rack in the computer model) to simulate the possibility of placing fuel assemblies closer to the side of the fuel rack rather than uniformly distributed. Provide the following information in TR-54: (1) the fill used for each rack and the location of the assumed fuel assemblies to represent possible offsets in the Run 5 simulation (mixed loading case); (2) the modified gaps used in the Run 4 simulation versus the gaps used for the other cases; and (3) a full description of the three additional analyses (Runs 4, 5, and 9). The description should discuss the purpose, approach, results in comparison to the other cases, and clearly state that any subsequent stress evaluations for the racks were based on the worst-case results from all nine runs.

2. Explain why the tabulated displacements in Table 2-10 have not been revised in view of the statement made in Section 2.8.1.4 of TR-54, Revision 2 that the racks did impact the pool walls. The statement implies that the racks displace at least 8.13 cm (3.2 in), which is the available gap between the racks and the pool walls shown on Figure 2-1. In addition, if the displacement of Rack A1, adjacent to the tool storage area, is greater than 8.13 cm (3.2 in) in the south direction, then the 86.36 cm (34 in) referenced clearance shown on Figure 2-1 would need to be revised to ensure that the rack does not displace into the tool storage area boundary.

During the August 2009 audit, the staff discussed with the applicant the need to address the items described above. In a letter dated September 14, 2009, the applicant submitted a revision to its RAI response, addressing these items. The staff confirmed that the necessary changes to TR-54 are included in TR-54, Revision 3. Therefore, RAI-TR54-25 was resolved.

In RAI-TR54-26, the staff requested the applicant address the following: what are the gaps and tolerances for each of the gaps between the fuel to cell wall, rack to rack, and rack to wall? What are the assumed initial locations of the various components (fuel assemblies and each rack) and what is the technical basis for this assumption? Were any studies done for different initial conditions (considering tolerances); if not, explain why. What requirements are in the DCD to ensure that the assumed gaps (considering tolerances) will always be maintained throughout the licensing period?

In a letter dated May 17, 2007, the applicant stated that all gaps between fuel assemblies and cell walls, between racks, and between racks and pool walls are set to match the nominal gaps provided on the Westinghouse Drawing APP-FS02-V2-002, Revision 0, “Discrete Zone Two Region Spent Fuel Rack Pool Layout.” An attached table summarized the gap information used in the dynamic analyses. The applicant further stated that fuel is assumed centrally located in the cell. This is conservative since minimizing gap on one or two walls will generally produce a larger hydrodynamic coupling effect. Numerical studies were done on other HOLTEC rack projects; the studies generally showed a small influence on results. A larger influence occurs if the gaps are assumed to be displacement-dependent, rather than always being held constant at their initial value. Neglecting this effect is conservative.

The applicant also stated that, once racks are installed in the SFP, the only way the rack-to-rack and rack-to-wall gaps would change over time would be by the action of a seismic event. COL applicants will have a procedure in place to measure the post-earthquake gaps, to evaluate the acceptability of the configuration, or to take appropriate corrective actions.

During the May 2008 audit, the staff reviewed HOLTEC Report HI-2063523, Revision 2, and confirmed that an additional case (Run 4) was analyzed to consider the effect of the installation tolerances for the nominal gaps. Run 4 corresponded to the base case conditions (Run 1 - COF equal to 0.8, fully loaded racks, integration time step = 1×10^{-5}) but it increased all of the gaps between adjacent racks by 1.27 cm (0.5 in). The results of this additional run demonstrated that the response of the racks was within 8 percent of the base case except for the maximum shear force on the rack pedestal, which was 32 percent higher. The applicant demonstrated that even with this higher pedestal shear force, the pedestal stress factor (ratio of calculated maximum shear stress to allowable shear stress) is equal to 0.092, which is very low. For completeness, the results of Run 4 were included in the design of the racks.

During the August 2009 audit, the staff determined that the drawings showing gaps and tolerances needed to be revised again, to reflect the latest analysis results for revised seismic loading. Subsequent rack design changes and a final revision to the seismic loading, following the August 2009 audit, required further revision of the drawings.

During the June 2010 audit, the staff and the applicant reviewed the final gaps and tolerances. In a letter dated July 20, 2010, the applicant submitted a revised RAI response that addressed the applicable figures in TR-54, Revision 4. The staff reviewed the response, and found the figures to be consistent with the gap and tolerance information in TR-54, Revision 4 and presented at the June 2010 audit.

In RAI-TR54-27, the staff requested the applicant provide more detailed information about how the fluid coupling was calculated and implemented in the AP1000 simulations. Describe the approaches used for fluid coupling of fuel assemblies to fuel cell walls, rack to rack, and rack to pool wall because there would be some differences among these. For the rack to rack and rack to wall fluid coupling, explain how fluid flow was considered horizontally as well as vertically over the top of the racks and flow to the bottom of the rack. Describe and justify any assumptions made in the approach. For example, small vibratory deflections relative to the gaps are probably assumed and the fluid gaps are not updated according to the rack displacements (see Section 2.4 of this report).

In a letter dated May 17, 2007, the applicant provided the following response:

> A mathematical explanation of the manner in which fluid coupling is calculated and implemented in the AP1000 simulations is provided.
>
> The problem to be investigated is shown in Figure TR54-27.1, which shows an orthogonal array of 8 rectangles which represent a unit depth of the 8 spent fuel racks in the AP1000 Spent Fuel Pool. The rectangles are surrounded by narrow fluid filled channels whose width is much smaller than the characteristic length or width of any of the racks. The spent fuel pool walls are shown enclosing the entire array of racks.
>
> The dimensions of the channels are such that an assumption of uni-directional fluid flow in a channel is an engineering assumption consistent with classical fluid mechanics principles. Each rectangular body (fuel rack) has horizontal velocity components U and V parallel to the x and y axes, and the channels are parallel to either the x or y axes. The pool walls are also assumed to move.
>
> It is conservatively assumed that the channels are filled with an inviscid, incompressible fluid. Due to a seismic event, the pool walls and the spent fuel racks are subject to inertia forces that induce motion to the rectangular racks and to the walls. This motion causes the channel widths to depart from their initial nominal values and causes flow to occur in each of the channels. Because all of the channels are connected, the equations of classical fluid mechanics can be used to establish the fluid velocity (hence, the fluid kinetic energy) in terms of the motion of the spent fuel racks.
>
> For the case in question, there are 22 channels of fluid identified.
> Figure TR54-27.2 shows a typical rack (box) with four adjacent boxes with the fluid and box velocities identified. [See Westinghouse response for calculation and figures.]
>
> There are a total of 15 + 8 = 23 equations which can be formally written; one circulation equation, however, is not independent of the other. This reflects the fact that the sum total of the 8 circulation equations must also equal zero, representing the fact that the circulation around a path enclosing all racks is equal to zero. Thus, there are exactly 22 independent algebraic equations to determine the 22 unknown mean velocities in this configuration.
>
> Once the velocities are determined in terms of the rack motion, the kinetic energy can be written and the fluid mass matrix identified using the HOLTEC

> International QA validated pre processor program CHANBP6. The fluid mass matrix is subsequently apportioned between the upper and lower portions of the actual rack in a manner consistent with the assumed rack deformation shape as a function of height in each of the two horizontal directions. The HOLTEC International pre processor program VMCHANGE performs this operation. Finally, structural mass effects and the hydrodynamic effect from fluid within the narrow annulus in each cell between the fuel assembly and the cell wall are incorporated using the HOLTEC International pre processor program MULTI155.

The staff reviewed the RAI response and concluded that the response only addressed how fluid coupling of rack to rack and rack to wall is calculated and implemented in the AP1000 simulation. As requested in the RAI, the applicant should also provide a description of the approach used for simulating the fluid coupling of the fuel assemblies to the fuel cell walls. Due to the complex nature of the fluid coupling approach used for the rack to rack and rack to wall, and the use of several HOLTEC in-house computer codes, how has the approach been verified (e.g., test data or alternate analytical methods with known solutions)?

In a letter dated April 18, 2008, the applicant revised its response, replacing the last two paragraphs, and adding references as shown below:

> "Once the velocities are determined in terms of the rack motion, the kinetic energy can be written and the fluid mass matrix identified using the HOLTEC International QA validated pre processor program CHANBP6. The fluid mass matrix is subsequently apportioned between the upper and lower portions of the actual rack in a manner consistent with the assumed rack deformation shape as a function of height in each of the two horizontal directions. The HOLTEC International pre processor program VMCHANGE performs this operation.
>
> "The approach used for fluid coupling between the fuel assemblies and the cell walls is presented in Reference 2, and it is based upon Fritz's classical two body fluid coupling model (Reference 3). References 2 and 3 were previously provided to the NRC as part of the April 9, 2007 RAI response submittal (Reference 4 - Westinghouse Letter DCP/NRC1860). The structural mass effects and the hydrodynamic effect from fluid within the narrow annulus in each cell between the fuel assembly and the cell wall is incorporated using the HOLTEC International preprocessor program MULTI155."

The staff noted that the fluid coupling between the fuel assemblies and the cell walls is described in a paper "Seismic Responses of Free Standing Fuel Rack Constructions to 3 D Motions," by Soler, A.I. and Singh, K.P., Nuclear Engineering and Design, Volume 80, pp. 315 329 (1984), and it is based upon Fritz's classical two-body fluid coupling model presented in "The Effects of Liquids on the Dynamic Motions of Immersed Solids," by Fritz, R.J., Journal of Engineering for Industry, Trans. of the ASME, February 1972, pp. 167-172. This methodology for modeling the fluid coupling effects has been accepted for predicting the response of spent fuel racks in NUREG/CR-5912. It has been used in past licensing of spent fuel racking, and reviewed and approved by the NRC. Therefore, RAI-TR54-27 was resolved.

The load combinations specified in Table 2-5 of TR-54 and Table 9.1-1 (markup version of the DCD provided with the subject report) did not match NUREG-0800 Section 3.8.4, Appendix D criteria. The staff issued RAI-TR54-29, which reads as follows:

a. No load combinations are specified for the spent fuel racks corresponding to service Level A.

b. Temperature conditions T_o and T_a are not included in Table 2-5; however, they are included in the markup DCD Table 9.1-1. A footnote in the markup of DCD Table 9.1-1 states that "For the faulted load combination, thermal loads will be neglected when they are secondary and self limiting in nature and the material is ductile. In freestanding spent fuel racks, thermal effects mainly affect the temperature that is used in specifying the allowable stress and Young's Modulus." Based on this statement:

   (i) Regarding the first quoted sentence above, Table 2-5, Load Combination corresponding to service levels A and B (which are not the faulted condition) should include T_o.

   (ii) Regarding the last quoted sentence above, SRP 3.8.4, Appendix D indicates that thermal loads due to temperature effects and temperature gradients across the rack structure need to be considered. Temperature gradients can occur due to differential heating effects between one or more filled cell(s) and one or more adjacent empty cell(s). The stresses from these types of thermal loads should be considered because they can still lead to localized failure of the structure. When responding to this, consider temperature loads due to normal and accident conditions, as noted in your Table 9.1-1 and SRP 3.8.4, Appendix D.

c. Table 2-5 in the report and DCD Table 9.1-1 indicate that the load term P_f is the uplift force on the rack caused by a postulated stuck fuel assembly accident condition or the force developed on the rack from the drop of a fuel assembly during handling to the top of the rack or the baseplate through an empty cell. SRP 3.8.4, Appendix D, separates these two accident events into Pf for the uplift force event and Pd for the drop load event. This is necessary because SRP 3.8.4, Appendix D specifies that the acceptance limits for these two events (in combination with deadweight + live load + thermal) are different.

d. Table 2-5, last load combination with E', does not provide the Service Limit. If the same Service Limit, D(1), as indicated in the load combination above the last load combination was intended, then explain whether the functionality capability requirement in footnote (1) (which is applicable to only the new racks) is in addition to or in-place of Level D limits.

In a letter dated May 17, 2007, the applicant provided the following response:

> Table 2-5 of technical report (TR)-54 and DCD Table 9.1 1 will be revised as follows (which is derived from Appendix D to SRP Section 3.8.4):
>
> a. Table 2 5 of the subject report and DCD Table 9.1 1 will be modified to specify the load combinations D + L and D + L + T_o for Service Level A, as shown above.

b. (i) Table 2 5 of the subject report will be modified to include T_o for Service Levels A and B, as shown above.

   (ii) The temperature gradients across the rack structure caused by differential heating effects between one or more filled cells and one or more adjacent empty cells are considered. The worst thermal stress field in a fuel rack is obtained when an isolated storage location has a fuel assembly generating heat at maximum postulated rate and the surrounding storage locations contain no fuel. This secondary stress condition is evaluated alone and not combined with primary stresses from other load conditions. A thermal gradient between cells will develop when an isolated storage location contains a fuel assembly emitting maximum postulated heat, while the surrounding locations are empty. A conservative estimate of the weld stresses along the length of an isolated hot cell is obtained by considering a beam strip uniformly heated by 10.00 °C (50 °F), and restrained from growth along one long edge. The 50 °F temperature rise envelops the difference between the maximum local spent fuel pool water temperature (174 °F) inside a storage cell and the bulk pool temperature (140 °F) based on the thermal hydraulic analysis of the spent fuel pool. The cell wall configuration considered here is shown in figure below.

c. The definition of P_f in Table 2-5 of the subject report and DCD Table 9.1-1 is incorrect. The referenced tables will be revised to clearly distinguish between P_f and F_d.

d. Level D service limits apply to load combination D + L + Ta + E'. Per Appendix D of SRP Section 3.8.4, the functional capability of the fuel racks should be demonstrated for the accidental drop event (D + L + F_d). This requirement is in place of the Level D service limits since it is recognized that the rack may sustain permanent damage due to the impact force, and therefore it may not be possible to meet Level D service limits at all locations within the rack. The functional capability of the spent fuel racks is generally defined as the continued ability of rack to store spent fuel assemblies in a subcritical arrangement.

The staff reviewed the RAI response, and concluded that several additional items needed to be addressed by the applicant. In a letter dated April 18, 2008, the applicant provided a revised response to this RAI, which provided additional explanations.

The staff reviewed the revised response, and noted that proposed TR-54 Table 2-5 and DCD Table 9.1-1 include the missing load combination. In addition, the applicant: (1) explained why a secondary stress is not combined with primary stresses from other loads; (2) provided the calculation for the analysis of thermal stresses in the rack cell considering the differential heating between a cell containing a fuel assembly emitting maximum postulated heat and empty cells surrounding the heated cell; and (3) explained that the shear stress in the weld is caused by thermal loading, which is classified by the ASME Code as a secondary stress. In summary, the staff accepted the applicant's explanations pending submittal of revisions to TR-54 and the DCD. The staff subsequently confirmed that TR-54, Revision 2, and DCD Revision 17 had been appropriately revised. Therefore, RAI-TR54-29 was resolved.

The staff noted that TR-54 does not address seismic-induced sloshing effects. In RAI-TR54-31, the staff requested that the applicant provide a description of the sloshing calculation approach and results for both horizontal directions.

In a letter date May 17, 2007, the applicant stated that “sloshing” may be defined as the dynamic behavior and associated load of the water produced by wave-like motion at the surface of the pool. TID-7024, “Nuclear Reactors and Earthquakes,” Chapter 6, is commonly used to evaluate the dynamic response of the water within the SFP. Figure 6.2(a) of TID-7024 depicts the two masses of water that the total bulk is considered to be split into, as described in the text. The upper portion of the water, denoted in the figure as “water in motion,” produces convective forces and the lower portion of the water, denoted as “constrained water,” produces impulsive forces. The latter bulk of water has an associated mass (identified as weight W0) and is effectively a rigid body that moves along with the tank (refer to Figure 6.1 and the first paragraph of Section 6.4). The horizontal force produced by this mass of water when accelerated by the earthquake acts at a height of h_o from the bottom of the tank. This parameter is determined in the table given at the end of Section 6.3 to be equal to 3/8 times the height of the fluid. This height is not dependent upon the magnitude of the earthquake. For the SFP, the water depth is approximately 12.19 m (40 ft) and the height h_o would be 4.57 m (15 ft) from the bottom. Since the impulsive force acts at the approximate centroid of the rigid water mass, the top elevation of this bulk of water is above this point. As the racks are approximately 515.6 cm (203 in) tall, which is only slightly higher than the height h_o, the racks reside in the impulsive water mass at the bottom of the pool and the sloshing portion of the water is above this elevation. Therefore, seismic sloshing of the SFP water does not influence the dynamic response of the spent fuel racks in either horizontal direction.

The staff concluded that the applicant’s description of the sloshing effect in the SFP, based on using the method presented in TID-7024, Chapter 6, demonstrates that the racks reside in the impulsive water mass region of the pool and the sloshing portion of the water is above the top of the racks. Therefore, RAI-TR54-31 was resolved.

Section 2.3.4.3 of TR-54, fourth bullet, develops the faulted allowable maximum weld stress for the weld material. In RAI-TR54-33, the staff asked the applicant why an allowable maximum weld stress based on the base metal isn’t also developed. Normally welds are checked for both weld material and base metal, as was done for Levels A and B in Section 2.3.4.1.

In a letter dated May 17, 2007, the applicant stated:

> The required capacity evaluation for Level A conditions are presented below using the material properties associated with the material. Using the ASME Code allowable strengths for weld and base metal in Subsection NF, the shear capacities are:
>
> V(base) = (0.4Sy)Al; V(throat) = (0.3Su)(0.707Al);
> V(throat)/V(base) = 0.2121Su/(0.4Sy) = 0.53025Su/Sy, where Su = ultimate strength of weld material (assumed equal to that of the base metal for purposes of this calculation); Sy = yield strength of base metal; Al = fillet weld leg area; At = fillet weld throat area = 0.707Al.
>
> The above result for Level A conditions shows that the weld throat controls the capacity only if 0.53025Su < Sy. For the AP1000 spent fuel racks, Su=66.2 ksi; Sy=21.3 ksi at temperature, so that V(throat)/V(base) = 1.648, indicating that

base shear capacity controls the joint for a Level A event. For Levels B, C, and D, the joint capacities are simply increased by a factor so that the determination of the governing section remains the same.

Appendix F of the ASME Code does not explicitly require weld calculations for Level D events. If, however, the weld capacity evaluations are performed using material strengths inferred by certain sub sections of Appendix F, HOLTEC evaluates the capacity of the weld throat by using the amplifier 1.8 on the Level A capacity to obtain V(throat) = 1.8 (0.2121SuAl) = 0.38278SuAl

ASME Code Appendix F contains the following subsections that refer to allowable strengths for shear calculations. Using the 1998 Edition,
F-1331 - Criteria for Components (F-1331.1(d)) - The average primary shear stress across a section loaded in pure shear shall not exceed 0.42Su.
F-1332 - Criteria for Plate and Shell Type Supports (F-1332.4 Pure Shear) - The average primary shear stress across a section loaded in pure shear shall not exceed 0.42Su.
F-1334 - Criteria for Linear Type Supports (F-1334.2 Stresses in Shear) - The shear stress on the gross section shall not exceed the lesser of 0.72Sy and 0.42Su. Gross section shall be determined in accordance with NF 3322.1(b). [Note that Code reference to NB 3322.1(b) is a typo as the referenced NB section has nothing to do with section evaluation.]

It is stipulated that F-1334.2 is intended for setting limits for the shear stress in the base metal of gross sections associated with steel structural members and should not be applied to any weld calculation (as can be inferred by the title of Subsection NF-3322 B Design Requirements for Structural Steel Members). Even if one accepts that there is an implied requirement in Appendix F to check weld capacity for Level D events, the appropriate base metal shear stress limit should be 0.42Su (viz. F-1331.1(d), F-1332.4, or F-1334.2), which would therefore give the capacity of the base metal as V(base) = 0.42SuAl.

V(throat)/V(base) = 0.911 indicating that weld throat shear capacity always controls the joint for a Level D event independent of the material. This is why only the weld throat is checked when examining welds in the Level D configuration.

The staff reviewed the above explanation and found that it demonstrates that following the requirements in Appendix F for components and supports, and using the ultimate strength value and yield strengths for the materials of the spent fuel racks, welded joints are governed by the weld throat shear capacity, not the base metal capacity. That is why only the weld throat was checked for Level D when examining the structural adequacy of welds. The staff found this acceptable. Therefore, RAI-TR54-33 was resolved.

Section 2.3.5 of TR-54 discusses dimensionless stress factors. It states that “R1 is the ratio of direct tensile or compressive stress on a net section to its allowable value (note pedestals only resist compression).” In RAI-TR54-34, the staff requested the applicant explain why this indicates that pedestals only resist compression, since horizontal forces are also generated due to friction during a seismic event. These forces could be quite high and also would introduce shear and moments into the pedestal and rack structure.

In its response, the applicant stated that Section 2.3.5 of the report defines seven stress factors (R1 through R7), which correspond to the ASME Code Section III, Subsection NF stress limits for Class 3 components. R1 is defined as the ratio of direct tensile or compressive stress on a net section to its allowable value. Since the spent fuel racks are freestanding, the net cross section of the support pedestals can only be subjected to direct compressive stress. This is the explanation for the note in parentheses. The applicant further stated that horizontal forces are generated due to friction between the support pedestals and the SFP floor and that these forces produce shear and bending stresses in the pedestals. The shear and bending stresses in the support pedestals, as well as the combined compression and bending stress, are measured by the other six stress factors (i.e., R2 through R7), which are defined in Section 2.3.5 of this report. The staff reviewed the RAI response and concluded that the explanation is acceptable. Therefore, RAI-TR54-34 was resolved.

Section 2.8.1.4 of TR-54 describes the impact loads and states that these loads do not result in damage to the racks that would prevent retrievability. In RAI-TR54-35, the staff requested the applicant confirm that the acceptance criteria for these impacts include both retrievability and meeting the stress limits for Level D in accordance with ASME Code, Section III, Subsection NF; and to provide the stress ratios for the most critical cells adjacent to the worst case impact.

In a letter dated May 17, 2007, the applicant stated that the ability to retrieve the fuel is based solely on evaluating the rack structure to show that there is no instability that would collapse the cell. Subsection NF stress limits for Level D do not apply to the local stress state in the impacted cells because: (a) the fuel racks are analyzed as linear type supports (i.e., beam type members) in accordance with Appendix D of NUREG-0800 Section 3.8.4; and (b) rack to rack impact loads near the top of the rack produce secondary stresses, for which there is no prescribed limit in ASME Code, Section III, Subsection NF for Level D. Away from the point of impact, the rack to rack impact loads do produce primary bending and shear stresses in the rack beam, which are reflected in the maximum stress factors reported in TR-54, Table 2-9.

The staff reviewed the response, and requested additional information explaining what acceptance criteria are used to ensure that the fuel assemblies can be retrieved following the impact: If a quantitative stress limit criteria is not utilized, then what is the specific criterion used (e.g., are the cross-sectional opening dimensions in each cell checked for any permanent deformation that would infringe on the fuel assembly outside dimension)?

In a letter dated April 18, 2008, the applicant stated that in order to ensure fuel retrievability is maintained, the impact loads at the rack top elevation are compared against 2/3 of the critical buckling load for the cell walls, as required by Table NF-3523(b)-1 of the ASME Code for primary plus secondary stresses. The critical buckling load calculation is included in HOLTEC Report No. HI-2063523, “Spent Fuel Rack Structural/Seismic Analysis for Westinghouse AP1000,” Revision 0. The impact load is assumed to spread uniformly over a 15.24 cm (6 in) vertical span of the cell wall, which is equal to the minimum length of the intermittent cell to cell welds. The average compressive stress in the cell walls due to the maximum rack-to-rack impact load is 132 MPa (19,120 psi). This stress is less than two thirds of the critical buckling load. Therefore, the spent fuel rack design meets the requirements of Table NF-3523(b)-1 of the ASME Code for the primary plus secondary stress category.

The staff concluded that the calculation adequately demonstrated that the stress due to the maximum impact load is below 2/3 of the critical buckling load, and that the spent fuel racks meet the requirements of Table NF-3523(b)-1 for primary plus secondary stress category, which covers buckling. The staff found this approach to demonstrate retrievability acceptable. The staff requested the applicant expand the limited one-sentence conclusion presented in Section 2.8.1.4 of the TR-54, to summarize the information in the RAI response and the buckling calculation. The staff subsequently reviewed TR-54, Revision 2, and related sections in DCD Revision 17, to confirm the inclusion of additional descriptive information. Therefore, RAI-TR54-35 was resolved.

Some of the information provided in Section 2.8.2 (Rack Structural Evaluation) and Tables 2-9 through 2-15 (stress results) of TR-54, Revision 0, was not clear. The staff issued RAI-TR54-36 which reads as follows:

a. Section 2.8.2.1, 2nd paragraph, indicates that the tables also report the stress factors for the AP1000 Spent Fuel Storage Racks cellular cross section just above and below the baseplate. This implies that the fuel cells continue below the baseplate. Explain.

b. The same paragraph refers to "pedestal five in the first sheet of the summary tables for each simulation (that is, 9.M.0 where M stands for run number)." Explain what this means since the tables do not reflect this terminology.

c. The same paragraph refers to "ensures that the overall structural criteria set forth in Subsection 2.2.3 are met." Structural criteria are not presented in Subsection 2.2.3.

d. Section 2.8.2.2 a., refers to a stress factor of 2.1516 which it states is given in the tables. However, no such stress factor is given, please explain. Also, are all cells welded to the baseplate on all four sides?

e. Section 2.8.2.2 a., first bullet, calculates the stress in the weld, connecting the cell walls to the baseplate, equal to 25,047 psi; however, Table 2-12 shows a smaller (maximum) weld stress of 22,647. Explain.

f. Section 2.8.2.2 b. indicates that a separate finite element model is used to check the baseplate to pedestal welds. Provide a short description of the model, computer code, loading, and location of the maximum tabulated stress in the weld referred to in Table 2-14.

g. Section 2.8.2.2 c. indicates that for calculation of cell welds, the fuel assemblies in adjacent cells are conservatively calculated by assuming that the fuel assemblies in adjacent cells are moving out of phase with one another. It then states that cell to cell weld calculations are based on the maximum stress factor from all runs. However, elsewhere in the report it was stated that all of the fuel assemblies in the simulation are assumed to vibrate in phase. Provide more information to explain this. Also, this paragraph indicates that both the weld and the base metal shear results (for cell to cell) are reported in Table 2-14; however, Table 2-14 is labeled baseplate to pedestal welds. If reference was intended to Table 2-15, then note that Table 2-15 provides the shear stress only for the base metal.

h. Section 2.8.2.3 refers to Tables 2-9 through 2-14 for limiting pedestal thread shear stresses for every pedestal. These tables do not seem to apply to pedestal thread shear stress. Therefore, clarify or correct this information.

i. Table 2-9, Summary: identify what rack component/element applies to each of the column headings (i.e., Max. Stress Factor, Max. Shear Load, Max. Fuel to Cell Wall Impact). Similarly, for the other tables, identify what rack component/element the table applies to (e.g., Tables 2-13 and 2-15 are missing this information).

j. Table 2-10 provides maximum rack-to-rack displacements relative to the floor. Also provide maximum & minimum relative displacements to the walls.

k. Why are results for "Run 1 and 2" given for some tables and not others? Both should be provided or an explanation should be given why they are included for some tables and not for others.

l. Table 2-15, why is this table labeled “Allowable Shear Stress ...” versus the labeling of other tables and why is it labeled Level D, versus other tables where there is no indication of Levels? All tables should identify which load level they apply to.

In a letter dated June 14, 2007, the applicant provided the following response:

a. The fuel cells do not continue below the baseplate. Stress factors are computed just above the baseplate, where the fuel cells are welded to the baseplate and just below the baseplate where the support pedestals are welded. Section 2.8.2.1 (2nd paragraph, 2nd sentence) will be revised as follows:

   The tables also report the stress factors for the AP1000 Spent Fuel Storage Racks cellular cross section just above the baseplate.

b. The computer code DYNAPOST, which is listed in Table 2-8, computes the stress factors for the four support pedestals and for the cellular structure just above the baseplate based on the time history analysis results. For convenience, these five locations are identified as pedestal numbers 1 through 5 in the DYNAPOST output tables, which are not included in technical report APP-GW-GLR-033. Therefore, the sentence, "The locations above the base plate ... are referred to as pedestal five in the first sheet of the summary tables for each simulation (that is, 9.M.0 where M stands for run number)." is not relevant to the report and will be deleted.

c. The reference to Subsection 2.2.3 is a typo. The correct reference is Subsection 2.3.3.

d. The factor of 2.1516 is not provided in the tables as stated in text. Section 2.8.2.2 a. (2nd paragraph) will be revised as follows:

   Weld stresses are determined through the use of a simple conversion (ratio) factor (based on area ratios) applied to the corresponding stress factor in the adjacent rack material. This conversion factor is developed from the differences in base material thickness and length versus weld throat dimension and length:

   All fuel cells are welded to the baseplate on all four sides.

e. The correct stress in the weld is 25,047 psi. Table 2 12 will be revised to change 22,647 psi to 25,047 psi, as shown [in Table 2-12 of the RAI response].

f. The finite element code ANSYS is used to resolve the tension and compression stresses in the pedestal weld due to the combined effects of a vertical compressive load in the pedestal and a bending moment caused by pedestal friction. The compression interface between the baseplate and the pedestal is modeled using contact elements. The perimeter nodes on the pedestal are connected to the baseplate by spring elements in order to simulate tension in the weld. The maximum instantaneous friction force on a single pedestal from the rack seismic analysis is conservatively applied to the finite element model in the horizontal x and y directions simultaneously, along with the concurrent vertical load, at the appropriate offset location. The perimeter nodes on the pedestal are restrained to move only in the vertical direction so that the spring elements only resist bending. The limiting ANSYS results are combined with the maximum horizontal shear loads to obtain the maximum weld stress. The maximum weld stress reported in Table 2-14 occurs at the corner of the pedestal where the tensile stress in the weld due to bending is at its maximum.

g. All stored fuel assemblies within a rack are assumed to rattle in phase for the seismic analysis of the spent fuel racks using the HOLTEC proprietary computer code MR216 (a.k.a. DYNARACK). This analysis yields the maximum impact force between a single fuel assembly and the surrounding cell walls. When evaluating the weld connection between adjacent storage cells, the maximum fuel to cell impact force from the dynamic analysis is conservatively multiplied by a factor of 2 to consider out of phase fuel rattling. The reference to Table 2-14 in Section 2.8.2.2 c is incorrect. The shear stress results for the cell to cell weld connection are not provided in Table 2-14 or Table 2-15. The shear stress in the cell to cell weld and the adjacent base metal are 11,646 psi and 8,235 psi, respectively. The allowable stress limits are 35,748 psi and 18,000 psi, respectively. Tables 2-16 and 2-17 (see below) will be added to technical report APP-GW-GLR-033 to provide the shear stress results for the cell to cell weld and the adjacent base metal, respectively.

h. The reference to "Tables 2-9 through 2-14" in Section 2.8.2.3 is incorrect. The first sentence in Section 2.8.2.3 will be revised as follows: "Table 2-15 provides the limiting thread stress under faulted conditions."

i. In Table 2-9, the "Max. Stress Factor" column applies to the rack cell structure. The "Max. Vertical Load" and "Max. Shear Load" columns apply to a single rack pedestal. The "Max. Fuel to Cell Wall Impact" column provides the maximum impact force between a single fuel assembly and the surrounding cell wall at any of the five rattling fuel mass elevations (refer to Figure 2-5 of the report).

   Table 2-13 applies to the base metal adjacent to the baseplate to cell welds. Table 2-15 applies to the pedestal internal threads.

j. Table 2-10 provides the maximum displacement in any direction (x or y) for all racks, relative to the floor. In other words, the rack displacements in Table 2-10 are the bounding displacements for all rack to rack and rack to wall gaps. The results in Table 2-10 also represent the maximum rack displacements relative to the pool walls since the SFP structure is assumed to be rigid for the purpose of the rack seismic analysis (i.e., the SFP floor and walls displace equally). The minimum rack displacement relative to the SFP walls (which is interpreted as maximum distance that a rack displaces away from the SFP walls) is also bounded by the results in Table 2-10, since the reported displacements are the maximum (absolute value) displacements for all racks.

k. The stress results in Tables 2-12 through 2-15 are the maximum values from Run 1 and Run 2.

l. Table 2-15 should be labeled "Pedestal Thread Shear Stress" instead of "Allowable Shear Stress for Level D". The allowable stresses reported in Tables 2-12 through 2-15 are Level D stress limits since the design basis ASB99 earthquake is a faulted condition (Level D).

The staff reviewed the response, and concluded that for parts (a) through (d), (h), (i), (k), and (l), the clarifications and editorial corrections are acceptable; however, revision of TR-54 would be required as noted in the response. For part (e), correction of the stress result in Table 2-12 is acceptable; however, with this correction the safety factor noted in the table is no longer correct and needs to be revised. For part (f), the description of the separate finite element model to check the baseplate to pedestal welds is acceptable and should be included in the next revision of TR-54. For part (g), the response explained why in the dynamic analyses the in-phase assumption for fuel assembly motion was utilized, while for the design of the welds between adjacent cells, the out-of-phase motion of fuel rattling was used. This approach is considered to be acceptable because it would maximize the rack motion and impact forces in the dynamic analyses while the out of phase motion of the fuel assembly would be more conservative for the evaluation of the welds between adjacent cells. However, the shear stress results refer to the wrong table, as indicated in the response, and two new tables have been developed which need to be inserted in TR-54. For part (j), additional clarification is needed to explain: (1) whether the individual maximum displacements are at the base or at any elevation of the rack model including the top of the rack since the rotation of the racks about a leg would amplify the horizontal motion from the base; and (2) how do these displacements compare to the initial available gap to the pool walls and rack-to-rack gaps at the top and bottom. This would demonstrate whether impacts with the pool wall occur.

During the May 2008 audit, the staff reviewed TR-54, Revision 1, and concluded that the applicant’s responses to all parts of this RAI are technically acceptable, and appropriately addressed in the TR and the DCD. Therefore, RAI-TR54-36 was resolved.

Section 2.8.4 of TR-54 indicates that this section presents evaluations for potential cell wall buckling and the secondary stresses produced by temperature effects. The staff noted that the description of secondary stresses produced by temperature effects is not included in this section. In RAI-TR54-37, the staff requested the applicant add this information to the report, and to confirm that the R5 stress factor used for the buckling calculation includes the worst impact forces generated, including the impacts at the top of the racks.

In a letter dated May 17, 2007, the applicant stated that the secondary stresses produced by temperature effects (an isolated hot cell) were inadvertently omitted, and that TR-54 Section 2.8.4 would be revised to include an evaluation of secondary stresses produced by temperature effects. The stress factor R5 is a stress factor that is used to get the vertical stress near the base of a corner cell and includes the effect of lateral impact forces at the top of the rack. That is, at any instant the rack is under beam action so that a lateral impact load at the top of a rack develops a vertical load at the base of the rack as the rack resists rocking.

During the May 2008 audit, the staff reviewed TR-54, Revision 2, and confirmed that the evaluation of the secondary stresses produced by temperature effects was included in Section 2.8.4.2 of the TR. The thermal analysis did not consider the contribution from seismic loads. The applicant explained that this was done because the extreme thermal analysis was based on the conservative case of a single cell with a fuel assembly surrounded by all empty cells. The seismic stress contribution for this rack configuration would be insignificant. The applicant demonstrated this by presenting the results for Run 9, which considered all racks empty. These results showed that the maximum stress factor was 0.074, which is extremely small compared to 1.0. Therefore, RAI-TR54-37 was resolved.

The staff noted that the computer code MR216 (a.k.a. DYNARACK) as well as the other computer analysis codes should have complete validation documentation, available for review during an audit. In RAI-TR54-39, the staff inquired if any of the computer codes have been previously reviewed and approved by the staff on other licensing applications, for the same version of the code.

In its response dated April 9, 2007, the applicant stated that all computer analysis codes used to perform the seismic analysis of the spent fuel racks have been validated in accordance with HOLTEC's 10 CFR 50 Appendix B quality assurance program. The validation documentation will be available for review during the audit. The validation documentation for the computer code MR216 has been previously submitted by HOLTEC International to the NRC staff for review and approval several times. Most recently it was reviewed by the NRC in 1998 in Docket Number 50-382 for the Waterford 3 Steam Electric Station.

During the April 2007 audit, the applicant indicated that the version of the MR216 code previously used on the Waterford 3 Steam Electric Station and the version used for the AP1000 are identical, except that the code was revised to accept an additional input at the top of the structure being analyzed. This change has been validated; however, this feature is not used in the AP1000 analyses.

During the October 2007 audit, the staff reviewed the DYNARACK computer validation package. The validation package provided for staff review was the HOLTEC I.D. No. HI-91700 (Generic), "DYNARACK Validation Manual," Revision 1, approved January 28, 1998. The approach used to validate DYNARACK was to demonstrate that it meets the validation requirements of NUREG-0800 Section 3.8.1. The procedure followed for the validation of the code was Section II.4.F (in the current March 2007 version) of NUREG-0800 Section 3.8.1. A series of validation problems were performed and described in the validation manual, demonstrating that criteria (ii) and (iii) in Section II.4.F were met. The staff reviewed a representative test problem included in the validation package. Based on this review, and the accepted use of DYNRACK on a number of other rack analyses for nuclear power plant licensing submittals, the staff concluded that this validation package for DYNARACK is acceptable.

The staff also reviewed the computer program validation package for the DYNAPOST code. The validation package is HOLTEC Report No. HI-971648, "QA Validation of Program DYNAPOST for Generic," Revision 1, approved October 31, 1997. This program was developed to post process the results obtained from the whole pool multi-rack analysis performed with DYNARACK. Based on the review, the staff concluded that the validation package for DYNAPOST is acceptable.

The staff concluded that the computer codes used for the seismic response analysis of the fuel racks have been validated and supporting documentation exists. Therefore, RAI-TR54-39 was resolved.

In RAI-TR54-40, the staff requested the applicant explain what provisions are provided for performance of inservice examination of the rack, as specified in 10 CFR 50.55a(g)(3) for ASME Code Class 3 component supports.

In a letter dated May 17, 2007, the applicant stated that the spent fuel racks are passive structures in the SFP. They operate in a relatively mild environment compared to reactor coolant system (RCS) primary components. There are no moving parts on the spent fuel racks, and they do not require any instrumentation. Therefore, there is no compelling need to perform inservice examination of the spent fuel racks. However, the spent fuel racks can be accessed from above by way of an empty storage cell location(s) to enable the performance of inservice examination, as mandated by 10 CFR 50.55a(g)(3) for ASME Code Class 3 component supports. At the base of each storage cell (except at the four designated lifting locations), there is a 15.24 cm (6 in) diameter thru-hole in the baseplate, which provides access below the baseplate. Also, access below the baseplate can be gained from the area of the SFP that does not contain spent fuel racks. In summary, the spent fuel racks are designed to provide access to all surfaces that may come in contact with spent fuel assemblies and to the support pedestals beneath the baseplate, to support inservice examinations as needed.

The staff concluded that adequate accessibility has been provided to accommodate inservice inspection of the spent fuel racks. Therefore, RAI-TR54-40 was resolved.

Section 2.1.1 was revised in TR-54, Revision 2, to state that "Per DCD Subsection 3.7.5.2, COL applicants will prepare site-specific procedures for activities following an earthquake. An activity will be to address measurement of the post-seismic event gaps between spent fuel racks and to take appropriate corrective actions." This statement was previously in Section 2.9 "Conclusions," in TR-54, Revision 0 and Revision 1, and was moved to Section 2.1.1 in TR-54, Revision 2.

The staff noted that DCD Section 3.7.5.2 does not discuss the need for COL applicants to prepare site-specific procedures for checking the gaps between the fuel racks following an earthquake. In RAI-SRP9.1.2-SEB1-04, the staff requested the applicant explain how this requirement is conveyed to the COL applicants and to identify the COL action item, inspections, tests, analyses, and acceptance criteria (ITAAC), or other interface requirement that addresses this.

In its response dated February 24, 2009, the applicant submitted a proposed markup to Section 3.7.5.2 of the DCD, requiring COL applications to include in their post-earthquake a procedure to check the gaps between racks and between the racks and walls, and to take appropriate actions to restore the design-basis gaps. The staff found this acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Section 2.4 “Assumptions” was revised in TR-54, Revision 2, to state that “Modeling the total effect of n individual fuel assemblies rattling inside the storage cells in a horizontal plane as one lumped mass at each of five levels in the fuel rack is a conservative assumption. Thus, the effects of chaotic fuel mass movement are incorporated into the analysis by introducing a fuel ratio factor of 0.75 (75 percent of the fuel weight is used in the analysis).”

The staff noted that the use of a 0.75 fuel ratio factor is a departure from prior revisions of TR-54, where a fuel ratio factor of 1.0 was assumed. In RAI-SRP9.1.2-SEB1-05, the staff requested the applicant provide a detailed technical basis for utilizing a fuel ratio factor of 0.75.

During the August 2009 audit, the staff and the applicant discussed this issue in depth. The applicant agreed to conduct additional analysis to justify a fuel ratio factor less than 1.0. In a letter dated November 11, 2009, the applicant reported that it could not justify a fuel ratio factor less than 1.0. Consequently, this approach to reducing the seismic loads was abandoned. The applicant implemented a number of rack design changes to demonstrate adequacy for the loads based on a 1.0 fuel ratio factor. The staff confirmed that in TR-54, Revision 3, reference to fuel ratio factor was deleted. Therefore, RAI-SRP9.1.2-SEB1-05 was resolved.

During the review of TR-54, Revision 2, the staff noted that Section 2.8.1.4, “Rack-to-Rack and Rack-to-Wall Impacts,” was revised, and indicated that the re-analysis of the spent fuel racks, to incorporate the updated seismic loading and revisions in the design of the racks, resulted in two rack-to-wall impacts: in Run 5, rack A1 impacts the west wall at a force of 45,690 lb; and in Run 4, rack B4 impacts the north wall at a force of 67,800 lb. In RAI-SRP9.1.2-SEB1-06, the staff requested the applicant describe in detail how these additional impact loads had been considered in the design of the fuel pool structure (including the liner) and in the design of the fuel racks, and also to identify where this would be described in the AP1000 DCD.

In a letter dated June 12, 2009, the applicant submitted its initial response to RAI-SRP9.1.2-SEB1-06. The staff and the applicant discussed the response at the August 2009 audit, and concluded that the rack-to-rack and rack-to-wall impact loads could increase, depending on the final resolution of the fuel ratio factor issue discussed in RAI-SRP9.1.2-SEB1-05 above. In a letter dated November 11, 2009, the applicant submitted a revised response, documenting the increased impact loads and describing the analysis method used to evaluate cell wall buckling at the top of the rack for the worst case impact load. The applicant stated that the details of the analysis were included in TR-54, Revision 3 (November 2009). The staff reviewed TR-54, Revision 3. The applicant conducted a nonlinear analysis using the LS-DYNA computer code; the results showed that the required safety factor of 1.5 is achieved before failure of the cell wall. The staff determined that the applicant’s analysis constituted an acceptable method to check the adequacy of the spent fuel rack design for the worst case top impact load. During the June 2010 audit, the staff audited the Westinghouse/HOLTEC calculation for the impact analysis, and discussed the results with the applicant. The staff found that the calculation is consistent with the information in TR-54, Revision 3, and is acceptable. The applicant also identified several DCD changes to describe the impact analysis.

In the November 11, 2009 RAI response, the applicant also stated that the impact load between the rack and the SFP wall increased from 36,741 kg (81,000 lb) to 163,293 kg (360,000 lb), but that this had only a marginal effect on the required steel liner thickness. The staff noted that it would be necessary to audit the applicable calculations, before it could accept this result. The staff attempted to audit the applicable calculations at the June 2010 fuel rack audit; however, the applicant's staff was unable to answer staff questions on the calculations.

At the DCD Section 3.8 regulatory audit conducted during the week of June 28, 2010, the staff again attempted to audit the AP1000 calculations that evaluate the spent fuel rack impact forces on the SFP walls. Again, the applicant was not able to address the questions raised by the staff.

Therefore, the staff requested the applicant to augment its prior RAI response to address the following: (1) describe how the tri-axial state of stress in the impacted faceplate has been addressed in design check, when considering the impact load in addition to other concurrent loadings; and (2) provide a comparison between the load combination with seismic load only and the load combination with seismic load and impact load, in order to confirm that the impact load is insignificant.

At the structural issues regulatory audit conducted August 18-20, 2010, the staff and the applicant discussed the results of the applicant's analyses to address the staff's questions, and the applicant's initial draft of the RAI response. The staff requested several additions to the RAI response, to which the applicant agreed. In a letter dated August 25, 2010, the applicant formally submitted its revised response, which included: (1) the calculation for the third principal stress in the faceplate of the spent fuel wall, due to the rack impact load on the wall, and a comparison of the stress intensities with and without the third principal stress, at several locations in the face plate; and (2) a comparison of the element member forces at several critical locations on the SFP wall between the load combination with seismic load only and the load combination with seismic load and impact load.

The staff reviewed the revised response and found it acceptable because the calculation results demonstrate that: (1) the effect of the increased impact force from a spent fuel rack onto the SFP walls is insignificant, for the design of SFP wall; and (2) the design of the spent fuel wall still meets the specified acceptance criteria when the impact load is included with other concurrent loads. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Section 2.8.4.1, "Cell Wall Buckling Evaluation," was revised in TR-54, Revision 2. A different buckling equation and different boundary conditions are indicated. The rectangular flat plate model representing the lower cell wall region is now assumed to be clamped on all 4 edges. Even with the assumption of clamped on all 4 edges; a very small safety margin against buckling is indicated in Revision 2. The staff determined that only one edge can truly be treated as clamped, and the other 3 edges can rotate somewhat due to the flexibility of the adjacent sections.

In RAI-SRP9.1.2-SEB1-07, the staff requested the applicant: (1) provide the technical basis for changing the boundary conditions to clamped on all four edges; and (2) identify the minimum acceptable factor of safety and the technical basis for its selection.

In a letter dated April 19, 2009, the applicant submitted its response to RAI-SRP9.1.2-SEB1-07, in which it provided its technical basis for the revised calculation of buckling for the cell wall. The staff reviewed the response and determined that the information provided was insufficient, and that a significantly expanded technical basis would be needed before the staff could accept the cell wall buckling calculation. At the August 2009 audit, HOLTEC informed the staff that it was conducting a detailed nonlinear analysis of the bottom of the rack for vertical compressive load, and presented the ANSYS computer model and preliminary results. The staff found this to be a considerable analytical improvement.

In a letter dated November 11, 2009, the applicant submitted a revised RAI response, indicating it had re-evaluated the buckling capacity of the spent fuel storage rack cells at the base of the rack using an ANSYS finite element analysis. The results show that the spent fuel rack cells remain in a stable configuration when subjected to 1.5 times the maximum seismic load without any gross yielding of the storage cell; therefore, the ASME Code requirements for Level D conditions in this area are satisfied. The ANSYS analysis and results were included in TR-54, Revision 3 (November, 2009).

During the June 2010 audit, the staff reviewed HOLTEC's final results of the ANSYS buckling evaluation of the cell walls, at the base of the spent fuel rack. The calculation shows that a 1.5 factor of safety, in accordance with the acceptance criterion in ASME Code Section III, Subsection NF, has been achieved. The staff found the analytical method used and the results obtained to be acceptable, based on its detailed review of HOLTEC's calculation. Therefore, RAI-SRP9.1.2-SEB1-07 is resolved.

In addition to the SFP rack and pool liner, the staff also performed a review of the integrity of the spent fuel assemblies during a design basis seismic event. NUREG-0800 Section 3.8.4, Appendix D, provides guidance for evaluating the consequences of seismic loads on the fuel assemblies. The applicant described its evaluation of the spent fuel rack design (including fuel assemblies) in TR-54, "Spent Fuel Storage Racks Structural/Seismic Analysis," Revision 4. The applicant calculated the maximum deceleration of a fuel assembly due to lateral SFP seismic demands as 3.38 g, assuming that all assemblies move in phase. The worst-case maximum deceleration of a fuel assembly due to out-of-phase motion, fuel-to-fuel impacts, or fuel-to-wall impacts was reported as 5.69 g. This seismic demand was less than the reported Westinghouse minimum allowable grid impact capacity of 8.92 g and results in a factor of safety of approximately 1.57.

The staff's review of TR-54, Revision 4, found that the technical basis for the minimum allowable grid impact capacity (8.92 g) was not sufficiently described in the report. To address this, the staff performed an audit on July 14, 2011, to review TR-54 supporting documentation. The staff reviewed the applicant's grid crush strength test results summarized in report NFRE-07-08, "AP1000 RFA-2 Mid Grid Dynamic Crush Strength Preliminary Verification Report," which was used to develop the AP1000 minimum allowable grid impact force. The staff confirmed that the tests were performed in accordance with previously accepted practices and that the resultant grid crush data supported the stated minimum allowable grid impact force presented in TR-54.

The staff ensured that the applicant identified the limiting failure mechanism by reviewing two research reports pertaining to spent fuel cladding integrity developed by Sandia National Laboratory (SNL) and Lawrence Livermore National Laboratory (LLNL). The staff's review of these reports (ML042710347 and ML061990439, respectively) found that spent fuel cladding can withstand forces (accelerations) of up to 10 times the grid loading limits proposed by the applicant. The staff could not, however, make conclusions with respect to grid integrity from the data within these reports, as both reports were focused on cladding ruptures and did not investigate buckling of the grids. However, data presented in the reports related to cladding were sufficient when combined with the information provided in TR-54 for the staff to conclude that grid buckling was the limiting failure mechanism for the AP1000 fuel design.

Based on the following review findings: (a) the applicant's fuel grid testing was performed in accordance with NUREG-0800 Section 4.2; (b) significant margin in the fuel assembly grid (factor of safety of 1.57); and (c) indication that grid failure is the limiting fuel assembly failure mode, the staff concludes that there is reasonable assurance that the AP1000 spent fuel assemblies, when stored in the spent fuel racks in the SFP, will retain their structural integrity when subjected to SSE level demands.

9.1.2.2.1.1.3 Conclusion

The staff has conducted a detailed review of TR-54, which addresses DCD Revision 15 COL Information Item 9.1-3: "Perform a confirmatory structural dynamic and stress analysis for the spent fuel rack, as described in Subsection 9.1.2.2.1. This includes reconciliation of loads imposed by the spent fuel rack on the SFP structure described in Subsection 3.8.4." The staff finds the spent fuel rack design, as described in TR-54, Revision 4, to be acceptable. On the basis of its review, the staff concludes that the substance of the COL information item is completely addressed by TR-54, and that completion of this COL information item is no longer needed.

In its previous evaluation of AP1000 DCD, Section 9.1.2, the staff identified that the spent fuel rack design must meet the relevant requirements in GDC 2 and GDC 4. Based on its review, the staff has concluded that the spent fuel rack design meets these 10 CFR Part 50 requirements.

9.1.2.2.1.2 Spent Fuel Rack Density

In the AP1000 DCD, Revision 17, the applicant increased the SFP storage rack density from high density to higher density racks. GDC 61 requires in part that fuel storage systems be designed with a residual heat removal capability having reliability that reflects the importance to safety of decay heat removal. As indicated in NUREG-0800 Section 9.1.2, III.1, the staff considers the design of high-density fuel storage systems to be acceptable in this regard if (among other things) low-density storage is used, at a minimum, for the most recently discharged fuel to enhance the capability to cool it. The applicant's fuel storage system design does not use low-density racks as specified by NUREG-0800 Section 9.1.2.III.1, and this difference between the proposed design and the staff's acceptance criteria has not been explained and justified. In RAI-SRP9.1.2-SBPA-14, the staff requested that the applicant address this difference and explain how the proposed fuel storage system design is adequate for satisfying GDC 61 requirements commensurate with the staff's review criteria. The staff requested that the AP1000 DCD be revised to include this information. The staff identified this as Open Item OI-SRP9.1.2-SBPA-14.

In a letter dated September 22, 2009, the applicant stated that in the previously approved DCD revision, the SFP uses only high density racks. In Revision 17 of the DCD, the applicant further increased the SFP density in order to increase storage capacity. The applicant clarified that the SFP cooling system is designed to remove the decay heat produced by the spent fuel assemblies during all modes of plant operation, regardless of the spent fuel assemblies' storage locations in the pool.

The staff evaluated the applicant's response and determined that using a SFP cooling system design with sufficient cooing capability to maintain the stored fuel cooled is an acceptable method of meeting the requirements of GDC 61. Therefore, the staff finds that the applicant's response is acceptable and the staff's concerns discussed in Open Item OI-SRP9.1.2-SBPA-14 are resolved.

The staff's detailed evaluation of the SFP cooling system capacity is documented in Section 9.1.3 of this report

9.1.2.2.2 Spent Fuel Pool Water Level Increase

The applicant proposed a series of changes related to an increase in normal SFP water level in DCD Section 9.1.2.2. The bases for these changes are addressed in TR-121. These changes include:

1. Increase the normal water volume of the pool from 685,159 to 721,121 liters (181,000 to 190,500 gallons).

2. Raise the water level from 76 cm (30 in) below the operating deck to 38 cm (15 in) below the operating deck.

3. Delete reference to "a minimum of 10 feet of shielding water above the spent fuel assemblies" and replace with "a minimum of 8.75 feet of shielding water above the active fuel height of spent fuel assemblies."

In describing spent fuel transfer operation, AP1000 DCD, Revision 15, stated that waterways are of sufficient depth to maintain "a minimum of 10 feet of shielding water above the active fuel height." AP1000 DCD, Revision 17, proposes to change Section 9.1.2.2 to state that waterways are of sufficient depth to maintain "a minimum of 8.75 feet of shielding water above the active fuel height." This corresponds to a decrease in minimum shielding of 38.10 cm (15 in) in minimum shielding from DCD Revision 15.

Also, in the AP1000 DCD, Revision 17, Tier 1, Table 2.1.1-1, "Inspections, Tests, Analysis and Acceptance Criteria," line 5, the applicant proposes to change the maximum elevation to which the bottom of a fuel bundle can be lifted from 7.70 meters (m) (25 ft, 3 in) below the operating deck to 7.47 m (24 ft, 6 in) below the operating deck. This corresponds to an additional lift of 22.86 cm (9 in).

In AP1000 DCD, Revision 17, Table 9.1-2, "Spent Fuel Pool Cooling and Purification System Design Parameters," the applicant proposes to change the SFP normal water level from 30.48 cm (12 in) below the operating deck to 38.10 cm (15 in) below the operating deck. This corresponds to a decrease in normal water level of 7.62 cm (3 in).

With the increased fuel bundle lift of 22.86 cm (9 in) and a decreased normal SFP water level of 7.62 cm (3 in), the staff believes that the change in minimum water shielding is be a decrease of 30.48 cm (12 in), not a decrease of 22.86 cm (9 in).

In RAI-SRP9.1.2-SBPA-09, the staff requested the applicant to clarify the proposed changes described above in the DCD so that the decrease in minimum shielding can be accurately determined.

On June 25, 2009, the staff conducted a regulatory audit of the DCD Revision 17 documentation and met with the applicant's personnel to identify the specific information required in order to resolve this RAI and other Chapter 9 RAIs.

During the June 25, 2009 audit, the applicant stated that the change in minimum shielding from 2.89 m (9.5 ft) to 2.67 m (8.75 ft) does not exceed the limit of 2.5 millirem to the bridge operator. The justification for this change is documented in calculation APP-GW-N2C and is discussed in the applicant's response to RAI-SRP12.3-CHPB-02.

With respect to the maximum elevation to which the bottom of the fuel bundle can be lifted, the applicant identified an ITAAC limit for mechanical hard stops. The mechanical hard stops provide 2.59 m (102 in) of water shielding.

The staff's evaluation of the justification for the minimum shielding change, as discussed in the applicant response to RAI-SRP12.3-CHPB-02, was reviewed and documented in Section 12.3 of this report. The staff identified this as Open Item OI-SRP9.1.2-SBPA-09.

In a response dated September 18, 2009, the applicant stated that DCD Revision 17, Tier 1, Table 2.1.1-1, Paragraph 5, limits the fuel assembly raise height to 7.4 m (24 ft, 6 in) between the bottom nozzle and the operating floor; elevation 41.15 m (135 ft, 3 in). This corresponds to 2.6 m (8.5 ft) of water shielding above the active portion of the fuel when the refueling cavity/SFP water level is at the 40.84 m (134 ft) elevation (minimum water elevation for fuel movement). This limit is established as a mechanical hard stop limit for the refueling machine (RM) and the FHM.

DCD Revision 17, Tier 2, throughout Section 9.1 and Section 12 establishes the minimum water coverage as 2.7 m (8.75 ft), 32 m (105 ft) elevation, above the active portion of the fuel when the refueling cavity/SFP water level is at the 40.84 m (134 ft) elevation. This is a 0.23 m (9 in) reduction in shielding. The RM and FHM would have controls to limit the hoist up travel to satisfy this requirement. Section 12.3 of this report evaluates the impact of this change on radiation protection considerations.

The staff finds that the RAI response discussed above clearly shows how the minimum shielding has been impacted by the changes in the RM limit set points. The staff determined that, based on the above discussion, Open Item OI-SRP9.1.2-SBPA-09 is resolved. The remaining changes are reviewed in Section 9.1.3 and 12.3 of this report. The staff determined that these changes made to DCD Section 9.1.2 are conforming changes and do not impact the staff's safety evaluation of DCD Section 9.1.2. Therefore, the staff finds the proposed changes acceptable.

9.1.2.2.3 Fuel Handling Crane Change

The applicant proposed to delete references to the fuel handling jib crane and replace them with references to the new-fuel handling crane in DCD Section 9.1.2.2.1. However, in response to RAI-SRP9.1.4-SBPB-01, the applicant stated in a letter dated June 26, 2008, that the function of moving new fuel will be transferred to the FHM and that the new-fuel handling crane will be eliminated. The evaluation of this change is reviewed in Section 9.1.4 of this report. The staff determined that this change made to DCD Section 9.1.2 is a conforming change that does not impact the staff's safety evaluation of DCD Section 9.1.2. Therefore, the staff finds the proposed change acceptable.

9.1.2.2.4 Spent Fuel Criticality Analysis

9.1.2.2.4.1 Summary of Technical information

In the certified DCD Revision 15, Section 9.1.2, "Fuel Storage and Handling," it is stated in Section 9.1.6 that the COL applicant is responsible for a confirmatory criticality analysis for the spent fuel rack, as described in Section 9.1.2.3. In DCD Revision 17, the applicant proposed to change this COL action by performing the confirmatory criticality analysis so that the COL action item is no longer necessary. DCD Section 9.1.2.3 is revised to reflect that the criticality analysis is now complete, and Section 9.1.6 is revised to state that the COL information requested in this section has been completely addressed in TR-65, Revision 2, and the applicable changes are incorporated into the DCD. The applicant stated that no additional work is required by the COL applicant. The technical details of the criticality analysis for the AP1000 spent fuel storage design is presented in TR-65, Revision 2. This report provides the technical support for the changes found in Section 9.1.2 of DCD Revision 17. The staff's review of the criticality analysis of AP1000 spent fuel storage includes DCD Revision 17, Section 9.1.2 and the supporting TR-65, Revision 2.

In a letter dated September 16, 2009, the applicant stated that it will be submitting an alternate loading pattern with a restriction, which will preclude the need for using burnup credit in the Region 2 rack criticality analysis. This will result in a change to the technical specifications (TS). Open Item OI-SRP9.1.1-SRSB-08 was created to track all changes related to this restricted loading pattern and the corresponding analysis.

Subsequently, in a letter dated July 28, 2010, the applicant retracted the September 16, 2009 proposal that suggested a restricted loading pattern and clarified the applicant's intent to rely on the analysis presented in TR-65, Revision 2, with full loading as the basis for the AP1000 Revision 17 SFP criticality analysis. Furthermore, the applicant provided a response to Open Item OI-SRP9.1.1-SRSB-08 in the July 28, 2010, letter that demonstrates consistency with the burnup credit methodology used and approved in current reactors. The staff has reviewed TR-65, Revision 2, and the RAI response from the July 28, 2010, letter against NUREG-0800 Section 9.1.1, the guidance in the August 19, 1998, NRC memorandum authored by Larry Kopp "Guidance on the Regulatory Requirements for Criticality Analysis of Fuel Storage at Light-Water Reactor Power Plants" (the Kopp guidance) and past precedence examples. The staff concludes that the applicant follows the current available guidance and therefore the response and burnup credit analysis are acceptable. Therefore, Open Item OI-SRP9.1.1-SRSB-08 is satisfied and closed.

The AP1000 design includes facilities for the onsite storage of irradiated spent fuel. The spent fuel storage facility is located within the seismic Category I auxiliary building fuel handling area.

Irradiated fuel is stored in a stainless steel-lined concrete SFP containing 8 racks capable of holding a total of 889 assemblies. The spent fuel racks are divided into two regions within the common pool. The Region 1 rack consists of stainless steel cells with neutron absorbing material (Metamic®) attached to all sides facing other storage locations. Cells are separated by a water gap. There is no absorber on the cell faces adjacent to the pool wall or when SFP geometry does not require neutron absorber panels to remain subcritical. Metamic® panels are located on Region 1 edges in locations that could physically hold an assembly between the Region 1 and 2 racks or between the Region 1 rack and pool wall. Region 2 racks consist of the same stainless steel box structure as Region 1 with fixed neutron absorber attached to the outside of the walls, but there is no intervening water gap in this case. In addition, there are five damaged fuel locations, which are of the same design as the Region 1 storage racks.

The spent fuel storage facilities are designed to meet seismic Category I requirements and maintain a subcritical storage configuration of fuel during normal storage and accident conditions.

The applicant has provided a system description in Section 9.1.2 of the DCD. In addition, TR-65, Revision 2, is reviewed as part of the AP1000 DC application. The criticality analysis is summarized here, in part, as follows:

Criticality analyses are performed for the AP1000 spent fuel storage racks to demonstrate K_{eff} ≤.95 during normal conditions, assuming a maximum nominal initial enrichment of 4.95 w% U-235 and taking into consideration uncertainties due to fuel and rack manufacturing tolerances. In addition, the spent fuel storage racks will remain subcritical under optimum moderation conditions. TR-65, Revision 2, provides the criticality analyses, including a description of the analytical methods used in the criticality analyses, as well as a description of the analytical uncertainties, equipment manufacturing tolerances, and other analysis assumptions.

In DCD Tier 1 Table 2.1.1-1, ITAAC Item 7 addresses criticality control during normal operation, design basis seismic events, and design basis dropped fuel assembly accidents.

COL Information Item 9.1-4

In Revision 17 of the AP1000 DCD, the applicant proposed to resolve COL Information Item 9.1-4 by performing a confirmatory criticality analysis for the spent fuel racks. The applicant submitted TR-65, Revision 0, for the staff's review to demonstrate that it had met the requirements of COL Information Item 9.1-4. COL Information Item 9.1-4 in the DCD is also discussed in NUREG-1793 as COL Action Item 9.1.6-4. This evaluation is a secondary review for COL Information Item 9.1-4 with respect to the compatibility of the neutron absorbing materials used in the spent fuel racks with the spent fuel environment.

In Revision 15, Section 9.1.6 to the AP1000 DCD, COL Information Item 9.1-4 states:

> The Combined License applicant is responsible for a confirmatory criticality analysis for the spent fuel racks, as described in Subsection 9.1.2.3. This analysis should address the degradation of integral neutron absorbing material in the spent fuel pool storage racks as identified in GL-96-04, and assess the integral neutron absorbing material capability to maintain a 5 percent subcriticality margin.

In Revision 17 of the AP1000 DCD, the applicant proposed to resolve the COL information item with the following:

> The Combined License information requested in this subsection has been completely addressed in TR-65, and the applicable changes are incorporated into the DCD. No additional work is required by the Combined License applicant.

9.1.2.2.4.2 Evaluation

The staff's review of AP1000 DCD Section 9.1.2 follows the procedures outlined in NUREG-0800 Section 9.1.1, "Criticality Safety of Fresh and Spent Fuel Storage and Handling," Revision 3. Compliance with regulatory requirements was verified based on the criteria defined by GDC 62 and 10 CFR 50.68, "Criticality accident requirements."

The TS identified in NUREG-0800 Section 9.1.1, Section III, are reviewed in the applicable sections of this report.

Design Bases

DCD Tier 2, Section 4.3.2.6.1 is consistent with TR-65, Revision 2, in stating that the K_{eff} of fully loaded spent fuel storage racks will not exceed 0.95, assuming that the racks are flooded with potential moderator. DCD Tier 2, Section 4.3.2.6.1 also states that the maximum new fuel enrichment level must be less than or equal to 5.0 w% U-235. This is not consistent with the maximum nominal initial enrichment of 4.95 w% U-235 stated in TR-65, Revision 2.

Revision 17 of the DCD states that criticality analyses will demonstrate that the fuel storage rack geometry in combination with the integral neutron absorber material is sufficient to maintain the fuel in a subcritical condition as given above. TR-65 states that the applicant will follow the guidance in American National Standards Institute/American Nuclear Society (ANSI/ANS)-8.17, "Criticality Safety Criteria for the Handling, Storage, and Transportation of LWR Fuel Outside Reactors," with regard to criticality safety.

By following the guidelines in NUREG-0800 Section 9.1.1, the staff finds that the design bases described above for the fuel storage and handling systems meet the requirements of GDC 62 and 10 CFR 50.68(b).

Criticality Analysis Methodology

The primary method for determining the multiplication factor for the various configurations being considered in this analysis is the Monte Carlo Code MCNP-4a, with the attached nuclear data libraries ENDF/B-V and ENDF/B-VI. The applicant validated this combination against relevant critical experiments as defined in the Organization for Economic Cooperation and Development/Nuclear Energy Agency (OECD/NEA) International Handbook of Evaluated Criticality Safety Benchmark Experiments. This validation is used to determine the inherent bias implicit in this approach, which is added to ensure that the multiplication factor is below the acceptable limit. The MCNP calculations used an appropriate number of cycles, histories per cycle, and skipped cycles to ensure that the MCNP calculation was converged.

The design criteria are consistent with the requirements outlined in 10 CFR 50.68(b)(4) for spent fuel racks. The requirement states that: for fully loaded spent fuel racks the multiplication factor must be below 0.95 including all uncertainties and biases, and taking credit for soluble boron in the cooling water. In addition, the multiplication factor must be less than 1.0 when the fully loaded rack is flooded with fresh water. In all cases rack cells are assumed to be loaded with fuel of maximum reactivity. These criteria are used in conjunction with the latest evaluation techniques described in ANSI/ANS-8.17-2004, which can be summarized in the following relationship:

$$k_{eff} = k_c + \Delta k_p + \Delta k_c$$

Where

k_{eff} = maximum multiplication factor.
k_c = calculated multiplication factor determined by MCNP.
Δk_p = allowance for convergence, modeling, and manufacturing limitations.
Δk_c = bias uncertainty associated with code validation.

The allowance for convergence and manufacturing tolerances included the statistical accuracy of the MCNP calculations, rack tolerances, fuel tolerances, and depletion uncertainties. The code bias uncertainties are based on the comparisons with critical experiments.

The MCNP calculations are generally carried out on infinite arrays of fuel cells. This is achieved by assuming a single unit cell with reflecting or periodic boundary conditions.

The methodology presented in TR-65, Revision 2 is consistent with standard industry practice and with past NRC approved techniques. The staff, therefore, approves of the criticality analysis methodology as described in TR-65, Revision 2.

Assumptions

In Section 4 of TR-65, the applicant listed the modeling assumptions used in the analysis to ensure a conservative approach. The staff reviewed these assumptions to ensure that they maximized the k_{eff} calculations and would therefore be conservative. The staff concluded that all but one of the assumptions was conservative. The remaining assumption involved ignoring certain minor components, which the applicant claimed would in effect remove the neutron absorption by these components that would normally occur. While the staff agrees with this statement, the staff also notes that by ignoring the components in the modeling, the applicant is in effect replacing them with borated water which would also act as an absorber. The net effect is not specified; however, based on previous experience the staff feels that the change to k_{eff} based on this assumption would be insignificant and more than bounded by the other assumptions. Therefore, the staff approves of the approximations used in this calculation based on the preceeding discussion.

Input Data

The applicant used the basic input data required for the calculations as described in TR-65, Revision 2. This data covers geometric input for the racks and fuel assemblies, core operating history, burnable poison treatment and axial burnup distribution.

The staff found that borosilicate glass burnable absorber rods were not considered in the analysis. In RAI-SRP9.1.1-SRSB-07, the staff requested that the applicant describe how the use of borosilicate glass burnable absorbers affects the analysis. In its response dated September 29, 2009, the applicant stated that TR-65 was revised to include borosilicate glass burnable absorbers. The revised TR shows that they are bounded by other combinations of inserts and, therefore, have no impact on the results. The staff finds this response acceptable.

Computer Codes

The two computer codes used in this analysis are MCNP-4a and CASMO-4. They are used to determine the multiplication factors, and the core depletion behavior and sensitivity to manufacturing tolerances, respectively.

MCNP-4a

1) Appendix A of TR-65 presents a series of critical experiments that were analyzed to determine the bias and uncertainty associated with the use of MCNP-4a and its attached nuclear data library. In addition, the KENO5a Monte Carlo code and its nuclear data library are used to analyze the same experiments as a cross check of the calculated results

The staff reviewed the experiments chosen for this comparison and concludes that they include the magnitudes of the most important parameters of the fuel assemblies to be stored in the racks. The resulting values of the multiplication factor as a function of energy of the average lethargy causing fission (EALF) was analyzed using linear regression analysis. The result showed no strong trends, since the correlation coefficients are low. These calculated values for bias and uncertainties are used in calculating the maximum multiplication factor for the storage racks.

The applicant investigated the possibility of the multiplication factor having a systematic trend. The staff reviewed this investigation and agrees with the applicant's conclusion that the multiplication factor showed no discernable trend with the parameters investigated. In addition to the investigation of potential trends in the multiplication factor, the applicant investigated the sensitivity of several parameters on the multiplication factor. The staff concludes that the use of these systematic trend and parametric study investigations follows the guidance to account for all biases and uncertainties provided in the NRC memo authored by Larry Kopp, which is currently used by the industry and previously accepted by the agency.

The applicant analyzed a small number of critical experiments that included Mixed Oxide (MOX) fuel. In this manner the ability of the combination of MCNP-4a and its attached nuclear data library to handle MOX fuel could be estimated. The staff reviewed these comparisons of critical experiments to the results of the applicant's analysis. It is noted that there is a discrepancy introduced by ^{241}Pu decay and the implied growth of ^{241}Am; however, the staff concludes that this discrepancy does not appreciably affect the results. The staff concludes that the applicant's methodology provides overall conservative results and is therefore acceptable.

Based on the staff's review of the benchmark calculations presented in Appendix A of TR-65, Revision 2 as detailed in the preceding discussion, the staff finds the use of MCNP-4a and the calculated MCNP-4a bias and bias uncertainty values to be acceptable.

CASMO-4

The applicant uses CASMO-4 for the following two purposes in this analysis:

1) Depletion and decay calculations to determine the isotopic content of spent fuel, and
2) Determinations of changes in the multiplication factor introduced by perturbations in the storage rack.

CASMO-4 is an industry standard transport theory depletion code originally developed for core analyses. It has been used for SFP depletion calculations previously and approved by NRC staff. In Appendix B of TR-65, Revision 2, the applicant provides benchmarking results for CASMO-4 including reactor critical comparisons, cross section library comparisons, and code to code comparisons.

> The applicant compared the k-inf values calculated with CASMO-4 to experimental reactor critical data. This database covered a wide range of design conditions to ensure the calculated uncertainties would be applicable to the AP1000 design.
>
> The applicant investigated the effects of using different available cross-section data libraries. The results did not indicate a significant difference between the investigated libraries.
>
> The applicant provided a code to code reactivity difference comparison with MCNP-4a as an additional check on top of the critical experiments comparisons. These comparisons showed good agreement and did not result in differences that required additional scrutiny.

The staff reviewed the methodology of the depletion code benchmarking against the Kopp memo as well as other recently approved license amendment request applications. The staff reached the following conclusions regarding the depletion code benchmarking:

(1) The applicant compared the calculated results to a variety of relevant critical experiments. While it is recognized that more recent relevant data have been made available, the experiments used by the applicant provide reasonable assurance that the relevant biases can be determined. In RAI-SRP9.1.1-SRSB-06, the staff requested additional information regarding the effects of performing the analyses at maximum water density (4 °C) and the lack of Tungsten gray rod data in the benchmark tests. In response, the applicant explained that the extrapolation from the minimum temperature used in the analysis to 4 °C results in a negligible effect on the uncertainty calculations. The staff determined that while this effect should normally be quantified, the additional analytical margin included on top of the calculated bias uncertainty is sufficient to bound the small effect that would result from slightly more dense water. The applicant addressed the question regarding lack of Tungsten gray rod data by stating that the effect of tungsten inserts would not appreciably affect the benchmark studies which already include various other absorber inserts. The staff agrees that this observation is most likely correct, but notes that there currently is no database to support this conclusion as this is a new material. The staff approves the use of the applicant's methodology based on the wide range of other parameters investigated, but recognizes that small future changes could occur based on the collection of new data.

(2) Based on the comparison of the cross-section libraries, the staff finds that the library selection between current industry standard libraries has little effect on the reactivity calculation. Therefore the staff finds that the library used by the applicant is acceptable.

(3) The staff confirmed that applicable permutations were investigated to determine the appropriate depletion uncertainties.

(4) The applicant included an additional analytical margin on top of the calculated bias uncertainty.

Therefore, the staff approves the use of CASMO-4 for the depletion calculations necessary for the AP1000 SFP criticality analysis.

Criticality Analysis

In this section the review of the criticality calculations for the Region 1 and Region 2 racks from TR-65, Revision 2 is presented. In addition, the review of the consequences due to possible abnormal and accident scenarios is discussed.

The Region 1 and Region 2 racks are represented by detailed 2-D MCNP models, with reflecting boundary conditions on the surfaces separating one cell from the other. In this manner, an infinite array of fuel cells is represented in the calculation. Additionally, MCNP models that explicitly involve more storage cells are used to analyze the abnormal or accident conditions.

The 3-D MCNP calculations have the same detail in the X-Y plane as the 2-D models, and are extended axially in the Z-direction. The model includes a 30 cm axial water reflector, which does not include any boron, even for those cases that include boron in the water in the storage cells.

The CASMO calculations are 2-D, and thus the regions above and below the fuel are not represented. CASMO is used to determine the perturbations in the multiplication factor due to manufacturing tolerances. These perturbations are presented as adjustment factors to the multiplication factor determined for a nominal fuel loading case.

Region 1 Storage Racks

Region 1 storage racks are qualified to store fresh fuel with an enrichment of up to 4.95 w% U-235. There are 243 Region 1 storage locations in the storage pool. The geometric representation is as described previously in this report.

As part of the Region 1 criticality analysis, the applicant analyzed various abnormal conditions in addition to the standard loading. These included eccentric fuel assembly positioning, uncertainties due to manufacturing tolerances, water temperature/density, and accident conditions.

The staff reviewed the criticality analyses for Region 1 as presented against the guidance in NUREG-0800 Section 9.1.1. As part of a regulatory audit held May 6-7, 2009, the staff inspected the computer runs used by the applicant to ensure that the methodology was correctly followed. Based on the review of the methodology and its application, the staff finds the Region 1 racks to be acceptable for use as presented in TR-65.

Region 2 Storage Racks

The applicant performed the Region 2 SFP criticality analysis in a manner similar to the Region 1 analysis, except that the analysis included the use of burnup credit in order to meet the requirements of 10 CFR 50.68. The applicant followed the guidelines provided by the Kopp memo as well as the methodology of recently approved license amendment requests in calculating the burnup credit.

In RAI-SRP9.1.1-SRSB-08, NRC staff questioned the applicant's burnup credit assumption that a 5 percent reactivity uncertainty penalty included the effects of missing nuclide data on the computational biases and uncertainties. In response to this RAI, the applicant's September 16, 2009, letter described a loading pattern restriction on the Region 2 racks and its plan to submit a simplified analysis that does not require burnup credit. This plan will not require any changes to the physical rack design as presented in TR-65. Subsequently, after SFP license amendment requests that included similar burnup credit methods were accepted by the agency, the applicant submitted a letter dated July 28, 2010, requesting that the agency return to reviewing the full-capacity SFP criticality design in TR-65 Revision 2.

The staff compared the applicant's burnup credit methodology to the guidance provided in the Kopp memo as well as to SERs for recently approved SFP license amendment requests. The staff notes that the burnup credit guidance does not explicitly state how an applicant should handle biases and bias uncertainties and whether or not the 5 percent reactivity uncertainty covers them when considering potential lack of data regarding specific isotopes.

As a result of reviewing the recent SERs, the staff determined that the submittals had been based on approaches to the implementation of burnup credit similar to that used by the applicant in TR-65, Revision 2. The staff determined that past precedent supports the applicant's position that the use of the 5 percent reactivity uncertainty penalty has been approved previously to cover the depletion bias uncertainty. The staff considers Open Item OI-SRP9.1.1-SRSB-08 closed.

During the regulatory audit held May 6-7, 2009, the staff reviewed the depletion and criticality calculations used by the applicant in the AP1000 Region 2 SFP criticality analysis. The staff determined that the applicant used the codes previously approved in this section and correctly applied the applicable code biases and bias uncertainties while calculating the values for k_{eff}. Based on the staff's review of the methodology and analysis, as detailed in this section, along with the precedent set by the recent approval of applications using burnup credit, the staff concludes that the applicant's analysis of the Region 2 SFP criticality demonstrates compliance with the requirements of 10 CFR 50.68 by following the Kopp memo.

Revised Rack Dimensions

DCD Revision 18 introduced an increased thickness of the Region 1, Region 2 and damaged fuel storage rack cell walls, for the purposes of increased structural stability. DCD Revision 19 includes additional changes related to this change in thickness. In a letter dated March 3, 2011, the applicant submitted TR-65 Revision 3. Revised criticality analyses based on the latest spent fuel pool rack design are located in Supplement 1 of TR-65, Revision 3.

Following the same methodology as found in TR-65 Revision 2, the new analyses provide new k_{eff} calculations based on the burnup loading curve found in TS 3.7.12 (Figure 3.7.12-1) of the DCD. These new calculations demonstrate that the k_{eff} values are lower for all of the analyzed fuel as compared with the previous analysis (TR-65, Revision 2), except for the fuel with 2.5 wt% and 4.0 wt% enrichment. The calculations of k_{eff} for fuel with 2.5 wt% and 4.0 wt% enrichment demonstrate an increase, but this increase is within the administrative margin maintained by the applicant in the previous analysis (TR-65, Revision 2). These increased k_{eff} values do not violate the limits specified in 10 CFR 50.68.

The staff reviewed the calculations included in Supplement 1 of TR-65, Revision 3 and confirmed that the same methodology presented in Revision 2 was used including the determination and use of biases and uncertainties. The revised k_{eff} values do not violate the regulatory limits. Therefore, staff finds the AP1000 spent fuel pool criticality calculations based on TR-65, Revision 3 acceptable.

Restrictions and Limitations

The AP1000 SFP design as presented in TR-65, Revision 2 is approved for use with the following limitation:

> Limitation #1: Applicability
>
> The AP1000 SFP is approved for storing the fuel types presented in (or bounded by) TR-65, Revision 2. Any fuel not bounded by those used in TR-65, Revision 2 (higher enrichment, different burnable absorbers designs than analyzed, etc.) will require further analysis.

<u>COL Information Item 9.1-4 Evaluation</u>

To assure compliance with GDC 4, NUREG-0800 Section 9.1.2 III.2.G states the reviewer should verify that "the materials wetted in the SFP, (e.g., spent fuel racks, fixed neutron poison, and the SFP liner) and, if applicable, the new fuel vault are chemically compatible and stable. The review also verifies whether there are potential mechanisms to alter the dispersion of any strong fixed neutron absorbers. The secondary reviewer provides input for this review." NUREG-0800 Section 9.1.2 I.11.B further states that "the reactivity of fuel in the SFP is controlled by plates or inserts attached to spent fuel racks containing neutron poison dispersed in a matrix. In some environments, the matrix may degrade and release the neutron poison, resulting in some reduction of neutron absorbing properties of the panels. The licensee should have a program for monitoring the effectiveness of the neutron poison present in the neutron absorbing panels."

The staff has reviewed the information included in TR-65, which identifies the neutron absorber material in the spent fuel storage racks as Metamic®, a metal matrix composite material consisting of a Type 6061 aluminum (Al 6061) alloy matrix reinforced with boron carbide (B_4C). TR-65, Section 2.4.8 describes testing to qualify the Metamic® material for spent fuel rack service, including short and long-term elevated temperature tests, accelerated corrosion and radiation tests, mechanical properties and neutron transmission testing. The staff has previously issued an SER approving a topical report supporting the use of the Metamic® material in spent fuel racks in an operating plant. The operating plant subsequently submitted a license amendment request to use the Metamic® material in the SFP, which was approved via an SER issued by the NRC staff. The staff noted that the same generic vendor report supporting the application to use Metamic® in the operating plant is referenced in TR-65. The SER for the license amendment at the operating plant placed conditions on the use of the Metamic® material: specifically, implementation of a coupon sampling program to ensure performance consistent with the laboratory qualification testing.

The Metamic® absorber material is relied upon in the TR-65 criticality analysis to maintain the required 5 percent subcriticality margin. While TR-65, Section 2.4.8 indicates no significant loss of neutron absorbing capacity is expected for the Metamic® material based on the testing conducted, the Metamic® material is a new material with very little operating experience in the SFP environment. Spent fuel racks with Metamic® have been installed at the operating plant but the time in service for these racks as of March 2008 has been only a few months, and no coupons have been withdrawn or tested. TR-65 and the DCD include no mention of the coupon surveillance program implemented by the operating plant, nor do they recommend a similar program for the AP1000 plants.

Although the data from the operating plant surveillance program could be used to confirm the laboratory test results and could be extrapolated to the Metamic® in the AP1000, a relatively small amount of data from the operating plant will be available when construction begins for the first AP1000 plants. Further, the service conditions for the Metamic® material in the operating plant may not be identical to the expected service conditions for the Metamic® material in the AP1000 design. Additionally, some qualification tests such as the radiation testing only encompassed a 40 year rather than a 60 year life. Therefore, the staff considered that a coupon sampling plan similar to that implemented in the operating plant should be implemented for the AP1000 plants. Therefore, in RAI-SRP9.1.2-CIB-01, the staff requested that the applicant provide the following information, and include the information in the next revision to the AP1000 DCD:

1) A description of the neutron absorbing material to be used in the spent fuel storage racks. The description should include the material type, chemical composition, and mechanical properties, and a discussion of the suitability of the absorber material for long-term use in the SFP environment. Include a description of any testing performed to qualify the material for 60 years service in the SFP environment, specifically with respect to corrosion and radiation degradation. The description should also address whether the absorber material has an anodized finish, the anodizing process used, and the cleaning process to ensure removal of surface contaminants prior to installation.

2) A description of the recommended program to be implemented by the licensee to confirm that the behavior of the neutron absorbing material is consistent with the behavior of the material in the qualification tests. For example, the DCD may need to identify a COL item requiring the COL applicant to include a description in the COL application of the coupon sampling or monitoring program for the licensee to implement when the plant is placed into commercial operation.

The applicant responded by letter dated April 18, 2008. With regard to question #1, the applicant stated that the material that will be used in the AP1000 fuel storage racks is Metamic, a metal matrix composite material consisting of a Type 6061 aluminum alloy matrix reinforced with boron carbide (B_4C) as described in TR-65. The Metamic® will be in the form of sheets having a nominal thickness of 0.269 cm (0.106 in) and a minimum ^{10}B areal density of 0.0304 gm/cm^2 (minimum 30.5 wt percent B_4C). The panels are not intended to be anodized, but will be cleaned via glass bead blasting and washing with demineralized water to ensure removal of surface contamination prior to installation. The applicant also included the density, yield and ultimate strength, and elongation of the material in its description of the material.

In the April 18, 2008 letter, the applicant also described the testing performed to qualify the Metamic® material for 60 years service in the SFP environment. The applicant referenced proprietary testing by a vendor (HOLTEC) as documented in HOLTEC Report HI-2043215, "Source Book for Metamic® Performance Assessment," Revision 2, HOLTEC International, dated September 2006 (not publicly available) (hereafter referred to as the "HOLTEC report") as its basis for qualification of the material:

- Elevated temperature testing of 31 w% B_4C Metamic® at 398.9 °C (750 °F) in air for nearly a year. There was no reduction in thickness, change in weight, reduction in ^{10}B

content or change in density. The applicant stated that the results of this test demonstrate that exposure to a temperature of 48.9 °C (120 °F) in the SFP will not detrimentally affect the condition of the Metamic® panels.

- Accelerated corrosion testing at 93.30 °C (200 °F) for 90 days. No corrosion was observed and no significant change of ^{10}B areal density. The applicant stated that while these tests were carried out at a temperature only 26.7 °C (80 °F) higher than the typical upper bound, this is sufficient to yield results representative of longer periods. The applicant referenced Department of Energy (DOE) fundamentals Handbook DOE-HDBK-1015/1-93 Module 2 – Corrosion, which states "A temperature rise in the range of -6.7 °C to 10 °C (20 °F to 50 °F) doubles the corrosion rate until the formation of the protective oxide film is complete." The applicant also stated that the aluminum oxide layer that forms on the Metamic® is largely inert and that once the protective oxide film forms the corrosion rate becomes approximately zero. The applicant also referenced the DOE handbook with regard to the effect of pH on corrosion rate. The handbook indicates essentially zero corrosion rate at pH 5.5 and a corrosion rate of nearly zero in a pH range of 4-8. The applicant stated that the normal pH of the AP1000 SFP is within this range. The applicant stated that the complete lack of any chemical changes in these tests, combined with the knowledge of the effects of temperature and pH on corrosion rate, is sufficient to show that the aqueous pool environment, even for 60 years or more, will not detrimentally affect the condition of the Metamic® Panels Radiation testing of 31 w% B_4C with both gamma (1.5 x 10^9 Gy (1.5 x 10^{11} rads)) and fast neutron (1.7 x 10^{18} to 5.8 x 10^{19} n/cm^2) components. The conclusions of the post irradiation testing were that the Metamic® exhibited excellent dimensional stability after irradiation, and there was no change in Boron-10 areal density.

In response to the second part of the RAI, the applicant stated that an in-situ surveillance program to monitor the condition of the Metamic® in the racks will be implemented for the AP1000 spent fuel racks. The program uses representative material coupons, and is patterned after similar programs used for years at operating plants. The specific Metamic® monitoring program will be developed by the COL applicant. The applicant recommended the following tests to be performed on the coupons:

1) Neutron attenuation measurements (to verify the continued presence of boron)

    a. Acceptance criteria – A decrease of no more than 5 percent in Boron-10 content, as determined by neutron attenuation, is acceptable.

2) Thickness measurement (as a monitor of potential swelling)

    a. Acceptance criteria – An increase of thickness at any point should not exceed 10 percent of the initial thickness at that point

The applicant also included a markup for DCD Section 9.1.2.2.1 including a description of the Metamic® material (including all the information described above) and the qualification testing performed. The applicant also included a markup for a new COL Information Item 9.1.6.7 in Section 9.1.6 of the DCD, which reads as follows:

> The COL holder shall implement a spent fuel rack Metamic® coupon sampling or monitoring program when the plant is placed into commercial operation.

The staff reviewed the response to RAI-SRP9.1.2-CIB-01 and finds that the applicant provided an adequate description of the material.

The topical report SER for the operating plant placed conditions upon the use of the material; specifically, that a coupon surveillance program be implemented. The coupon surveillance program was to include the following attributes:

- size and types of coupons to be used (i.e., similar in fabrication and layout to the proposed insert including welds and proximity to stainless steel);
- technique for measuring the initial B_4C content of the coupons;
- simulation of scratches on the coupons;
- frequency of coupon sampling and its justification; and tests to be performed on coupons (e.g., weight measurement, measurement of dimensions (length, width and thickness), and B_4C content); these tests should also address, at a minimum, any bubbling, blistering, cracking, flaking, or areal density changes of the coupons, any dose changes to the coupons, or the effects of any fluid movement and temperature fluctuations of the pool water.

The coupon surveillance program approved for the operating reactor included visual examination and photography, measurement of weight and density, and measurement of the length and width dimensions in addition to thickness.

The acceptance criterion proposed by the applicant for ^{10}B content is a decrease of no more than 5 percent as determined by neutron attenuation, which is essentially the same as the acceptance criteria approved for the operating plant of any change in ^{10}B content of 5 percent. The staff finds the applicant's proposed criterion for ^{10}B content acceptable since it is consistent with that previously approved by the staff.

The acceptance criterion for thickness for the operating plant is any change in thickness of (+/-) 0.025 cm (0.01 in) for a 0.25 cm (0.1 in) coupon. The applicant's proposed acceptance criterion for thickness is no increase in thickness greater than 10 percent. The staff finds that the applicant's criterion is acceptable because it will detect significant swelling of the material thickness.

As part of the material qualification, the applicant also cited the results of radiation testing of 31 wt percent B_4C with both gamma (1.5×10^9 Gy (1.5×10^{11} rads)) and fast neutron (1.7×10^{18} to 5.8×10^{19} n/cm^2) components. An appendix to the HOLTEC report indicates that the gamma dose of 1.5×10^9 Gy (1.5×10^{11} rads) is roughly equivalent to the exposure Metamic® would receive in 40 years of actual fuel rack service. Although the AP1000 plant design life is 60 years, the staff finds the use of a gamma dose equivalent to 40 years exposure acceptable since the plant license duration will be 40 years, and the recommended monitoring program includes testing to verify the continued capability of the Metamic® materials to provide the required neutron absorption capacity. The HOLTEC report did not compare the fast neutron exposure expected in fuel pool service to the fast neutron exposure in the qualification program. However, the coupon monitoring program recommended by the applicant is likely to detect any degradation associated with fast neutron exposure.

The staff finds the referenced corrosion testing is appropriate. The accelerated corrosion testing resulted in essentially no corrosion of the material. Aluminum and aluminum alloys form a passive oxide film in most air or water environments that limits general corrosion to negligible rates. In the corrosion testing, some Metamic® coupons with a mill finish experienced pitting corrosion. The topical report summarized the results of a corrosion test program performed by Electrical Power Research Institute (EPRI). The duration of the EPRI corrosion tests was slightly over one year. The pitting in the EPRI tests was attributed to impurities present on the coupon surface based on the fact that the coupons cleaned by glass beading (as the AP1000 Metamic® material will be cleaned) or chemically cleaned prior to anodizing did not experience pitting. The corrosion testing performed by EPRI was verified by tests documented in the HOLTEC report performed in similar environments, but for a shorter duration (90 days). The applicant concluded the accelerated test results are sufficient to show that the aqueous SFP environment, even for 60 years, will not detrimentally affect the condition of the Metamic® panels. However, the applicant did not provide a quantitative basis for extrapolating the corrosion test results to 60 years. Although the staff agrees that corrosion appears to have been stopped by the formation of a passive film, due to the limited experience with Metamic® in operating reactors, the staff did not agree that a corrosion concern can be completely precluded for Metamic.

In the response to RAI-SRP9.1.2 CIB1-01, the applicant described the mounting and location of the coupons in the SFP, but did not provide the size. The applicant indicated that the coupons would be precharacterized for weight, dimensions (especially thickness) and ^{10}B loading, but did not provide: the technique for measuring the initial B_4C content; a recommended schedule for withdrawal and testing of the coupons; whether coupons included scratches; recommended tests to address bubbling, blistering, cracking, flaking, or areal density changes of the coupons; any dose changes to the coupons; or the effects of any fluid movement and temperature fluctuations of the pool water.

Since the applicant did not provide recommended criteria for several of the items addressed in the conditions on the use of Metamic® in the SER, and due to the limited experience with Metamic® material in operating reactors, particularly with regard to long-term corrosion behavior, in an April 28, 2008 supplement to RAI-SRP9.1.2-CIB1-01, the staff requested the following additional information:

> Provide a recommendation to the COL applicant for the following aspects of the Metamic® coupon surveillance program, and include the same information in the next revision to the DCD:
>
> - recommended coupon withdrawal schedule
> - size and types of coupons to be used (i.e., similar in fabrication and layout as the proposed insert including welds and proximity to stainless steel);
> - technique for measuring the initial B4C content of the coupons;
> - whether the coupons should include simulated scratches, or explain why simulated scratches are unnecessary.
> - tests to monitor bubbling, blistering, cracking, or flaking.

- test to monitor for corrosion, such as weight loss measurements and/or visual examination.

If any of these items are not recommended, provide a justification for excluding the item from the program.

In response to the supplementary request, the applicant submitted a revised response to RAI-SRP9.1.2-CIB1-01, dated June 20, 2008. The response to the supplementary request stated that the applicant and the COL applicants together are providing a Metamic® coupon surveillance program. The applicant is responsible for the design aspects of the Metamic® coupon surveillance program and the COL applicants are responsible for the programmatic aspects.

The supplemental response also stated the following items should be included in the site surveillance program, and indicated whether the applicant or the COL applicant was responsible for each item as follows:

- Recommended coupon withdrawal schedule-the applicant
- Size and types of coupons to be used (i.e., similar in fabrication and layout as the proposed insert including welds and proximity to stainless steel)- the applicant
- Technique for measuring the initial B4C content of the coupons-COL applicants
- Whether the coupons should include simulated scratches, or explain why simulated scratches are unnecessary-the applicant
- Tests to monitor bubbling, blistering, cracking, or flaking-COL applicants
- Test to monitor for corrosion, such as weight loss measurements and/or visual examination-COL applicants

The supplemental response further stated that this information is described in the COL holder's Metamic® coupon surveillance program, and that the applicant has worked with HOLTEC to design the Metamic® Coupon Tree requiring eight coupons for 60 years of surveillance. Based on this, the applicant has specified a coupon tree with 14 coupons (six additional coupons). The applicant provided a revision of the DCD markup from the original response to RAI-SRP9.1.2-CIB1-01 describing the number and size of the coupons, and showing the recommended coupon withdrawal schedule. The staff finds the information provided on the sizes and types of coupons is acceptable because the coupons are cut from the actual Metamic® absorber panels; therefore, the coupons are representative of the actual absorber panels, including the presence of any scratches. Therefore, scratches will not be deliberately added to the coupons. The staff also finds the proposed coupon surveillance schedule acceptable because it requires more frequent testing of the coupons early in plant life when problems are more likely to be detected, and covers the entire 60-year design life of the plant. The applicant also included a markup of DCD Table 1.8-2 showing COL Information Item 9.1-7 for a Metamic® Monitoring Program (also included in the original RAI response).
Section 9.1.6.7 of the proposed DCD markup included the text of the COL information item:

> The COL holder shall implement a spent fuel rack Metamic® coupon sampling or monitoring program when the plant is placed into commercial operation.

However, the staff found this wording did not include a sufficient level of detail to provide direction to the COL applicant with respect to the Metamic® Monitoring Program elements, as described in the supplemental RAI response.

The staff held a telephone conference with the applicant on July 11, 2008, to clarify whether the DCD would be revised to incorporate all the information provided in the supplemental response, and clarify the requirements for the Metamic® Monitoring Program. During the teleconference, the applicant agreed to provide a revised supplemental response that would include the text for COL Information Item 9.1-7 describing the elements of the Metamic® Monitoring Program for which the COL applicant is responsible. The revised supplemental response was received via letter dated August 21, 2008. In the revised response, the applicant provided a markup of DCD Section 9.1.6.7, which added details of the Metamic® Monitoring Program. The additional information stated that this program would include tests to monitor bubbling, blistering, cracking, or flaking and a test to monitor for corrosion such as weight loss measurements and or visual examination. However, the tests listed did not include the two tests originally proposed by the applicant in its original April 18, 2008, response to RAI-SRP9.1.2-CIB1-01, namely neutron attenuation and thickness tests.

In a response dated April 21, 2009, the applicant provided a revised markup of DCD Section 9.1.6.7 that includes the neutron attenuation and thickness tests in the COL information item text, in addition to those tests previously identified. The staff, therefore, considers this response acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The portion of COL Information Item 9.1-4 that addresses compatibility of the neutron absorbing materials used in the spent fuel racks with the spent fuel environment meets GDC 4. Therefore, the staff finds that the DCD changes regarding this issue, as proposed by the applicant in TR-65, are acceptable.

9.1.2.2.4.3 Conclusion

The staff has reviewed the AP1000 SFP criticality analysis and methodology as presented in TR-65 Revision 2 and concludes that the AP1000 SFP design is acceptable for spent fuel storage as described in the application and with the limitations as listed in this safety evaluation.

The staff finds the applicant’s proposed resolution to AP1000 COL Information Item 9.1-4, which addresses the compatibility of the neutron absorbing materials used in the spent fuel racks with the spent fuel environment, meets GDC 4 and is, therefore, acceptable. Furthermore, the staff finds that the TR-65 conclusions regarding the evaluation for compatibility of the neutron absorbing materials used in the spent fuel racks with the spent fuel environment are generic and are expected to apply to all COL applications referencing the AP1000 DC.

9.1.2.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for the DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

In its previous evaluations of AP1000 DCD, Section 9.1.2, the staff identified acceptance criteria based on the design's meeting relevant requirements in GDC 2, GDC 4, GDC 5, GDC 61, GDC 62, and in GDC 63. The staff found that the AP1000 spent fuel pool cooling system (SFS) design was in compliance with these requirements of NUREG-0800 Section 9.1.2 and determined that the design of the AP1000 spent fuel storage, as documented in AP1000 DCD, Revision 15, was acceptable because the design conformed to all applicable acceptance criteria.

The staff reviewed the applicant's proposed changes to the AP1000 spent fuel storage as documented in AP1000 DCD, Revision 17 against the relevant acceptance criteria as listed above and in NUREG-0800 Section 9.1.1, and 9.1.2. The staff finds that the applicant's proposed changes do not affect the ability of the spent fuel storage to meet the applicable acceptance criteria. The staff also finds that the design changes have been properly incorporated into the appropriate sections of AP1000 DCD, Revision 17. The staff concludes that the AP1000 new fuel storage design continues to meet all applicable acceptance criteria. These DCD changes are generic and are expected for all COL applications referencing the AP1000 certified design. At this time, the NRC has not issued a COL for any AP1000 plant. The proposed changes to the spent fuel rack design and criticality analysis contribute to the increased standardization of the certification information in the AP1000 DCD and, thus, meet the requirements of 10 CFR 52.63(a)(1)(vii). Therefore, the staff finds that the proposed changes to AP1000 Section 9.1.2 are acceptable.

9.1.3 SFP Cooling and Purification

9.1.3.1 Summary of Technical Information

Section 9.1.3, "SFP Cooling System," of the AP1000 DCD, Revision 15, was approved by the staff in the certified design. In AP1000 DCD, Revision 17, the applicant proposed the following changes to Section 9.1.3 of the certified design:

1. The applicant proposed to increase the SFS pumps' common suction pipe diameter from 15.24 cm (6 in) to 25.4 cm (10 in) from the SFP to the penetration at the SFS pump room and then reduced from 25.4 cm (10 in) to 20.32 cm (8 in). Where the common suction pipe branches off to the individual SFS pumps, the pipe is reduced again, to 15.24 cm (6 in). The applicant documented this change in TR-103, "Fluid System Changes," APP-GW-GLN-019, Revision 2 of October 2007.

2. The applicant proposed to increase the SFS pumps' common discharge pipe diameter from 15.24 cm (6 in) to 20.32 cm (8 in). The applicant documented this change in TR-103.

3. The applicant proposed to increase the number of spent fuel storage locations in the SFP from 619 fuel assemblies to 889 fuel assemblies. The applicant documented this change in TR-103.

In the AP1000 DCD, Revision 17, the applicant submitted changes documented in its response to RAI-TR103-SBPA-01 on November 9, 2007. The additional changes included the following:

a. The applicant modified Section 9.1.3.1.3.1, "Partial Core," for the assumed heat load to be based on the decay heat generated by the accumulated maximum number of fuel assemblies stored in the SFP, including 44 percent of a core (69 assemblies) placed in the pool beginning at 120 hours after shutdown.

b. The applicant modified Section 9.1.3.1.3.2, "Full Core Off-Load," for the assumed heat load to be based on the decay heat generated by the accumulated maximum number of fuel assemblies stored in the SFP, plus one full core placed in the pool at 120 hours after shutdown.

c. The applicant modified Table 9.1-2, "SFP Cooling and Purification System Design Parameters," to reflect the new SFP storage capacity of 889 fuel assemblies.

d. The applicant modified Section 9.1.3.4.3, "Abnormal Conditions," with regard to the decay heat levels in the SFP and the amount of makeup water required to provide fuel pool cooling in the event of an extended loss of normal SFP cooling. The applicant also reduced the lengths of time when no makeup is needed and when safety-related makeup from the cask washdown area is sufficient to achieve SFP cooling from 7 days to 72 hours.

e. The applicant modified Table 9.1-4, "Station Blackout/Seismic Event Times," with regard to the event descriptions, time to saturation, and height of water above fuel at 72 hours and at 7 days. In addition, the applicant revised note 7 for Table 9.1-4.

f. As a result of design changes to the shield building, the availability of the water in the passive containment cooling water storage tank (PCCWST) for refilling the SFP has changed. This impacted the basis of several scenarios of the SFP thermal analysis. These changes include:

    (i) The applicant modified TS, DCD Chapter 16, Section 3.6.7, "Passive Containment Cooling System (PCS) – Shutdown," to lower the required reactor decay heat limit for air-only containment cooling from 9 megawatts thermal (MWt) (30.7 million British thermal units (MBtu)) to 6 MWt (20.5 MBtu).

    (ii) The applicant modified Section 9.1.3.4.3, "Abnormal Conditions," with regard to the required safety-related makeup water sources. The cask loading pit (CLP) is now credited as a safety-related makeup water source when the PCSWST is not available to provide safety-related makeup water to the SFP and the SFP heat load is higher than 5.6 MWt (19.1 MBtu) and less than 7.2 MWt (24.6 MBtu).

(iii) The applicant modified TS 3.7.9, "Fuel Storage Pool Makeup Water Sources," to verify that the CLP is available and communicated to the SFP before it is needed as a makeup water source.

(iv) The applicant modified Section 9.1.3.4.3 with regard to required makeup water flow from the passive containment cooling ancillary water storage tank (PCCAWST) for post 72 hour cooling. The change allows the system to adjust the makeup flow between 132.5 Lpm (liters per minute (35 gallons per minute (gpm)) and 189.3 Lpm (50 gpm) as needed.

(v) The applicant modified Table 9.1-4, with regard to the event descriptions and time to saturation at 72 hours and at 7 days.

4. The applicant proposed to raise the specified maximum allowable elevation for the bottom of a spent fuel assembly to be within 7.47 m (24 ft, 6 in) of the operating deck. The applicant documented a change to maximum allowable elevation in TR-121 and a subsequent change in AP1000 DCD, Revision 17.

   The applicant proposed to revise AP1000 DCD, Tier 1, Table 2.1.1-1, "Inspections, Test, Analysis, and Acceptance Criteria," and changed the acceptance criteria for design commitment number 5, to say, "the bottom of the dummy fuel assembly cannot be raised to within 24 ft, 6 in of the operating deck floor."

   The applicant also proposed to change the normal water level in the SFP from 0.610 m (2 ft) below the operating deck to 0.381 m (15 in) below the operating deck. This change results in an increase in normal water inventory in the SFP from 685,159 liters (181,000 gallons) to 721,121 liters (190,500 gallons).

5. The applicant proposed to modify the design basis refueling boron concentration to be 2700 parts per million (ppm). The applicant documented this change in TR-18, "AP1000 Core & Fuel Design," APP-GW-GLR-059 (WCAP-16652-NP), Revision 0 of October 2006.

6. The applicant proposed to revise the description of where the main suction line for the SFP cooling system connects to the SFP from "at an elevation 0.61 m (2 ft.) below the normal water level of the pool" to "at an elevation 1.83 m (6 ft.) below the operating deck."

   The applicant also revised the description of SFP alarms in the main control room (MCR) from stating that alarm in the MCR from safety-related instrumentation occurs "when water level reaches either the high level or low level setpoint" to "when level in the SFP reaches the low-low level setpoint."

7. The applicant modified the limiting site interface air temperatures in AP1000 DCD. These changes are evaluated in Section 2.3.1, "Regional Climatology"; Section 12.2, "Ensuring that Occupational Radiation Doses Are as Low as Is Reasonably Achievable"; and Section 12.4, "Radiation Protection Design" of this report. Section 9.1.3.1.3.1 and Section 9.1.3.1.3.2 were modified to reflect these changes. Additionally, Section 9.1.3.1.3.1 and Section 9.1.3.1.3.2 were modified to clearly describe when the different temperature limits are applicable to the SFS.

9.1.3.2 Evaluation

The staff reviewed all changes to the SFS in accordance with NUREG-0800 Section 9.1.3, "Spent Fuel Pool Cooling and Cleanup System." The staff reviewed all changes identified in AP1000 DCD, Revision 17. The staff did not re-review descriptions and evaluations of the SFS in AP1000 DCD, Revision 15, that were previously approved and that are not affected by the new changes. All technical changes in the DCD are supported by information presented in the applicant's TRs, RAI responses, and the DCD itself.

The regulatory basis for AP1000 DCD, Section 9.1.3, is documented in NUREG-1793. The staff has reviewed the proposed changes to DCD Section 9.1.3 against the applicable acceptance criteria of NUREG-0800 Section 9.1.3. The following evaluations discuss the results of the staff's review.

The specific criteria that apply to the proposed DCD changes are; 10 CFR 52.63(a)(1)(vi), which concerns substantially increasing overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security; and 10 CFR 52.63(a)(1)(vii), which concerns contribution to the increased standardization of the certification information in the AP1000 DCD.

9.1.3.2.1 SFS Pump Common Suction Pipe Diameter Increase

In Revision 17 of the AP1000 DCD the applicant proposed to increase the SFS pumps' suction pipe diameter. The basis for this change is documented in TR-103. In TR-103, Section II.B.6, the applicant states that the previously specified SFS pumps' suction pipe diameter of 15.24 cm (6 in) from the SFP to the individual pumps resulted in large pressure drops, which could cause cavitation in the SFS pump suction lines when the SFP temperature is elevated. The large suction line pressure drop created an unacceptable condition in which SFP cooling with the SFS pumps could have become incapable of restoration following a temporary loss of SFP cooling. The increase in suction line diameter will reduce the pressure drop in the suction line and increase the net positive suction head available (NPSHa) for SFS pump operation.

The staff finds that the safety function of the SFS continues to be met because the change does not affect SFP water level or makeup capability, and capability to keep the spent fuel assemblies cooled and covered with water is not affected by this change. In addition, the staff finds that the operational flexibility of the SFS pumps is increased because NPSHa will be adequate under a wider range of operating conditions. The staff finds that the system continues to comply with GDC 61 with regard to decay heat removal and capability to prevent reduction in fuel storage coolant inventory under accident conditions and that this change is needed because it increases the NPSHa for the SFS pumps and provides increased operational flexibility to support restart of the pumps following a loss of cooling event in which the SFP temperature becomes elevated. Therefore, the staff finds the proposed change to be acceptable.

9.1.3.2.2 SFS Pump Common Discharge Pipe Diameter Increase

In TR-103, Section II.B.6, the applicant states that the increase in the SFS pump common discharge pipe diameter, combined with the increased suction pressure provided by the increased SFS pumps' common suction pipe diameter, reduces the SFS pumps' required head and allows the pumps' horsepower at normal operating conditions to be lowered by approximately 35 percent. This change provides additional operational flexibility by supporting a decrease in the required pump horsepower without degrading safety-related functions or operating margins in the SFS. The staff finds that the safety function of the SFS continues to be met because the change does not affect SFP water level or makeup capability, and capability to keep the spent fuel assemblies cooled and covered with water is not affected by this change. The staff finds that this change is acceptable because it provides additional operational flexibility for the SFS pumps, and the design continues to comply with GDC 61 with regard to decay heat removal and capability to prevent reduction in fuel storage coolant inventory under accident conditions. The staff noted that there was an AP1000 documentation discrepancy because this change, which is described in TR-103, Revision 2, was not reflected in AP1000 DCD, Revision 16.

In RAI-SRP9.1.3-SBPA-02, dated April 16, 2008, the staff requested that the applicant update the application to reflect the proposed change in SFS pump common discharge pipe diameter. In its response dated May 28, 2008, the applicant stated that the increase in SFS pump common discharge pipe diameter should have been reflected in Revision 16 of the AP1000 DCD and that it would be captured in the next revision of the AP1000 DCD. In DCD Revision 17, Figure 9.1-6 “Spent Fuel Pool Cooling System Piping and Instrumentation Diagram,” the applicant proposed to change the SFS common discharge pipe diameter to 20.32 cm (8 in) as identified in the response to RAI-SRP9.1.3-SBPA-02. Therefore, the staff finds the applicant’s response to RAI-SRP9.1.3-SBPA-02 to be acceptable.

9.1.3.2.3 Increase in Number of Spent Fuel Storage Locations

In TR-103, Section II.B.17, the applicant states that the storage capacity of the spent fuel storage racks in the SFP has been updated to provide 889 spent fuel storage locations, an increase of 270 from the previous 619 locations. As a result of the increased spent fuel storage capacity, the maximum decay heat input to the SFP is increased under various refueling offload conditions. The applicant updated the SFP thermal analysis to demonstrate that the SFS can maintain the stored fuel, cooled and submerged under water for 72 hours after the initiating event from safety-related sources and up to 7 days from internal sources.

During the June 25, 2009 audit, the staff requested clarification with respect to the AP1000 DCD, Revision 17 change in Figure 9.1-4, “Spent Fuel Storage Pool Layout (889 Storage Locations).” In RAI-SRP9.1.3-SBPA-15, the staff asked the applicant to explain the inconsistency in Figure 9.1-4 between Revision 16 and 17 in that Rack C1 contained an arrangement of 12 x 10 (minus 7 cells) assemblies in Revision 16 and 12 x 10 (minus 2 cells) assemblies in Revision 17.

In its response dated August 25, 2009, the applicant described that the Revision 16 Rack C1 label was incorrect and was corrected in Revision 17 to be arranged in a 12 x 10 module, with 2 cells missing in the North-South direction. The staff determined that this change was an editorial correction and not a design change. The rack description provided in the DCD is consistent with this correction. Based on the above discussion, the staff finds the applicant’s response to RAI-SRP9.1.3-SBPA-15 to be acceptable and the issue is resolved.

In Revision 17 of the DCD the applicant updated Tier 2, Table 9.1-4 to reflect the calculated height of water above the fuel at 72 hours and at 7 days after the seismic event, for the three limiting offload scenarios. Table 9.1-4 contained a number of notes. Note 6 stated:

> Alignment of the PCS ancillary water storage tank and initiation of PCS recirculation pumps provide a makeup water supply to maintain this pool level or higher above the top of the fuel.

In Revision 15 of the DCD, this note only applied to SFP cooling for the period of time between 72 hours and 7 days. AP1000 DCD, Revision 17 added this note to the first offload scenario described in Table 9.1-4 for the period of time prior to 72 hours.

The staff determined that this change was inconsistent with the system description provided in the TS Basis for TS 3.7.9, and inconsistent with the staff's position documented in NUREG-1793 for AP600, AP1000 Revision15, SECY-94-084, "Policy and Technical Issues Associated with the Regulatory Treatment of Non-Safety Systems in Passive Plant Designs"; and SECY-98-161, "The Westinghouse AP600 Standard Design as it Relates to the Fire Protection and the Spent Fuel Pool Cooling Systems."

In Revision 1 to Open Item OI-SRP9.1.3-SBPA-13, the staff requested that the applicant clarify/justify if the AP1000 design is in accordance with the established staff position, or if the design is being changed to introduce a new design basis.

In its response dated August 20, 2010, the applicant stated that PCCAWST was never credited for SFP makeup prior to 72 hours, and the addition of Note 6 to the height of water above the fuel prior to 72 hours was an editorial error. The applicant's response also included a markup of Table 9.1-4 removing Note 6 from the height of water above the fuel prior to 72 hours.

Based on the applicant's response, the staff found the applicant's response acceptable and Revision 1 of Open Item OI-SRP9.1.3-SBPA-13 is considered resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

In Revision 15 of the DCD Tier 2 Section 9.1.3.1.3.1, the applicant stated that the assumed partial core heat load is based on the decay heat generated by the accumulated fuel assemblies stored in the fuel pool for 10 years plus 44 percent of a core (68 assemblies) being placed into the pool. In Revision 17 of the DCD Tier 2 Section 9.1.3.1.3.1, the applicant states that the assumed partial core heat load is based on the decay heat generated by the accumulated maximum number of fuel assemblies stored in the fuel pool, which includes 44 percent of a core (69 assemblies) being placed into the pool. Additionally, in Revision 15 of the DCD Tier 2 Section 9.1.3.1.3.2, the applicant stated that the assumed full core offload heat load is based on the decay heat generated by the accumulated fuel assemblies stored in the fuel pool for 10 years, plus one full core placed in the pool. In Revision 17 of the DCD Tier 2 Section 9.1.3.1.3.2, the applicant states that the assumed full core offload heat load is based on the decay heat generated by the accumulated maximum number of fuel assemblies stored in the fuel pool, plus one full core placed in the pool.

The staff reviewed these changes and determined that by assuming that all SFP locations are filled, the calculated heat load bounds the worst possible offload scenario. The staff found that these changes were consistent with the increase in SFP capacity, were conservative in nature, and resulted in more limiting conditions. Therefore, the staff finds the proposed change to increase the total number of fuel assemblies used to calculate the heat load in the SFP for the partial core and the full core offload scenarios acceptable.

AP1000 DCD, Revision 15, Section 9.1.3, discusses three offload scenarios that represent the bounding SFP heat loads for all anticipated accident conditions. These decay heat loads are inputs for the thermal analysis of the SFP cooling.

- The first offload scenario postulates that a seismic event (concurrent with a station blackout) occurs while the reactor is operating immediately following a 44 percent core refueling. Since the reactor is operating when the event occurs, the thermal analysis assumes that the decay heat of the reactor is higher, or equal to 9 megawatt-hours MWh (30.7 MBtu); therefore, the PCCWST is reserved for containment cooling and it cannot be credited to provide safety-related makeup water to the SFP.

- The second offload scenario postulates that a seismic event (concurrent with a station blackout) occurs after a refueling is completed, and that this refueling occurred immediately following a previous 44 percent core offload. After a refueling is completed, the decay heat in the reactor is lower than 9 MWh (30.7 MBtu); therefore, the PCCWST can be credited to provide safety-related makeup water to the SFP.

- The third offload scenario postulates that a seismic event (concurrent with a station blackout) occurs after an emergency full core offload has been completed, and that this occurred immediately following a previous 44 percent core offload. This offload scenario represents the highest possible decay heat load in the SFP. Since the reactor is assumed to be empty, the PCCWST is credited for providing safety-related makeup water to the SFP.

The AP1000 DCD Revision 15 SFP is designed to use safety-related water sources to remove the SFP decay heat for the first 72 hours following events when the normal SFP cooling system is unavailable. For all the offload scenarios discussed above, the stored fuel in the SFP remains covered with water using only safety-related makeup water sources for the first 72 hours after the onset of the event. After the first 72 hours and before 7 days, the SFP credits the use of regulatory treatment of nonsafety systems (RTNSS) to provide makeup water to the SFP. The minimum water level necessary to achieve sufficient cooling of the stored fuel is the subcooled, collapsed water level (without vapor voids) required to cover the top of the fuel assemblies.

In AP1000 DCD Revision 15, the thermal analysis credits the water volume in the SFP (below the minimum water inventory level), the fuel transfer canal (including gate volume), the cask wash-down pit, and the PCCWST as the safety-related makeup water sources available for the first 72 hours of the event (depending on the offload scenario evaluated, some sources may not be available). Establishing makeup from the cask wash-down pit and the PCCWST requires operator action to re-position manual valves. The AP1000 DCD Revision 15 credits providing makeup water from the nonsafety-related water source in the PCCAWST to the SFP between 72 hours and 7 days after the event. This water source, piping segments, and the pumps are classified as RTNSS Class B in Westinghouse Commercial Atomic Power (WCAP)-15985, Revision 2, “AP1000 Implementation of the Regulatory Treatment of Nonsafety-Related Systems Process,” dated August 2003, and have availability controls.

In AP1000 DCD Revision 17, the applicant proposed several changes to Section 9.1.3 related to the thermal analysis. The basis for these changes were documented in; TR-103; TR-54; TR-65; TR-105, APP-GW-GLN-105, “Building and Structure Configuration, Layout, and General Arrangement Design Updates” Revision 2 of October 2007; and TR-108, APP-GW-GLN-108, “AP1000 Site Interface Temperature Limits,” Revision 2 of September, 2007.

The staff reviewed all of these TRs and the SFP thermal analysis report documented in APP-SFS-M3C-012, "AP1000 Spent Fuel Pool Heatup, Boiloff, and Emergency Makeup on Loss of Cooling," and determined that additional information was needed. The staff submitted RAI-TR103-SBPA-01, RAI-SRP9.1.3-SBPA-04, RAI-SRP9.1.3-SBPA-08, RAI-SRP9.1.3-SBPA-13, and RAI-SRP9.1.3-SBPA-05; requesting additional information related to the SFP thermal analysis inputs, assumptions, methodology and results. The staff's concerns related to the SFP thermal analysis inputs, assumptions, and results were identified as Open Item OI-SRP9.1.3-SBPA-04.

In response to RAI-TR103-SBPA-01 and RAI-SRP9.1.3-SBPA-04, the applicant stated that the conditions assumed for the calculated decay heat levels are the off-load conditions described in AP1000 DCD Sections 9.1.3.1.3.1 and 9.1.3.1.3.2 and that the calculated values are representative of the limiting off-load conditions as described in the applicable AP1000 DCD sections.

During the June 25, 2009 regulatory audit of the SFP thermal analysis report, the staff identified that the thermal analysis credited non-conservative assumptions related to the initial SFP water level. The staff identified this issue as Open Item OI-SRP9.1.3-SBPA-08(b), and requested that the applicant correct or justify these report findings. The applicant responded to the staff's question by revising the thermal analysis report eliminating the non-conservative assumption. On December 8, 2009, the staff performed a regulatory audit of the revised thermal analysis report and confirmed that the initial SFP water level after a seismic event had been reduced. This reduction in water level eliminated the non-conservative assumption identified by the staff in Open Item OI-SRP9.1.3-SBPA-08(b); therefore, the staff considers Open Item OI-SRP9.1.3-SBPA-08(b) closed.

The applicant also confirmed that there is no nonsafety-related piping connections in the SFP below an elevation of 39.27 m (128.83 ft), which is the minimum water level assumed in the SFP thermal analysis report. The SFP piping that extends below an elevation of 39.27 m (128.83 ft) are equipped with anti-siphon devices that prevent draining the SFP below the minimum inventory limit and are designed to be capable of performing their safety function following a design basis seismic event. During the audit of the applicant's SFP thermal analysis report, the staff verified that the analysis assumes that the initial water level is 39.27 m (128.83 ft). Therefore, the staff finds that the SFP thermal analysis was performed using assumptions in accordance with the system design and the system description provided in DCD Section 9.1.3.

The applicant subsequently revised the thermal analysis by introducing a change in methodology. The new methodology assumed that the boiling temperature of the water in the SFP would be affected by the pressure produced by the elevation of the column of water. This assumption allowed the SFP water temperature to rise above 100 °C (212 °F) before boiling. The staff determined that the applicant had not properly justified this assumption and requested that the applicant provide justification for this assumption or revise the thermal analysis calculation.

In response the applicant revised the thermal analysis removing the assumption that the SFP water temperature would rise above 100 °C (212 °F) before boiling. On January 25, 2010, the staff performed a regulatory audit of this revised thermal analysis and confirmed that this assumption had been removed. Therefore, the staff finds this acceptable, since the thermal analysis no longer changes the previously approved methodology.

Since the staff audits confirmed that the revised SFP thermal analysis used an approved methodology and used conservative inputs and assumptions, the staff considers Open Item OI-SRP9.1.3-SBPA-04 resolved.

In Revision 17 of the DCD the applicant updated Tier 2, Table 9.1-4, “Station Blackout/Seismic Event Times,” to reflect the results of the revised thermal analysis calculation. The table showed that the time to boil for all three limiting offload scenarios had decreased. For the most limiting scenario (full core offload) the time to boil decreased from 2.5 hours to 1.37 hours. In a later revision to the SFP thermal analysis report, the time to boil for this offload scenario was raised to 2.33 hours. The staff’s evaluation of this increase in time to boil is evaluated further below in this SE section.

In RAI-SRP9.1.3-SBPA-13, the staff requested that the applicant update the DCD in order to address the impact of the initial decrease in SFP time to boil on the required operator actions needed to cope with this event. The staff also pointed out that due to changes in the SFP thermal analysis, the information in Note 8 of Table 9.1-4 needed to be updated.

The applicant responded to RAI-SRP9.1.3-SBPA-13 in letters dated August 25, 2009, and February 10, 2010. The applicant’s response proposed to modify Note 8 to properly represent the revised thermal analysis. The staff found this acceptable since the DCD table is now consistent with the revised thermal analysis. The applicant’s response also stated that under most limiting conditions with the highest SFP decay heat, the operator will have more than 18 hours after boiling has begun to establish safety-related makeup. In addition, the applicant proposed to add a new Note 9 to Tier 2, Table 9.1-4 applicable to all off-loading scenarios analyzed.

The proposed Note 9 stated “operator action to align makeup water to the spent fuel pool must occur within 18 hours of the seismic event.” The staff determined that the proposed wording of Note 9 did not clearly reflect the minimum time available for operator action. This was identified as Open Item OI-SRP9.1.3-SBPA-13 in the SER with open items.

In letter dated August 6, 2010, the applicant submitted for staff review APP-GW-GLR-096 Revision 1, (Proprietary) and APP-GW-GLR-097 Revision 1 (Non-Proprietary), "Evaluation of the Effect of the AP1000 Enhanced Shield Building Design on the Containment Response and Safety Analyses." In a letter dated March 10, 2011, the applicant submitted for staff review APP GW GLR 096 Revision 2, (Proprietary) and APP GW GLR 097 Revision 1 (Non Proprietary). These letters also included markups of the DCD sections impacted by this change. These changes to the Shield Building impacted the availability of the safety-related water source in the PCCWST to be used as makeup to the SFP for two of the offload scenarios discussed in the DCD. The evaluation of the shield building design changes are evaluated in Section 6.2 of this report. This section evaluates the impact of these changes on the SFS.

The DCD markups included a proposed revision to Note 9 of Tier 2, Table 9.1 4. The revised note states that “[a] minimum of 18 hours is available for operator action to align makeup water to the spent fuel pool after a seismic event.” The revised Note 9 clearly states the minimum time that the operator has to perform the required actions to align safety-related makeup water to the SFP. The staff finds that the applicant’s calculation demonstrates that the operator will have sufficient time to take the required actions to align the SFP makeup sources to prevent the SFP boildown to a water level that would uncover the stored fuel. Therefore, the staff concerns identified in Open Item OI-SRP9.1.3-SBPA-13 are considered closed. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

AP1000 DCD, Revision 15, TS 3.6.7, “Passive Containment Cooling System (PCS) - Shutdown,” required that while the reactor decay heat is at or higher than 9 MWh (30.7 MBtu) , the PCCWST is reserved for containment cooling. When the decay heat in the reactor is below 9 MWh (30.7 MBtu), the PCCWST is credited for providing SFP safety-related water makeup. As a result of the design changes to the shield building described in the August 6, 2010 letter, the PCCWST is now reserved for containment cooling while the reactor decay heat is at or higher than 6 MWh (20.5 MBtu).

AP1000 DCD, Revision 15, TS 3.7.9, “Fuel Storage Pool Makeup Water Sources,” states that the PCCWST is required in order to increase the SFP heat load above 5.4 MWh (18.4 MBtu). The PCCWST is not available for both containment cooling and SFP makeup simultaneously. Once enough fuel has been transferred to the SFP to raise the decay heat in the SFP to 5.4 MWh (18.4 MBtu), the PCCWST needs to be available as a safety-related source for SFP makeup. However, during normal refueling operations, the reactor decay heat would still be greater than 6 MWh (20.5 MBtu); therefore, the PCCWST would not be available for SFP makeup since it is still required as safety-related source for containment cooling. TS 3.7.9 prevents additional fuel offloading until the PCCWST can be credited to provide safety-related makeup water to the SFP. In order to reduce the impact of this change on the refueling schedule, the applicant proposed to credit the CLP as a safety-related makeup water source.

The applicant revised the SFP thermal analysis to take credit for the water stored in the CLP as a safety-related makeup water source. While revising the SFP thermal analysis, the applicant identified an error in the calculation. The calculation erroneously assumed that at the onset of the initiating event, the SFP already had received 1 hour of decay heat. This error affects all of the calculated times to boil. On July 16, 2010, the staff audited the most recent and the previous thermal analysis calculation and confirmed that previous thermal analysis had also included this error. The applicant also identified that even after the PCCWST is required to be available for the SFP makeup, the PCCWST isolation valves (V001A/B/C) can still be automatically actuated. If the PCCWST isolation valves are opened the water would be drained onto containment instead of being sent to the SFP. The operators have 24 hours to take action to close the valves until Surveillance Requirement (SR) 3.7.9.1 is violated (the PCCWST volume is drained to < 1.514×10^6 liters (L) (400,000 gallons)). To prevent inadvertent actuation of these valves, the applicant proposed to modify SR 3.7.9.1 to ensure that one motor-operated valve (MOV) isolation valve (gate valve) is closed and secured prior to the PCCWST becoming operable for SFP makeup. The PCCWST air-operated isolation valves (V001A/B) cannot be used because they are fail-open. During a loss of onsite and offsite power the valves will lose compressed air and eventually open.

The staff evaluated the justification and the markups included in APP-GW-GLR-096, Revision 1, and determined that this proposed change to SR 3.7.9.1 provides assurance that the safety-related makeup water volume needed for SFP cooling would be available when needed. The staff evaluated APP GW GLR 096, Revision 2 and determined that this revision did not introduce any new changes to the information discussed above. Therefore, the staff finds the proposed change to SR 3.7.9.1 acceptable.

The revised thermal analysis concluded that the CLP contains sufficient water to allow the SFP decay heat limit to be raised 7.2 MWh (24.6 MBtu). The report also identified that if the accident scenario were to occur during a refueling outage, when the reactor decay heat is higher than 6

MWh (20.5 MBtu) and the SFP heat load is below 7.2 MWh (24.6 MBtu), the PCCASWT flow rate limits will not be sufficient for maintaining the stored fuel covered. DCD Section 6.2.2.4.2, “Preoperational Testing,” and Section 9.1.3.4.3, “Abnormal Conditions,” states that the PCCASWT has the capability of providing a total of 378 Lpm (100 gpm) to the PCCWST for containment cooling while providing 132 Lpm (35 gpm) to the SFP for SFP cooling. With the higher SFP heat load, the boiloff rate at 72 hours is higher and the rate of water makeup is also higher.

APP-GW-GLR-097, Revision 1 described the scenario in which the SFP heat load is at its highest, and that this peak is not coincident with the peak demand for containment cooling. The PCCAWST provides SFP water makeup and containment cooling, simultaneously, for the period of time between 72 hours and 7 days after the onset of the event. The applicant proposed to revise DCD Sections 6.2 and 9.1.3 to specify that the makeup flow from the PCCAWST will be throttle/adjusted to provide 303 Lpm (80 gpm) to the PCCWST and over 189 Lpm (50 gpm) to the SFP when additional flow is required in the SFP. The applicant stated that these new flow rates provide sufficient cooling for both the containment and the SFP cooling.

The staff confirmed that a flow rate of 189 Lpm (50 gpm) is higher than the anticipated boiloff rate at 72 hours (for this offload scenario). The staff also verified the proposed update to DCD Section 9.1.3.4.3 presented in the DCD markups and determined that the new description of the system operation is in accordance with the new design. Therefore, the change was found to be acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant also proposed to modify TS 3.7.9 to reflect the new thermal analysis assumptions. The modified TS require the CWP to be operable when the SFP decay heat load is higher than or equal to 4.6 MWh (15.7 MBtu) and less than 7.2 MWh (24.6 MBtu). The change adds the requirement of having the CLP available when the SFP decay heat load is higher than 5.6 MWh (19.1 MBtu) and less than or equal to 7.2 MWh (24.6 MBtu). The PCCWST is required as SFP makeup water source if the SFP decay heat is higher than 7.2 MWh (24.6 MBtu) and the reactor decay heat load is less than 6 MWh (20.5 MBtu). The applicant proposed to modify DCD Section 9.1.3, TS surveillance requirements, and the TS basis to reflect these changes. The staff identified an apparent inconsistency between TS 3.7.9 and DCD Section 9.1.3, related to the maximum decay heat that the spent fuel pool is capable of dissipating in 72 hrs with no additional makeup. In a letter dated February 25, 2011, the applicant proposed to change all references to the maximum decay heat limit for the SFP with no makeup available from 4.6 MWh (15.7 MBtu) to 4.7 MWh (16.0 MBtu). The staff found the new limit is in accordance with the SFP thermal analysis report previously evaluated by the staff and, therefore, the proposed changes were found acceptable. In a subsequent revision to the AP1000 DCD, the applicant made appropriate changes to the DCD text,which resolve this issue.

Establishing makeup water flow from the CLP following the initiating event requires no operator action. The applicant proposes to establish makeup water flow by opening the gate that separates the SFP and the CLP. New SR 3.7.9.4 requires verification that the CLP water level is at or higher than 4.2 m (13.75 ft) (minimum level) and that the CLP and the SFP are in communication, prior to exceeding the new SFP decay heat load limit of 5.6 MWh (19.1 MBtu). The staff finds this proposed SR 3.7.9.4 provides assurance that the required safety-related makeup water is going to be available when needed; therefore, the staff finds the proposed

SR 3.7.9.4 acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The staff finds that the applicant's thermal analysis has demonstrated that, with the increased spent fuel storage capacity, sufficient water inventory and sufficient makeup capability are available to keep the spent fuel covered with water under all limiting conditions, consistent with the safety functions described in DCD Section 9.1.3.5, and in accordance with NUREG-0800 Section 9.1.3. As a result of the SFP capacity increase, the time to reach saturation and the height of water coverage over stored spent fuel has changed.

For the first offload scenario (seismic event occurred while the reactor is at power immediately following a 44 percent refueling), saturation is reached in 7.38 hours. During the first 72 hours, crediting only safety-related sources, the height of water above the fuel is maintained at 0.42 m (1.4 ft). Between 72 hours and 7 days, the applicant credits the use of the PCCAWST (a RTNSS Class B system) to provide makeup water to the SFP and maintain the height of water above the fuel at 0.42 m (1.4 ft).

For the second limiting offload scenario (seismic event occurred after refueling, immediately following a 44 percent refueling), saturation is reached in 5.59 hours. If the decay heat inside the reactor is at or higher than 6 MWh (20.5 MBtu), the PCCWST is not available to provide safety-related makeup water to the SFP, and TS 3.7.9 limits the SFP heat load to 7.2 MWh (24.6 MBtu). The remaining safety-related water sources have sufficient water inventory to cover the stored fuel for 72 hours. If the decay heat inside the reactor is below 6 MWh (20.5 MBtu), the PCCWST is available to provide safety-related makeup water to the SFP. Therefore, offloading operations can continue and the SFP decay heat load can be higher than 7.2 MWh (24.6 MBtu). During the first 72 hours, crediting only safety-related sources; the height of water above the fuel is maintained at 1.3 m (4.2 ft). Between 72 hours and 7 days, the applicant credits the use of the PCCAWST to provide makeup water to the SFP and maintain the height of water above the fuel at 1.3 m (4.2 ft).

For the third limiting offload scenario (seismic event occurred after completing and emergency full core offload, immediately following a 44 percent refueling), saturation is reached in 2.33 hours. There is no fuel in the reactor; therefore the PCCWST is available to provide safety-related makeup water to the SFP. During the first 72 hours, crediting only safety-related sources, the height of water above the fuel is maintained at 2.43 m (8 ft). Between 72 hours and 7 days, the applicant credits the use of the PCCAWST to provide makeup water to the SFP and maintain the height of water above the fuel at 2.43 m (8 ft).

With the increased number of spent fuel assemblies, the staff finds that the SFP continues to maintain water coverage above the spent fuel assemblies for at least 72 hours following a loss of the nonsafety-related SFP cooling system, using only safety-related makeup water, and that adequate time is available for operators to establish the required makeup water.

The staff also finds that the SFP continues to maintain water coverage above the spent fuel assemblies for at least 7 days following a loss of the nonsafety-related SFP cooling system, using RTNSS "B" makeup water, and that adequate time is available for operators to establish makeup water from on-site sources. Because adequate cooling and coverage of spent fuel bundles is maintained, the staff finds that the SFS continues to comply with requirements of GDC 61 related to provisions for decay heat removal and capability to prevent reduction in fuel storage coolant inventory under accident conditions. Based on the capability of the SFP and the SFS to maintain adequate cooling for spent fuel under limiting conditions and continued compliance with requirements of GDC 61, the staff finds the proposed change to credit the CLP as a safety-related makeup water source, and the increase in SFP spent fuel locations from 619 to 889 locations, acceptable.

9.1.3.2.4 Increase in Maximum Allowable Elevation of a Spent Fuel Assembly and Increase in Normal SFP Water Level

In AP1000 DCD Revision 17 the applicant proposed to increase the maximum allowable elevation of a spent fuel assembly and increase the normal SFP water level. Both Tier 1 and Tier 2 information are affected by these changes. The justification for these changes is included in TR-121.

To support the increased fuel assembly height, the applicant proposed to increase the specified normal SFP water level from 40.61 m (133.25 ft) to 40.92 m (134.25 ft). In AP1000 DCD, Section 9.1.3.1.4, "Spent Fuel Purification," the applicant revised the discussion of exposure rates to say, "The spent fuel pool cooling system is designed to limit exposure rates to personnel on the SFP fuel handling machine to less than 2.5 millirem per hour." In AP1000 DCD, Table 9.1-2, "Spent Fuel Pool Cooling and Purification System Design Parameters," the applicant updated the SFP water volume to 724,906 L (191,500 gallons), including racks without fuel, at a water level of 30.48 cm (12 in) below the operating deck. Previously, in AP1000 DCD, Revision 15, the SFP water volume was stated as 685,159 L (181,000 gallons), including racks without fuel, at a water level of 76 cm (30 in) below the operating deck.

The staff noted the applicant's statement in TR-121 that SFP water level increases .31 m (1 ft) from 40.61 m (133.25 ft) to 40.92 m (134.25 ft) is inconsistent with the applicant's statement that before the proposed change the normal SFP water level is 76 cm (30 in) below the operating deck, and after the proposed change the normal SFP water level would be 30.48 cm (12 in) below the operating deck. In RAI-SRP9.1.3-SBPA-03, dated April 16, 2008, the staff asked the applicant to clarify the amount of increase in normal SFP water level and to discuss how the water level change impacts previous analyses.

In its response dated May 28, 2008, the applicant stated that the correct SFP water level is 40.92 m (134.25 ft), and that this is consistent with a water level that is 30.48 cm (12 in) below the operating deck. The applicant stated that Revision 15 of the AP1000 DCD was inconsistent in that it stated that the water level was at an elevation 40.61 m (133.25 ft), but it also stated that the water level was 76 cm (30 in) below the operating deck. The applicant stated that TR-121 and Revision 16 of the DCD corrected this inconsistency and that all affected analyses were included in TR-121 and were performed assuming an SFP water level of 40.92 m (134.25 ft). The staff noted that in Revision 17 to the DCD, the applicant had changed the normal SFP water level from 30.48 cm (12 in) below the operating deck to 38.1 cm (15 in) below the operating deck, which correlates to a SFP water volume decrease of approximately 3785 L (1000 gallons). During the June 25, 2009 audit, the staff asked the applicant to verify that the Revision 17 change in normal SFP water volume did not impact the calculations in APP-SFS-M3C-012 and to discuss all assumptions that changed in the decay heat calculations.

The applicant clarified that the decay heat calculations in APP-SFS-M3C-012 are based on a SFP water level that correlates to the lowest non-seismic component connected to the SFP, because the assumption is that all non-seismic components attached to the SFP will fail. The lowest non-seismic component connected to the SFP is the SFS main suction line, which is below the normal operating water level.

Based on its review, the staff finds the applicant's response acceptable because the applicant corrected the inconsistency between SFP water level elevation and SFP surface location below the operating deck. On the basis that the updated values, as stated in TR-121 and Revision 17 of the AP1000 DCD, are consistent and these values have been evaluated against the decay heat analysis calculations in APP-SFS-M3C-012, the staff's concerns described in RAI-SRP9.1.3-SBPA-03 are resolved.

The staff noted that in Revision 17 to the DCD the applicant had increased the minimum combined water volume of the SFP and fuel transfer canal. In RAI-SRP9.1.3-SBPA-07 the staff asked the applicant to justify the increase in minimum combined water volume of the SFP and fuel transfer canal from 176,778 L (46,700 gallons) in Revision 16 of DCD Table 9.1-2 to 490,210 L (129,500 gallons) in Revision 17 of DCD Table 9.1-2, and to identify the effects, if any, on the decay heat calculations. During the June 25, 2009 audit, the applicant clarified that the Revision 16 value was an error and the decay heat calculations assumed the minimum combined water volume of 490,210 L (129,500 gallons) in Revision 17 of DCD Table 9.1-2. The staff verified this information and subsequently withdrew RAI-SRP9.1.3-SBPA-07.

The staff's evaluation in Section 9.1.3 of this report is limited to consideration of the operating and thermal hydraulic performance characteristics of the SFS. The proposed change to increase the maximum allowable elevation of a spent fuel assembly does not affect the operating and thermal hydraulic performance characteristics of the SFS. The heat input to the SFP and heat removal capability of the SFS is not affected by this change. The staff finds the proposed increase in maximum allowable elevation of a spent fuel assembly to be acceptable from the standpoint of effects on operation and thermal hydraulic performance of the SFS. The impact of this change on fuel handling is evaluated by the staff in Section 9.1.4 of this supplement to NUREG-1793. The impact of this change on radiation exposure of operating personnel is evaluated by the staff in Section 12.2 and Section 12.4 of this supplement to NUREG-1793.

The staff reviewed the proposed change to increase the available SFP coolant inventory and the NPSH available at the suction of the SFS pumps. The staff finds that these changes improve or enhance the previously available operating margins for the SFS pumps under normal operating conditions. Under conditions where loss of SFP cooling might occur, the staff finds that the increased water inventory in the SFP allows for a longer time before the SFP would reach saturation and provides longer times for operators to take corrective actions to reestablish SFP cooling. The staff finds that the SFS continues to comply with requirements of GDC 61, related to provisions for decay heat removal and capability to prevent reduction in fuel storage coolant inventory under accident conditions. Because operating margins are improved and the system continues to conform to requirements of GDC 61, the staff finds that the proposed increase in SFP water level is acceptable with regard to effects on the operating and thermal-hydraulic performance characteristics of the SFS.

9.1.3.2.5 Increase in Specified Design Basis Refueling Boron Concentration

In TR-18, Revision 0, the applicant proposed a change in the specified design basis refueling boron concentration, increasing the specified boron concentration from 2500 ppm to 2700 ppm in the SFP water. The applicant stated that this change is for consistency with the accumulator boron concentration value provided in the DCD Chapter 15 accident analysis. The staff noted that the accumulator boron concentration value stated in AP1000 DCD, Chapter 15 accident analysis is 2600 ppm, not 2700 ppm.

In RAI-SRP9.1.3-SBPA-01, dated April 16, 2008, the staff asked the applicant to clarify what the correct value for boron concentration is and to resolve any inconsistencies in the documentation.

In its response dated May 28, 2008, the applicant stated that the correct SFP boron concentration is 2700 ppm and that this is consistent with values stated in Section 9.1.3.2 and Table 9.1-2 of Revision 16 of the AP1000 DCD and the in-containment refueling water storage tank (IRWST) boron concentration. The applicant stated that the accumulator boron concentration in Chapter 15 is stated as 2600 ppm and that this is consistent with TS SR 3.5.1.4, which requires the boron concentration in each accumulator to be between 2600 and 2900 ppm.

In its evaluation, the staff noted that the change in SFP boron concentration from 2500 ppm to 2700 ppm is consistent with the allowable boron concentration values specified for the accumulators credited in the DCD Chapter 15 accident analysis. The staff noted that the accumulator boron concentration value stated in the DCD Chapter 15 accident analysis is 2600 ppm because that is the minimum boron concentration permitted by TS SR 3.5.1.4. The staff finds this provides a satisfactory explanation of what is meant by the statement that "this change is made for consistency with the accumulator boron concentration values." Therefore, the staff finds the applicant's response to be acceptable and the staff's concern in RAI-SRP9.1.3-SBPA-01 is resolved.

The reactivity control effects of this change are evaluated in Section 4.3 of this supplement to NUREG-1793. The effects of this change on the criticality evaluation of the stored spent fuel are evaluated in Section 9.1.2 of this report. With regard to operational and thermal-hydraulic performance of the SFP cooling system, the staff finds this change acceptable because the boron content of the SFP water has no effect on the heat input to the SFP, the heat removal capability of the SFS, the operating margins or the performance characteristics of the SFS.

9.1.3.2.6 Changes to Piping Diagrams for the Spent Fuel Pool Cooling and Safety-Related Instrumentation

The staff noted that, in the AP1000 DCD Revision 17, Figure 9.1-5, "Piping Diagrams for Spent Fuel Pool Cooling (Normal Operation)," the applicant removed branch lines shown to and from the cask pit, changed the SFP connection to chemical and volume control system (CVS) from a separate penetration to a connection shared with the SFS pump suction, deleted the return line from the SFS discharge going to the in-containment refueling water storage tank, and changed several valve types on the drawing.

In RAI-SRP9.1.3-SBPA-10, the staff requested the applicant to provide justification for the changes mentioned above and to discuss whether any of these changes impact the safety conclusions. Also, for the CVCS connection, the staff requested the applicant to clarify whether the previously used SFP penetration has been removed entirely or whether it remains as "unused and capped," which is what the revised drawing appears to indicate. This was identified as Open Item OI-SRP-9.1.3-SBPA-10 in the SER with open items.

During the June 25, 2009 audit, the applicant explained that deleting the cask pit branch lines was not a change in design. The cask pit was originally designed with a common drain line; and the drawing was corrected to represent the actual design. With respect to the CVCS connection, the change also represented a correction in the drawing, and not a design change.

The design of the CVCS never had a penetration in the SFP. It was designed to connect to the SFS pump suction line, as represented in DCD Revision 17, Figure 9.1-5.

In a letter dated September 17, 2009, the applicant stated that none of the clarifications on Figure 9.1-5 represented changes to the safety conclusions for the AP1000 SFS. These changes were introduced to correct discrepancies between Figure 9.1-6 (which represented the correct design of the SFS) and Figure 9.1-5, which included errors.

The staff reviewed the applicant's response and determined that none of the changes in Figure 9.1-5 represents a technical change; they are corrections to represent the actual SFS design as described in Section 9.1.3. The staff considers Open Item OI-SRP9.1.3-SBPA-10 resolved.

In AP1000 DCD Revision 17, Section 9.1.3.7.D, the applicant proposed to change the description of MCR alarms. In DCD Revision 15, the applicant stated that safety-related instrumentation is provided to give an alarm in the MCR when the water level in the SFP reaches either the high level or low level setpoint. In DCD Revision 17, the applicant states that safety-related instrumentation is provided to give an alarm in the MCR when the water level in the SFP reaches the low-low-level setpoint. The staff issued RAI-SRP9.1.3-SBPA-11, which reads as follows:

a) Provide the basis for the safety-related level instrumentation change,

b) Clarify whether any MCR or local alarms are available to give an alarm on high level or on low level setpoints in the SFP, as previously described in AP1000 DCD, Revision 15, and

c) Justify the impact of the change in SFP level alarms to previously performed safety evaluations or operator response evaluations.

During the June 25, 2009 audit, and in an RAI response dated October 2, 2009, the applicant clarified that only the safety-related low-low level alarm is located in the safety-related instrumentation; the high and low level setpoint signals come from nonsafety-related instrumentation and, therefore, are not referred to as safety-related instrumentation in Revision 17 of the DCD. This was identified as Open Item OI-SRP9.1.3-SBPA-11 in the SER with open items.

In the RAI-SRP9.1.3-SBPA-11 response letter dated October 2, 2009, the applicant clarified that the high and low level alarms were not removed from the design; these alarms will be available to alert operators of SFP water level fluctuations. In the RAI response, the applicant proposed to change DCD Tier 2, Section 9.1.3.7 to clarify that the nonsafety-related instrumentation and alarms are available to alert operators. The staff verified that the High and Low level alarms were never intended to be safety-related alarms; therefore, the change in instrumentations does not impact the previous safety conclusion. Thus, Open Item OI-SRP-9.1.3-SBPA-11 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The staff noted that, in the AP1000 DCD Revision 17, Table 6.2.3-1, "Containment Mechanical Penetrations and Isolation Valves," the applicant lists each containment penetration and provides a summary of the containment isolation characteristics. In DCD Table 6.2.3-1 Sheet 2 of 4, the applicant identifies the containment isolation valves related to the SFP. Valve

SFS-PL-V067 is a pressure release valve located between SFS-PL-V034 and SFS-PL-V035. In DCD Tier 1 Table 2.2.1-1, the applicant also identifies the same pressure release valve but DCD Tier 2 Figure 9.1-6, "Spent Fuel Pool Cooling System Piping and Instrumentation Diagram," Sheet 1 of 2 does not show valve SFS-PL-V067. In RAI-SRP9.1.3-SBPA-12, the staff asked the applicant to update Figure 9.1-6, Sheet 1 to include valve SFS-PL-V067.

In its response dated August 25, 2009, the applicant agreed to revise DCD Figure 9.1-6 in the next DCD revision and illustrated the change in its response. The staff finds the change to be acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

9.1.3.2.7 Modification of the limiting site interface air temperatures

The applicant modified the wet bulb air temperature in AP1000 DCD, Section 9.1.3.1.3 and the discussion on exposure rates to personnel in Section 9.1.3.1.4. These changes are evaluated in Section 2.3.1, "Regional Climatology"; Section 12.2, "Ensuring that Occupational Radiation Doses Are as Low as Is Reasonably Achievable"; and Section 12.4, "Radiation Protection Design," of this report. The site temperature (wet and dry bulb) impacts the cooling tower performance, which affects the temperature of the component cooling water system (CCS). The SFS heat exchanger (HX) is cooled by the CCS, and a change in the CCS temperature affects the performance of the SFS.

Westinghouse Impact Document 36 (APP-GW-GLE-036), "Impact of a Revision to the Current Wet Bulb Temperature Identified in Table 5.0-1 (Tier 1) and Table 2-1 (Sheet 1 of 3) of the DCD (Revision 16)," Revision 0 of June 27, 2008, documents the impact of increasing the maximum safety wet bulb non-coincident temperature from 29.7 °C (85.5 °F) to 30.1 °C (86.1 °F) and the maximum safety wet bulb coincident temperature from 26.7 °C (80 °F) to 30.1 °C (86.1 °F). The TR indicates that the SFP heat removal capability has been affected by this change. The thermal analysis results presented in the TR demonstrate that the SFS is capable of maintaining the SFP below 48.9 °C (120 °F) following a partial core fuel shuffle refueling, with the wet bulb temperature at the maximum safety limit (most limiting case). For a full core offload scenario, the thermal analysis demonstrated that the SFS is capable of maintaining the SFP at or below 48.9 °C (120 °F) based upon a service water heat sink at a maximum normal ambient wet bulb temperature at or below 60 °C (140 °F).

During the July 16, 2010, regulatory audit of the thermal calculation the staff discussed with the applicant the need to clarify DCD Tier 2 Section 9.1.3.1.3.1 "Partial Core." This section describes that the thermal analysis for the SFP cooling partial core scenario is based on a CCS supply temperature limited by the maximum normal ambient wet bulb temperature. The staff considered that this statement was not entirely correct, as while the reactor is at power, the CCS temperature limit is based on the maximum safety ambient wet bulb temperature.

In Open Item OI-SRP9.1.3-SBPA-13, Additional Question 3, the staff requested that the applicant clarify that DCD Section 9.1.3.1.3.1 properly represents the thermal analysis basis of the SFS. In a response letter dated August 20, 2010, the applicant presented the markups for modifying DCD Section 9.1.3.1.3.1 and Section 9.1.3.1.3.2 to clearly indicate when either the safety limit or the normal limit is credited. The staff found that the applicant's response properly addresses the staff concerns and clarified the DCD statement that could cause confusion. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

9.1.3.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

In its previous evaluations of AP1000 DCD, Section 9.1.3, "Spent Fuel Pool Cooling System," the staff identified acceptance criteria based on the design meeting relevant requirements in 10 CFR Part 50, Appendix A, GDC 2; GDC 4; GDC 5; GDC 44, "Cooling Water"; GDC 45, "Inspection of Cooling Water Systems"; GDC 46, "Testing of Cooling Water Systems"; GDC 61; GDC 63; and in 10 CFR 20.1101(b), "Radiation protection programs," as it relates to radiation dose being kept as low as is reasonably achievable (ALARA). The staff found that the AP1000 SFS design was in compliance with these requirements, as referenced in NUREG-0800 Section 9.1.3 and determined that the design of the AP1000 SFS, as documented in AP1000 DCD, Revision 15, was acceptable because the design conformed to all applicable acceptance criteria.

The staff reviewed the applicant's proposed changes to the AP1000 SFS as documented in AP1000 DCD, Revision 17 against the relevant acceptance criteria as listed above and in NUREG-0800 Section 9.1.3. The staff finds that the applicant's proposed changes do not affect the ability of the AP1000 SFS to meet the applicable acceptance criteria. The staff also finds that the design changes have been properly incorporated into the appropriate sections of AP1000 DCD. The staff concludes that the AP1000 SFS design continues to meet all applicable acceptance criteria and the proposed changes are properly documented in the updated AP1000 DCD. The proposed changes meet the criteria of 10 CFR 52.63(a)(1)(vii) on the basis that they contribute to the increased standardization of the certification information in the AP1000 DCD. Therefore, the staff finds that the proposed changes to the AP1000 SFS are acceptable.

9.1.4 Light Load Handling System (Related to Refueling)

9.1.4.1 Summary of Technical Information

In NUREG-1793 the staff approved Section 9.1.4, "Light Load Handling Systems" (LLHS) of the AP1000 DCD, Revision 15. In AP1000 DCD, Revision 17, the applicant has proposed to make changes to Section 9.1.4 of the DCD.

The applicant proposed 5 technical changes in the DCD supported by information presented in TR-106 and TR-121.

The staff reviewed the following changes to the AP1000 DCD, Section 9.1.4:

1. The applicant proposed to change the name, type and crane capacity of the new-fuel handling crane. In the previously approved DCD Revision 15, the new-fuel handling crane was called the fuel handling jib crane with a crane capacity of 907 kg (2000 lb). In DCD Revision 17, the applicant changed the name of the fuel handling jib crane to the new-fuel handling crane since the final crane specified may not be a jib crane. The new-fuel handling crane capacity was increased to lift a new fuel assembly, control rod assembly and handling tool [total weight of 919 kg (2,027 lb]. The basis for this change was documented in TR-106. In its June 26, 2008, response to RAI-SRP9.1.4-SBPB-01,

the applicant stated that the function of moving new fuel will be transferred to the FHM and that the new-fuel handling crane will be eliminated.

The applicant identified this change in AP1000 DCD, Tier 2, Sections 9.1.1.1, 9.1.1.2, 9.1.1.2.1, and 9.1.1.3.

2. The applicant proposed to change the safety and seismic classification of the FHM and SFHT. In the previously approved DCD Revision 15, the FHM and SFHT were classified safety Class C, seismic Category I. The applicant changed the classification for both items to AP1000 Class D nonsafety-related, seismic Category II. The basis for this change is documented in TR-106.

   The applicant identified this change in DCD Tier 2, Sections 3.2.2.5, 3.2.2.6, and Table 3.2-3.

3. The applicant proposed to change the description of the FHM. In the previously approved DCD Revision 15, the FHM was described as “the same design as the refueling machine and includes the same safety features.” The applicant changed the description of the FHM to “the fuel handling machine has the same design functions as the refueling machine and includes the same safety features.” The basis for this change is documented in TR-106. This section was later changed in response to RAI-SRP-9.1.4-SBPB-03 to provide of the FHM safety features.

   The applicant identified this change in DCD Tier 2, Sections 9.1.4.3.3.

4. The applicant proposed to change Tier 1, Table 2.1.1-1, “ITAAC Acceptance Criteria for Design Commitment 5.” The revised acceptance criterion would state that “[t]he bottom of the dummy fuel assembly cannot be raised to within 24 ft, 6 in. [7.46 m] of the operating deck floor.” This change is documented in TR-121. This height restriction was later revised as reviewed in Section 9.1.4.2.4 below.

5. The applicant indicated that due to the radius of the FHM manipulator mast and the proximity to the SFP walls, approximately 25 percent of the SFP storage cells cannot be serviced by the mast crane. Also, there are instances where fuel inspection and/or fuel repair require the fuel to be moved from the SFP storage racks to the designated fuel inspection or fuel repair workstation. These non-normal fuel transfer operations are performed using the SFHT. The SFHT is a long handled tool, which latches onto the fuel assembly top nozzle via manually actuated grippers. Lifting of the SFHT and attached fuel assembly is performed using a hoist on the FHM. The applicant later changed the FHM configuration to eliminate the need for the mast crane and replace it with two hoists to handle fuel with the SFHT and new-fuel handling tool. This is reviewed in Section 9.1.4.2.5 below.

6. The applicant proposed to eliminate from the AP1000 design the mounting of the rod cluster control storage station from the reactor cavity wall and, therefore, its intended use. In DCD Section 9.1.4, the applicant has changed the title of paragraph K under the section heading Component Description from “Rod Cluster Control Storage Station” to “Not used.” In addition, the description of the rod cluster control storage station in paragraph K has been removed.

7. The applicant proposed to add the spent fuel assembly handling tool to the list of tools itemized under the section heading Fuel Handling Tools and Equipment. In the DCD Section 9.1.4, the applicant added to this section paragraph C with the title “Spent Fuel Assembly Handling Tool.” The new paragraph describes some operational aspects of the tool and preoperational testing.

   The applicant identified this change in DCD Tier 2, Section 9.1.4.3.4.

8. In DCD Revision 17, the applicant proposed to change the refueling water and reactor coolant nominal boron concentration. The applicant completed the “Spent Fuel Storage Racks Criticality Analysis,” for the new SFP racks and documented its results in TR-65. The applicant proposed the changes to boron concentration in DCD Section 9.1.4 to be consistent with the analyses presented in TR-65. This change is evaluated in Section 9.1.2.2.4 of this report.

9. In DCD Revision 17, Sections 9.1.4.2.3 and 9.1.4.3.7, the applicant changed the distance between the top of the active fuel to the surface of the spent fuel water. In Section 9.1.4.3.7, the applicant proposed to change the dose rate at the surface of the water during spent fuel transfer from 20 millirem/hour or less to an exposure rate for an operator to 2.5 millirem per hour or less. These changes are reviewed in Section 12.3 of this report.

9.1.4.2 Evaluation

The staff reviewed all changes to the LLHS in the AP1000 DCD Revision 17 in accordance with NUREG-0800 Section 9.1.4, “Light Load Handling System (Related to Refueling).” The regulatory basis for Section 9.1.4 of the AP1000 DCD is documented in NUREG-1793, which states that staff acceptance of the design, is contingent on compliance with the following requirements:

- GDC 2, as it relates to the ability of structures, systems, and components (SSCs) to withstand the effects of earthquakes

- GDC 5, as it relates to whether shared SSCs important to safety are capable of performing required safety functions

- GDC 61, as it relates to a radioactivity release resulting from fuel damage and the avoidance of excessive personnel radiation exposure

- GDC 62, as it relates to criticality prevention

The specific criteria that apply to the proposed DCD changes are; 10 CFR 52.63(a)(1)(vi), which concerns substantially increasing overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security; and 10 CFR 52.63(a)(1)(vii) which concerns contribution to the increased standardization of the certification information in the AP1000 DCD.

9.1.4.2.1 Name Change and Crane Capacity Change for New-Fuel Handling Crane

The applicant proposed to change the name, type and crane capacity of the new-fuel handling crane. In Revision 17 to the DCD, the applicant deleted the classification of new-fuel handling crane as a jib crane. Based on TR-106, the applicant made this change because the final crane specified may not be a jib crane. Accordingly, the applicant changed the name of this crane to the new-fuel handling crane (from the fuel handling jib crane). The applicant also changed the capacity of the new-fuel handling crane from 907 kg (2000 lb) to 919 kg (2027 lb), which is the total combined weight of a new fuel assembly, control rod assembly and handling tool. Subsequently, the applicant stated in a letter dated June 26, 2008, that the function of moving new fuel will be transferred to the FHM and that the new-fuel handling crane will be eliminated. This issue is discussed below.

In accordance with NUREG-0800 Section 9.1.4, the LLHS needs to meet the requirements of GDC 2, GDC 5, GDC 61 and GDC 62. The NUREG-0800 Section 9.1.4 acceptance criteria for meeting the requirements of GDC 61 and GDC 62 are based on meeting the guidelines of ANSI/ANS 57.1-1992, "Design Requirements for Light Water Reactor Fuel Handling Systems." The staff finds that by changing the name of the new-fuel handling crane, removing its designation as a jib crane, and increasing its capacity, the applicant will continue to comply with the requirements of GDCs 5, 61 and 62.

The NUREG-0800 Section 9.1.4 acceptance criteria for meeting the requirements of GDC 2 are based on compliance with meeting the Regulatory Positions C.1 and C.2 of RG 1.29. The new-fuel handling crane, which handles new fuel and loads the new fuel into the SFP, was designed to be a seismic Category II component. Regulatory Position C.2 of RG 1.29 and Section 3.2.1.1.2 of DCD Revision 17, describe the guidance for seismic Category II SSCs. These state, in part, that seismic Category II SSC should be designed to preclude their structural failure during a safe shutdown earthquake (SSE) or interaction with seismic Category I items that could degrade the functioning of safety-related SSCs to an unacceptable level. In order to be seismic Category II, DCD Sections 9.1.1.2.1.D and 9.1.2.2.1.E state that the new-fuel handling crane will neither fall into the new fuel storage pit nor collapse into the SFP during a seismic event. Although the new-fuel handling crane will neither fall nor collapse during a seismic event as stated above, DCD Sections 9.1.1.2.1.D and 9.1.2.2.1.E did not state that the new fueling handling crane will continue to hold its maximum load (not drop the load) during the seismic event. Since a load drop could degrade the functioning of safety-related SSCs to an unacceptable level, the staff asked the applicant in RAI-SRP9.1.4-SBPB-01 to explain how this crane will meet seismic Category II criteria considering the maximum load carried by the crane.

The applicant responded in a letter dated June 26, 2008, indicating that the function of moving new fuel will be transferred to the FHM and that the new-fuel handling crane will be eliminated. The applicant stated that the FHM will be changed from a sigma style crane to a bridge style crane. The applicant stated that the FHM will remain a seismic Category II component and will not drop a fuel element under SSE conditions. The staff found the applicant's response satisfactory because the function of the new-fuel handling crane will be performed by the FHM and the FHM will continue to be a seismic Category II component in order to not drop its load during an SSE. Thus, the applicant will need to comply with GDC 2 when the new-fuel handling crane is eliminated and replaced by the FHM.

The applicant provided the staff with Revision 1 to its response to RAI-SRP9.1.4-SBPB-01 in a letter dated April 3, 2009. The applicant's revised response states that the words, "The fuel handling machine is designed to maintain its load carrying and structural integrity functions during a safe shutdown earthquake," will be inserted into DCD Tier 2, Section 9.1.1.2.1.D, "New Fuel Rack Design," and DCD Tier 2, Section 9.1.2.2.1.E, "Spent Fuel Rack Design." In the response, the applicant provided markups of DCD Tier 2, Sections 9.1.1.2.1 D and 9.1.2.2.1 E, which showed how the additional text will be added in the next DCD revision. However, in Revision 1 to the RAI response the applicant also made the statement that these changes support the statement in DCD Tier 1, Section 2.1.1, "Fuel Handling and Refueling System," Item 6, "The RM (refueling machine) and FHM are designed to maintain their load carrying and structural integrity functions during a safe shutdown earthquake." While the Revision 1 response addressed the FHM seismic capabilities, the RM seismic capabilities were not addressed even though the RAI response implied that they would be addressed.

In a letter dated September 4, 2009, the applicant provided Revision 2 to the response to RAI-SRP9.1.4-SBPB-01. The applicant's revised response stated that the words, "the refueling machine is designed to maintain its load carrying and structural integrity functions during a safe shutdown earthquake" will be included in Tier 2 of the DCD. The staff finds this acceptable because the DCD will address both RM and FHM ability to hold their load during an SSE, and the DCD will provide Tier 2 seismic information to support Tier 1 content. Therefore, RAI-SRP9.1.4-SBPB-01 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

9.1.4.2.2 Non Safety-related Classification for AP1000 Fuel Handling Equipment:

The applicant proposed to change the safety and seismic classification of the FHM and SFHT. As documented in TR-106, the applicant reclassified the FHM and the SFHT as nonsafety-related, seismic Category II. As stated in Section 9.1.4.1.1 of this report, NUREG-0800 Section 9.1.4 states that the LLHS needs to meet the requirements of GDC 2, GDC 5, GDC 61 and GDC 62. The staff determined that this change does not affect the LLHS meeting the requirements of GDC 5 because this change will not cause the sharing of equipment important to safety between nuclear power units.

The NUREG-0800 Section 9.1.4 acceptance criteria for meeting the requirements of GDC 61 and GDC 62 are based on meeting the guidelines of ANSI/ANS 57.1-1992. The staff finds that the nonsafety classification of the FHM and the SFHT is consistent with ANSI/ANS 57.1-1992. Therefore, the staff finds the reclassification of FHM and the SFHT as nonsafety-related to be acceptable.

The NUREG-0800 Section 9.1.4 acceptance criteria for meeting the requirements of GDC 2 are based on compliance with meeting the Regulatory Positions C.1 and C.2 of RG 1.29. Since these SSCs have been accepted by the staff as nonsafety-related, Regulatory Position C.2 of RG 1.29 is applicable in meeting the requirements of GDC 2. Regulatory Position C.2 states that seismic Category II SSCs need to be designed to preclude their failure, which could reduce the function of any seismic Category I SSC during an SSE to an unacceptable safety level.

The staff asked the applicant in RAI-SRP9.1.4-SBPB-02, to verify that the FHM and the SFHT will continue to hold their design load during an SSE. The applicant responded in a letter dated June 26, 2008, that the FHM will be designed to maintain its structural integrity and load carrying ability during an SSE. The staff found the applicant's response satisfactory because it complies with Regulatory Position C.2 of RG 1.29 and thus, the requirements of GDC 2 are met. Although the AP1000 DCD, Revision 16 stated that the FHM maintains its structural integrity during an SSE, the DCD did not state that the FHM maintains its load carrying capability during an SSE.

The applicant provided the staff with Revision 1 to its response to RAI-SRP9.1.4-SBPB-02, dated April 3, 2009. The applicant's revised response referred to the changes made in its Revision 1 response to RAI-SRP9.1.4-SBPB-01. As stated above, while the Revision 1 response to RAI-SRP9.1.4-SBPB-01 addressed the FHM seismic capabilities, the RM seismic capabilities were not addressed as the RAI response implied. The applicant's September 4, 2009, revised response to RAI-SRP9.1.4-SBPB-01 included information related to RAI-SRP9.1.4-SBPB-02 addressing the RM seismic capability. The staff finds this response acceptable because it ensures the RM and FHM seismic capability to hold load during an SSE.

However, in DCD Revision 16, Table 3.2-3, the applicant designated dual seismic classification to the FHM. This was the only SSC in Table 3.2-3 that had a dual seismic classification of "II/NS," and no reason for the dual seismic classification was given by the applicant. Therefore, the staff requested in RAI-SRP9.1.4-SBPB-02 that the applicant provide justification for the dual seismic classification. The applicant responded in a letter dated June 26, 2008, that the FHM was a seismic Category II component and that Table 3.2-3 would be updated in Revision 17 of the DCD. The applicant provided a DCD markup page of Table 3.2-3. The staff has confirmed that Revision 17 of the DCD Tier 2, Table 3.2-3 was revised as committed in the RAI response. Furthermore, the staff finds that the issue concerning the seismic classification of the FHM has been adequately addressed and resolved by the applicant, because the FHM complies with Regulatory Position C.2 of RG 1.29 and thereby the requirements of GDC 2. Therefore, the staff's concern described in RAI-SRP9.1.4-SBPB-02 is resolved.

With the designation of the FHM and RM as seismic Category II, the staff finds that the LLHS will continue to meet the requirements of GDC 2 as it relates to the ability of SSCs to withstand the effects of earthquakes, GDC 61 as it relates to adequate safety from radioactivity resulting from fuel damage, and GDC 62 as it relates to prevention of criticality.

9.1.4.2.3 Fuel Handling Machine Generic Description

The applicant proposed to change the safety evaluation description of the FHM. In accordance with TR-106, the applicant revised the description of the FHM. In DCD Revision 16, Section 9.1.4.3.3, the applicant stated that the FHM "has the same design functions as the RM and includes the same safety features." However, DCD Revision 16, Sections 9.1.4.2.4 and 9.1.4.2.2.3 stated that the RM services the core—including the function to latch and unlatch control rods. No such function was attributed to the FHM. Additionally, DCD Revision 16, Section 9.1.4.2.3 stated that the FHM is used to load spent fuel into the shipping casks. No such function was attributed to the RM. Additionally, the RM operated exclusively in containment while the FHM operated exclusively in the fuel handling area. Therefore, the staff requested, in RAI-SRP9.1.4-SBPB-03, that the applicant explain how the FHM has the same design functions as the RM.

The applicant responded in a letter dated June 26, 2008, that the FHM design will be changed to a bridge/gantry style machine with two 2-ton overhead hoists. The applicant then described the safety interlocks, bridge hold-down devices, hoist braking system, and the fuel assembly support system for the FHM. The staff addresses the adequacy of the applicant's description of the FHM in Section 9.1.4.2.5 of this report.

9.1.4.2.4 Tier 1, Table 2.1.1-1, ITAAC Acceptance Criteria for Design Commitment 5

In the previously approved AP1000 DCD Revision 15, Tier 1, Table 2.1.1-1, ITAAC Acceptance Criteria for Design Commitment 5 stated that "[t]he bottom of the dummy fuel assembly cannot be raised to within 26 ft, 1 in. [7.9 m] of the operating deck floor." In DCD Revision 17, Tier 1, Table 2.1.1-1, the applicant proposed to change the lift height to 7.46 m (24 ft, 6 in). The bases for these changes are included in TR-121, and these changes are reviewed by the staff in Section 9.1.3 and Section 12.3 of this report. Some of the potential effects on DCD Section 9.1.4 are summarized in the applicant's response to RAI-SRP9.1.4-SBPB-04, Revision 1. The staff determined that these changes made to DCD Tier 2, Section 9.1.4 and Tier 1, Table 2.1.1-1 are conforming changes to the changes made in DCD Section 9.1.3 and do not impact the staff's safety evaluation of DCD Section 9.1.4. In addition, the staff's evaluation of the justification for the minimum shielding change is discussed in the applicant response to RAI-SRP12.3-CHPB-02 and is reviewed and documented in Section 12.3 of this report. The new lift height limit of 7.46 m (24 ft, 6 in) continues to demonstrate that the FHM will not raise a fuel assembly above the minimum required depth of water shielding.

9.1.4.2.5 Moving Spent Fuel With the SFHT and Auxiliary Hoist of the FHM

NUREG-0800 Section 9.1.4, "Light Load Handling System (Related to Refueling)," invokes GDC 61 for avoidance of excessive personnel radiation exposure. NUREG-0800 Section 9.1.4 acceptance criteria for meeting the relevant aspects of GDC 61 are based in part on the guidelines of ANSI/ANS 57.1-1992. Section 6.1.1 of this standard states, "Mechanical or electrical safety devices shall be designed into the system to prevent damage to fuel units and conditions that pose a radiation hazard or an unintentional radiation exposure risk to personnel." Section 6.4.1.2 of this standard recommended testing of these safety devices. In RAI-SRP9.1.4-SBPB-04, the staff asked the applicant to explain how they meet ANSI/ANS 57.1-1992 for the auxiliary hoist of the FHM, and the staff asked what ITAAC will test the functionality of the aforementioned safety devices.

The applicant responded to RAI-SRP9.1.4-SBPB-04 in a letter dated June 26, 2008, that the mast and auxiliary hoist was eliminated from the FHM and replaced with two overhead/trolley hoists. Since the applicant eliminated the mast and replaced it with an overhead hoist, the applicant needed to address the effects upon safe movement of fuel without the stability and position accuracy of a mast, in not causing mechanical damage to the new and spent fuel assemblies during movements of fuel assemblies. Movements of fuel within the refueling area include loading spent fuel into the spent fuel racks and moving spent and new fuel between the SFP and the fuel transfer canal.

The applicant provided the staff with Revision 1 to its response to RAI-SRP9.1.4-SBPB-04 in a letter dated May 20, 2009. The applicant's revised response stated that use of an overhead hoist design with an SFHT is common industry practice and has been accepted in previous designs. The applicant further stated: (1) the FHM is unable to raise the fuel to an unsafe radiological height in the SFP at any time during transport, storage, and installation activities; (2) features of the lifting devices' control circuitry and procedural operation prevent inadvertent unsafe movement of the fuel; (3) fuel transit speed, as operating limits or obstructions are approached, is automatically reduced to prevent overtravel or excessive sway of a fuel assembly. The staff finds this method of moving spent fuel with the SFHT acceptable since this type of design is consistent with common industry practice and is currently used in operating plants.

The applicant stated in a letter dated June 26, 2008, that both FHM hoists will be equipped with the safety devices identified in ANSI/ANS 57.1-1992, Section 6.3.1 with the exception of (9) Grapple Release as this feature is the manual operation of the fuel handling tool. A staff review of the applicant's proposed changes to the DCD, as described in its response to RAI-SRP9.1.4-SBPB-04, found that the down-position (interlock), end-travel (hardstop), up-limit (hardstop), translation inhibit (interlock) were not described. Furthermore, the applicant was not clear in its response whether the bridge travel (interlock) and trolley travel (interlock) are part of the design of the FHM. The applicant needed to clarify in the DCD that the FHM hoists have the safety devices identified in ANSI/ANS 57.1-1992, Section 6.3.1.

In its May 20, 2009 revised response to RAI-SRP9.1.4-SBPB-04, the applicant also proposed to include a description that clarifies the safety interlocks for the FHM in Section 9.1.4.3.3. Additional content was proposed in the RAI- SRP9.1.4-SBPB-03 response dated June 4, 2009 to incorporate a description of FHM bridge hold-down devices, hoist braking system, and the fuel assembly support system into Section 9.1.4.3.3. The applicant also stated that portions of the DCD "Light Load Handling System (Related to Refueling)" text will be clarified to indicate that the safety features listed include the safety requirements listed in ANSI/ANS 57.1. The clarifying text, which states that the safety features listed include the safety requirements listed in ANSI/ANS 57.1, will be added to DCD Sections 9.1.4.3.1, "Refueling Machine"; 9.1.4.3.2, "Fuel Transfer System"; and 9.1.4.3.3, "Fuel Handling Machine." In Section 9.1.4.3.3, there is one exception to ANSI/ANS 57.1 for the grapple release, as this feature is the manual operation of a fuel handling tool. In its response, the applicant provided markups of DCD Tier 2 Sections 9.1.4.3.1, 9.1.4.3.2 and 9.1.4.3.3 to be added in the next revision to the DCD. The staff finds this response acceptable since the safety requirements listed in ANSI/ANS 57.1 will be applied to the RM, fuel transfer system, and FHM; this meets GDC 61 and GDC 62. The staff's concern described in RAI-SRP9.1.4-SBPB-04 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

To address the part of the staff's RAI-SRP9.1.4-SBPB-04 request to identify the ITAAC that will test the functionality of the auxiliary hoist of the FHM, the applicant proposed, in Revision 17 of DCD Tier 1, changes to Section 2.1.1, "Fuel Handling and Refueling System," paragraphs 4, 5 and Table 2.1.1-1 (ITAAC) for associated Design Commitments 4 and 5. Based on its review, the staff finds that the changes to the above ITAAC are acceptable since they will adequately verify that the FHM/SFHT gripper assemblies are designed to prevent opening while the weight of the fuel assembly is suspended from the grippers. ITAAC Design Commitment 5 will also verify that the FHM hoists are limited such that the minimum required depth of water is maintained.

Single failure and non-single-failure proof hoists

In the June 26, 2008, response to RAI-SRP9.1.4-SBPB-04, the applicant stated that the FHM design will be changed to a bridge style machine with two 2-ton overhead hoists, one of which is single-failure proof. It was stated that a single-failure proof hoist and the new fuel handling tool will be used to handle new fuel and a nonsingle-failure proof hoist and the SFHT will be used to handle spent fuel. The applicant initially stated that the single-failure proof hoist may also handle spent fuel, but it would not have access to all spent fuel handling/storage locations. In a March 18, 2009, public meeting between the staff and the applicant, the use of the FHM single-failure proof hoist and nonsingle-failure proof hoist was discussed in detail. The applicant stated that the new FHM will handle new fuel and spent fuel.

In the June 26, 2008 response to RAI-SRP9.1.4-SBPB-03, the applicant also stated, “The fuel handling machine is restricted to raising a fuel assembly to a height at which the water provides a safe radiation shield,” and in response to RAI-SRP9.1.4-SBPB-04, the applicant stated that “each FHM hoist will have a mechanical limit based on maximum hoist up travel and spent fuel handling tool length.” Since the new FHM will be moving both new fuel and spent fuel, and new fuel is handled above deck level when it is transferred to the new fuel racks and transferred from the new fuel storage vault into the SFP, the applicant did not state in the DCD how the same cranes that are restricted in hoist uptravel can handle new fuel above deck level. Use of the FHM hoist for new fuel also apparently conflicted with the revised Tier 1 ITAAC Table 2.1.1-1 Item 5, which stated, “FHM hoists are limited such that the minimum required depth of water shielding is maintained.”

The applicant provided Revision 1 to its response to RAI-SRP9.1.4-SBPB-04 in a letter dated May 20, 2009 and Revision 1 to its response to RAI-SRP9.1.4-SBPB-03 in a letter dated June 4, 2009. Both of the applicant’s revised RAI responses include the same additional paragraph, which defined some restrictions to the use of the nonsingle-failure proof hoist and the single-failure proof hoist of the FHM for handling new fuel and other loads throughout the fuel handling area. The single-failure proof hoist in conjunction with the SFHT is not capable of raising spent fuel to a height that clears the spent fuel racks, fuel transfer system fuel basket, spent fuel shipping cask, or the new fuel elevator. The staff found that the applicant’s Revision 1 responses to RAI-SRP9.1.4-SBPB-03 and RAI-SRP9.1.4-SBPB-04 did not adequately address how the single-failure proof crane of the FHM with hoist uptravel restrictions can handle new fuel above the deck level.

The applicant’s Revision 2 to its RAI-SRP9.1.4-SBPB-03 response was issued in a letter dated October 15, 2009. The letter provides a clarifying description of the fuel movement process using the FHM. The design for the movement of spent fuel utilizes the nonsingle-failure proof hoist and its associated SFHT. The new fuel handling tool is used with the single-failure proof hoist to move new fuel. The SFHT and the new fuel handling tool are manually operated tools and differ in length by approximately 9.14 m (30 ft). The single-failure proof hoist does not have the lift height to raise a spent fuel assembly clear of the spent fuel racks, fuel transfer system fuel basket, spent fuel shipping cask, or the new fuel elevator when using the SFHT. When spent fuel is stored in the spent fuel racks, or other interim storage locations, spent fuel movement with either hoist would be physically impossible using the new fuel handling tool, as the operating handle of the tool would be submerged in approximately 6.09 m (20 ft) of water.

Therefore, a description of the fuel movement (new and spent) process for both FHM hoists using their handling tools, and a discussion of their interlocks, needed to be included in the DCD. This was identified as Open Item OI-SRP9.1.4-SBPA-03.

To address Open Item OI-SRP9.1.4-SBPA-03, the applicant provided a response dated March 31, 2010. The response proposed to revise DCD Section 9.1.4.2.4 to incorporate the statement provided in RAI-SRP9.1.4-SBPB-03 and RAI-SRP9.1.4-SBPB-04 regarding the restrictions for use of single and nonsingle-failure proof hoists in the DCD. However, when further requested to clearly define the usage of the single and nonsingle-failure proof hoists, the applicant submitted a revised response to Open Item OI-SRP9.1.4-SBPA-03 dated May 19, 2010. This revised response proposed to revise DCD Section 9.1.4.2.4 to define the use of hoists above deck. This response also described the availability of a selector switch to choose the correct hoist and integrated controls to avoid inadvertent use of the incorrect hoist. The response also defined the intended use of each hoist as follows:

The single-failure proof hoist will be used for;

- primarily handling new fuel
- the movement of loads <1814 kg (4000 lb) in the fuel handling area of the auxiliary building
- a redundant hoist over the SFP for the handling of control components

The nonsingle-failure proof crane will be used for;

- handling fuel and control components in the SFP
- the hoist shall be restricted from handling a load above the operating floor within 4.6 m (15 ft) of the SFP

The proposed additions to Section 9.1.4.2.4 clarify that the nonsingle-failure proof hoist is primarily used for submerged handling activities in the SFP. There are areas in the fuel handling area of the auxiliary building that the single-failure proof hoist is not capable of accessing due to travel limitations. Therefore, the response stated that it is necessary for the nonsingle-failure proof hoist to be used in areas other than the SFP. As a safety precaution, the applicant indicated that the nonsingle-failure proof hoist will be restricted from handling a load above the operating floor within 4.6 m (15 ft) of the SFP. The applicant further stated that the single-failure proof hoist will be capable of handling loads in the new fuel handling area and the spent fuel handling area with operator warnings associated with the handling of spent fuel and proposed corresponding changes to DCD.

Although the proposed DCD changes addressed restriction on the nonsingle-failure proof hoist travelling over SFP, it was unclear what provisions are provided to prevent the single-failure proof hoist from handling new fuel over SFP with the new fuel handling tool. For additional clarification of new fuel movement, the applicant provided a revised response to Open Item OI-SRP9.1.4-SBPA-03 dated July 9, 2010, which further defined the restrictions of new fuel movement above deck while using the new fuel handling tool. The open item response proposed a revision to the DCD to indicate that the nonsingle-failure proof hoist is restricted from handling new fuel above the operating floor. The applicant also clarified that the new fuel elevator fuel carrier is located in the tool storage area of the SFP. The open item response revised DCD Figure 9.1-4 to indicate the location of the new fuel elevator and defined the safety interlocks to prevent the transporting of new fuel above the operating floor over the spent fuel racks by the single-failure proof hoist in Section 9.1.4.2.4.

Based on the above, the staff finds that there is reasonable assurance that the use of the single and nonsingle-failure proof hoist configuration on the FHM will minimize the potential for damage to fuel, fuel assemblies, and to storage or transport containers. The restrictions on fuel movement and safety interlocks provide safe movement of new and spent fuel in the auxiliary building using these hoists. Therefore, Open Item OI-SRP9.1.4-SBPA-03 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

To address the section part of the staff’s RAI-SRP9.1.4-SBPB-04 to identify the ITAAC that will test the functionality of the auxiliary hoist of the FHM, the applicant proposed, in Revision 17, Tier 1, changes to DCD Tier 1, Section 2.1.1, “Fuel Handling and Refueling System” paragraphs 4 and 5 and DCD Tier 1 Table 2.1.1-1 (ITAAC) for associated Design Commitments 4 and 5. Based on its review, the staff finds that the changes to the above ITAAC are acceptable.

Table 9.1-1 in Section 9.1.4.2.8 of this report provides a summary of the fuel handling operations of the FHM discussed above.

9.1.4.2.6 Elimination of Rod Cluster Control Storage Station from Reactor Cavity Wall

In DCD Tier 2, Revision 17, the applicant proposed to eliminate from the AP1000 design the mounting of the rod cluster control storage station from the reactor cavity wall and, therefore, its intended use. The applicant proposed that it will instead perform rod cluster control assembly inspections in the auxiliary building. As stated in Section 9.1.4.1.1 of this report, NUREG-0800 Section 9.1.4 states that the LLHS needs to meet the requirements of GDC 2, GDC 5, GDC 61 and GDC 62. The staff determined that this change of eliminating the rod cluster control storage station from the reactor cavity wall will have no effect on the remaining LLHS components from meeting the applicable GDC.

9.1.4.2.7 Addition of Spent Fuel Assembly Handling Tool under Fuel Handling Tools and Equipment Section

In DCD Tier 2, Revision 17, the applicant proposed to add the spent fuel assembly handling tool to the list of tools itemized under the Section 9.1.4.3.4. This change is associated with the comprehensive changes made to Section 9.1.4 by the applicant due to the elimination of the new-fuel handling crane as discussed in the applicant's responses to RAI-SRP9.1.4-SBPB-01 through RAI-SRP9.1.4-SBPB-04. The staff determined that the addition of the spent fuel assembly handling tool to the list of tools itemized under the section heading fuel handling tools and equipment is acceptable, because it represents additional changes needed to Section 9.1.4, which were not previously presented in the responses to RAI-SRP9.1.4-SBPB-01 through RAI-SRP9.1.4-SBPB-04.

9.1.4.2.8 Fuel Handling Summary Table

Table 9.1-14. Fuel Handling Machine (FHM) Hoist Operations

Fuel Handling Scenario	Fuel Handling Machine (FHM) Hoist Operations			
	Non-Single-Failure-Proof Hoist		Single-Failure-Proof Hoist	
	New Fuel Assembly Handling Tool	Spent Fuel Assembly Handling Tool	New Fuel Assembly Handling Tool	Spent Fuel Assembly Handling Tool
Moves new fuel (NF) above the fuel handling area (FHA) operating floor/deck over spent fuel (SF) racks.	No	No	No	No
Moves NF above the FHA operating floor/deck.	No	No	**Yes**	No

Table 9.1-14. Fuel Handling Machine (FHM) Hoist Operations

Fuel Handling Scenario	Fuel Handling Machine (FHM) Hoist Operations			
	Non-Single-Failure-Proof Hoist		Single-Failure-Proof Hoist	
	New Fuel Assembly Handling Tool	Spent Fuel Assembly Handling Tool	New Fuel Assembly Handling Tool	Spent Fuel Assembly Handling Tool
Moves NF over the NF racks. (Same as Scenario 2)	No	No	**Yes**	No
Moves NF over the NF Elevator (elevator up).	No	No	**Yes**	No
Moves NF over the NF Elevator (elevator down).	No	**Yes**	No	No
Moves NF within the SFP over the SF racks.	No	**Yes**	No	No
Moves SF within the SFP over the SF racks.	No	**Yes**	No	No

9.1.4.3 Conclusion

In NUREG-1793 and Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the applicant's proposed changes to the AP1000 LLHS as documented in DCD, Revision 17 against the relevant acceptance criteria as listed above and in NUREG-0800 Section 9.1.4. The staff finds that the applicant's proposed changes do not affect the ability of the AP1000 LLHS to meet the applicable acceptance criteria. The staff also finds that the design changes have been properly incorporated into the appropriate sections of AP1000 DCD, Revision 17. The staff concludes that the AP1000 LLHS design continues to meet all applicable acceptance criteria and the proposed changes are properly documented in the updated AP1000 DCD. The proposed changes meet the criteria of: 10 CFR 52.63(a)(1)(vi), on the basis that they substantially increase overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security; and 10 CFR 52.63(a)(1)(vii), on the basis that they contribute to the increased standardization of the certification information in the AP1000 DCD. Therefore, the staff finds that the proposed changes to the AP1000 LLHS are acceptable.

9.1.5 Overhead Heavy Load Handling Systems

9.1.5.1 Summary of Technical Information

In NUREG-1793 the staff approved Section 9.1.5, "Overhead Heavy Load Handling Systems" (OHLHS) of the AP1000 DCD, Revision 15. In AP1000 DCD, Revision 17, the applicant has proposed to make changes to Section 9.1.5 of the DCD.

The applicant proposed changes in the DCD, which are supported by information presented in TR-106.

The staff reviewed the proposed changes to Section 9.1.5 of the AP1000 DCD, Revision 15.

1. The applicant proposed to rename the cask handling crane, upgrade its seismic classification, and make the cask handling crane single-failure proof. In the previously approved AP1000 DCD Revision 15, the applicant named this crane the spent fuel shipping cask crane. In DCD Revision 17, the applicant has changed the name of this crane to the cask handling crane, and changed the design basis to single-failure proof and seismic Category I.

   The applicant has also proposed to classify the maintenance hatch hoist as single-failure proof. In the previously approved AP1000 DCD Revision 15, this hoist was seismic Category I, but not single-failure proof. In DCD Revision 17, the applicant has added single-failure proof design criteria for the maintenance hatch hoist.

   In DCD Revision 17, the applicant also added two new safety-related functions for the mechanical handling system (MHS), those being the prevention of the uncontrolled lowering of a heavy load by both the cask handling crane and the maintenance hatch hoist. The applicant also added the cask handling crane and the maintenance hatch hoist to Tables 2.3.5-1 and 2.3.5-3 in Tier 1 to add these components to the tables that list seismic Category I equipment and component locations for the MHS. The applicant also added the cask handling crane and the maintenance hatch hoist to ITAAC in Table 2.3.5-2 of Tier 1.

   The bases for these changes are documented in the applicant's TR-106.

   The applicant identified these changes in AP1000 DCD Revision 17, Tier 1, Section 2.3.5, "Mechanical Handling System," and Tables 2.3.5-1, 2.3.5-2, and 2.3.5-3; Tier 2, Sections 9.1.5.1.1, "Safety Design Basis," 9.1.5.2, "System Description," and 9.1.5.3, "Safety Evaluation," Table 9.1-5, "Nuclear Island Heavy Load Handling Systems," and Table 3.2-3, "AP1000 Classification of Mechanical and Fluid Systems, Components, and Equipment."

2. The applicant proposed to modify the codes and standards applicable to the polar crane, cask handling crane and other overhead cranes and hoists. In the previously approved AP1000 DCD Revision 15, overhead cranes were designed to ASME NOG-1, "Rules for Construction of Overhead and Gantry Cranes (Top Running Bridge, Multiple Girder)." Other cranes and hoists that handle heavy loads were designed according to the applicable ANSI standard. AP1000 cranes were designed to ASME NOG-1 and NUREG-0612, "Control of Heavy Loads at Nuclear Power Plants." The spent fuel shipping cask crane was designed to ASME NOG-1 for a Type III crane and

ANSI/ANS-57.1 and ANSI/ANS-57.2, "Design Requirements Light Water Reactor Spent Fuel Storage Facilities at Nuclear Power Plants." In DCD Revision 17, the applicant has changed the polar crane and cask handling crane to be designed according to NUREG-0554 supplemented by ASME NOG-1 for a Type I single-failure proof crane. Other cranes and hoists which handle heavy loads will be designed according to ASME NOG-1 and to the applicable ANSI standard. In addition, the design of AP1000 cranes will comply with the guidance in NUREG-0612. The bases for all these changes are documented in TR-106.

The applicant identified these changes in DCD Revision 17, Tier 2, Sections 9.1.5.1.2, "Codes and Standards," and 9.1.5.2.1.2, "Component Descriptions," and Table 3.2-3, "AP1000 Classification of Mechanical and Fluid Systems, Components, and Equipment."

3. The applicant proposed to change one method by which the movements of the bridge, trolley, main, and auxiliary hoists of the polar crane can be controlled. In DCD Revision 15, the polar crane was controlled from either the operator's cab or from a pendant suspended from the crane. In DCD Revision 17, the applicant has changed control from a pendant to remote control. The remote control of the crane will have the same control functions, push button functions, and interlocks as the previous pendant design. The basis for this change is documented in TR-106.

   The applicant has identified this change in DCD Revision 17, Tier 2, Section 9.1.5.2.1.1, "System Operation."

4. The applicant proposed a new description for the cask handling crane. In the previously approved DCD Revision 15, the applicant did not describe the cask handling crane, formerly called the spent fuel shipping cask crane. In DCD Revision 17, with the upgrade of the crane to single-failure proof and seismic Category I, the applicant added the following sections and titles to describe the cask handling crane and its operation:

   9.1.5.2.2 Cask Handling Crane General Description
   9.1.5.2.2.1 System Operation
   9.1.5.2.2.2 Component Descriptions.
   9.1.5.2.2.3 Instrumentation Applications

   The bases for these changes are documented in TR-106.

5. The applicant proposed to change the maximum load rating of the containment polar crane. In the previously approved DCD Revision 15, the maximum load rating of the containment polar crane was 249.48 metric tons (275 tons). In DCD Revision 17, the applicant proposed to change the maximum load rating for the containment polar crane to 272.16 metric tons (300 tons). The basis for this change is documented in TR-106.

   The applicant identified this change in DCD Revision 17 in Table 9.1-5, "Nuclear Island Heavy Load Handling Systems."

6. The applicant proposed to change the tabular information in Table 9.1.5-1 for the cask handling crane (previously spent fuel shipping cask crane in DCD Revision 15). In the previously approved DCD Revision 15, the table was for a nonsingle-failure proof spent fuel cask crane and listed exceptions and clarifications to ANSI/ANS 57.1 and ANSI/ANS 57.2. In DCD Revision 16, the applicant removes the exceptions table and

replaces it with design information for the bridge, trolley, main hoist and auxiliary hoist of the cask handling crane.

The applicant identified this change in DCD Revision 17 in Table 9.1.5-1, "Cask Handling Crane Component Data."

7. The applicant proposed to specify the main hook of the polar crane to handle the RCP pump/motor shell. In the previously approved DCD Revision 15, the auxiliary hook of the polar crane was used to handle the RCP pump/motor shell. In DCD Revision 17, the applicant proposed to change Table 9.1.5-2, "Special Lifting Devices Used for the Handling of Critical Loads," to designate the main hook of the polar crane to be used with the RCP special lifting device to lift the RCP pump/motor shell. The basis for this change is documented in TR-106.

   The applicant identified this change in Table 9.1.5-2, "Special Lifting Devices Used for the Handling of Critical Loads."

8. The applicant proposed to change the approximate capacity of the polar crane auxiliary hoist from 68.04 metric tons (75 tons) to 22.68 metric tons (25 tons). In the previously approved DCD Revision 15 in Table 9.1.5-3, "Polar Crane Component Data," 68.04 metric tons (75 tons) was listed as the approximate capacity of the auxiliary hoist of the polar crane. In DCD Revision 17, the applicant proposed to change the approximate capacity of the polar crane auxiliary hoist to 22.68 metric tons (25 tons). The basis for this change is documented in TR-106.

   The applicant identified this change in Table 9.1.5-3, "Polar Crane Component Data."

9.1.5.2 Evaluation

The staff reviewed all changes to the OHLHS in the AP1000 DCD Revision 17 in accordance with NUREG-0800 Section 9.1.5, "Overhead Heavy Load Handling Systems." The staff did not re-review descriptions and evaluations of Section 9.1.5 of DCD Revision 15 that were previously approved and are not affected by the new changes. The regulatory basis for Section 9.1.5 of the DCD is documented in NUREG-1793.

The specific criteria that applies to the proposed DCD changes are; 10 CFR 52.63(a)(1)(vi), which concerns substantially increasing overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security; and 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

9.1.5.2.1 Cask Handling Crane and Containment Maintenance Hatch Hoist Design Basis Changes (Single-failure Proof and Seismic Category I)

TR-106 states that the AP1000 cask handling crane design was neither seismically qualified, nor single-failure proof to protect against dropping a cask. Since a cask drop could cause significant plant damage, a design change was initiated to upgrade the cask handling crane to single-failure proof and seismic Category I. This change was made to reduce the possibility of a serious plant event. With this design change the crane name was changed from the spent fuel shipping cask crane to the cask handling crane. The cask handling crane will thus be designed to support a critical load during and after a safe shutdown earthquake and is classified as seismic Category I.

TR-106 further states that the maintenance hatch hoist [9.07 metric tons (10 ton capacity)] is not specified in the DCD as single-failure proof. For personnel and equipment safety reasons, the maintenance hatch hoist design has also been changed to be single-failure proof. The equipment hatch hoist which was already designated a single-failure proof crane had its name changed to containment equipment hatch hoist to be specific in its plant location.

On the basis that upgrading of the cask handling crane and maintenance hatch hoist to single-failure proof and upgrading the cask handling crane to seismic Category I will result in greater safety during the handling of critical loads within the nuclear island, the staff finds the design changes acceptable.

However, the applicant, in DCD Tier 1 Section 2.3.5, “Mechanical Handling System,” did not list single-failure proof as certified design information with ITAAC for the polar crane, the cask handling crane, the containment equipment hatch hoist or the containment maintenance hatch hoist. One design criterion for Tier 1 information is that it should include features and functions that could have a significant effect on the safety of a nuclear plant or are important in preventing or mitigating severe accidents. A drop of the reactor vessel head or a spent fuel cask could affect plant safety. Without heavy load drop analyses that proves the safety of a load drop, single-failure proof design criteria for the associated crane/hoist is necessary for plant safety and should be part of the Tier 1 safety significant design criteria for the polar crane and the cask handling crane. Therefore, the staff requested the applicant in RAI-SRP9.1.5-SBPB-09 to explain why they did not include single-failure proof design criteria and ITAAC in Tier 1 of the DCD for the polar crane, the cask handling crane, the containment equipment hatch hoist and the containment maintenance hatch hoist.

In its response dated September 3, 2008, the applicant stated that the single-failure proof criteria within ITAAC Table 2.3.5-2 for components 3a (polar crane), 3b (cask handling crane), 3c (equipment hatch hoist), and 3d (maintenance hatch hoist) will be incorporated.

The applicant also provided proposed revisions to DCD Revision 16, Tier 1, Section 2.3.5, Paragraph 3 under the heading “Design Description,” to state the containment polar crane, cask handling crane, equipment hatch hoist and maintenance hatch hoist are single-failure proof. Also, in Tier 1 Table 2.3.5-2, the applicant proposed changes to ITAAC for the polar crane, the cask handling crane, the equipment hatch hoist and the maintenance hatch hoist.

Based on its evaluation, the staff finds that the applicant demonstrated in the proposed revisions that single-failure proof design criteria and ITAAC are identified in Tier 1 of the DCD for the polar crane, cask handling crane, containment equipment hatch hoist and the containment maintenance hatch hoist. The staff finds the applicant’s response acceptable in that the applicant has now included single-failure proof design criteria and ITAAC in Tier 1 of the DCD for the four load handling systems. The staff confirmed that the applicant made the changes in DCD Tier 1 Revision 17, as described above.

However, the staff finds that the acceptance criteria for the proposed ITAAC should include, not only a report that concludes the acceptability of the proposed inspections, tests, and analyses, but also a certificate of conformance from the vendor stating that the crane/hoist is single-failure proof.

To address the staff's concern regarding the certification of the cranes and hoists as single-failure proof, the applicant provided the staff with Revision 1 to its response to RAI-SRP9.1.5-SBPB-09 in a letter dated June 4, 2009. In the revised response, the applicant stated that single-failure proof criteria will be updated in DCD Tier 1 ITAAC Table 2.3.5-2 for Design Commitments 3a, 3b, 3c and 3d, which are for the two cranes and two hoists. The proposed acceptance criteria for the ITAAC to be incorporated into the next DCD revision will include a certificate of conformance from the crane or hoist vendor stating that the crane or hoist is single-failure proof. The staff finds the response acceptable since the requirement for the crane or hoist vendor to provide a certificate of conformance for being single-failure proof will be added to the acceptance criteria for the crane or hoist ITAAC.

The staff's concern described in RAI-SRP9.1.5-SBPB-09 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

9.1.5.2.2 Codes and Standards for Design of OHLHS Cranes and Hoists

This design change corrects wording to state that the polar crane and cask handling crane are designed in accordance with the guidelines of NUREG-0554 supplemented by ASME NOG-1 for a Type I, single-failure proof crane. This change made the DCD consistent with NUREG-0800 Section 9.1.5. Therefore, the staff finds this design change acceptable.

However, for the single-failure proof equipment hatch hoist and maintenance hatch hoist, the applicant only specified ASME NOG-1 and the applicable ANSI standard. ASME NOG-1 can specify non single-failure proof components in the Type II and Type III designs. DCD Revision 16 also stated under Section 9.1.5.2, that the containment equipment hatch hoist and maintenance hatch hoist incorporate single-failure proof features based on NUREG-0612 guidelines. Unlike the polar crane and cask handling crane, there were no detailed descriptions and no specific sections of ASME NOG-1 specified for the containment equipment hatch hoist and maintenance hatch hoist in DCD Section 9.1.5 to make them single-failure proof. Therefore, the staff found the classification for the single-failure proof hoists did not state all necessary design specifications for a single-failure proof component and requested the applicant in RAI-SRP9.1.5-SBPB-01 to provide more design specifications for single-failure proof hoists and a description of the hoists in the DCD.

In its response dated June 26, 2008, the applicant stated that the design specification for the maintenance hatch hoist system and equipment hatch hoist system would follow the guidelines of NUREG-0554, supplemented by ASME NOG-1. The applicant further stated that Table 3.2-3 of the DCD would be revised to reflect these guidelines.

In DCD Revision 17, Tier 2, Table 3.2-3 (Sheet 8 of 65), the applicant revised the table to show the principal construction code for the maintenance hatch hoist and equipment hatch hoist as NUREG-0554, supplemented by ASME NOG-1. However, although the applicant revised DCD Table 3.2-3 to reflect the principal construction code for the two hoists as NUREG-0554, supplemented by ASME NOG-1, the staff noted that the text in DCD Sections 9.1.5.1.2 and 9.1.5.2 has not been changed to reflect the change in the two hoists' construction code, which are NUREG-0554, supplemented by ASME NOG-1 <u>for a Type 1 single-failure proof hoist</u>.

To address the staff's concern, the applicant provided Revision 1 to its response to RAI-SRP9.1.5-SBPB-01 in a letter dated April 13, 2009. The applicant stated that ASME NOG-1, Type 1 designation is not applicable for equipment hatch hoists and maintenance hatch hoists, as it applies to the design of overhead and gantry cranes from the rails to the load hook. The applicant further proposed that the single-failure proof hatch hoists are designed, fabricated, examined and tested in accordance with cmAA 70 and the guidelines of NUREG-0554, supplemented by provision of ASME NOG-1 as it relates to single-failure proof hoists. The staff found the applicant's Revision 1 response to RAI-SRP9.1.5-SBPB-01 unacceptable. In the response, the applicant stated that the requirements of ASME NOG-1, Type 1 do not apply to equipment hatch hosts and maintenance hatch hoists, but the applicant proposed to apply portions of the NOG-1 requirements anyway. Since the applicant proposed to apply only portions of the applicable single-failure proof criteria to the hatch hoists, the staff asked the applicant to clearly define which portions of NRC guidance (e.g., NUREG-0554 and NUREG-0612) and ASME NOG-1 are applied to the heavy load handling cranes in order to classify them as single-failure proof cranes. The staff also asked the applicant to clarify the ambiguous use of the term "NUREG-0554 supplemented by ASME NOG-1," for all of the single-failure proof cranes. It is unclear whether all of ASME NOG-1, Type I, is applied to the polar and cask handling cranes. Revision 15 of the DCD clearly defined the polar crane as designed to ASME NOG-1 for a Type I, single-failure proof crane. However, DCD Revision 17 indicates "NUREG-0554 supplemented by ASME NOG-1." In RAI-SRP9.1.5-SBPB-01, the applicant was asked to provide justification and clearly define how the proposed polar crane, cask handling crane and hatch hoists designs would satisfy the single-failure proof criteria from the NRC guidance and industry standards with references to the specific paragraphs. In RAI-SRP9.1.5-SBPB-01, the applicant was also requested to provide an evaluation of the selected hoist standard to applicable portions of NUREG-0554 to avoid consideration of potential load drops by classification of the hoist as single-failure proof. This issue was tracked as Open Item OI-SRP9.1.5-SBPB-01 in the SER with open items. To address the staff's concern, the applicant provided a Revision 2 to its response to RAI-SRP9.1.5-SBPB-01 in a letter dated November 11, 2009. The applicant's response provided a detailed description of the hatch hoists to include in DCD Sections 9.1.5.2.3 and 9.1.5.2.4. These sections provide specific design criteria of the foot-mounted equipment hatch hoist, with content similar to what is specified for the polar crane and cask handling cranes. A revision to Section 9.1.5.2.3.2, "Component Descriptions," was proposed to incorporate the hoists description and elaborate on how the code requirements are implemented in the design of key safety-related components. The staff found finds the incorporation of the hatch hoist information in the DCD to be acceptable.

However, based on the applicant's clarification that the hatch hoists are foot-mounted on a platform supported by the containment structure, the applicant needed to justify how the structural loads on containment from the hoist are evaluated. For the proposed single-failure proof hatch hoists, there was no assurance that the evaluation considered the lifted load in conjunction with the seismic accelerations because the previous non-single-failure proof hoist was not required to hold a load during and following a seismic event. This became Open Item OI-SRP9.1.5-SBPB-01 in the SER with open items.

The applicant provided a response to Open Item OI-SRP9.1.5-SBPB-01 on March 31, 2010 describing the methodology for its seismic evaluation of the equipment hatch hoist. The response defined the acceptance criteria as "after a seismic event occurs while the hoist is holding the critical load, the containment vessel will continue to perform its intended safety functions." On May 19, 2010, the applicant provided an additional response to Open Item OI-SRP9.1.5-SBPB-01 indicating that the final loads were expected to be bounded by the current CV Design Specification. As a follow-up, the applicant provided an additional Open Item OI-SRP9.1.5-SBPB-01 response dated June 30, 2010, which indicated that the calculation number APP-MH40-S2C-002 includes the hatch hoist platform structural analysis and that the applicant has included the hatch hoist configuration in its structural analysis.

On August 16, 2010, the staff conducted a regulatory audit review of the AP1000, “Hatch Hoist Platform Structural Qualification,” (APP-MH40-S2C-002). In this design analysis, the applicant constructed a 3D finite element model for the platform structural analysis using a commercially available general purpose code (ANSYS). The platform model consists of a 3D beam (including rigid beams), plate/shell elements and lumped masses to represent both the platform and the hatch hoist system. The methodology, input/output and boundary conditions used were reviewed and found acceptable. Three loading cases were considered: (1) dead weight (1 g); (2) dead weight plus seismic; and (3) dead weight minus seismic. The maximum stresses for each structural component are obtained from the equivalent static analysis and used for design purposes. It was shown that use of 8x8x 5/16 beam and 10x10x5/16 beam with an E70xx fillet weld of 0.635 cm (0.25 in) thickness at the connection to the reactor vessel wall is in compliance with ANSI/American Institute of Steel Construction (AISC) N690-1994, “Specification for the Design, Fabrication, and Erection of Steel Safety-Related Structures for Nuclear Facilities (SC-I),” the calculation is acceptable as it provides assurance of an adequate design to support the heavy hatch hoist system under design-basis seismic loading conditions.

Based on the above review, the staff considers Open Item OI-SRP9.1.5-SBPB-01 resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

9.1.5.2.3 Remote Control Operation Change for Polar Crane and Cask Handling Crane

In TR-106 Revision 1, the applicant states that allowing the cask handling crane to be operated by radio remote control instead of the operator’s cab will allow for an unobstructed view of the load at all times. Special consideration was given to loads being lifted and lowered out of and into the truck/rail bay. The cask handling crane radio remote will meet ASME NOG-1 paragraph 6110 guidelines. TR-106 Revision 1 also states that wording for the polar crane operation is changed from "pendant controls" to "remote control" as a secondary means of control. This would ensure consistency in design and operations of the two single-failure proof cranes (polar and cask handling). The staff reviewed TR-106 Revision 1 specifically for the addition of the radio remote control for the cask handling crane and remote control for the polar crane, and found the additions acceptable. The design change is in compliance with GDCs 4, 5, 13, and 24.

However, the licensing basis for the remote control features of the polar crane and the cask handling crane needs to be established in the DCD along with an appropriate ITAAC to verify that the plant meets the licensing basis. The DCD should include information indicating that: a) the remote control features of the polar crane and cask handling crane will not interfere with any SSC important to safety in accordance with GDC 4; b) the remote control systems will not be shared with multiple unit sites or interfere with other units at the site in accordance with GDC 5; c) remote control systems will maintain variables and systems within prescribed operating ranges in accordance with GDC 13; and d) remote control systems will be separate from protection systems, such that failure of the control system leaves the protection systems intact satisfying all reliability, redundancy, and independence requirements in accordance with GDC 24.

In RAI-SRP9.1.5-SBPB-12, the staff requested that the applicant specify the licensing basis for the remote control features of the polar crane and the cask handling crane in the DCD and establish ITAAC to verify the plant meets the licensing basis.

In its response to RAI-SRP9.1.5-SBPB-12, dated January 12, 2009, the applicant addressed each of the licensing basis questions by stating: a) the remote control system will comply with Section 8, Electromagnetic Compatibility (EMC Qualifications) of the Equipment Methodology (EQ) plan, APP-GW-G1-002, Revision 1. The transmitter power of the remote control system for the two cranes will be set to a level that will allow continuous communications with the crane receivers throughout their areas of operation. The signal strength will be adjusted to minimize signal propagation to areas outside of the two cranes normal operating areas; b and c) the two cranes' remote control systems will be designed so that they are integrated into the operating site's frequency plan; and d) the remote control systems will be designed to fail into a safe mode of operation in the event of a loss of communications or failure of the portable remote unit. Should a system failure occur, all crane movements are halted.

The staff finds the applicant's response acceptable since the addition of the remote control systems to the polar and cask handling cranes does not impact the conclusions made in this report about the heavy load handling systems. The design and operation of the actual crane portions of the polar and cask handling cranes does not change with the use of radio remote controls as the controls are the same as the pendant (cask handling crane) and cab controls (polar crane). Therefore, the applicant does not need to provide additional licensing basis and ITAAC verification.

The applicant updated DCD Sections 9.1.5.2.1 and 9.1.5.2.2.1 in Revision 16 to include the use of radio remote control for the polar and cask handling cranes. No further DCD updates are necessary for remote control design changes/additions, and the staff's concern described in RAI-SRP9.1.5-SBPB-12 is resolved.

9.1.5.2.4 Upgrade of Cask Handling Crane to Single-failure Proof and Detailed Description Addition

TR-106 Revision 1 states the AP1000 cask handling crane design was neither seismically qualified nor single-failure proof to protect against dropping a cask. Since a cask drop could cause significant plant damage, a design change was initiated to upgrade the cask handling crane to single-failure proof. This change was made to reduce the possibility of a serious plant event.

With this design change, the applicant revised the name of the crane from the spent fuel shipping cask crane to the cask handling crane and upgraded it to single-failure proof. TR-106 Revision 1 provided a detailed description of the new single-failure proof cask handling crane which was added to DCD Revision 17. Because both the polar crane and cask handling crane are single-failure proof, the added detailed description of the cask handling crane is very similar to the polar crane detailed description. Because the design and system operation of the cask handling crane is described almost identically to that of the polar crane, which was found to be in compliance with GDC 2, 4, 5 and 61, the staff finds this design change of adding a detailed description of the cask handling crane to the AP1000 OHLHS acceptable.

NUREG-0800 Section 9.1.5 and NUREG-0612 provide guidance that states that safe load paths should be defined for movement of heavy loads. However, the applicant had not provided procedures and equipment layout drawings that show safe load paths for movement of heavy loads to minimize the potential to impact irradiated fuel in the reactor vessel and in the SFP and safe shutdown equipment. Therefore, the staff requested the applicant in RAI-SRP9.1.5-SBPB-05 to provide equipment layout drawings that show safe load paths and to provide a COL information item for COL applicants to provide procedures that define safe load paths.

In its response dated June 26, 2008, the applicant stated that the equipment layout drawings that show safe load paths are not provided in the DCD. This information is part of the operational programs and is covered by Section 13.4 of the DCD. The staff finds that Section 13.4 does not necessarily state that the COL applicant will develop procedures that show safe load paths. In evaluating the response, the staff determined that the applicant had not complied with the guidelines specified in NUREG-0800 Section 9.1.5 and NUREG-0612 as stated in that safe load paths had not been identified. Since the AP1000 is a standard design nuclear power plant where the location of all stationary equipment in non-site specific structures has been determined, generic safe load path figures should be developed for known heavy load lifts, such as the reactor vessel head and the spent fuel cask by the applicant for the AP1000 design.

To address the staff's concern, the applicant provided Revision 1 to its response to RAI-SRP9.1.5-SBPB-05, dated April 13, 2009. The applicant stated that a COL information item would be incorporated into the DCD requiring COL applicants to provide a heavy load handling program. The applicant proposed to modify DCD Section 9.1.5 to include a statement pointing out that DCD Section 13.5.1 addresses the development of heavy lift safe load paths. Following the guidance in NUREG-0800 Section 9.1.5 and NUREG-0612, the applicant proposed to modify DCD Section 13.5.1 to include the information that COL applicants referencing the AP1000 certified design would provide a heavy load handling program, which would include safe load paths for movement of heavy loads, to be referenced in procedures and shown on equipment layout drawings. DCD Section 13.5.1 includes the statement that the program and associated procedures will minimize the potential to impact irradiated fuel in the reactor vessel and in the SFP, and safe shutdown equipment from movement of heavy loads. The applicant also stated that it is currently developing drawings identifying safe load paths for the handling of heavy loads, which will then be provided to COL applicants for incorporation into their heavy load handling programs.

The applicant indicated that the revisions to DCD Tier 2 Sections 9.1.5 and 13.5.1 requiring that a COL applicant referencing the AP1000 certified design would provide a heavy load handling program, including safe load paths, would be added to the next DCD revision.

The staff finds the response acceptable since the applicant is developing standard safe load path drawings for heavy loads, which would be provided to the COL applicants. The applicant also added a COL information item for COL applicants to provide a heavy load handling program, which includes safe load paths to be referenced in procedures and shown on equipment layout drawings. It should be noted that the applicant has not created a completely new COL information item but added the requirement for a COL applicant to provide a heavy loads program to existing COL Information Item 13.5.1, which requires COL applicants to provide plant procedures.

The staff's concern described in RAI-SRP9.1.5-SBPB-05 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

NUREG-0800 Section 9.1.5 and NUREG-0612 provide guidance for applicants to describe a heavy load handling program for design, operation, testing, maintenance and inspection of heavy load handling systems. The applicant had not provided a heavy load handling program. Therefore, the staff requested the applicant in RAI-SRP9.1.5-SBPB-06 to provide a COL information item to ensure that the COL applicant will provide such a heavy load handling program.

In its response dated June 26, 2008, the applicant stated that it would provide the COL holders with the Operations and Maintenance Manuals for heavy load handling systems so that the manuals could be used when they created their programs. The applicant further stated that operations programs and procedures were discussed in Sections 13.4 and 13.5 of the DCD to include existing COL information items and no further COL Information Items were necessary. The staff determined that Sections 13.4 and 13.5 did not specify that the COL applicant would provide the heavy load handling program elements specified in NUREG-0800 Section 9.1.5 Section III.3 and NUREG-0612 Section 5.1.1. Therefore, the staff asked the applicant to revise the DCD to include a COL information item similar to RG 1.206, “Combined License Applications for Nuclear Power Plants,” Regulatory Position Part III, Section C.I.9.1.5.

To address the staff’s concern, the applicant provided Revision 1 to its response to RAI-SRP9.1.5-SBPB-06, dated April 13, 2009. The applicant’s revised response states that this concern is addressed in the applicant’s RAI-SRP9.1.5-SBPB-05, Revision 1 response.

The staff finds the applicant’s RAI-SRP9.1.5-SBPB-05, Revision 1 response, as discussed above, adequately addresses the addition of a DCD COL information item requiring a COL applicant to develop a heavy loads handling program. Therefore, RAI-SRP9.1.5-SBPB-06 is resolved.

In DCD Revision 17, Section 9.1.5.2.2.2, “Component Descriptions,” under the heading “Lifting Devices Not Specially Designed,” (for the cask handling crane), the applicant states that for the handling of <u>critical</u> loads, dual or redundant slings are used, or a sling having a load rating twice that required for a <u>non-critical</u> load is used. Therefore, the staff requested in RAI-SRP9.1.5-SBPB-02 that the applicant explain how the statements are in conformance with the NUREG-0612 criteria, when a sling having a load rating twice that required for a <u>non-critical</u> load is used instead of a load rating twice that required for a <u>critical</u> load. This same issue is in Section 9.1.5.2.1.2 of DCD Revision 16.

In its response dated June 26, 2008, the applicant stated that in selecting the proper sling for rigging, the load capacity of the sling should be greater than the sum of the maximum static and dynamic load to be lifted. The applicant then stated that no matter what type of load is being lifted “critical lift or non-critical lift,” the sling rating needs to take into account both static and dynamic loading. The response stated:

> But when you are making a “critical lift” then you must either:
>
> 1) Use two (2) of the properly rated slings per the formula above [the summation of the static and dynamic loads], OR
>
> 2) Use one (1) sling with twice (2x) the proper rating per the formula above.

In evaluating the response, the staff finds the applicant has clearly stated the application of the requirements of NUREG-0612 for selecting slings for lifting critical loads. The applicant has properly stated that for critical loads, redundant slings must be used or the selected sling must have a load rating of twice the minimum required capacity. In DCD Revision 17, the applicant elected to use the term “non-critical load” in making a comparison between the normal selection of a sling for lifting a load and the selection of a sling or redundant slings under NUREG-0612 for lifting a load that has been designated a critical load. A “non-critical” load would require only a single sling rated for the summation of the static and dynamic load required to be lifted. However, if the same load was declared a “critical” load, the capacity of the single sling would have to be doubled, or twice the capacity required for the “non-critical” load. Based on its review, the staff finds the applicant’s clarification of the DCD text acceptable and RAI-SRP9.1.5-SBPB-02 is resolved.

In DCD Revision 16, Sections 9.1.5.2.1.2 and 9.1.5.2.2.2, both titled “Component Descriptions,” the applicant stated under the headings “Lifting Devices Not Specially Designed” that slings or other lifting devices not specially designed are selected in accordance with ANSI B30.9, “Slings,” except that the load rating is based on the combined maximum static and dynamic loads that could be imparted to the sling. The two separate headings are associated with the polar crane and cask handling crane, respectively. NUREG-0800 Section 9.1.5 Revision 1, “Overhead Heavy Load Handling Systems,” states in Paragraph III.4.C.ii (2), that slings should satisfy the criteria of ASME B30.9 and be constructed of metallic material (chain or wire rope). Therefore, the staff requested the applicant, in RAI-SRP9.1.5-SBPB-03, to explain how the criterion that slings be constructed of metallic material (chain or wire rope) for single-failure proof cranes and hoists that are handling critical loads is satisfied.

In its response dated June 26, 2008, the applicant stated that in addition to the polar crane and cask handling crane, the maintenance hatch hoist and equipment hatch hoist use lifting devices not specially designed that meet the safety factor requirements of ASME B30.26 2004, “Rigging Hardware.” The applicant also stated the design specifications for the polar crane and cask handling crane reference ASME B30.9, “Slings,” and the NRC Regulatory Issue Summary (RIS) 2005-25, Supplement 1, “Clarification of NRC Guidelines for Control of Heavy Loads,” and that these references were added to the DCD. The supplement states that: Slings should satisfy the criteria of ASME B30.9-2003, “Slings,” and be constructed of metallic material (chain or wire rope). Revision 17 of DCD Sections 9.1.5.2.1.2 and 9.1.5.2.2.2 was revised to indicate that the slings shall be constructed of metallic material (chain or wire rope) per NRC RIS 2005-25, Supplement 1.

The staff finds the applicant committed to using slings made from metallic material when lifting critical loads. The applicant demonstrated that it is in compliance with NUREG-0800 Section 9.1.5, Revision 1, Paragraph III.4.C.ii (2), which specifies that slings should satisfy the criteria of ASME B30.9 and be constructed of metallic material (chain or wire rope). Therefore, the staff finds the applicant’s response to be acceptable and the staff’s concern described in RAI-SRP9.1.5-SBPB-03 is resolved.

In DCD Revision 16, Section 9.1.5.2.2.2, “Component Descriptions,” under the heading “Special Lifting Devices” (for the cask handling crane), the applicant stated that the special lifting devices used for the handling of critical loads are listed in Table 9.1.5-2. The staff’s review of Table 9.1.5-2 finds only special lifting devices for the polar crane and none for the cask handling crane. Existing plant operating experience demonstrates that a special lifting device is normally used between a cask and the cask handling crane hook due to the shape and size of the cask. Therefore, the staff requested the applicant in RAI-SRP9.1.5-SBPB-04 to explain if a special lifting device will be used between the cask and cask handling crane hook and if so, why it is not listed in Table 9.1.5-2. If a special lifting device is not used, the staff asked the applicant to explain the anticipated rigging of the cask to the cask handling crane hook.

In its response dated June 26, 2008, the applicant stated that special lifting devices will be used with the cask handling crane and will be added to the DCD in Table 9.1.5-2. The applicant, in its response, provided a markup of DCD Table 9.1.5-2, "Special Lifting Devices Used for the Handling of Critical Loads." The applicant added the following special lifting devices to Table 9.1.5-2 for the cask handling crane: cask lift yoke, cask lift yoke extension, and loaded canister handling equipment. The following description was also added to the table for these devices: These devices are used for the handling of the casks and loaded canisters, which provide the interface between the cask handling crane and the shipping cask or loaded canister.

In DCD Tier 2, Table 9.1.5-2 Revision 17, the applicant revised the table to show the special lifting devices to be used with the cask handling crane and also provided a description of the use of these devices. With the addition of the cask handling crane special lifting devices to DCD Table 9.1.5-2, the staff finds the applicant's response acceptable and the staff's concern described in RAI-SRP9.1.5-SBPB-04 is resolved.

9.1.5.2.5 Increase in Polar Crane Maximum Load Rating

TR-106 Revision 1 states the critical lift for the polar crane is the lifting of the Integrated Head Package from the Reactor Vessel to the in-containment storage stand during a refueling outage. The critical lift weight for the polar crane has been increased from 249.48 metric tons (275 tons) to 272.16 metric tons (300 tons) to ensure adequate lifting margin. Because the weight of the integrated head package is the critical lift for the polar crane that requires the polar crane to have its maximum load rating increased to 272.16 metric tons (300 tons), while still being a single-failure proof crane in compliance with GDC 2, 4, 5 and 61, the staff finds this design change to be acceptable.

9.1.5.2.6 Addition of Cask Handling Crane Component Data

TR-106 Revision 1 states the AP1000 cask handling crane design was neither seismically qualified, nor single-failure proof to protect against dropping a cask. Since a cask drop could cause significant plant damage; a design change was initiated to upgrade the cask handling crane to single-failure proof. This change was made to reduce the possibility of a serious plant event.

With this design change the crane name was changed from the spent fuel shipping cask crane to the cask handling crane. With the changing of the design of the cask handling crane (previously spent fuel shipping cask crane in DCD Revision 15) to single-failure proof in DCD Revision 17, Table 9.1.5-1 has been completely changed to provide cask handling crane component data. The previous information in Table 9.1.5-1 under Revision 15 was for a non-single-failure proof spent fuel cask crane. DCD Revision 17 Table 9.1.5-1 provides design information for the cask handling crane bridge, trolley, main hoist and auxiliary hoist. Because the addition of the component data for the cask handling crane in Table 9.1.5-1 is similar to the data provided in Table 9.1.5-3 for the polar crane and does not affect the single-failure proof cask handling crane's compliance with GDC 2, 4, 5 and 61, the staff finds this design change to be acceptable.

9.1.5.2.7 Polar Crane Main Hook Used to Lift RCP

TR-106 Revision 1 states the main hook on the polar crane, instead of the auxiliary hook of the polar crane, will be used to install and remove the RCPs. Since the main hook has a larger load capacity than the auxiliary hook and is single-failure proof, the applicant remains in compliance with GDC 4. Therefore the staff finds this design change to be acceptable.

9.1.5.2.8 Decrease in Polar Crane Auxiliary Hook Capacity

TR-106 Revision 1 states the auxiliary hook on the polar crane has been reduced from 68.04 metric tons (75 tons) to 22.68 metric tons (25 tons) now that it is no longer being used to install and remove the RCPs. Because the polar crane main hook will now be used with the RCP special lifting device instead of the auxiliary hook, the capacity of the auxiliary hook can be reduced from 68.04 metric tons (75 tons) to 22.68 metric tons (25 tons). The staff finds that with the change in lift capacity of the auxiliary hook, the polar crane remains a single-failure proof crane and in compliance with GDC 2, 4, 5 and 61.

9.1.5.2.9 Additional Staff Inquiries Associated With Overhead Heavy Load Handling

In RAI-SRP9.1.5-SBPB-07, the staff asked the applicant the following six clarifying questions to provide a better understanding of the applicant's submitted technical information:

a) In RAI-SRP9.1.5-SBPB-07, Subpart a, the staff asked the applicant to clarify if the cask handling crane was to be operated from either a radio remote control, operator's cab or a pendant suspended from the crane since it was not totally clear after a review of the information in TR-106 Revision 1.

In its response dated June 26, 2008, the applicant stated that the cask handling crane will be operated by radio remote control or from a pendant suspended from the crane and that the crane does not have an operator's cab.

Based on its review, the staff finds the applicant's response clarifies the wording in TR-106 and is consistent with DCD Revision 17, in that the applicant clarifies that the cask handling crane will be operated by either radio remote control or from a pendant suspended from the crane. The applicant also updated DCD Sections 9.1.5.2.1 and 9.1.5.2.2.1 to include the use of radio remote control for the polar and cask handling cranes. Therefore, the staff's concern described in RAI-SRP9.1.5-SBPB-07, Subpart a is resolved.

b) In RAI-SRP9.1.5-SBPB-07, Subpart b, the staff asked the applicant to clarify why in TR-106 Revision 1 for Design Change 256 the title of the design change is for the maintenance hatch hoist design while the cask handling crane is mentioned twice in the text explaining the design change.

In its response dated June 26, 2008, the applicant provided an excerpt from TR-106 Revision 1 of the text from Design Change 256 with the cask handling crane words crossed out in two places and replaced with the words Maintenance Hatch Hoist. No technical information that would affect the DCD was changed.

Based on its review, the staff finds the applicant's response acceptable because the applicant proposed corrections to the identification of the crane in TR-106 Revision 1, Design Change 256 from the cask handling crane to the maintenance hatch hoist; making the design change text agree with the design change title in TR-106. Therefore, no change to the DCD was needed and the staff's concern described in RAI-SRP9.1.5-SBPB-07, Subpart b is resolved.

c) In RAI-SRP9.1.5-SBPB-07, Subpart c, the staff asked the applicant to provide the correct section to which a reader is referred in the paragraph under Section 9.1.5.2, System Description, of AP1000 DCD Revision 16, since the currently referenced section does not exist.

In its response dated June 26, 2008, the applicant stated the correct referenced section is 9.1.5.3, not 9.1.5.2.3, and provided a markup of paragraph 9.1.5.2 from DCD Revision 16 showing the correction.

In DCD Tier 2, DCD Section 9.1.5.2 Revision 17, the applicant revised the referenced subsection to show 9.1.5.3. Therefore, the staff's concern described in RAI-SRP9.1.5-SBPB-07, Subpart c is resolved.

d) In RAI-SRP9.1.5-SBPB-07, Subpart d, the staff provided an excerpt from TR-106, Revision 1, Design Change Description for Design Change 170 (polar crane Design) which states: The critical lift for the polar crane is the lifting of the integrated head package (IHP) from the reactor vessel head to the in-containment storage stand during a refueling outage. The staff asked the applicant to clarify if the IHP is lifted by the polar crane from the reactor vessel head or from the reactor vessel, which components comprise the IHP, and if the IHP and reactor vessel head are two separate lifts by the polar crane.

In its response dated June 26, 2008, the applicant stated that the IHP is lifted by the polar crane from the reactor vessel. The IHP includes the reactor vessel head, the shield shroud, the control rod drive mechanism cooling fans, and the lifting rig. The IHP and the reactor vessel head are not two separate lifts.

Based on its review, the staff finds the applicant's response acceptable because the applicant clarified that the IHP is not lifted from the reactor vessel head as stated in TR-106, Revision 1, Design Change Description for Design Change 170. The IHP is lifted from the reactor vessel by the polar crane. The IHP and the reactor vessel head are not two separate lifts and the IHP is properly defined in Section 3.9.7 of the DCD. Therefore, the staff's concern described in RAI-SRP9.1.5-SBPB-07, Subpart d is resolved.

e) In RAI-SRP9.1.5-SBPB-07, Subpart e, the staff asked the applicant why the title for Section 9.1.6.5 of the AP1000 DCD Revision 16 was "Inservice Inspection Light Load Handling System," and did not include the OHLHS.

In its response dated June 26, 2008, the applicant stated the title for Section 9.1.6.5 should be changed to "Inservice Inspection Load Handling System" from "Inservice Inspection Light Load Handling System." Based on its review, the staff finds the applicant's response acceptable because the applicant proposes to revise the title of DCD Section 9.1.6.5 to cover both light and heavy load handling systems.

In DCD Tier 2, DCD Section 9.1.6.5 Revision 17, the applicant changed the name of this section from Inservice Inspection Light Load Handling Systems to Inservice Inspection Load Handling Systems. Therefore, the staff's concern described in RAI-SRP9.1.5-SBPB-07, Subpart e is resolved.

f) In RAI-SRP9.1.5-SBPB-07, Subpart f, the staff stated that the cask handling crane was still referred to as the spent fuel shipping cask crane in Tier 1 Section 2.3.5, Item Number 4 of AP1000 DCD Revision 16 and the section needed correction.

In its response dated June 26, 2008, the applicant states the cask handling crane should not be referred to as the spent fuel shipping cask crane and the DCD needs to be changed in four sections to make the correction. The applicant provides two excerpts from Tier 1 and two excerpts from Tier 2 of the DCD showing where the words spent fuel shipping cask had been crossed out and replaced with cask handling. Based on its review, the staff finds the applicant's response acceptable because the applicant corrected the name of the cask handling crane from spent fuel shipping cask crane in four sections of DCD Revision 17. In DCD Tier 1, Revision 17, Section 2.3.5 and Table 2.3.5-2, the applicant changed the name of the previously shown spent fuel shipping cask crane to cask handling crane. In DCD Tier 2, Revision 17, Sections 9.1.5.3 and 14.2.9.4.14, the applicant also changed the name of the previously shown spent fuel shipping cask crane to cask handling crane. Therefore, the staff's concern described in RAI-SRP9.1.5-SBPB-07, Subpart f is resolved.

In RAI-SRP9.1.5-SBPB-10, the staff requested additional information related to heavy load drop analysis. In the AP1000 DCD Tier 2, Revision 16, Section 9.1.5.3, "Safety Evaluation," the applicant states: "Postulated load drops are evaluated in the heavy load analysis." In the last sentence of Section 9.1.5.3 the applicant states, "The heavy load analysis is to confirm that a postulated load drop analysis does not cause unacceptable damage to reactor fuel elements, or loss of safe shutdown or decay heat removal capability." The staff asked the applicant to describe what heavy load drop analyses were performed and to describe the results of the analyses.

In its response dated September 3, 2008, the applicant stated that the polar crane, cask handling crane, equipment hatch hoist, and maintenance hatch hoist are single-failure proof, which satisfies the requirements for moving heavy loads, and no heavy load drop analysis was performed. The applicant added single-failure proof criteria to ITAAC Table 2.3.5-2 in DCD Revision 17 for all four of these load handling systems, as identified in its response to RAI-SRP9.1.5-SBPB-09. Additionally, the applicant stated that the main steam isolation valve (MSIV) monorail hoists A and B are used to perform maintenance on the MSIVs. However, the hoists will not be used during plant operation and, therefore, failure of the hoists (while lifting loads) will not prevent the plant from shutting down safely because the plant will already be shut down.

Based on its review, the staff finds acceptable the part of the applicant's response, that states that no heavy load drop analyses are required for the polar crane, cask handling crane, equipment hatch hoist, and maintenance hatch hoist because they are designed single-failure proof. However, the staff determined that the response was unacceptable regarding the MSIV monorail hoists A and B, because the applicant did not address the effect of a load drop on equipment needed for decay heat removal.

To address the staff's concern, the applicant provided Revision 1 to its RAI-SRP9.1.5-SBPB-10 response, dated January 28, 2009. The applicant stated the plant modes in which the main steam isolation values must be operable. Because the MSIVs and main steam safety valves (MSSVs) have to be operable or closed during plant modes 1, 2, 3, and 4, the MSIV monorail hoists shall not be used to service the MSIVs or MSSVs during Modes 1, 2, 3, or 4. The applicant further stated that during Modes 5 and 6 the steam generators are not utilized for nonsafety-related decay heat removal and the MSIVs could be taken out of service. Therefore, a load drop by the MSIV monorail hoists during modes 5 or 6 would not affect decay heat removal capability of the AP1000.

Based upon its review, the staff determined that the response was unacceptable regarding the MSIV monorail hoists A and B, because the applicant did not address the effect of a load drop on equipment needed for decay heat removal.

To address the staff's concern, the applicant provided Revision 2 to its RAI-SRP9.1.5-SBPB-10 response, dated April 13, 2009. The applicant's revised response states that equipment and components required for decay heat removal during Modes 5 or 6 are not located in the load path for the MSIV monorail hoists.

In the revised response, the applicant proposed revisions to DCD Tier 2 Section 9.1.5.3 that explicitly state that the equipment and components required for decay heat removal during Modes 5 or 6 are not located in the load path of the MSIV monorail hoists.

The staff finds the response acceptable since the applicant clarified that equipment and components required for decay heat removal during Modes 5 or 6 are not located in the load path for the MSIV monorail hoists. The staff's concern described in RAI-SRP9.1.5-SBPB-10 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

9.1.5.2.10 Staff Inquiry Regarding Design Changes in TR-106 not reflected in DCD Revision 16

In RAI-SRP9.1.5-SBPB-08, the staff stated that TR-106, Revision 1 in Section V described post AP1000 Revision 16 changes. The staff provided paragraphs a through d of TR-106, Section V showing the post DCD Revision 16 changes and asked the applicant to verify if the changes would be documented in the DCD.

In its response dated June 26, 2008, the applicant stated that all the post AP1000 Revision 16 design changes described in TR-106, Revision 1, Section V would be incorporated in Revision 17 of the DCD.

In Revision 17 of the DCD Tier 2, Sections 9.1.5.2.1.3, 9.1.5.2.2.3 (both sections titled "Instrumentation Applications"); 9.1.5.3, "Safety Evaluation": Table 9.1.5-1, "Cask Handling Crane Component Data"; and Table 9.1.5-3, "Polar Crane Component Data," the applicant has incorporated the changes shown in TR-106 Revision 1 Section V.

In the three DCD Tier 2 sections and two DCD Tier 2 Tables listed above, the applicant proposed changes to align DCD Section 9.1.5 and the associated tables with ASME NOG-1 and NUREG-0554 for single-failure proof cranes.

Specific DCD Revision 17 changes include:

1. In DCD Section 9.1.5.3 the applicant stated that either redundancy or double design factor for load bearing components such as the hoisting ropes, sheaves, equalizer assembly, hooks and holding brakes of single-failure proof cranes is permitted.

The staff determined that the proposed change for potentially allowing redundancy for all load bearing components was unacceptable because it describes a non-redundant equalizer device as acceptable and because the new statement regarding which components must be redundant was ambiguous. Every component of the reeving system must be redundant except the rope drum, the upper block, the load block, and the hook (which is part of the load block). Among the components listed in TR-106, only design of the hook to twice the normal design load is acceptable in place of redundant hooks. The staff determined that the reference to NUREG-0554, Paragraph 4.3 in TR-106 does not provide the criteria for alternatives to redundancy in load attachment points; those criteria are in Appendix C to NUREG-0612 and ASME NOG-1.

In a letter dated September 8, 2009, the applicant provided a revised response to RAI-SRP9.1.5-SBPB-08. The applicant provided additional changes to DCD Section 9.1.5.3 to provide additional clarification to comply with ASME NOG-1. The staff finds the proposed changes comply with NOG-1 and are acceptable. Therefore, the staff's concern described in RAI-SRP9.1.5-SBPB-08 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

2. In DCD Tables 9.1.5-1 and 9.1.5-3, the applicant changed wording for the Bridge and Trolley sections to reflect that service, emergency, and parking functions may be performed by a single friction brake.

3. In DCD Sections 9.1.5.2.1.3 and 9.1.5.2.2.3, the applicant stated that the hoist in the raising direction for the polar crane and cask handling crane has block-actuated limit switches, which directly interrupt power to the hoist motor and cause the hoist brakes to set.

4. In DCD Tables 9.1.5-1 and 9.1.5-3, the applicant added information on control, holding and emergency brakes for the main hoist and auxiliary hoist.

TR-106 Revision 1 states that changes 2, 3 and 4 were made to better align the DCD design data for the single-failure proof polar crane and cask handling crane. The staff finds changes 2, 3, and 4 acceptable, since the guidance in NUREG-0554, as supplemented by ASME NOG-1 for single-failure proof cranes, is followed. In accordance with NUREG-0800 Section 9.1.5, cranes designed to the criteria of NOG-1 for a Type 1 crane are acceptable under the guidelines of NUREG-0554 for construction of a single-failure proof crane.

9.1.5.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for the DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the applicant's proposed changes to the AP1000 OHLHS as documented in AP1000 DCD, Revision 17, and in TR-106, Revision 1, which include a design description for the cask handling crane, an upgrade designation of the cask handling crane to seismic Category I and single-failure proof, an upgrade of the maintenance hatch hoist to single-failure proof, a designation of ASME NOG-1 for a Type 1 crane for single-failure proof cranes and hoists, the replacement of pendant control to remote control for the polar crane, and the change in design capacity of the main and auxiliary hooks of the polar crane. The staff concludes that the AP1000 OHLHS design continues to meet all applicable acceptance criteria and the proposed changes are properly documented in the updated AP1000 DCD. The proposed changes meet the criteria of; 10 CFR 52.63(a)(1)(vi), on the basis that they substantially increase overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security; and 10 CFR 52.63(a)(1)(vii), on the basis that they contribute to the increased standardization of the certification information in the AP1000 DCD. Therefore, the staff finds that the proposed changes to the AP1000 OHLHS are acceptable.

9.2 Water Systems

9.2.1 Service Water System

9.2.1.1 Summary of Technical Information

Revision 17 of the AP1000 DCD includes proposed changes to the service water system (SWS) in order to accommodate increased heat loads, establish increased wet and dry bulb temperature limits for the site, and to provide additional design flexibility for COL applicants. The details of these proposed changes are discussed in TR-111, “Component Cooling System and Service Water System Changes Required for Increased Heat Loads,” APP-GW-GLN-111, Revision 0, dated May 2007; TR-108, and TR-103.

In AP1000 DCD Revision 17, the applicant proposed Tier 2 changes associated with SWS Section 9.2.1.2.2 “Component Description – Piping Requirements.” The applicant corrected the referenced code to use for nonmetallic piping from “ASME B31.1” to “ANSI B31.1, Appendix III.”

The applicant proposed a change to Tier 1 Table 5.0-1, “Site Parameters,” to increase the maximum safety coincident wet bulb temperature from 29.7 °C (85.5 °F) to 30.1 °C (86.1 °F) and non-coincident wet bulb temperature from 29.7 °C (85.5 °F) to 30.1 °C (86.1 °F). The details of this change are discussed in APP-GW-GLE-036, Revision 0. Because this change could impact the SWS performance, it is evaluated below. In Revision 17, the applicant made no changes to DCD Tier 1, Section 2.3.8, “Service Water System.”

9.2.1.2 Evaluation

The regulatory basis for evaluating the SWS is documented in Section 9.2.1, “Station Service Water System,” of NUREG-1793. While the SWS (including heat sink) is nonsafety-related, it is considered to be important to safety because it supports the normal defense-in-depth (DID) capability of removing reactor and spent fuel decay heat, it is part of the first line of defense for reducing challenges to passive safety systems in the event of transients and plant upsets, and its cooling function is important for reducing shutdown risk when the RCS is open (e.g., mid-loop condition). The risk importance of the SWS makes it subject to RTNSS in accordance with the Commission’s RTNSS policy in SECY-94-084 for passive reactor plant designs. The staff’s evaluation of the changes that are proposed focuses primarily on confirming that the changes will not adversely affect safety-related SSCs, the capability of the SWS to perform its DID and RTNSS functions, and the adequacy of ITAAC, test program specifications, and RTNSS availability controls that have been established for the SWS. The proposed changes were evaluated using the guidance provided by NUREG-0800 Section 9.2.1, “Station Service Water System,” as it pertains to these considerations. Acceptability is judged based upon conformance with the existing AP1000 licensing basis, the guidance specified by NUREG-0800 Section 9.2.1 (as applicable), and SECY-94-084.

The specific criteria that apply to the changes referred to above include 10 CFR 52.63(a)(1)(iii), which concerns the proposed changes reducing unnecessary regulatory burden while maintaining protection to public health and safety and the common defense and security; and 10 CFR 52.63(a)(1)(vii), which concerns the proposed changes contribution to increased standardization of the certification information.

9.2.1.2.1 SWS Design Changes Required for Increased Heat Loads

As discussed in TR-111, increased CCS heat loads and flow rates have resulted in the need for corresponding increases in SWS flow and pump capacity, pipe and component size, and cooling tower heat dissipation capability and makeup rate. The proposed SWS changes are reflected in the AP1000 DCD, Tier 1, Table 2.3.8-2, ITAAC Design Commitment Item 2 relative to the capability to support plant shutdown and spent fuel cooling; Tier 2, Table 9.2.1-1, “Nominal Service Water Flows and Heat Loads at Different Operating Modes;” and Tier 2, Table 16.3-2, “Investment Protection Short-Term Availability Controls (IPSAC),” Section 2.4, “Service Water System (SWS) – RCS Open,” SR 2.4.1 with respect to the minimum required SWS flow rate. Section 9.2.2 provides an evaluation of the increased CCS heat loads.

<u>Proposed Increases in SWS Flow Rate and Heat Dissipation Capability</u>

The applicant proposed to increase the minimum required SWS flow rate and heat dissipation capability in order to accommodate the higher heat loads that are proposed for the AP1000 plant design. The values listed in Tier 2 of the DCD, Table 9.2.1-1, and the ITAAC specified by Tier 1 of the DCD, Table 2.3.8-2, reflect these changes. The ITAAC requires COL applicants to demonstrate that the SWS design is capable of supporting plant shutdown and spent fuel cooling. The applicant proposed to change the flow rate value in the ITAAC that demonstrates, by testing, that each SWS pump can deliver at least 37,854 Lpm (10,000 gpm) flow to each CCS HX. The applicant also proposed to increase the required heat transfer rate that is specified for each cooling tower cell to be greater than or equal to 1.8×10^8 kilojoules per hour (kJ/h) (1.7×10^8 Btu/h) at a cold water temperature of 32.2 °C (90 °F). The proposed changes in the ITAAC acceptance criteria relative to SWS flow rate and heat load are consistent with the revised values that are reflected in Tier 2, Table 9.2.1-1, and they appear to be acceptable from this perspective. However, the applicant did not specifically identify how the revised values were determined and on what basis they are considered to be appropriate. For example, the applicant did not explain how the maximum heat load was determined and how much margin is afforded by the ITAAC acceptance criterion. The applicant did not compare the available margin with the amount of margin that is needed based on industry experience to accommodate degradation that is anticipated to occur over time and provide necessary flexibility. Also, the applicant did not explain why the bases for these values and the industry experience that is credited applies to all COL applicants.

The applicant was asked, in RAI-SRP9.2.1-SBPA-01, to provide a more detailed description of the basis for the proposed changes relative to SWS flow rate and cooling tower performance in Tier 2 of the DCD. The applicant responded to the staff’s request in a letter dated June 26, 2008. The applicant referred to information in the application that was considered by the staff when preparing this question, but a more detailed description was not provided. The applicant also provided information to explain how cooling tower performance and SWS flow rates would be maintained over time. While this information is useful, no provisions were established to assure implementation by COL applicants. The RAI response did not adequately address RAI-SRP9.2.1-SBPA-01 because more information was needed regarding RTNSS and systems supporting the ability to achieve cold shutdown operations.

During the June 25, 2009 audit, the staff explained that in order to resolve the RAI, the applicant should provide more detail explaining how the design margins were established and the maintenance and testing activities that ensure that the margins are adequately preserved over the life of the plant.

In a letter dated August 31, 2009, the applicant provided additional information specific to the design margins, appended to its original response to RAI-SRP9.2.1-SBPA-01. Additionally, the applicant provided a proposed mark up of DCD Tier 2, Section 9.2.1.2.3.4 that supports the information provided in the additional information.

The response identified that the SWS is designed with sufficient margin to ensure that system flow rates and cooling tower performance will be maintained such that RTNSS and DID functions can be performed over the life of the plant. The response described the following functions that meet criteria for DID functions of the CCS as they relate to the SWS:

- For normal residual heat removal system (RNS) cooling, the SWS and CCS are needed to cool the RNS HXs and pumps during RCS cooldown and cold shutdown operation, in order to avoid actuation of the passive residual heat removal (PRHR) HX. The SWS and CCS also provide cooling to the RNS during refueling operation, to avoid heat up of the water in the refueling cavity.

- For SFS cooling, the SWS and CCS provide cooling to the SFS HXs during all modes of plant operation to prevent heat up and boiloff of water in the SFP.

- For CVS miniflow HX cooling, the SWS and CCS provide cooling to the miniflow HXs of the CVS injection pumps. This allows proper operation of the CVS injection pumps, in order to avoid core makeup tank (CMT) actuation.

- For reduced inventory cooling, the SWS and CCS provide cooling to the RNS HXs and pumps during reduced reactor coolant inventory operation.

The response specified that the SWS also supports a function of the CCS that is important for equipment protection by providing necessary cooling to the RCP external HX to avoid reaching high bearing water temperatures and its resulting RCP trip.

The response also identified the SWS heat loads as requested by the staff. The heat loads include the RCP external HX, the SFS HX, and the CVS miniflow HX. The response stated that the cooling functions for the CCS and SWS are dependent on the temperature supplied by the CCS HX. The response also explained that, of these three functions, the RCP external HX cooling function has the lowest design temperature requirements and, therefore, provides the high CCS design temperature.

The ability of the CCS to meet the RCP cooling requirement was evaluated by considering the design operating mode for the CCS HX, which is normal power operation. The CCS HX overall coefficient of heat transfer (U) and required heat transfer area (A) was computed by ensuring that the high CCS design temperature limit was not exceeded during this design case. The total normal power operating heat duty included the maximum SFS heat duty (which is immediately after refueling), maximum heat dissipation by the RCPs, as well as a 20 percent margin above the maximum central chilled water system (VWS) chiller heat load. The SWS temperature supplied to the CCS HX also included additional margin, since the maximum cooling tower approach temperature was added to the maximum safety wet bulb.

The response explained that the SWS cooling towers are sized for both plant cooldown (higher heat loads) and normal power operation (lower heat loads). The CCS HX design is able to supply cooling water that meets all of the DID and investment protection cooling requirements under the most limiting conditions. The CCS HX specification also includes an additional 10 percent of heat transfer area above the design value to account for fouling and degradation over the HX's operating life. Additional frame length is also included so that 20 percent more than the nominal plate number required to provide the design heat transfer capability can be added to the HX if additional performance is needed.

SWS cooling tower performance is maintained by providing substantial margin in the sizing of the cooling tower. The SWS cooling towers were sized using a peak cooldown heat duty that includes significant conservatism. The cooling towers must be able to remove sufficient heat to cool down the RCS via the RNS, starting 4 hours after reactor shutdown, to cold shutdown conditions 96 hours after shutdown, assuming the persistence of the ambient wet bulb temperature at the maximum normal value of 26.7 °C (80.1 °F). This assumption itself provides substantial margin since the definition of the AP1000 maximum normal temperature value is based on the 1 percent seasonal exceedance wet bulb temperature, which can be experienced for fewer than 30 hours per year. The sizing case assumes that all four RCPs and variable frequency drives (VFDs) are operating at maximum allowable speed, though procedurally only two RCPs and RCP VFDs should run at 50 percent speed (or less) during this condition. Significant margins in the SFS and VWS chiller heat loads were included, as they were for the normal power operating design case. The margin included in these major heat loads, as well as several others, results in approximately 30 percent margin in the SWS cooling tower design heat duty, with respect to the expected heat duty during a realistic plant cooldown. Since the SWS tower cells are sized to meet cooldown time requirements under this extremely conservative operating case, any long term degradation in cooling ability under more realistic heat duties would not prevent the tower from meeting its heat transfer performance requirements.

It should also be noted that the DID and RTNSS functions of RNS cooling during RCS cooldown and RNS cooling during reduced coolant inventory operation require that the CCS provide cooling during these operating modes, and does not require specific temperature limitations or impose defined time to temperature requirements on the CCS and SWS. The CCS and SWS need to be designed to prevent heat up of the RCS if one train of CCS and SWS is not operable. Heat-up needs to be prevented even under maximum normal ambient wet bulb temperature conditions, though the time to cool down can be extended. This capability of the CCS and SWS also ensures that the DID function of the CCS and SWS can be fulfilled even assuming significant degradation in the CCS HX and SWS cooling tower performance, when both trains are operable. Similarly, ambient conditions above the maximum normal wet bulb temperature would not prohibit the CCS and SWS from performing this function, though cooldown times would be extended. The ability of the CCS and SWS to cool the RNS HXs during reduced coolant inventory operation (Modes 5 and 6) is further assured since the heat duty in this mode of operation is significantly reduced. The overall heat duty of the CCS and SWS in this mode is approximately 33 percent of the heat duty at the beginning of normal RNS cooldown,

The SWS pumps are required to provide a nominal flow rate of 39,750 Lpm (10,500 gpm) to cool the CCS HX for all normal operating modes, though a degraded minimum flow rate of

(10,000 gpm) can support decay heat removal from the RNS and SFS systems. In the RAI response, the applicant stated that the SWS flow analysis indicates that the selected SWS pump delivers 39,750 Lpm (10,500 gpm) to the CCS HX for all normal operating modes with all flow resistances (k-values) in the system increased by 10 percent. An additional 7 percent margin in pump-developed head at the design point is added to the system pump curve, specifically to offset any long-term degradation of pump performance during the life of the plant.

There is also a SR in the SWS investment protection short-term availability controls to verify that each SWS pump provides a flow rate of 37,850 Lpm (10,000 gpm) one day prior to entering Mode 5 and reduced-inventory operation.

The staff's review of the applicant's response to RAI-SRP-9.2.1-SBPA-01 finds that it adequately explains how the margins in SWS system design were developed. Also the staff finds that the response adequately explained how the flow margins would be tested and maintained for the life of the plant since testing/surveillance is performed before entering Mode 5. The staff also reviewed the proposed changes to DCD Section 9.2.1.2.3.4 and finds that they adequately provide a high level description of the SWS margin. Therefore, RAI-SRP9.2.1-SBPA-01 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Design Considerations

In addition to accommodating the higher CCS heat load while maintaining appropriate SWS flow velocities and pressure drops, the SWS return temperature to the cooling tower is not allowed to exceed 48.9 °C (120 °F) under design heat load conditions. As discussed in Section 3.4.1 of TR-111, this limit is set to prevent long-term degradation of the cooling tower fill material. In order to assure that this temperature limit will not be exceeded upon initiation of shutdown cooling when the SWS heat load is maximized at 3.65 x 10^8 kJoules/hr (3.46 x 10^8 Btu/hr), the applicant proposes to use larger capacity SWS pumps with a flow rate of 37,747 Lpm (10,500 gpm) per train. The use of larger capacity pumps will avoid delays when cooling down the plant in preparation for refueling and this is considered to be acceptable by the staff since the shutdown timeframe is enhanced. However, this design capability does not ensure that plant operators will adhere to this temperature limit. The staff requested, in RAI-SRP9.2.1-SBPA-02, that the applicant identify and describe in Tier 2 of the DCD those SWS design limitations that should be adhered to and explain how adherence to these limitations is assured. The applicant responded to the staff's request in a letter dated June 26, 2008. The applicant provided additional information about the system design margins, alarms, and capabilities, and discussed cooling tower fill material options that are available for higher temperature situations. However, the response did not adequately address the staff's request in that SWS design limitations and provisions to ensure adherence were not discussed. More information was requested in RAI-SRP9.2.1-SBPA-02 regarding RTNSS and systems supporting the ability to achieve cold shutdown operations.

During the June 25, 2009 audit, the staff explained that in order to resolve this RAI, the applicant should provide more detail identifying in Tier 2 of the DCD those SWS design limitations that should be adhered to and to explain how these limitations are assured including the addition of instrumentation if required. In a letter dated August 31, 2009, the applicant provided additional information specific to the design limitations appended to its original response to RAI-SRP9.2.1-SBPA-02.

The applicant agreed that SWS cooling tower basin water level Instrumentation was necessary and should be included in ITAAC. The response stated that this parameter is needed to verify that SWS pumps will be supplied with adequate net positive suction head (NPSH). Testing to verify adequate NPSH is also discussed in Tier 2 Section 14.2.9.2.6, "Service Water System Testing," in the item (d) of the 'General Test Acceptance Criteria and Methods. The applicant proposed to revise DCD Tier 1 Table 2.3.8-2 to identify the service water cooling tower basin level instrument, SWS-009.

The staff reviewed the applicant's additional information in its response to RAI-SRP9.2.1-SBPA-02 and finds that it provides an adequate means to measure the service water cooling tower basin level and ensures adequate SWS NPSH that can be verified by testing. The staff also reviewed the proposed changes to the DCD and finds that they adequately provide the instrumentation required to ensure adequate SWS NPSH. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The proposed increase in SWS capacity and flow rate is expected to result in an increase in the minimum water inventory that must be maintained in the cooling tower basin. The applicant did not describe specifically what water inventory should be maintained in the cooling tower basin in order to support SWS operation and, in particular, to assure adequate net positive suction head for the SWS pumps. In RAI-SRP9.2.1-SBPA-03 the staff asked the applicant to identify and describe in Tier 2 of the DCD the cooling tower basin water inventory requirements, the basis for this determination, and how this inventory is assured to be maintained. The applicant responded to the staff's request in a letter dated June 26, 2008. The applicant provided information to explain the design capability of the cooling tower basin inventory and while this information is useful, specific quantitative information is needed to verify the adequacy of design. For example, the specific NPSH requirements for the SWS pumps was not provided and design details of the cooling tower basin were not provided to show that the NPSH requirement was satisfied; other considerations such as vortexing were not addressed. Furthermore, this information was not included in the Tier 1 and Tier 2 descriptions as appropriate, and there was no discussion about how implementation of operational assumptions is assured. Additionally, the response made reference to use of a raw water system (RWS) for providing makeup to the SWS cooling tower basin, which has not been described for the AP1000 design in accordance with 10 CFR 52.47(24), "Contents of applications; technical information" requirements. Consequently, the response did not adequately address RAI-SRP9.2.1-SBPA-03.

During the June 25, 2009 audit, the staff explained that in order to resolve this RAI, the applicant should provide more information on its evaluation of whether it is reasonable to have a cooling tower level requirement prior to going to mid-loop operations for RTNSS considerations, and entering Modes 5 and 6. The staff also asked the applicant to evaluate and describe the differences in water level versus usable volume (in the SWS cooling tower basins) between normal operation and RTNSS.

In a letter dated August 31, 2009, the applicant provided additional information specific to the design limitations appended to its original response to RAI-SRP9.2.1-SBPA-03. In the response, the applicant agrees with the need to add SWS cooling tower basin usable volume to the ITAAC for SWS. A minimum SWS cooling tower basin reserve volume is required to provide water inventory for up to 12 hours when normal makeup capability from the RWS is lost. The basin is sized to contain 870,600 L (230,000 gallons) between the low level alarm setpoint (elevation 30.2 m (99 ft)) and the lowest usable level (28.5 m(93 ft, 6 in)), which coincides with the low-low level alarm setpoint. This is the minimum cooling tower usable volume needed to support a plant cooldown for 12 hours without makeup. The response states that a criterion will be added to the SWS ITAAC to ensure that the SWS cooling tower basin is constructed to provide this minimum reserve volume with water level at the low level alarm setpoint. Additionally, the applicant proposes to revise Table 2.3.8-2, ITAAC Item 2 to add testing requirements confirming that the SWS cooling tower basin has adequate reserve volume of at least 870,600 L (230,000 gallons) corresponding to its low level alarm setpoint. Additionally, the applicant proposed to revise Tier 2 DCD Section 9.2.1.2.2 for the cooling tower to identify that a minimum usable volume of 870,600 L (230,000 gallons) exists.

The staff reviewed the applicant's additional information in its response to RAI-SRP9.2.1-SBPA-03 and finds that it adequately identifies that the service water cooling tower basin level will have a usable minimum of 870,600 L (230,000 gallons) corresponding to its low level alarm setpoint. The staff also reviewed the proposed changes to the DCD and finds that they adequately provide ITAAC criteria ensuring the testing to confirm the usable volume. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The increased water inventory and flow rates in the SWS piping and cooling towers could result in more severe flooding consequences than previously analyzed. The information that was provided did not describe the impact of the proposed SWS modifications on the consequences of flooding and whether or not safety-related equipment could be adversely affected. The applicant was asked, in RAI-SRP9.2.1-SBPA-04, to address the potential impact of the proposed SWS modifications on safety-related equipment and on the consequences of flooding.

In a letter dated June 26, 2008, the applicant provided information specific to flooding. In the response the applicant stated that there is no safety-related equipment in the turbine building. The component cooling water and service water components on elevation 30.5 m (100 ft), which provide the RTNSS support for the normal RNS are expected to remain functional following a flooding event in the turbine building since the pump motors and valve operators are above the expected flood level. Flooding caused by an SWS piping break in the compartment at the southern end of the turbine building will flow out the open doorway to the turbine hall, and openings in the base of the wall between the compartment and the turbine hall. The increased flooding rate and volume associated with the increase in SWS pump size and basin inventory will not challenge the operability of the CCS pumps nor any other DID or Investment Protection equipment located in this area. Flooding from the circulating water system (CWS) (or from any other turbine hall water source) will flow out of the turbine building onto the ground through access doors without affecting equipment at the southern end of the building.

The staff reviewed the RAI response and concluded that the RTNSS components (CCW and SWS) would remain functional since the pump motors and valve operators are above the expected flood levels and there are no safety-related components in the turbine building. Therefore, RAI-SRP9.2.1-SBPA-04 is considered closed.

9.2.1.2.2 Proposed Increase in the Maximum SWS Supply Temperature

Proposed Revision 16 of the DCD, Tier 2, Sections 9.2.1.1.2 and 9.2.1.2.3.3, reflects an increase in the maximum allowed SWS cooling water temperature being supplied to the CCS HXs during normal power operation. The proposed temperature increase is from a value of 31.7 °C (89 °F) to 34.2 °C (93.5 °F). This is not the same as the maximum SWS supply temperature of 31.4 °C (88.5 °F) that is specified in Tier 2 of the DCD, Section 9.2.1.2.3.4, for plant cooldown/shutdown. This change is not discussed or explained in the information that the applicant provided, and it is not clear how the SWS can perform its DID and RTNSS functions if the SWS supply temperature exceeds the limit that is assumed for shutdown cooling. In RAI-SRP9.2.1-SBPA-05 the staff requested that the applicant describe in Tier 2 of the DCD the basis and justification for the proposed increase in the maximum allowed normal operating SWS supply temperature.

The applicant responded to the staff's request in a letter dated June 26, 2008. The applicant discussed differences in assumptions that were used for dissipating heat during normal power operation and during plant cooldown. The difference in the cooling water temperature values noted above stems from the use of a less conservative wet bulb temperature for the most limiting SWS DID function (plant cooldown with concurrent spent fuel cooling). However, the applicant did not explain how the SWS DID and RTNSS functional capabilities are assured for those periods when humidity is at its maximum. There is an increased chance of plant trip during hot, humid conditions due to increased electrical demand and it is illogical to assume less humid conditions for the plant cooldown case than what can be experienced during normal power operation. In accordance with SECY-94-084, the SWS should be capable of performing its DID and RTNSS functions over the full range of postulated operating conditions, and the applicant has not demonstrated this to be the case. The applicant response also referred to another increase that is proposed for the maximum safety wet bulb temperature in order to accommodate the Levy site. Because the RAI response did not adequately address the DID and RTNSS functional capabilities of the SWS over the full range of plant operating conditions, satisfactory resolution of RAI-SRP9.2.1-SBPA-05 was not achieved.

On March 18, 2009, the staff conducted a public meeting with the applicant to discuss this RAI. After this meeting, the applicant provided a revised RAI response on May 13, 2009, which addressed wet bulb temperature values related to the SWS to accommodate the Levy site environmental parameters. The applicant stated that the maximum normal non-coincident wet bulb temperature remains at 26.7 °C (80.1 °F) for RTNSS and DID SWS functions and that there was sufficient margin in the system and component design.

In a letter dated May 13, 2009, the applicant stated that higher ambient temperatures (30.0 °C (86.1 °F) vs. 26.7 °C (80.1 °F)) will not impact safety or investment protection and would only result in an extended time to achieve cooldown. During the June 25, 2009 audit, the applicant clarified its original response and supplemental responses. The staff agreed that the responses were acceptable because safety was not impacted while cooldown time was extended; therefore, RAI-SRP9.2.1-SBPA-05 is resolved.

9.2.1.2.3 Impact of Revised Site Interface Temperature Limits on Cooling Tower Performance

As discussed in TR-108, the applicant proposes to change the site interface temperature limits to encompass a broader range of potential sites for AP1000 plants. In particular, Tier 1 of the DCD, Table 5.0-1, “Site Parameters,” is revised to specify a maximum (noncoincident) wet bulb temperature of 29.7 °C (85.5 °F) instead of 27.2 °C (81 °F). Tier 2 of the DCD, Table 2-1, “Site Parameters,” is revised to reflect this higher (noncoincident) wet bulb temperature as the Maximum Safety (or 0 percent exceedance) value, and the Maximum Normal (or 1 percent exceedance) wet bulb temperature is revised from 25 °C (77 °F) to 26.7 °C (80.1 °F) for the coincident value and from 26.7 °C (80 °F) to 26.7 °C (80.1 °F) for the noncoincident value. The proposed change to the maximum normal noncoincident value is reflected in the DCD Tier 1 ITAAC that are specified in Table 2.3.8-2 and is referred to in DCD Tier 2, Section 9.2.1.2.3.4, “Plant Cooldown/ Shutdown.”

The ITAAC requires COL applicants to demonstrate that each cooling tower cell is capable of dissipating the specified shutdown and spent fuel heat loads at the maximum normal (non-coincident) wet bulb temperature. The proposed change in the ITAAC relative to the wet bulb temperature assumption is consistent with the proposed changes in the site interface temperature limits, and it is acceptable from this perspective. However, the difference between the maximum normal and maximum safety non-coincident wet bulb temperatures was rather trivial, only 0.5 °C (1 °F) before the proposed change; but after the proposed change the gap is widened to 3 °C (5.4 °F). This larger delta between the maximum normal and maximum safety non-coincident wet bulb temperature values warrants further consideration to assure that cooling tower performance is adequate for accomplishing its DID and RTNSS functions. Also, because Tier 2 of the DCD, Sections 5.4.7.1.2.3 and 9.2.2.1.2.1 indicate that cooling tower performance is based upon the maximum safety non-coincident wet bulb temperature as a limiting assumption, it is not clear how this capability is assured. Furthermore, the cooling tower cold water temperature that is specified by the ITAAC is revised from 37.8 °C (100 °F) to 32.2 °C (90 °F) without explanation or justification. This does not appear to be consistent with the supply temperature of 34.2 °C (93.5 °F) that is assumed in Tier 2 of the DCD, Section 9.2.1.1.2. Given these observations, the staff requested In RAI-SRP9.2.1-SBPA-06 that the applicant identify and explain in Tier 2 of the DCD the limiting assumptions and bounding conditions that are important relative to cooling tower design, performance, and operation for assuring that the SWS is capable of and can be relied upon to perform its DID and RTNSS functions, what provisions exist to ensure that these limiting assumptions and bounding conditions will be satisfied by COL applicants over the life of the plant, and what the potential consequences are of exceeding the maximum normal non-coincident wet bulb temperature during operating and shutdown conditions.

The applicant responded to the staff's request in a letter dated June 26, 2008. The applicant explained that the DID functions for the SWS are based on the maximum normal non-coincident wet bulb temperature for the site. The response also indicated that the SWS cooling function is not needed for maintaining the plant in a long-term safe condition. The applicant further indicated that SWS flow and cooling tower performance would be monitored on a continuous basis and that licensees will perform testing at regular intervals to determine cooling tower heat transfer capability, but a COL action item does not exist and one was not established to specify this action by COL applicants. The RAI response did not adequately address RAI-SRP9.2.1-SBPA-06 because more information was needed regarding the DID and RTNSS functional capability of the SWS over the full range of plant operating conditions.

During the June 25, 2009 audit, the staff expressed a concern regarding system reliability for RTNSS and DID over full range of operating conditions. The staff referred to similarities to RAI-SRP9.2.1 SBPA-01 and RAI-SRP9.2.1 SBPA-02 above, discussing what instruments are available to the control room for monitoring system performance.

The staff determined that the revised response to RAI-SRP9.2.1-SBPA-01 above resolves this issue because adequate explanation was provided with respect to RTNSS, cooldown, and DID considerations. Further, the discussion identified that the answer to the instrumentation portion of this concern can be found as part of the response to RAI-SRP9.2.1-SBPA-02. Therefore, RAI-SRP9.2.1-SBPA-06 is resolved.

In APP-GW-GLE-036 , the applicant described the impact of changing the current Maximum Safety wet bulb non-coincident temperature from 29.7 °C (85.5 °F) to 30.1 °C (86.1 °F) and the maximum safety wet bulb coincident temperature from 26.7 °C (80 °F) to 30.1 °C (86.1 °F) to encompass more sites in the eastern United States. In APP-GW-GLE-036, the applicant performed an evaluation of the effect on CCS and SWS to determine if sufficient margin exists to accommodate these changes in Maximum Safety wet bulb temperatures.

The CCS and SWS system provide heat removal from numerous plant loads for normal and abnormal modes of operation. During power operation, the systems are designed to accommodate the Maximum Safety temperature conditions (0 percent exceedance) with a single train in service whereas during shutdown operations the system is designed for the Maximum Normal conditions (1 percent exceedance) with both trains in service.

The applicant concluded that the SWS cooling tower is not expected to require changes to accommodate the higher Maximum Safety wet bulb temperature since the cooling tower sizing case is for plant cooldown at 4 hours after reactor shutdown, and is based on the Maximum Normal 1 percent exceedance value of 26.7 °C (80.1 °F), which is unchanged. The SWS cooling water supply temperature for the Maximum Safety case will be 33.1 °C (91.6 °F), resulting in a maximum CCS supply temperature of 36.1 °C (97.0 °F).

Based on its review of the changes to maximum safety wet bulb temperatures as evaluated by the applicant in APP-GW-GLE-036, the staff finds that the applicant adequately explained the increase in wet bulb temperature limits identified in DCD Tier 1 Table 5.0-1 and Tier 2 Table 2-1 and the applicant demonstrated that the changes in wet bulb temperature limits would not adversely impact performance of the CCS.

9.2.1.2.4 Miscellaneous Changes

DCD Tier 2, Revision 17, incorporates two changes in Section 9.2.1 that are described in TR-103. These changes include provisions for using nonmetallic piping and the removal of "smart valves."

Use of Nonmetallic Piping

The applicant proposed a change to Tier 2 of the DCD, Section 9.2.1.2.2, "Component Description," to allow COL applicants the option of using black polyethylene piping (High Density Polyethylene or HDPE) for SWS applications in accordance with the ASME B31.1 Power Piping Code if deemed appropriate by evaluation. In particular, HDPE could be used in areas of low pressure and low temperature, up to 1,034 kilopascal (kPa) (150 psi) and 60 °C (140 °F). Although the SWS is subject to RTNSS, it is not relied upon for post-72 hour cooling following an accident and the design provisions that pertain to seismic, flooding, and hurricane conditions do not apply. Therefore, from this perspective, the proposed use of HDPE is acceptable. However, since the SWS function is considered to be risk important during shutdown conditions when the reactor is open, the impact of using HDPE on SWS reliability and availability assumptions should be considered and addressed. Also, the review criteria specified by NUREG-0800 Section 3.6.1 relative to pipe failure evaluations is based on the use of metal pipe. Unless otherwise justified by the applicant, the potential consequences of pipe failure (including flooding) should be evaluated assuming the complete failure of all HDPE piping during seismic events coincident with metallic pipe failures that are postulated and other considerations that are specified by NUREG-0800. Finally, the specific criteria for allowing the use of HDPE should be specified in the DCD to ensure clarity of the plant licensing basis. The applicant was asked, in RAI-SRP9.2.1-SBPA-07, to revise the DCD (Tier 1 and Tier 2 as appropriate) to address these considerations.

The applicant responded to the staff's request in a letter dated June 26, 2008, and referred to its earlier response to RAI-TR103-EMB2-02 dated February 22, 2008. Also, additional clarifying information was provided to specify that HDPE will be used for the underground portions of the auxiliary makeup line from the secondary fire water tank and for the underground portions of the SWS blowdown to the circulating water system cooling tower. However, the applicant did not address the specific question that was asked by the staff in RAI-SRP9.2.1-SBPA-07. As a separate matter, the staff also requested the applicant to describe how the requirements specified by 10 CFR 20.1406, "Minimization of Contamination" are satisfied with respect to SWS considerations, including provisions that have been established for buried SWS pipe. Consequently, the RAI response did not adequately address RAI-SRP9.2.1-SBPA-07 because more information was needed regarding the use of nonmetallic piping and its potential effects on RTNSS and systems supporting the ability to achieve cold shutdown operations.

In a letter dated August 31, 2009, the applicant provided additional information specific to the use of HDPE nonmetallic piping in the SWS by proposing to revise DCD Tier 2 Section 9.2.1.2.2, "Piping," to specify that instead of nonmetallic piping, only high density polyethylene piping is used for the underground portions of the auxiliary makeup line from the Secondary Fire Water tank, and for the underground portions of the SWS blowdown line to the CWS cooling tower.

The staff reviewed the applicant's additional information in its response to RAI-SRP-9.2.1-SBPA-07 and finds that it adequately explains the use of nonmetallic piping in the SWS system design. The staff also reviewed the proposed changes to DCD Section 9.2.1.2.2 and finds that they adequately specify that only HDPE is used in the SWS. Therefore, RAI-SRP9.2.1-SBPA-07 was resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Related to 10 CFR 20.1406, in the applicant's submittal of TR-98, "Compliance with 10 CFR 20.1406," APP-GW-GLN-098, dated April 10, 2007, and the applicant's response to RAI-SRP- 12.1-CHPB-01, dated September 9, 2008, all radioactive piping is located inside the auxiliary building which minimizes the potential for leakage to the groundwater from piping and fittings. In addition, no piping containing radioactive fluid is directly buried in the ground. Based on the staff's review, the staff determined 10 CFR 20.1406 has been adequately addressed since the buried SWS does not normally contain radioactive fluids. In the event the SWS contains radioactive fluid, a radiation monitor with a high alarm is provided to monitor the service water blowdown flow. The component cooling water HXs and tower blowdown flow can be isolated by remote manual control. 10 CFR 20.1406 design considerations are further discussed in Chapter 12 of this report.

Removal of Smart Valves

The AP1000 design specifies the use of "smart valves" (i.e., valves that contain instrumentation such as temperature, flow and pressure that is used for control or indication) for some system applications. In the case of the SWS, smart valves (V009 and V011) are specified for the cooling tower makeup and blowdown control valves. The applicant proposed to remove the requirement for using smart valves for these functions to provide flexibility in the design for COL applicants. The proposed change replaces the instrumentation that is included in the smart valve design with standard inline instrumentation as illustrated in Figure 9.2.1-1 of the DCD, Tier 2, and references to valves with internal instrumentation are removed from the description provided in Section 9.2.1.5. This proposed change does not eliminate or alter the functional capabilities of any SWS valves or instruments, and should not degrade the capability or reliability of the SWS to perform its function. If anything, this less complicated arrangement is expected to improve the capability to service and maintain the affected instrumentation, which would tend to improve SWS availability and reliability consistent with SECY-94-084. Therefore, the staff considers the proposed changes to use standard inline instrumentation to be acceptable.

9.2.1.2.5 Investment Protection Short-Term Availability Controls (IPSAC)

The applicant proposed to change the minimum required flow rate specified by SR 2.4.1 in DCD Tier 2, Table 16.3-2, "Investment Protection Short-Term Availability Controls," to be consistent with the SWS design changes discussed above in Section 9.2.1.1.1. The minimum required flow rate for each SWS pump would be changed from more than 32,555 Lpm (8600 gpm) to more than 37,854 Lpm (10,000 gpm). The proposed change is consistent with the minimum required SWS flow rate discussed in Section 9.2.1.1.1 and from this perspective, it is appropriate. On this basis, the staff finds this acceptable.

9.2.1.2.6 Inspections, Tests, Analyses, and Acceptance Criteria (ITAAC) Considerations

The applicant proposed to change SWS flow rate, heat dissipation capability, and temperature conditions that are specified in ITAAC Table 2.3.8-2 to reflect proposed changes that are discussed above in Sections 9.2.1.1.1 and 9.2.1.1.3. The changes that are proposed for the SWS ITAAC are consistent with the specific changes that are proposed in these sections. On this basis the staff finds this acceptable.

9.2.1.2.7 Initial Test Program Considerations

The initial test program for the SWS is discussed in Tier 2 of the DCD, Section 14.2.9.2.6, "Service Water System Testing." The stated purpose of the SWS test program is to verify the capability of the as-installed system to transfer heat from the CCS HXs to the environment. Prerequisites are specified to assure that the SWS is properly configured and ready for testing, that plant conditions are appropriate, and provisions for collecting data have been established as necessary. SWS performance is observed and recorded during a series of individual component and integrated system tests in order to demonstrate that the SWS properly performs its DID functions. While most of the testing appeared to be appropriate and adequate for demonstrating the SWS DID capabilities, the staff noted that adequate performance for the most limiting situations was not specifically addressed, such as confirming adequate NPSH for the most limiting level, temperature, and flow rate situations and likewise for confirming adequate cooling tower performance; and adequate cooling tower makeup capability does not appear to be verified by the testing that is completed.

In RAI-SRP9.2.1-SBPA-08, the applicant was asked to address these considerations and in particular, to explain how the DID capability of the SWS is assured for the most limiting situations such that system reliability and availability assumptions are valid. The applicant responded to the staff's request in a letter dated June 26, 2008, referring the staff to Tier 2 Section 14.2.9.2.6 of the DCD. The applicant also provided additional information concerning the nature and extent of testing that would be performed. However, much of the information was not reflected in Tier 2 of the DCD, and the stated purpose of the test continues to be very narrowly focused on demonstrating the capability of the CCW HXs to transfer heat to the environment. For example, testing is not specified to confirm that hydraulic transients will not occur; especially following a loss of power and potential drain down of the system. Testing is not specified to demonstrate satisfactory performance during limiting conditions; the cooling tower makeup capability is not specified and confirmed, etc. Furthermore, the applicant credits COL applicants for performing ongoing surveillance and testing, but there are no COL action items to this effect.

In a letter dated August 31, 2009, the applicant provided additional information specific to the design margins, appended to its original response to RAI-SRP-SBPA-08 to clarify that Section 9.2.1.2.3.6 in Tier 2 of the DCD, actions are taken to prevent drain down and water hammer in the SWS during a loss of normal alternating current (ac) power. The motor-operated SWS tower inlet valves, which are loaded onto the diesel generators (DGs), are automatically closed when power is lost.

The applicant further identified that the diesel-backed SWS pumps undergo their normal automatic start procedure, which is described in detail in Section 9.2.1.2.2 in the last paragraph of the 'Service Water Pumps' section. Since the motor-operated SWS pump discharge valve and the tower inlet valve are both powered by the DG, these valves can stroke open to allow partial flow during pump start, thereby maintaining a water solid system.

Further the applicant stated that Tier 2 Section 14.2.9.2.6 includes testing for the instrumentation, controls, actuation signals and interlocks, as described in item (b) of the 'General Test Acceptance Criteria and Methods' section. As indicated in the first bullet, automatic pump actuation is verified in case an operating pump stops. The testing of the valve interlocks will ensure that they are able to perform their automatic start functions during a loss of power transient.

Service water blowdown is also isolated during a loss of normal AC power condition, in order to reduce liquid loss from the system. The SWS blowdown flow control valve is designed to automatically close when power is lost, which is an interlock that will also be tested in accordance with Section 14.2.9.2.6. This flow control valve is isolated using an ac-powered solenoid, which is fed from a protected, inverter-backed bus.

The staff reviewed the applicant's additional information in its response to RAI-SRP-9.2.1-SBPA-01 and RAI-SRP-9.2.1-SBPA-08 and finds that it adequately explains SWS system operation during normal operation, testing, and operation during loss of normal ac power. Therefore RAI-SRP9.2.1-SBPA-08 is resolved.

9.2.1.3 Conclusions

The staff evaluated proposed changes to Revision 15 of the AP1000 DCD that pertain to the SWS. The proposed changes are documented in Revision 17 of the AP1000 DCD, Tier 2, Section 9.2.1, and are reflected in the Tier 1 ITAAC specified in Table 2.3.8-2 and the Tier 2 IPSAC specified in DCD Table 16.3-2, Section 2.4. The staff's evaluation, using the guidance provided by NUREG-0800 Section 9.2.1, confirmed that: a) the proposed changes will not adversely affect safety-related SSCs, b) the SWS is capable of performing its DID and RTNSS functions, and c) ITAAC, IPSAC, and initial test program considerations are adequate and appropriate. The proposed changes conform to the existing AP1000 licensing basis as documented in Revision 15 of the approved DCD. The proposed changes meet the criteria of; 10 CFR 52.63(a)(1)(iii), on the basis that they reduce unnecessary regulatory burden while maintaining protection to public health and safety and the common defense and security; and 10 CFR 52.63(a)(1)(vii) on the basis that they contribute to the increased standardization of the certification information in the AP1000 DCD.

9.2.2 Component Cooling Water System

9.2.2.1 Summary of Technical Information

In NUREG-1793 the staff approved Section 9.2.2, “Component Cooling Water System,” of the AP1000 DCD, Revision 15. In the AP1000, Revision 17, the applicant proposed changes to Section 9.2.1.

The applicant proposed the following technical changes to Revision 15 of the AP1000 DCD, which are supported by information in the TRs:

1. Proposed changes to the CCS in order to accommodate increased heat loads. This includes the CCS pump design capacity which was changed from 33900 Lpm (8960 gpm) to 35900 Lpm (9500 gpm).

2. The applicant changed the maximum CCS supply temperature to plant components from 35 °C (95 °F) to 37.8 °C (100 °F). Additionally, the applicant raised the wet bulb temperature for service water cooling at normal operations (maximum normal temperature per Table 2-1 for normal shutdown). The ambient design wet bulb temperature was raised from 29.7 °C (85.5 °F) to 30.1 °C (86.1 °F).

3. The applicant changed the RCPs component cooling water discharge isolation valves from MOV to air operated valves (AOV). The applicant changed the closing signal input to these valves to an AOV close signal generated by the plant control system. The close signal will use simultaneous CCS flow deviations in the RCP’s CCS supply and return lines. The applicant deleted reference to a tube rupture in the RCP motor cooling coil or thermal barrier as a source of reactor coolant leakage into the CCS and replaced this source of potential leakage with the RCP external HX. These changes conform to the applicant’s RCPs design change to canned RCPs, which includes a new RCP external HX that replaces the RCP motor cooling coils and thermal barriers what were cooled by CCS.

4. The applicant described changes to the flow sensors in the CCS inlet and outlet lines associated with each RCP external HX. The proposed change clarified that isolation valves used to isolate the component cooling water outlet line associated with its RCP are nonsafety-related. The changes associated with a canned RCP include the installation of a RCP external HX to replace the pump motor cooling coil and thermal barrier. The applicant identified that other plant alarms and indications can be used by the operator to manually initiate a RCP component cooling water system isolation.

5. The applicant provided additional detail for instrumentation for high-level and low-level alarms on the CCS surge tank, automatic actuation of the CCS surge tank makeup water valve for makeup flow from the demineralized water transfer and storage system into the CCS, and flow alarms in the MCR to indicate that a leak exists on the RCP external HX. The RCP external HX replaces the RCP motor cooling coils and thermal barriers and is cooled by CCS. In addition, the applicant identified that flow measuring instrumentation on the RCP component cooling water inlet and outlet lines provide an isolation signal to close an AOV and isolate the affected RCP external HX from the rest of the CCS.

6. The applicant corrected the referenced code to use for nonmetallic piping from "ASME B31.1" to "ANSI B31.1." The proposed change also clarified that ANSI B31.1 Appendix III also may be used for outside containment piping.

Details of these proposed changes are discussed in TR-111, TR-108 and TR-103, respectively.

9.2.2.2 Evaluation

The regulatory basis for evaluating the CCS is documented in Section 9.2.2 of NUREG-1793. While the CCS is a nonsafety-related system, it is considered to be important to safety because it supports the normal DID capability of removing reactor and spent fuel decay heat. It is also part of the first line of defense for reducing challenges to passive safety systems in the event of transients and plant upsets, and its cooling function is important for reducing shutdown risk when the RCS is open (e.g., mid-loop condition). The risk importance of the CCS makes it subject to RTNSS in accordance with SECY-94-084. The staff's evaluation of the changes that are proposed focused primarily on confirming that the changes will not adversely affect safety-related SSCs or those that satisfy the criteria for RTNSS; the capability of the CCS to perform its DID and RTNSS functions; and the adequacy of ITAAC, test program specifications, and availability controls that have been established for the CCS. The proposed changes were evaluated using the guidance provided by NUREG-0800 Section 9.2.2, "Reactor Auxiliary Cooling Water System," as it pertains to these considerations. Acceptability was judged based upon conformance with the existing AP1000 licensing basis, the guidance specified by NUREG-0800 Section 9.2.2 (as applicable), and SECY-94-084.

Modifications to approved standard plant DCs can be proposed provided (among other things) that the changes are deemed to be necessary in accordance with 10 CFR 52.63(a)(1). The proposed changes will allow additional flexibility for COL applicants, thereby reducing the need for departure requests. The specific criteria that apply to the proposed changes referred to above include: 10 CFR 52.63(a)(1)(iii), which concerns reducing unnecessary regulatory burden while maintaining protection to public health and safety and the common defense and security; and 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

During its evaluation, the staff noted that the description that is provided in Tier 2 of the AP1000 DCD, Section 9.2.2, "Component Cooling Water System," does not describe the DID, investment protection, and RTNSS design basis for the CCS. However, it is clear from the ITAAC specified in Tier 1 of the DCD, Section 2.3.1, "Component Cooling Water System;"," the initial test program described in Tier 2 of the DCD, Section 14.2.9.2.5, "Component Cooling Water System Testing," Table 16.3-2, "Investment Protection Short-Term Availability Controls," as it pertains to CCS, and Table 17.4-1, "Risk-Significant SSCs Within the Scope of D-RAP," that the CCS is important for both DID, investment protection, and RTNSS considerations. However, this information has not been adequately reflected in the description that is provided for the CCS in Tier 2 of the DCD, Section 9.2.2. In RAI-SRP9.2.2-SBPA-03 the applicant was asked to include additional information in Section 9.2.2 to better explain the DID, investment protection, and RTNSS design basis for the CCS (also see test considerations referred to below in Section 9.2.2.2.7). The applicant responded to the staff's request in a letter dated June 26, 2008. The applicant indicated that the information provided for the CCS is similar to what was provided for the SWS and other DID systems. The staff confirmed that the Tier 2 information for the CCS is similar to what was provided for other systems of this nature, with no description of the DID, investment protection, or RTNSS design basis for these systems.

During the June 25, 2009 audit, the staff explained that, in order to resolve the RAI, the applicant should provide more detail regarding the CCS RTNSS, Design Reliability Assurance Program (D-RAP), and IPSAC functions. In a letter dated August 31, 2009, the applicant provided additional information about the CCS functions by proposing to revise DCD Tier 2 Section 9.2.2 referring to DCD Tier 2 Section 17.4-1.

The staff reviewed the applicant's additional information in its response to RAI-SRP-9.2.2-SBPA-03 and finds that it adequately explains the CCS D-RAP functions by referencing DCD Tier 2 Section 17.4. The staff also reviewed the proposed changes to DCD Section 9.2.2.3.1 and finds that they adequately referenced the basis for including the CCS components within the scope of D-RAP. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

9.2.2.2.1 CCS Design Changes Required to Accommodate Increased Heat Loads

As discussed in TR-111, CCS modifications are necessary as a result of higher heat loads and flow rates for cooling the RCPs and the condensate pump oil coolers, adding the VFD for the RCPs as new CCS heat loads and relocating them from the northwest to the southwest side of the turbine building, and excessive CCS flow velocities at the CCS pump suction and discharge headers and inside containment due to the increased CCS flow demand that is necessary to satisfy increased component heat loads. Consequently, the applicant implemented CCS design changes to add new components, reconfigure the CCS piping layout and resize pipe as necessary, revise CCS pump and HX parameters, and increase the CCS design pressure. The CCS changes are reflected in the AP1000 DCD, Tier 1, Table 2.3.1-2, ITAAC Design Commitment, Item 3, relative to the capability to support plant shutdown and spent fuel cooling; Tier 2, Section 9.2.2, “Component Cooling Water System,” including Table 9.2.2-1, “Nominal Component Data – Component Cooling Water System,” Table 16.3-2, “Investment Protection Short-Term Availability Controls,” Section 2.3, “ Component Cooling Water System (CCS) – RCS Open,” SR 2.3.1 with respect to the minimum required CCS flow rate.

Relocating the VFDs to the southern end of the turbine building places them in close proximity to the CCS pumps and HXs. Failures associated with the VFDs could affect the capability of the CCS to perform its RTNSS function and additional information is needed to address this consideration. In RAI-SRP9.2.2-SBPA-04, additional information was requested to address relocating the VFDs. The applicant responded to the staff's request in a letter dated June 26, 2008. The applicant stated that typical failures expected for high power electronic equipment include fires and in this case loss of cooling water from the dedicated cooling system or from the CCS which supplies cooling water to the VFD internal cooling system HXs. Fires in the turbine building, caused specifically by a failure of VFD equipment, that disable both CCS pumps have been addressed by the inclusion of a means to provide 2271 Lpm (600 gpm) of cooling water to normal RNS HX ‘A’ from the FPS to provide continued capability to remove decay heat from the RCS following suppression of the fire. During suppression activities, the plant passive safety systems ensure that decay heat is removed from the core and therefore cooling of the RNS HXs with CCS is not required. SFS pool cooling is also provided by other means during this period of time. These provisions are described in DCD Revision 16, Tier 2, Sections 9.1.3.4.3, “Abnormal Conditions,” and 9.2.2.4.5.5. In addition, a break in the VFD internal cooling water lines or in the CCS lines supplying the HXs does not increase the risk of a flooding event, as a break of this size is enveloped by the bounding flooding case of breaks in larger CCS and SWS lines in the southern end of the turbine building.

The staff reviewed this response and determined that it did not address RTNSS considerations. In a revised RAI response dated April 13, 2009, the applicant stated that the variable frequency drive is used only during heatup and cooldown when the reactor trip breakers are open. During power operations, the drive is isolated and the RCP is run at constant speed; therefore, the VFDs are de-energized during suppression activities.

The staff reviewed the revised RAI response and determined that RTNSS considerations were adequately addressed since the flooding event is bounded by the larger CCS and SWS line breaks in the turbine building and the VFDs would not be energized during the period of time the CCS would be performing their RTNSS function in Mode 5 and 6. Therefore, RAI-SRP9.2.2-SBPA-04 is considered resolved.

In DCD Revision 16, the applicant reanalyzed the fluid pressures throughout the redesigned CCS and determined that the design pressure of the system should be increased from 1,034 kPa (150 pounds per square inch gauge (psig)) to 1,379 kPa (200 psig). However, the total design differential head of the CCS pumps is actually reduced substantially and it was not clear why the system pressure was increased. The staff asked the applicant, in RAI-SRP9.2.2-SBPA-05, to address this inconsistency. In response to RAI-SRP9.2.2-SBPA-05, the applicant referred to industry operating experience showing that relief valve actuations occur frequently during routine realignments (e.g., pump swaps) in CCS that are designed for 1,034 kPa (150 psig). Also, based upon the results of a hydraulic analysis that was performed, the applicant determined that the CCS operating pressure for AP1000 is just below the relief valve setpoint for a system design pressure of 1,034 kPa (150 psig). Consequently, the applicant increased the CCS design pressure to 1,379 kPa (200 psig) in order to minimize the occurrence of relief valve actuations and the likelihood of valve leakage. Based on the information that was provided, the staff finds that the proposed increase in the CCS design pressure will increase the available margin and make the system more robust. Additionally, because the higher relief valve set point will tend to minimize spurious actuations and valve leakage, the proposed increase in CCS design pressure reduces the likelihood of spreading radioactive contamination consistent with 10 CFR 20.1406 requirements. Therefore, the staff considers the proposed increase in CCS design pressure to be acceptable and RAI-SRP9.2.2-SBPA-05 was resolved.

Proposed Increases in CCS Flow Rate and Heat Removal Capability

The applicant proposed to increase the minimum required CCS flow rate and heat removal capability in order to accommodate the design changes referred to above. The values listed in Tier 2 of the DCD, Section 9.2.2 and Table 9.2.2-1, and the ITAAC specified by Tier 1 of the DCD, Table 2.3.1-2, reflect these changes.

The ITAAC specified in Tier 1 of the DCD, Table 2.3.1-2, require COL applicants to demonstrate that the CCS design is capable of supporting plant shutdown and spent fuel cooling. The applicant proposes to change the ITAAC acceptance criteria to demonstrate a flow rate for each CCS pump of at least 10,164 Lpm (2685 gpm) to one normal shutdown cooling HX (this is unchanged), plus 4542 Lpm (1200 gpm) to one SFP HX (this is increased by 284 Lpm (75 gpm) from the previous amount), and at least 16,713 Lpm (4415 gpm) to other CCS heat loads (this is increased by 12,397 Lpm (3275 gpm) from the previous amount), for a total required flow rate for each CCS pump of 31,419 Lpm (8300 gpm). This represents an increase in the total required flow rate for each CCS pump of 12,681 Lpm (3350 gpm). The total CCS pump flow rate that is specified for each pump is consistent with the proposed value that is listed in Tier 2 Table 9.2.2-1, and it is acceptable from this perspective. However, Tier 2 of the DCD, Section 9.2.2, does not identify what the minimum CCS flow requirements are for these three categories of heat loads that are listed in the ITAAC, how much excess margin is available for each one, the basis for this determination, and how the specified flow balance will be maintained over time. In RAI-SRP9.2.2-SBPA-06, the staff requested that the applicant address this missing information.

The applicant responded to RAI-SRP9.2.2-SBPA-06 in a letter dated June 26, 2008. The applicant provided additional information primarily related to CCS HX design and made reference to TR-111 for additional discussion. However, the applicant's response did not address the specific question that was asked by the staff.

During the June 25, 2009 audit, the staff explained that, in order to resolve the RAI, the applicant should provide more detail concerning how the ITAAC demonstrate adequate flow for RTNSS.

In a letter dated August 31, 2009, the applicant stated that CCS system flow analysis is performed to demonstrate that the selected CCS pump head and flow characteristics ensure delivery of the required flow to all CCS users and also verify that the flow balancing orifices are sized with margin to be adjusted in the field. Also, an additional 7 percent margin in head is added to the CCS pump curve developed from the flow analysis, specifically to offset the effects of any degradation of pump performance occurring during the life of the plant. However, changes in CCS flow performance over time are expected to be minimal, since the CCS is a closed-loop, chemically-treated system with orifices used for flow balancing.

The applicant also stated that the CCS ITAAC requires a minimum flow rate of 10,164 Lpm (2685 gpm) to transfer heat from the RNS during shutdown. This flow rate, which assumes 10 percent degradation from the normal RNS HX flow requirement, is the minimum flow rate needed to remove decay heat from the RNS when it is aligned 4 hours after reactor shutdown (Mode 4). This flow rate must also be verified one day before entering Modes 5 and 6, as a SR included in CCS IPSAC, Table 16.3-2. Since a flow rate of 10,164 Lpm (2685 gpm) is sufficient to remove decay heat during Mode 4, it is also bounding for decay heat removal during Modes 5 and 6, when the RCS decay heat level has been further reduced. As a result, this SR will ensure that the CCS will be able to adequately perform its RTNSS function. This CCS minimum flow rate of 10,164 Lpm (2685 gpm) to the RNS HX is added to Tier 2 Table 9.2.2 1 in the DCD markup, as well as a similar 10 percent degraded value of 4543 Lpm (1200 gpm) to the SFS HX.

The staff reviewed the applicant's additional information in its response to RAI-SRP9.2.2-SBPA-06 and finds that it adequately explains the CCS basis for flow required for its RTNSS functions with design adequate margins at 10 percent degraded values. The staff also reviewed the proposed changes to DCD Table 9.2.2-1 and finds that the table, as changed, adequately describes the basis for CCS flow rates. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant also proposes to increase the heat transfer capability of each CCS HX as specified in ITAAC Table 2.3.1-2. The current acceptance criterion specifies a UA value of 740×10^6 W/°C (12.1×10^6 Btu/hr-°F), and the applicant proposes to change this UA value to 856×10^6 W/°C (14.0×10^6 Btu/hr-°F). The value that is proposed as the ITAAC acceptance criterion is consistent with the revised value that is proposed in Tier 2, Table 9.2.2-1, and it is acceptable from this perspective. However, the applicant did not identify how the proposed CCS HX UA value was determined and how much margin is available to address operational considerations, on what basis this determination is appropriate and justified, and how the specified CCS heat transfer capability will be maintained over time. In RAI-SRP9.2.2-SBPA-07 the staff asked the applicant to address these heat transfer issues.

The applicant responded to RAI-SRP9.2.2-SBPA-07 in a letter dated June 26, 2008. The applicant provided additional information primarily related to CCS HX design and made reference to TR-111 for additional discussion. However, the response did not address the specific question that was asked.

During the June 25, 2009 audit, the staff explained that in order to resolve the RAI the applicant should provide more detail explaining how the proposed CCS HX coefficient of heat transfer (U) and required heat-transfer area (A) values were determined and how much margin is available to address operational considerations.

In a letter dated August 31, 2009, the applicant stated that the CCS HX UA was established to ensure that supply temperature did not exceed the RCP external HX cooling requirements, under maximum safety wet bulb temperatures. The design UA also bounds the UA value needed to meet the CCS temperature requirements for cooling down the RCS to cold shutdown conditions within 96 hours of reactor shutdown. Selecting a CCS HX UA, which meets temperature requirements during plant cooldown also ensures that the CCS HXs will be able to perform their DID and RTNSS functions of providing cooling to the RNS HXs during RCS cooldown and reduced reactor coolant inventory operation.

The staff reviewed the applicant's additional information in its response to RAI-SRP9.2.2-SBPA-07 and finds that it adequately explains how the CCS HX UA values were determined and how much margin is available to address operational considerations. The CCS HX specification requires the inclusion of additional heat transfer area above the design value to account for fouling and degradation over the HX's operating life. Additional frame length is also included so that additional plates can be added to the HX if additional performance is required. The HX margins are also discussed in Section 9.2.1 of this report and have been adequately addressed. Therefore, RAI-SRP9.2.2-SBPA-07 is resolved.

<u>CCS Pump Design Considerations</u>

Tier 2 Table 9.2.2-1 included additional proposed changes that had not been explained and justified. In particular, the bases for the proposed changes to the CCS pump design capacity and total developed head had not been addressed. Also, the bases for the proposed changes to the CCS HX design duty, design UA, and design flow rate (CCS side) had not been addressed. In RAI-SRP9.2.2-SBPA-08, the staff asked the applicant to address these heat transfer issues.

The applicant responded to RAI-SRP9.2.2-SBPA-08 in a letter dated June 26, 2008. The applicant indicated that the increased CCS pump design capacity is primarily due to increased cooling water flow requirements for the RCPs. The total developed head requirement for the CCS pumps was reduced substantially by increasing the diameter of several of the CCS main supply and return headers to minimize dynamic losses in the system that would otherwise result from the increase in CCS flow rate. The staff agrees that these particular changes are appropriate and justified for the reasons stated. However, the applicant's response did not adequately address and justify the proposed changes to the CCS HX design parameters.

During the June 25, 2009 audit, the applicant stated that the bases of the proposed CCS changes were discussed in TR-111. Further, the applicant clarified that other CCS changes (including lower CCS pump TDH, increasing piping sizes, and the reduction in flow velocities), were provided in TR-111.

The staff finds, based on the review of TR-111, that the UA of the CCS HX has been increased to meet all the CCS performance requirements with the increased heat loads for cooled components. The increase in CCS HX size is associated with an increased SWS flow rate as well as an increased CCS flow rate. On this basis the staff finds that RAI-SRP9.2.2-SBPA-08 is resolved.

CCS Cooling for RCPs, Instrumentation and Controls

In DCD Section 9.2.2.3.4, the applicant proposed to change the RCP component cooling water discharge isolation valves from MOVs to AOVs. The applicant changed the closing signal input to these valves to an AOV close signal generated by the plant control system. The close signal will use simultaneous CCS flow deviations in the RCP’s component cooling water supply and return lines. The applicant deleted reference to a tube rupture in the RCP motor cooling coil or thermal barrier as a source of reactor coolant leakage into the CCS and replaced this source of potential leakage with the RCP external HX. The staff finds that the proposed change does not eliminate the requirement that the RCP’s CCS outlet line be protected from overpressure by relief valves.

In DCD Section 9.2.2.4.5.2, the applicant further described the flow sensors in the CCS inlet and outlet lines associated with each RCP external HX and added that the cooling water outlet line isolation valves on each RCP are nonsafety-related. With the design change to a canned RCP, the applicant replaced the pump motor cooling coil and thermal barrier with an RCP external HX. The applicant also modified how the RCP component cooling water isolation signal is developed and further clarified the alarms an operator would receive.

In DCD Section 9.2.2.7, the applicant provided detail for the high-level and low-level alarms instrumentation on the CCS surge tank. There are two redundant level channels in the design to reduce the likelihood of reactor trip caused by a single downscale failure of a surge tank level channel. Such redundancy could preclude unnecessary tripping of CCS pumps which would subsequently cause loss of cooling flow to the RCPs and other cooled components. The CCS surge tank makeup water valve is automatically actuated by one of the two level channels, in order to provide makeup flow from the demineralized water transfer and storage system into the CCS. The applicant clarified that flow alarms in the MCR, produced by the two flow channels located on the CCS RCP cooling water inlet and outlet lines, will be used to alert the operator that a leak exists on the RCP external HX. The applicant identified that flow-measuring instrumentation on the RCP component cooling water inlet and outlet lines provides an isolation signal to close an AOV and isolates the leaking RCP external HX from the rest of the CCS.

The staff finds that changes to CCS valves, flow sensors, isolation signals and instrumentation provide an additional level of system reliability and do not result in negative or adverse system interactions. Based on its evaluation, the staff concludes that these valve and instrumentation changes are acceptable and do not change the NUREG-1793 Section 9.2.2 findings or conclusions.

9.2.2.2.2 Proposed Increase in the Maximum CCS Supply Temperature

Tier 2 of the AP1000 DCD, Section 9.2.2.1.2.1, "Normal Operation," proposes to increase the maximum allowed CCS supply temperature to plant components from 35 °C (95 °F) to 37.2 °C (99 °F) during normal plant operations, but the basis for this proposed change was not explained and justified. In RAI-SRP9.2.2-SBPA-09 the staff requested that the applicant justify this change.

The applicant responded to the staff's request in a letter dated June 26, 2008. The applicant explained that the increased CCS supply temperature was due to the proposed increase in the maximum safety non-coincident wet bulb temperature from 27.2 °C (81 °F) to 29.7 °C (85.5 °F) using a cooling tower that is designed for an approach to wet bulb temperature of 13.3 °C (8 °F). The applicant referenced page 11 of TR-108 for additional explanation. The applicant also provided information regarding a further increase in the maximum safety non-coincident wet bulb temperature that was being made (but not yet submitted) to accommodate the Levy site parameters. This information was not included within the scope of this evaluation. While the information that was provided by the applicant explains to some extent how the maximum service water supply temperature is achieved, it did not explain how the maximum CCS supply temperature was determined and justified. The staff also noted that the use of non-conservative temperature assumptions for the plant shutdown and refueling heat transfer analyses was not explained and justified. Furthermore, this approach was not consistent with the information provided in Tier 2 Section 5.4.7.1.2.3, "In-Containment Refueling Water Storage Tank Cooling," which indicates that the maximum safety non-coincident wet bulb temperature is assumed for normal conditions and transients that start at normal conditions.

During the June 25, 2009 audit, the applicant clarified that the normal wet bulb is a realistic value for evaluating DID on investment protection as stated in its May 13, 2009, supplemental response to RAI-SRP9.2.1-SBPA-05. The maximum safety wet bulb temperature of 30.0 °C (86.1 °F) is applicable for full power operations as stated earlier in the May 7, 2009, and May 13, 2009, supplemental RAI responses. The higher ambient temperatures 30.0 °C vs. 26.7 °C (86.1 °F vs. 80.1 °F) will not impact safety or investment protection and would only result in an extended time to achieve cooldown. The staff agreed that the information was previously adequately presented; therefore, RAI-SRP9.2.2-SBPA-09 is resolved. Wet bulb temperature considerations are also discussed in Section 9.2.1 of this report and have been resolved.

In DCD Section 9.2.2.1.2.1 Revision 17, the applicant proposed a change in the maximum CCS supply temperature to plant components from 37.2 °C (99 °F) to 37.8 °C (100 °F). Additionally, the applicant proposed to raise the wet bulb temperature for service water cooling at normal operations (maximum normal temperature per Tier 2 Table 2-1 for normal shutdown). Although the assumption of a 0 percent exceedance was not changed, the ambient design wet bulb temperature would be raised from 29.7 °C (85.5 °F) to 30.0 °C (86.1 °F).

In APP-GW-GLE-036, the applicant described the impact of changing the current maximum wet bulb non-coincident temperature from 29.7 °C (85.5 °F) to 30.0 °C (86.1 °F) and the maximum wet bulb coincident temperature from 26.7 °C (80 °F) to 30.0 °C (86.1 °F) to encompass more sites in the eastern United States. In APP-GW-GLE-036, the applicant performed an evaluation of the effect on CCS to determine if sufficient margin exists to accommodate a 3.3 °C (6.1 °F) change and a 0.3 °C (0.6 °F) for both coincident and non-coincident wet bulb temperatures:

The applicant performed a design assessment and identified the following areas associated with CCS that are affected by the increased maximum wet bulb temperature:

- Safety system design basis – additional cases for containment analysis were included in the safety analysis to support the revised coincident and non-coincident wet bulb temperature.
- Normal, decay and SFP heat removal (cases relying on use of the 0 percent exceedance wet bulb temperature only)
- Component cooling and service water design

Safety System Design Basis

The applicant stated that no changes to the AP1000 design are needed to accommodate any safety issues because evaluations have demonstrated that the current AP1000 accident analyses will bound the revised coincident 46.1°C/30.0 °C (115 °F/86.1 °F) and non-coincident 30.0 °C (86.1 °F) wet bulb temperatures. The applicant stated that the maximum containment peak pressure performance of the passive containment cooling system at the higher wet bulb temperature is bounded by the current analysis for which a bounding sensitivity was documented in the Nuclear Safety Containment Analysis for AP1000.

Normal, Decay and Spent Fuel Pool Heat Removal

The applicant evaluated the impact of wet bulb temperature change on the performance of the normal RNS, SFP cooling, CCS and SWSs. The applicant stated that the performance evaluations considered normal operating modes, the ability to meet post shutdown cooldown times, full core offloads, loss of all ac power, and heat up of the IRWST.

The applicant stated that all design criteria were met including cooldown times and temperature limits with the exception of normal plant power operation with maximum heat loads, one CCS train in service, and at the maximum safety temperature limit of 30.0 °C (86.1 °F) wet bulb. The applicant identified that the exception exists for less than 30 hours per year and that with only one train of CCS, the CCS temperature would rise above 35.0 °C (95 °F) and then return to less than 35.0 °C (95 °F) by the time the 1 percent exceedance temperature was reached. The applicant identified the RCP motor cooling system as the most limiting component, which was designed to operate for at least 6 hours duration with a temperature up to 37.8 °C (100 °F). The applicant's evaluation was that with the maximum allowable cooling water temperature of 36.1 °C (97 °F) for the RCPs (the most limiting component), this change was acceptable.

Component Cooling (CCS) and Service Water System (SWS) design

The applicant stated that CCS will accommodate the heat loads from operations without impacting performance or sizing of the CCS. The SWS cooling tower is not expected to require changes to accommodate the higher wet bulb temperatures since sizing is based on plant cooldown at 4 hours after reactor shutdown, and is based on the unchanged 1 percent exceedance value of 26.7 °C (80.1 °F). The applicant explained that the SWS cooling water supply temperature for the maximum safety case will be 33.1 °C (91.6 °F), which will result in a maximum CCS supply temperature of 36.1 °C (97.0 °F).

In APP-GW-GLE-036, the applicant states that the most limiting CCS component is the RCP motor cooling system and that temperatures of up to 37.8 °C (100 °F) for a duration of 6 hours are acceptable. In DCD Revision 17 Table 5.4-1, the RCP maximum continuous component cooling water inlet temperature is given as 35 °C (95 °F) with a 6 hour elevated temperature of up to 43.3 °C (110 °F). Additionally the applicant identified in the DCD that an input to a reactor trip is RCP “Hi Bearing Temperature” but there was no mention of high motor temperature. As a result of the design change to canned RCPs, the staff asked the applicant, in RAI-SRP9.2.2-SBPA-14, to verify that the RCP motor cooling system is still the most limiting CCS supply temperature: if the RCP motor cooling system is no longer the most limiting CCS cooled component, identify and provide the evaluation of the impacts of the revised wet bulb temperature limit on the plant for the new limiting component. The staff also asked the applicant, in RAI-SRP9.2.2-SBPA-14, to clarify a statement in APP-GW-GLE-036.

The applicant responded to RAI-SRP9.2.2-SBPA-14 on August 31, 2009 and stated that the RCP motor cooling system is still the most limiting component served by the CCS with respect to maximum temperature of the supplied cooling water. The limiting CCS supply temperature for RCP cooling is 37.7 °C (100 °F). The RCP can operate at full speed with CCS supply temperature at this level for up to 6 hours continuously. Since the CCS and SWS are both designed with significant thermal margin, the actual CCS supply temperature to the RCPs and to other CCS components with the plant at power will always be lower than the limiting value of 37.7 °C (100 °F), which assumes maximum operating heat load on the CCS, 4 °C (8 °F) cooling tower approach to wet bulb, and local ambient wet bulb temperature at the maximum safety (0 percent exeedence) level. During plant cooldown with RCPs operating, the CCS temperature may approach 37.7 °C (100 °F) for a few hours at the highest plant cooldown rate of 27.8 °C/h (50 °F/h), but the RCPs are operating at reduced speed in this mode and their cooling requirements are therefore less stringent than for full power, full speed operation.

The staff review determined that this response is acceptable since the design conditions of 37.7 °C (100 °F) have been established in DCD Section 9.2.2.1.2.1, “Normal Operations”. During the cooldown period, the component cooling water inlet temperature to the various components does not exceed 43.33 °C (110 °F) as described in DCD Section 9.2.2.4.3, “Plant Shutdown” which is consistent with Table 5.4-1. For this reason, the staff determined RAI-SRP9.2.2-SBPA-14 is resolved.

9.2.2.2.3 Revised Site Interface Temperature Limits

As discussed in TR-108, the applicant proposes to change the site interface temperature limits to encompass a broader range of potential sites for AP1000 plants. In particular, Tier 1 of the DCD, Table 5.0-1, “Site Parameters,” would be revised to specify a maximum (noncoincident) wet bulb temperature of 29.7 °C (85.5 °F) instead of 27.2 °C (81 °F). Tier 2 of the DCD, Table 2-1, “Site Parameters,” would be revised to reflect this higher (noncoincident) wet bulb temperature as the Maximum Safety (or 0 percent exceedance) value, and the Maximum Normal (or 1 percent exceedance) wet bulb temperature would be revised from 25 °C (77 °F) to 26.7 °C (80.1 °F) for the coincident value and from 26.7 °C (80 °F) to 26.7 °C (80.1 °F) for the noncoincident value.

The proposed changes to the site interface temperature limits are reflected in Tier 2 of the AP1000 DCD, Section 9.2.2, in place of the values that were previously listed. Although the values correspond to how they were used previously (i.e., the replaced values are “like-for-like”), the Tier 2 description does not explain why the maximum safety (noncoincident) wet bulb temperature is specified for normal operation and the maximum normal wet bulb temperature is specified for other cases. It is not clear why the maximum safety limit does not apply for the CCS DID and RTNSS functions. The staff asked the applicant, in RAI-SRP9.2.2-SBPA-10, to explain and justify this approach and to revise the Tier 2 information to clearly describe the plant design basis in this regard.

The applicant responded to RAI-SRP9.2.2-SPBA-10 in a letter dated June 26, 2008. The applicant explained that the maximum safety non-coincident wet bulb temperature does not apply to RTNSS and Investment Protection functions because they are not functions required to guarantee the safety of the plant. However, contrary to this logic, the applicant also explained that the maximum safety non-coincident wet bulb temperature is used in determining CCS and SWS performance for power operation since the peak ambient wet bulb temperature has a relatively high likelihood of occurrence during the operating portion of a refueling cycle. The applicant failed to recognize that elevated temperature conditions tend to increase the likelihood of plant trips and transients due to grid instability and assurance needs to be provided that DID and RTNSS SSCs are capable of performing their functions whenever the maximum normal wet bulb temperature is exceeded. The applicant's response did not address the staff's concerns in this regard.

During the June 25, 2009 audit, the applicant clarified that, as stated in its response to RAI-SRP9.2.1-SBPA-05, with respect to the 26.7 °C (80.1 °F) wet bulb for RTNSS, normal cooldown can be accomplished sooner than it can be accomplished with the 30.0 °C (86.1 °F) wet bulb. Further, the applicant clarified that all the temperature limits have margins. The applicant explained that passive safety systems are not needed. Further, the applicant clarified that the normal wet bulb temperature is a realistic value for evaluating DID on investment protection. The maximum safety wet bulb temperature of 30.0 °C (86.1 °F) is applicable for full power operations, as previously presented in the RAI-SRP9.2.2-SBPA-09 response dated May 7, 2009.

The staff agreed that the information was previously adequately presented; therefore, RAI-SRP9.2.2-SBPA-10 is resolved. The higher ambient temperatures 30.0 °C vs. 26.7 °C (86.1 °F vs. 80.1 °F) will not impact safety or investment protection and would only result in an extended time to achieve cooldown.

9.2.2.2.4 Use of Nonmetallic Pipe

The applicant proposed a change to Tier 2 of the DCD, Section 9.2.2.3.5, "Piping Requirements," to allow COL applicants the option of using black polyethylene piping (High Density Polyethylene or HDPE) for CCS applications in accordance with the ASME B31.1 Power Piping Code if deemed appropriate by evaluation. In particular, HDPE could be used in areas of low pressure and low temperature, up to 1,034 kPa (150 psi) and 60 °C (140 °F). The basis for the use of nonmetallic pipe for this application is described in TR-103.

Although the CCS is subject to RTNSS, it is not relied upon for post-72 hour cooling following an accident and the design provisions that pertain to seismic, flooding, and hurricane conditions do not apply. Therefore, from this perspective, the proposed use of HDPE is acceptable. However, since the CCS function is risk important during shutdown conditions when the reactor is open, the impact of using HDPE on CCS reliability and availability assumptions needs to be considered and addressed. Also, the review criteria specified by NUREG-0800 Section 3.6.1 relative to pipe failure evaluations is based on the use of metal pipe. Unless otherwise justified by the applicant, the potential consequences of pipe failure (including flooding) should be evaluated assuming the complete failure of all HDPE piping during seismic events coincident with metallic pipe failures that are postulated and other considerations that are specified by the SRP. Finally, the specific criteria for allowing the use of HDPE should be specified in the DCD to ensure clarity of the plant licensing basis. The applicant was asked, in RAI-SRP9.2.2-SBPA-11, to revise the DCD (Tier 1 and Tier 2 as appropriate) to address these considerations. The applicant responded to the staff's request in a letter dated June 26, 2008, and referred to its earlier response to RAI-TR103-EMB2-02 dated February 22, 2008. The applicant also indicated that HDPE is not used in the AP1000 CCS design and that there are no current plans to use HDPE in this system. However, because use of HDPE is proposed as an option for COL applicants, its use needed to be fully evaluated and justified by the applicant. The response that was provided by the applicant did not provide the information that was requested in RAI-SRP9.2.2-SBPA-11. As a separate matter, the staff also requested that the applicant describe how the requirements specified by 10 CFR 20.1406 are satisfied with respect to CCS considerations, including provisions that have been established for buried or inaccessible pipe.

During the June 25, 2009 audit, the staff explained that in order to resolve the RAI the applicant should provide more detail explaining the use of nonmetallic piping in the CCS.

In a letter dated August 31, 2009, the applicant stated that the provision for the use of nonmetallic piping is removed from DCD Tier 2 Section 9.2.2. The operating pressure and temperature for the CCS exceeds the limits for HDPE piping imposed by ANSI/ASME B31.1 and applicable code cases and is, therefore, prohibited for use in this application. Additionally, the applicant proposed to revise DCD Tier 2 Section 9.2.2.3.5 "Piping Requirements" to delete references to nonmetallic piping. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Related to 10 CFR 20.1406, in the applicant's submittal of APP-GW-GLN-098 dated April 10, 2007 and the applicant response to RAI-SRP-12.1-CHPB-01 dated September 9, 2008 all radioactive piping is located inside the auxiliary building, which minimizes the potential for leakage to the groundwater from piping and fittings. In addition, no piping containing radioactive fluid is directly buried in the ground. In addition, the use of embedded pipes is minimized to the extent possible, consistent with maintaining radiation doses ALARA as described in DCD Section 12.3.1.1.2, "Common Facility and Layout Designs of ALARA". To the extent possible, pipes are routed in accessible areas such as dedicated pipe routing tunnels or pipe trenches; this provides good conditions for decommissioning. Based on the staff's review, the staff determined 10 CFR 20.1406 has been adequately addressed since the CCS is not buried and radiation monitors, which monitor RCS leakage into CCS, alarm in the MCR. 10 CFR 20.1406 design considerations are further discussed in Chapter 12 of this report.

In DCD Section 9.2.2.3.5 Revision 17, the applicant corrected the code reference applicable to nonmetallic piping. The applicant changed the specification for nonmetallic piping from "used in accordance with ASME B31.1" to "constructed to the requirements of ANSI B31.1 Appendix III" and limited the use of nonmetallic piping to outside containment for the CCS system.

Based on its evaluation, the staff finds that this change limits the use of nonmetallic piping to areas outside containment which are outside the risk-important portions of the CCS function during shutdown conditions. Based on its evaluation, the staff concludes that these changes are acceptable and do not change the NUREG-1793 Section 9.2.2 findings or conclusions related to CCS piping requirements.

9.2.2.2.5 Investment Protection Short-Term Availability Controls

The applicant proposed to change the minimum required CCS flow rate that is specified for the normal shutdown cooling HX in DCD Tier 2, Table 16.3-2, "Investment Protection Short-Term Availability Controls," SR 2.3.1. This SR is revised to specify that each CCS pump needs to provide at least 10,164 Lpm (2685 gpm) through a normal shutdown cooling HX, which is consistent with the flow rate specified in ITAAC Table 2.3.1-2 for Design Commitment 3 (it is noted that a change is not being proposed for the ITAAC value that was originally established). However, SR 2.3.1 previously specified a minimum flow rate of 10,675 Lpm (2820 gpm), and it was not clear why the ITAAC value that was established was not the same as the value that was originally specified by SR 2.3.1 and why the ITAAC value was correct.

In RAI-SRP9.2.2-SBPA-12, the applicant was asked to explain this apparent inconsistency and to adequately justify the proposed change to reduce the minimum flow rate specified in IPSAC SR 2.3.1 in order for the staff to determine if the proposed change was acceptable.

The applicant responded to the staff's request in a letter dated June 26, 2008. The applicant indicated that 10,675 Lpm (2820 gpm) is the normal CCS flow rate to each of the shutdown cooling HXs and a flow rate of this value or higher is expected to be achieved with the CCS configured as required to perform the normal shutdown cooling function related to CCS flow (i.e., each CCS pump supplying one shutdown cooling HX, one spent fuel cooling HX, and CCS auxiliary loads). The value of 10,164 Lpm (2685 gpm) in DCD Tier 1, Table 2.3.1.2 represents the minimum required CCS flow rate to accomplish the shutdown cooling and is therefore the flow that must be demonstrated in the ITAAC.

The staff reviewed the changes in flow rate values and determined they were adequately explained since the value of 10,164 Lpm (2685 gpm) represents the 'minimum' required flow rate to accomplished the shutdown cooling and the value of 10,675 Lpm (2820 gpm) represents the 'normal' CCS flow rate to perform a 'normal' shutdown cooling function. Since the Tier 1 ITAAC and the SRs have consistent values, the staff determined that RAI-SRP9.2.2-SBPA-12 is resolved.

9.2.2.2.6 Inspections, Tests, Analyses, and Acceptance Criteria (ITAAC) Considerations

The applicant proposed to change the CCS flow rate and heat removal capability that are specified in ITAAC Table 2.3.1-2 to reflect proposed changes that are discussed above in Section 9.2.2.1.1. The changes that are proposed for the SWS ITAAC are consistent with the specific changes that are proposed in this section.

9.2.2.2.7 Initial Test Program Considerations

The initial test program for the CCS is discussed in Tier 2 of the DCD, Section 14.2.9.2.5, "Component Cooling Water System Testing." The stated purpose of the CCS test program is to verify that the as-installed CCS performs the DID functions described in DCD Tier 2 Section 9.2.2 of providing cooling water to DID components and transfer heat to the SWS; as well as providing cooling water to other non-safety-related components for heat removal.

9.2.2.3 Conclusion

The staff evaluated proposed changes to Revision 15 of the AP1000 DCD that pertain to the CCS. The proposed changes are documented in Revision 17 of the AP1000 DCD Tier 2, Section 9.2.2, and are reflected in the Tier 1 ITAAC specified in Table 2.3.1-2 and the Tier 2 IPSAC specified in Table 16.2, Section 2.3. The staff's evaluation, using the guidance provided by NUREG-0800 Section 9.2.2, confirmed that: a) the proposed changes will not adversely affect safety-related SSCs; b) the SWS is capable of performing its DID and RTNSS functions; and c) ITAAC, IPSAC, and initial test program considerations are adequate and appropriate. The proposed changes conform to the existing AP1000 licensing basis as documented in Revision 15 of the approved DCD. The changes contribute to the increased standardization of this aspect of the design. Therefore, these changes meet the finality criterion for changes in 10 CFR 52.63(a)(1)(vii). The staff finds that the proposed changes are acceptable.

9.2.5 Potable Water System

9.2.5.1 Summary of Technical Information

Section 9.2.5, "Potable Water System," (PWS) of the AP1000 DCD, Revision 15, was approved by the staff in the certified design. In AP1000 DCD, Revision 17, the applicant has proposed to delete the site-specific PWS design, including the supply source, from the scope of the certified design and to add a proposed COL information item to address this information.

The basis for this change is documented in TR-124, "Removal of PWS Source and WWS Retention Basins from the Westinghouse AP1000 Scope of Certification," APP-GW-GLN-124, Revision 0 of June 2007. The applicant has identified this change in AP1000 DCD Tier 2, Revision 17, Section 9.2.5.

9.2.5.2 Evaluation

The staff reviewed all changes to the PWS in AP1000 DCD Revision 17 in accordance with the guidance in NUREG-0800 Section 9.2.4, "Potable and Sanitary Water Systems." The staff did not re-review descriptions and evaluations of the PWS in AP1000 DCD, Revision 15, that were previously approved and that are not affected by the new changes. The regulatory basis for Section 9.2.5 of the AP1000 DCD is documented in NUREG-1793. The specific criterion that applies to the proposed DCD change is 10 CFR 52.63(a)(1)(vii) which concerns contribution to increased standardization of the certification information.

In TR-124, "Removal of PWS Source and WWS Retention Basins from the applicant AP1000 Scope of Certification", Revision 0, the applicant proposes to remove the PWS source from the certified design including the potable water storage tank, potable water pumps, potable water jockey pump, and their associated piping. The applicant proposes to transfer responsibility for addressing the supply source and components of the PWS outside of the power block to the COL applicant through the addition of COL Information Item 9.2.11.1. Proposed COL Information Item 9.2.11.1 in DCD Revision 17 states:

> The Combined License applicant will address the components of the potable water system outside of the power block, including supply source required to meet design pressure and capacity requirements, specific chemical selected for use as a biocide, and any storage requirements deemed necessary. A biocide such as sodium hypochlorite is recommended. Toxic gases such as chlorine are not recommended. The impact of toxic gases on the main control room compatibility is addressed in Section 6.4.

The staff identified a wording error in the last sentence of this proposed COL Information Item where "control room *habitability"* should be used in place of the proposed "control room *compatibility."* The applicant agreed during the March 18, 2009 Public Meeting that the correct wording is "control room *habitability."* The staff finds that the proposed COL information item adequately addresses the necessary information that was removed from the DCD by this change. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

In DCD Revision 17, the applicant states that no interconnections exist between the PWS and any potentially radioactive system or any system using water for purposes other than domestic water service. The changes to the PWS include the removal of portions of the PWS, and providing site specific information in COL Information Item 9.2.11.1. Because the changes are all outside the power block and do not involve possible contamination by radioactive water, the staff finds that the conclusions of NUREG-1793 Section 9.2.5 remain valid. Specifically, the staff finds that the PWS continues to satisfy GDC 60, "Control of Releases of Radioactive Materials to the Environment," as it relates to design provisions for controlling the release of water containing radioactive material and preventing contamination of the potable water.

9.2.5.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the applicant's application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the applicant's proposed changes to the AP1000 PWS as documented in DCD, and in TR-124. The staff finds that the applicant's proposed changes do not affect the ability of the AP1000 PWS to meet the applicable NUREG-0800 Section 9.2.4 acceptance criteria. The staff also finds that the design changes have been properly incorporated into the appropriate sections of AP1000 DCD, Revision 17. The AP1000 PWS design continues to meet all applicable acceptance criteria, and the proposed change meets the criterion of 10 CFR 52.63(a)(1)(vii), on the basis that it contributes to increased standardization of the certification information. The staff finds that all of the changes related to the system design of the AP1000 PWS are acceptable.

9.2.7 Central Chilled Water System

9.2.7.1 Summary of Technical Information

Revision 17 of the AP1000 DCD includes proposed changes to the VWS in order to specify increased wet and dry bulb temperatures for heat load considerations and to provide additional design flexibility for COL applicants. The basis for these proposed changes are discussed in TR-108, TR-103 and TR-107, "AP1000 Technical Support Center," APP-GW-GLR-107, Revision 1, of June 2007.

9.2.7.2 Evaluation

The containment isolation interface of the VWS is safety-related. The balance of the VWS is nonsafety-related and the regulatory basis for evaluating the safety and non-safety systems is documented in Section 9.2.7, "Central Chilled Water System," of NUREG-1793. Although the VWS is nonsafety-related, the low-capacity subsystem is considered to be important to safety because it provides chilled water for cooling safety-related and DID equipment rooms. The staff's evaluation of the changes that are proposed focused primarily on confirming that the changes will not adversely affect safety-related SSCs. In addition, the staff evaluation focused on those items that satisfy the criteria for RTNSS, the capability of the VWS to perform its RTNSS and DID cooling functions, and the adequacy of ITAAC, test program specifications, and RTNSS availability controls that have been established for the VWS. The proposed changes were evaluated using the guidance provided by NUREG-0800 Section 9.2.2, "Reactor Auxiliary Cooling Water System," as it pertains to these considerations. Acceptability was judged based upon conformance with the existing AP1000 licensing basis, the guidance specified by NUREG-0800 Section 9.2.2 (as applicable), and SECY-94-084.

The specific criterion that applies to the changes referred to above is 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

During its evaluation, the staff noted that the description that is provided in Revision 17 of the DCD, Section 9.2.7, does not describe the DID and investment protection functions of the VWS. However, the ITAAC specified in Tier 1 of the DCD, Section 2.7.2, "Central Chilled Water System," the initial test program described in Tier 2 of the DCD, Section 14.2.9.2.9, "Central Chilled Water System Testing," and Table 17.4-1, "Risk-Significant SSCs Within the Scope of D-RAP," indicate that the VWS is important for both DID and investment protection considerations. The staff found that this information was not reflected in the description that is provided for the VWS in Tier 2 of the DCD, Section 9.2.7, and that no investment protection short-term availability controls were established for this system. In RAI-SRP9.2.2-SBPA-02, the applicant was asked to provide clarification as necessary in the AP1000 DCD to better explain the DID and investment protection functions of the VWS, as well as to explain why IPSAC was not necessary recognizing that VWS is needed to support other DID non-safety systems. The applicant responded to the staff's request in a letter dated June 26, 2008. The applicant provided additional information concerning the DID and investment protection functions provided by the VWS, and similarly for IPSAC considerations. The staff determined that the additional information was incomplete and inadequate, and Tier 2 of the DCD was not revised to fully explain the VWS design basis relative to DID and investment protection considerations.

Following the June 25, 2009 audit, the applicant responded on September 4, 2009, with an RAI response revision that clarified that the VWS itself is not captured in the RTNSS program. The applicant clarified the functions of the low capacity subsystem that are to maintain the MCR, 1E electrical room and normal RNS pump rooms room temperatures and the associated concrete heat sink temperatures. The applicant identified components of the VWS that are determined to be risk-significant and are included in the scope of D-RAP. These components are identified as:

- Two pumps associated with the low capacity subsystem (as shown on DCD Tier 2 Figure 9.2.7-1 (Sheet 1), "Central Chilled Water System Piping and Instrumentation Diagram".

- Two air-cooled chillers associated with the low capacity subsystem (as shown on DCD Tier 2 Figure 9.2.7-1 (Sheet 1).

In addition the applicant provided a DCD markup adding the above items to Tier 2 DCD Section 9.2.7.2.2, "Component Description," including references to DCD Table 17.4-1, "Risk-Significant SSCs within the Scope of D-RAP." Also included in the DCD markup was a simplified drawing describing the high capacity subsystem (which was omitted in Revision 17 of the DCD) and clarification to DCD Table 9.2.7-1, "Component Data-Central Chilled Water

System," related to clarification of components between the high capacity subsystem and the low capacity subsystem.

The staff reviewed the material from the audit, RAI revision response, and DCD markup and concluded that the clarification to the D-RAP components was adequately addressed and the staff verified that there were no technical changes made to the DCD. In addition, the staff finds that the RAI response corrects the inconsistency between Section 9.2.7 of the DCD and Table 17.4-1. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

9.2.7.2.1 Impact of Proposed Changes on Safety-Related SSCs and Functional Capability

Increase in Site Interface Temperature Limits

As discussed in TR-108, the applicant proposes to change the site interface temperature limits to encompass a broader range of potential sites for AP1000 plants. The proposed changes for the VWS are reflected in Tier 2 of the DCD, Section 9.2.7.2.4, "System Operation." These changes relate to the design specifications for the VWS and do not result in new VWS failure modes or interactions that can adversely affect the capability of safety-related SSCs to mitigate postulated accident conditions. Also, TR-108 states that the limiting temperature specifications are used for properly sizing the air-cooled chiller, thereby assuring adequate DID cooling capability for the low-capacity subsystem. Therefore, as discussed in Section 9.2.2.2.3 of this report, the proposed changes to the site temperature interface limits are acceptable.

Removal of Smart Valves

The AP1000 design specifies the use of "smart valves" (i.e., valves that contain instrumentation such as temperature, flow and pressure that is used for control or indication) for some system applications. In the case of the VWS, smart valves (V272A/B and V261A/B/C/D) are specified as the modulating control valves. As discussed in TR-103, the applicant proposes to remove the requirement for using smart valves for this function so that standard valves can be used by COL applicants. The proposed change replaces the instrumentation that is included in the smart valve design with standard inline instrumentation as illustrated in Figure 9.2.7-1 of the DCD Tier 2. The staff determined the proposed change does not eliminate or alter the functional capabilities of any VWS valves or instruments, and will not degrade the capability or reliability of the VWS to perform its function. The staff expects this change to improve the capability to service and maintain the affected instrumentation which would tend to improve VWS availability and reliability consistent with the Commission's policy on RTNSS. Therefore, the staff considers the proposed changes to use standard inline instrumentation to be acceptable.

Design Temperature inside Containment

Tier 2 of the AP1000 DCD Revision 17, Section 9.2.7.2.2, modified the piping inside containment for the nonsafety high capacity chilled water system from a design temperature of 160 °C to 93.3 °C (320 °F to 200 °F) to accommodate both cooling and heating service. The staff finds that lowering the design temperature of the CWS piping inside containment is a reduction in conservatism. For this reason, the staff discussed this issue at the June 25, 2009, audit and issued RAI-SRP9.2.2-SBPA-13.

The applicant responded to this RAI on September 4, 2009 and stated the piping has a limit of 160 °C (320 °F) at 1,379 kPa (200 psig) and the applicant will restore the VWS piping design temperature back to 160 °C (320 °F). In addition, a DCD mark up was provided for Section 9.2.7.2.2.

The staff reviewed this response and finds that the proposed DCD change is acceptable since it returned to the design temperature based on its previous value. The higher temperature is based on the high capacity chilled water system being aligned to the hot water system for heating of containment. Since a DCD markup was provided as part of this RAI response, this item is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

9.2.7.2.2 Inspections, Tests, Analyses, and Acceptance Criteria (ITAAC) Considerations

Tier 1 of the AP1000 DCD, Section 2.7.2, “Central Chilled Water System,” specifies ITAAC for the VWS. The proposed changes referred to above include design considerations and editorial changes that do not alter or otherwise affect the design specifications that must be verified to assure the DID capability of the low capacity subsystem. Therefore, the staff finds that the ITAAC for VWS are not affected by the proposed changes and will continue to be acceptable.

9.2.7.2.3 Initial Test Program Considerations

The initial test program for the VWS is discussed in Tier 2 of the DCD, Section 14.2.9.2.9, “Central Chilled Water System Testing.” The purpose of VWS testing is primarily to verify that the as-installed low capacity subsystem adequately performs its DID cooling function, as well as confirming the proper function of the high capacity subsystem. The proposed changes referred to above do not alter the fundamental VWS performance considerations that apply and, therefore, the staff finds that the initial test program for VWS will continue to be acceptable.

9.2.7.3 Conclusion

The staff evaluated proposed changes to the VWS as discussed above and reflected in the AP1000 DCD, Tier 2, Section 9.2.9. The proposed changes involve a slight increase in the site temperature interface limits, elimination of smart valves from the VWS design, and design temperature changes inside containment. Based on the results of this evaluation, the staff has determined that the proposed changes will not adversely affect safety-related SSCs, the capability of the VWS to perform its DID cooling functions, or ITAAC and initial test program considerations. Consequently, the staff finds that the proposed changes are consistent with the AP1000 licensing basis and the applicable NRC review guidance specified by NUREG-0800 Section 9.2.2. The proposed changes meet the criterion of 10 CFR 52.63(a)(1)(vii), in that they contribute to increased standardization of the certification information; therefore, the proposed changes are acceptable.

9.2.8 Turbine Building Closed Cooling Water System

9.2.8.1 Summary of Technical Information

In NUREG-1793 the staff approved Section 9.2.8, “Turbine Building Closed Cooling System,” of the AP1000 DCD, Revision 15. In the AP1000, Revisions 16 and 17 the applicant proposed changes to Section 9.2.8.

The applicant proposed the following technical changes to Revision 15 of the AP1000 DCD, which are supported by information in the TRs:

1. Remove descriptive information that pertains to the alternative steam and power conversion design that no longer applies, eliminate nominal heat load values from Table 9.2.8-1, "Turbine Building Closed-Cooling Water System Equipment Load List," and revise the title of the table accordingly, and increase the maximum temperature specifications for the turbine building closed cooling water system (TCS) and its heat sink. Change Table 9.2.8-1 and delete, from the equipment load list, the condensate pump motor air cooler, condensate pump bearing oil cooler, feedwater pump motor air cooler, and condenser vacuum pump.

2. Allow the use of non-metallic pipe in the system design, designate that the heat sink for the TCS is conceptual design information (CDI) instead of the circulating water system, to specify that backwashable strainers are provided upstream of the TCS HXs, and to include information related to TCS HX and upstream strainer operation. Clarify that nonmetallic piping may be used in the TCS and deleted the reference to ASME B31.1, "Power Piping".

The bases for these proposed changes are discussed in TR-86, "Alternate Steam and Power Conversion Design," APP-GW-GLN-018, Revision 1, dated June 2007, and TR-103.

9.2.8.2 Evaluation

The TCS is nonsafety-related and the regulatory basis for evaluating this system is documented in Section 9.2.8 of NUREG-1793. The staff's evaluation of the changes that are proposed focuses on confirming that the changes will not adversely affect SSCs or those that satisfy the criteria for RTNSS. The proposed changes were evaluated using the guidance provided by NUREG-0800 Section 9.2.2, "Reactor Auxiliary Cooling Water System," as it pertains to these considerations. Acceptability was judged based upon conformance with the existing AP1000 licensing basis and the guidance specified by NUREG-0800 Section 9.2.2 (as applicable).

The specific criterion that applies to the changes referred to above is 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

<u>Impact of Proposed Changes on Safety-Related SSCs</u>

As discussed in Section 9.2.8 of NUREG-1793, TCS piping and components are located entirely within the turbine building. No safety-related equipment is located in the turbine building and, therefore, failure of the TCS cannot lead to the failure of any safety-related SSCs. On this basis, the staff found that the proposed change conforms to Regulatory Position C2 of RG 1.29, "Seismic Design Classification," thereby satisfying GDC 2 requirements and the applicable guidance of NUREG-0800 Section 9.2.2 with respect to impact on safety-related SSCs. The proposed changes referred to above and described in TR-86 and TR-103 relative to the TCS do not alter the location of the TCS relative to safety-related SSCs and, consequently, the basis for NRC approval in NUREG-1793 Section 9.2.8 remains valid in this respect.

The staff also noted that TR-103 (Page 23, Item 4) indicates that the cooling medium for the TCS HXs is changed from circulating water to a generic "cooling water" that can be provided by either circulating water and/or raw water makeup to the cooling tower basin. Section 9.2.8.1.2, "Power Generation Design Basis," describes the heat sink for the TCS as circulating water.

However, DCD Tier 2, Revision 17, Section 10.4.5.1.2, “Power Generation Design Basis,” for the circulating water system indicates that: “The CWS and/or makeup water from the raw water system supplies cooling water to the turbine building closed cooling water system (TCS) heat exchangers…” Consequently, the information provided in Sections 9.2.8 and 10.4.5 is inconsistent. It is not clear if the intent is to establish a CDI item for COL applicants to address or to provide the option of using the circulating water and/or raw water makeup to the cooling tower basin instead of establishing a CDI item. In RAI-SRP9.2.2-SBPA-01 the applicant was asked to provide additional information to explain the intention of the proposed change, and to revise Tier 2 of the DCD, Sections 9.2.8 and 10.4.5 as necessary to eliminate the inconsistency. The applicant indicated that the intent of the proposed change was not to establish a CDI item for COL applicants but rather to provide an option for COL applicants to utilize circulating water system (CWS) cooling tower makeup water flow or circulating water flow as the cooling water source, at the applicant’s discretion, for the TCS HXs. The applicant proposed an additional change to Tier 2 Section 10.4.5.2.2 of the DCD in order to eliminate this inconsistency.

The staff reviewed the proposed DCD markups and determined that the changes eliminated the inconsistency between DCD Tier 2 Sections 9.2.8 and 10.4.5. The staff verified that the proposed DCD markups in the RAI response were added to the DCD. Therefore, RAI-SRP9.2.2-SBPA-01 is resolved.

Impact of Removal of TCS Equipment Heat Loads from DCD Table 9.2.8-1

The applicant deleted equipment heat loads that were originally listed because the cooling water for the deleted equipment is a site-specific design rather than part of the AP1000 standard design.

Based on its evaluation, the staff finds this change acceptable because it does not affect the conclusions in NUREG-1793 Section 9.2.8.

Impact of TCS piping material clarification

The applicant deleted reference to ASME B31.1 and has added nonmetallic as a possible piping material to be utilized in the TCS.

The staff reviewed this clarification and determined that this change is consistent with Section 3.2.2.7, “Other Equipment Classes.” TCS is classified as ‘Class E’, and specific piping codes are not typically described in Section 3.2.2.7 for ‘Class E’ systems. In addition, the clarification to use nonmetallic piping in the TCS gives flexibility in the use of non-corrosive material as needed. In a corrosive water environment, nonmetallic piping material outperforms metallic materials whereas metallic piping material may require replacing over time. Based on the staff’s evaluation, the TCS piping material classification is acceptable.

9.2.8.3 Conclusion

The staff evaluated proposed changes to the TCS that are discussed above and are reflected in the AP1000 DCD, Tier 2, Revision 17, Section 9.2.8. Based on the results of this evaluation, the staff has determined that the proposed changes will not adversely affect safety-related SSCs, that they meet the criterion of 10 CFR 52.63(a)(1)(vii), in that they contribute to increased standardization of the certification information and are, therefore, acceptable.

9.2.9 Waste Water System

9.2.9.1 Summary of Technical Information

Section 9.2.9, "Waste Water System" of the AP1000 DCD, Revision 15, was approved by the staff in the certified design. In the AP1000 DCD, Revision 17, the applicant proposed to make several changes to Subsections 9.2.9.2.1, "General Description," 9.2.9.2.2, "Component Description," 9.2.9.5, "Instrumentation Applications," and 9.2.11.2, "Waste Water Retention Basin" of the certified design. The applicant also made changes to DCD Tier 1 Section 2.3.29, "Radioactive Waste Drain System," as a result of changes to the nonradioactive waste water system (WWS). All of these changes are related to the removal of the PWS from the scope of the DC, as described in TR-124.

9.2.9.2 Evaluation

The staff reviewed the proposed changes to Tier 2 Subsections 9.2.9.2.1, 9.2.9.2.2, 9.2.9.5, and 9.2.11.2, and Tier 1 Section 2.3.29, of the AP1000 DCD Revision 17, in accordance with the guidance of NUREG-0800 Section 9.3.3, "Equipment and Floor Drainage System." The regulatory basis for Section 9.2.9 of the AP1000 DCD is documented in Section 9.2.9 of NUREG-1793.

The specific criterion that applies to the proposed DCD changes is 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

The staff finds that the proposed changes in Section 9.2.9.2.1 are limited to the removal of references to the waste water retention basin pump and transfer pumps since these are no longer part of the DC. In addition, the applicant removed the description of the condenser waterbox drains, which were previously routed to the waste water retention basin. The applicant stated that the design and routing of the condenser waterbox drains will be incorporated into the site-specific CWS design (discussed in Section 10.4.5 of NUREG-1793, as supplemented by this report). Because the design includes site-specific criteria, the staff finds acceptable that the applicant defers the design details of the condenser waterbox drains to the COL applicant. However, the staff determined that this information should be included in the COL information item described in DCD Tier 2 Section 10.4.12. The staff requested that the applicant include this information in the DCD in RAI-SRP9.3.3–SBPA-01.

In DCD Section 9.2.9.5, the applicant removed references to the level instrumentation and pump controls located in the waste water retention basin. The staff finds this change acceptable because it is not related to the guidance and acceptance criteria in NUREG-0800 Section 9.3.3.

In a letter dated June 20, 2008, the applicant responded to RAI-SRP9.3.3-SBPA-01 by proposing a markup of Section 10.4.12.1 of the DCD to state that the COL applicant will identify the action of routing the condenser waterbox drains with the site-specific CWS. The staff finds this markup acceptable because the applicant made the DCD clear with regard to what is within the scope of the DC. This DCD change was incorporated into Revision 17; RAI-SRP9.3.3-SBPA-01 is, therefore, resolved.

In DCD Section 9.2.9.2.2, the applicant removed the component description of the waste water retention basin and its associated basin transfer pumps. The applicant replaced this information with a reference to the COL information item described in Section 9.2.11, which requires the

COL applicant to provide the site-specific information for these components. Because the waste water retention basin and its associated basin transfer pumps and piping are site-specific components, the staff finds it acceptable to defer this to the COL applicant.

In DCD Section 9.2.9.5, the applicant also relocated the radiation monitor from the waste water retention basin to the turbine building sump. The staff reviewed this change to ensure that all effluents in the WWS that discharge to the turbine building sump will be monitored prior to disposition, as required by GDC 60. However, based on the information provided, the staff was unable to verify that all nonradioactive effluents will be monitored prior to disposition. For example, in DCD Revision 15, the condenser waterbox drains were routed directly to the WWS retention basin. The staff requested that the applicant address this in RAI-SRP9.3.3–SBPA-02.

By letter dated June 20, 2008, the applicant responded to RAI-SRP9.3.3-SBPA-02. In its response, the applicant identified all the sources of waste water that will drain downstream of the turbine building sump, which include diesel fuel area sump (upstream of the oil separator), SWS/CWS backwash, and other site specific effluent (e.g., CWS waterbox drain). The service water flow is provided with a radiation monitor. All systems interfacing with the CWS that have plausible potential for radioactive contamination are provided with radiation monitoring. The diesel fuel area sump effluent does not interact with any potentially radioactive sources during operation, nor are there any recognized radioactive sources located in the vicinity of the portion of WWS. Effluents that are site specific are under the responsibility of the COL applicant to ensure proper radiation monitoring is designed into the system, as noted in COL Information Item 11.5-1 (Section 11.5.7 of the AP1000 DCD). Based on the above, the staff concludes that all potentially radioactive effluents from the standard plant are properly monitored for radiation prior to disposition off site, as required by GDC 60.

Based on the evaluation of the DCD information and the above response to RAI-SRP9.3.3-SBPA-02, the staff finds this change acceptable because it does not affect the NUREG-1793 Section 9.2.9 findings and conclusions related to controlling release of radioactive materials. Therefore, RAI-SRP9.3.3-SBPA-02 is resolved.

In DCD Revision 17, Tier 1, Section 2.3.29, the applicant removed the references to the waste water retention basin and replaced them with reference to the turbine building sump. These changes are consistent with the changes to Tier 2 Section 9.2.9.5 (discussed above). In short, since the waste water retention basin is no longer in the scope of the certification, the applicant relocated the system's detection and isolation functions to the turbine building sump, rather than the waste water retention basin, thus providing conformance with GDC 60. Therefore, the staff finds this Tier 1 change acceptable.

9.2.9.3 Conclusion

The staff reviewed the applicant's proposed changes to the AP1000 regarding the nonradioactive WWS as documented in AP1000 DCD Tier 2 Subsections 9.2.9.2.1, 9.2.9.2.2, 9.2.9.5, and 9.2.11.2, and Tier 1 Section 2.3.29. The staff finds that the proposed changes meet the acceptance criteria in NUREG-0800 Section 9.3.3. The staff concludes that the AP1000 WWS continues to meet all applicable acceptance criteria and that proposed changes are properly documented in the updated AP1000 DCD. The proposed changes meet the criterion of 10 CFR 52.63(a)(1)(vii); in that they contribute to increased standardization of the certification information.

9.2.10 Hot Water Heating System

9.2.10.1 Summary of Technical Information

In NUREG-1793 the staff approved Section 9.2.10, “Hot Water Heating System” of the AP1000 DCD, Revision 15.

In AP1000 DCD Revision 17, the applicant identified the following Tier 2 changes associated with the Hot Water Heating System, DCD Sections 9.2.10.2.1, 9.2.10.2.3, and 9.2.10.3.

1. The applicant proposed to modify the AP1000 DCD Section 9.2.10.2.1, “General Description,” to delete the method of matching the system heat load and regulating system temperature using a heater bypass valve.

2. The applicant proposed to modify the AP1000 DCD Section 9.2.10.2.3 “System Operation,” to delete reference to a three-way diverting valve that regulates the temperature of the hot water system. No technical basis for this change is provided. The staff notes that the system operation already includes a description of the intended method temperature control to individual heating coils. Temperature regulation through the use of a heater bypass is not required in order for the system to perform its functions.

3. The applicant proposed to modify the AP1000 DCD Section 9.2.10.3, “Safety Evaluation,” to delete reference to a three-way diverting valve that regulates the temperature of the hot water system.

The applicant identified no Tier 1 changes associated with the hot water heating system.

9.2.10.2 Evaluation

The specific criterion that applies to the proposed DCD changes is 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

The staff reviewed all changes to the hot water heating system (VYS) in the AP1000 DCD Revision 17 and finds them acceptable.

The VYS has no safety-related function and, therefore, no nuclear safety design basis. The following evaluation discusses the results of the staff’s review of the Revision 17 changes.

<u>Deletion of 3-Way Diverting Valve for Temperature Regulation</u>

In DCD Revision 17, Sections 9.2.10.2.1, 9.2.10.2.3, and 9.2.10.3, the applicant proposed to delete discussion of the method of regulating VYS system temperature through the use of a 3-way diverting valve that would bypass the hot water heaters. The applicant deleted this information to allow flexibility in designing and constructing the VYS. The staff finds this change acceptable, since it does not affect the NUREG-1793 Section 9.2.10 findings and conclusions.

9.2.10.3 Conclusion

In NUREG-1793, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the applicant's proposed changes to the AP1000 VYS as documented in DCD, Revision 17. The staff concludes that the VYS will continue to comply with the conclusions documented in NUREG-1793 Section 9.2.10. The proposed changes meet the criterion of 10 CFR 52.63(a)(1)(vii) on the basis that they contribute to increased standardization of the certification information.

9.3 Process Auxiliaries

9.3.1 Compressed and Instrument Air System

9.3.1.1 Summary of Technical Information

In the certified design, AP1000 DCD Revision 15, the staff approved Section 9.3.1, "Compressed and Instrument Air System."

In AP1000 DCD Revision 17 the applicant identified the following Tier 2 changes associated with the compressed and instrument air system (CAS), DCD Table 9.3.1-1. Table 9.3.1-2, Table 9.3.1-3, and Table 9.1.3-4.

1. The applicant proposed to change the AP1000 DCD Section 9.3.6.3.7, Table 9.3.1-1, and Figure 9.3.6-1 Sheet 1 of 2, such that the normal position of air operated containment isolation valve CVS-PL-V092 is open. CVS-PL-V092, "Hydrogen Addition Containment Isolation Valve," is now normally open and fails closed on loss of air. Conforming changes have been made to Table 9.3.1-1, Safety-Related Air-Operated Valves and Figure 9.3.6-1.

2. The applicant proposed to modify the AP1000 DCD Table 9.3.1-2, "Nominal Component Design Data – Instrument Air Subsystem," to clarify that the capacity of the air receivers is a minimum of 19 cubic meters (m^3) (672 cubic feet (f^3)) instead of exactly 19 m^3 (672 f^3). The technical basis for this change is to account for growth in demand on the system by ensuring that the receiver tank capacity is at least 19 m^3 (672 f^3).

3. The applicant proposed to modify the AP1000 DCD Table 9.3.1-3, "Nominal Component Design Data – Service Air Subsystem," to clarify that the capacity for the air receiver is a minimum of 19 m^3 (672 f^3) instead of exactly 19 m^3 (672 f^3). The technical basis for this change is to account for growth in demand on the system by ensuring that the receiver tank capacity is at least 19 m^3 (672 f^3).

4. The applicant proposed to modify the AP1000 DCD Table 9.3.1-4, "Nominal Component Design Data – High Pressure Air Subsystem," to clarify that the system design pressure is reduced from 34.5 MPa (5,000) psig to 27.6 MPa (4,000 psig). The technical basis for this change is to revise the system design pressure.

9.3.1.2 Evaluation

The staff reviewed all changes to the CAS in the AP1000 DCD Revision 17 in accordance with NUREG-0800 Section 9.3.1, "Compressed Air System." The regulatory basis for Section 9.3.1 of the AP1000 DCD is documented in NUREG-1793, which states that staff acceptance of the design is contingent on compliance with the following requirements in NUREG-0800 Section 9.3.1:

- GDC 1, as it relates to systems and components being designed, fabricated, and tested to quality standards in accordance with the importance of the safety functions to be performed.

- GDC 2, as it relates to the capability of safety-related CAS components to withstand the effects of earthquakes.

- GDC 5, as it relates to the capability of shared systems and components to perform required safety functions

The CAS has no safety-related function other than containment isolation. The following evaluation discusses the results of the staff's review of the Revision 17 changes.

The specific criterion that applies to the proposed DCD changes is 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

<u>Containment Isolation Valve CVS-PL-V092 Change in Normal Position</u>

In AP1000 DCD Table 9.3.1-1, the applicant proposed to change the normal position of air-operated containment isolation valve, CVS-PL-V092, from closed to open. The applicant made a conforming change on Figure 9.3.6-1 Sheet 1 of 2, "Chemical and Volume Control System Piping and Instrumentation Diagram," showing valve CVS-PL-V092 to be normally open, in order to facilitate zinc acetate injection into the RCS. The evaluation of the valve position is in Section 9.3.6 of this report. The basis for this proposed change is APP-GW-GLN-002 (TR-32).

Based on its evaluation, the staff finds that this change does not affect the NUREG-1793 Section 9.3.1 assumptions, findings, or conclusions with respect to compliance with GDC 1, 2, or 5, as referenced in NUREG-0800 Section 9.3.1, and is, therefore, acceptable.

The impact of this change in the containment isolation system is discussed in Section 6.2.4, "Containment Isolation System," of this report.

<u>DCD Tables 9.3.1-2 and 9.3.1-3, Nominal Component Design Data – Instrument Air and Service Air Subsystems</u>

In DCD Tables 9.3.1-2 and 9.3.1-3, the applicant clarified that the capacity of the air receivers is a minimum of 19 m^3 (672 f^3) instead of being exactly 19 m^3 (672 f^3). This change is conservative in that the receiver tank capacity can be greater than 19 m^3 (672 f^3) and still meet design criteria.

Based on its evaluation, the staff finds that this change does not affect the NUREG-1793 Section 9.3.1 assumptions, findings, or conclusions with respect to compliance with GDC 1, 2, or 5, as referenced in NUREG-0800 Section 9.3.1, and is, therefore, acceptable.

<u>DCD Table 9.3.1-4, Nominal Component Design Data – High Pressure Air Subsystem</u>

In DCD Table 9.3.1-4, the applicant modified the high-pressure air subsystem design pressure from 34.5 MPa (5,000) psig to 27.6 MPa (4,000 psig).

The staff finds that this change does not affect the NUREG-1793 Section 9.3.1 assumptions, findings, or conclusions with respect to compliance with GDC 1, 2, or 5, as referenced in NUREG-0800 Section 9.3.1, and is, therefore, acceptable.

9.3.1.3 Conclusion

In NUREG 1793 and Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the applicant's proposed changes to the AP1000 CAS as documented in DCD, Revision 17. The staff concludes that the CAS will continue to comply with GDC 1, 2, and 5 as stated in NUREG-1793 Section 9.3.1. The proposed changes meet the criterion of 10 CFR 52.63(a)(1)(vii) on the basis that they contribute to increased standardization of the certification information.

9.3.2 Plant Gas System

In the certified design, AP1000 DCD Revision 15, the staff approved Section 9.3.2, "Plant Gas System."

In DCD Revision 17, the applicant proposed to make the following changes to DCD Revision 15:

1. In Section 9.3.2.2.1, "General Description" the applicant proposed to change the location of both the packaged nitrogen system and the carbon dioxide portion of the plant gas system from inside the turbine building to "in the gas storage area in the yard."

2. In Section 9.3.2.2.2, "Component Description" the applicant proposed to change the cryogenic liquid carbon dioxide insulated storage tank from double wall to single wall.

Section 3.5.1.4 of this report includes an analysis of storage tanks as a potential missile source and Section 6.4 of this report includes analyses of onsite chemicals.

9.3.3 Primary Sampling System

9.3.3.1 Summary of Technical Information

In the certified design, AP1000 DCD Revision 15, the staff approved Section 9.3.3, "Primary Sampling System."

In DCD Revision 17, the applicant proposed to make the following change to DCD Revision 15:

- In Section 9.3.3.2.2, "Nuclear Sampling System - Gaseous" the applicant changed the discharge location of the purge gas return from the effluent holdup tank of the liquid radwaste system to the containment sump.

9.3.3.2 Evaluation

The staff reviewed the proposed change to Tier 2 Section 9.3.3.2.2 of the AP1000 DCD Revision 17, in accordance with the guidance of NUREG-0800 Sections 9.3.2, 9.3.3, and 11.5. The regulatory basis for Section 9.3.3 of the AP1000 DCD is documented in Section 9.3.3 of NUREG-1793.

The specific criterion that applies to the proposed DCD change is 10 CFR 52.63(a)(1)(vii) which concerns contribution to increased standardization of the certification information.

NUREG-0800 Section 9.3.2 states that provisions should be made to purge and drain sample streams back to the system of origin or to an appropriate waste treatment system in accordance with the requirements of 10 CFR 20.1101(b) to keep radiation exposures at ALARA. As the sample line for the containment atmosphere returns the purge gas back to the containment, the proposed change meets the acceptance criteria of the NUREG-0800 guidance and the ALARA requirements. The staff finds the change in location of the purge line discharge from the effluent holdup tank to the containment sump acceptable.

9.3.3.3 Conclusion

The staff reviewed the applicant's proposed changes to the AP1000 regarding the Primary Sampling System as documented in AP1000 DCD Tier 2 Section 9.3.3, Revision 17. The staff concludes that the AP1000 Primary Sampling System continues to meet all applicable acceptance criteria and the proposed changes are properly documented in the updated AP1000 DCD. The proposed change meets the criterion in 10 CFR 52.63(a)(1)(vii) on the basis that it contributes to increased standardization of the certification information and is, therefore, acceptable.

9.3.5 Equipment and Floor Drainage System

9.3.5.1 Summary of Technical Information

Section 9.3.5, "Equipment and Floor Drainage System" (EFDS) of the AP1000 DCD, Revision 15, was approved by the staff in the certified design. In the AP1000 DCD, Revision 17, the applicant proposed to make changes to Sections 9.3.5.1.2, "Power Generation Design Basis," and 9.3.5.2.2, "Component Description" of the certified design as follows:

1. The applicant clarified that an exception exists to the minimum slope of 10.42 millimeter per meter (mm/m) (1/8 inches per foot (in/ft)) for drain lines, which is the embedded drain piping in area 2 of the auxiliary building at elevation 20.27 m (66 ft, 6 in) with a minimum slope of 5.21 mm/m (1/16 in/ft) for embedded drain piping.

2. The applicant clarified that each sump is fitted with a vent connection to the radiologically controlled area ventilation system (VAS) exhaust system to exhaust potential sump gases, instead of exhausting into the room.

9.3.5.2 Evaluation

The staff reviewed the proposed changes to Tier 2 Sections 9.3.5.1.2 and 9.3.5.2.2 of the AP1000 DCD Revision 17, in accordance with the guidance of NUREG-0800 Section 9.3.3.

The regulatory basis for Section 9.3.5 of the AP1000 DCD is documented in Section 9.3.5 of NUREG-1793.

The specific criterion that applies to the proposed DCD changes is 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

DCD Revision 15, Section 9.3.5.1.2 provides for a minimum slope of 10.42 mm/m (1/8 in/ft) for embedded drain lines in Level 1 (Area 2) of the auxiliary building at elevation 20.27 m (66 ft, 6 in). In DCD Revision 17, Section 9.3.5.1.2, the applicant changed the minimum slope from 10.42 mm/m (1/8 in/ft) to 5.21 mm/m (1/16 in/ft) for embedded drain lines.

In order for the staff to complete its evaluation, the staff asked the applicant, in RAI-SRP9.3.5-SBPA-01, to justify the change from the minimum slope of 10.42 mm/m (1/8 in/ft) of drain pipe length, and to address its impact on flooding in that part of the auxiliary building by evaluation.

The applicant provided a response to RAI-SRP9.3.5-SBPA-01 in a letter dated September 17, 2009. The RAI response stated that the drain lines located in Level 1 of the auxiliary building (Elevation 20.3 m (66 ft, 6 in)), nonradioactive controlled area, are not credited in the flooding analysis. Because no credit is taken for the drains in this location, the staff finds the applicant's justification for the embedded drain piping slope in this area acceptable and, therefore, GDC 4 is met. Therefore, RAI-SRP9.3.5-SBPA-01 is resolved.

In DCD Section 9.3.5.2.2, the applicant clarified that each sump is fitted with a vent connection to the VAS exhaust system instead of exhausting directly into the room. This allows potential sump gases from each sump to be directed to an exhaust system for the control of airborne radioactivity. The staff finds that this change would minimize potential release of airborne radioactivity or other harmful gases in sump rooms and is, therefore, acceptable.

The staff finds that the applicant adequately identified changes that would not adversely impact the compliance of the EFDS with the guidance in NUREG-0800 Section 9.3.3. Thus, the staff finds that the applicant continues to meet GDC 2, 4, and 60.

9.3.5.3 Conclusion

In NUREG 1793, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the applicant's proposed changes to the AP1000 EFDS as documented in DCD, Revision 17. The staff concludes that the EFDS will continue to comply with the conclusions documented in NUREG-1793 Section 9.3.5. The proposed change meets the criterion of 10 CFR 52.63(a)(1)(vii); on the basis that it contributes to increased standardization of the certification information.

9.3.6 Chemical and Volume Control System

9.3.6.1 Summary of Technical Information

In a letter dated April 5, 2006, the applicant submitted TR-32, “Zinc Addition,” APP-GW-GLN-002, which proposed changes to the AP1000 CVS design to incorporate the ability to inject a small quantity of zinc acetate into the RCS through the CVS. In TR-80, “Markup of AP1000 Design Control Document Chapter 7,” APP-GW-GLR-080, Revision 0, of October 2007, the applicant proposed CVS design changes related to boron dilution events. In DCD Revision 17, the applicant proposed to change DCD Section 9.3.6, “Chemical and Volume Control System,” to incorporate the CVS design changes described in TR-32 and TR-80.

9.3.6.2 Evaluation

The AP1000 CVS as described in DCD Section 9.3.6 is designed to perform the functions of the RCS purification, inventory control and makeup, chemical shim and control, oxygen control, pressurizer auxiliary spray, and borated makeup to the auxiliary equipment. The safety evaluation accepting the CVS design of DCD Section 9.3.6, Revision 15, was described in NUREG-1793, Section 9.3.6. The review was performed using the guidance of NUREG-0800 Section 9.3.4, “Chemical and Volume Control System (PWR) (Including Boron Recovery System),” to assess compliance with the requirements for system performance of necessary functions during normal, abnormal, and accident conditions described in GDC 1; GDC 2; GDC 5; GDC 14, “Reactor Coolant Pressure Boundary”; GDC 29, “Protection Against Anticipated Operational Occurrences”; GDC 33, “Reactor Coolant Makeup”; GDC 35, “Emergency Core Cooling”; GDC 60; and GDC 61.

In Revision 17 of DCD, the applicant proposed changes to DCD Section 9.3.6 on the CVS design with: (1) the capability for zinc addition to the RCS; and (2) modifications related to boron dilution events. The staff’s review of these changes is to assure continued compliance with the relevant requirements specified in the above GDCs.

The specific criterion that applies to the changes referred to above include 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

<u>Zinc Addition</u>

In TR-32, the applicant proposed a modification to the CVS design to provide the capability to inject a small quantity of zinc acetate into the RCS. In DCD Revision 17, the following subsection is added to DCD Section 9.3.6.2 as one of the CVS chemical control functions:

> 9.3.6.2.3.3 Zinc Addition
>
> A soluble zinc compound may be added to the coolant as a means to reduce radiation fields within the primary system and to reduce the potential for crud-induced power shift (CIPS). The zinc used may be either natural zinc or zinc depleted of ^{64}Zn.

Also, DCD Section 9.3.6.2.1.1, “Ionic Purification,” is revised to include the removal of zinc during periods of zinc addition as an added ionic purification function of the mixed bed demineralizers in the purification loop, in addition to removing ionic corrosion products and certain ionic fission products.

TR-32 provides a description and evaluation of the proposed CVS design change to incorporate the ability to inject a small quantity of zinc acetate into the RCS through the CVS. For AP1000, zinc addition will be an optional mode of operation, and the equipment specifically used for storing and pressurizing the zinc acetate is not described. However, as discussed below, minor changes to the base AP1000 CVS design are required to allow for zinc addition to be used as an optional mode of operation.

TR-32 also states that zinc acetate will be added using the same piping and valving as the hydrogen (H_2) addition. The proposed hardware change is to replace a portion of the one-inch pipe downstream of the containment isolation valve with a heavier wall half-inch pipe. To accomplish this design change, in DCD Revision 17, Figure 9.3.6-1 was changed by (1) changing the hydrogen addition line from "H2 ADD" to a hydrogen/zinc addition line "H2/ZINC ADD"; (2) adding a 2.5 cm by 1.27 cm (1 in by .5 in) reducer downstream of valve V065 in the "H2/ZINC ADD" line; and (3) renumbering the portion of the "H2/ZINC ADD" line downstream of the reducer L064 with the specification changed from 2.5 cm (1 in) BBC to 1.27 cm (0.5 in) BBC. According to TR-32, this is made to reduce the piping volume and reduce the transit time for the H_2 and the zinc acetate supply, and will not alter the load of the supply piping. The staff finds this change acceptable because there is no effect on the integrity of the reactor coolant pressure boundary. Also, in DCD Revision 17, in Section 9.3.6.3.7, the hydrogen addition containment isolation valve V092, which is located outside the containment, was changed from the "normally closed, fail closed" position to "normally open, fail closed" position; and V092 in Figure 9.3.6-1 was changed to the "normally open" position. According to TR-32, this change is made to reflect the time that the valve must be open to permit zinc additions. The staff finds this change acceptable because this containment isolation valve automatically closes on a containment isolation signal from the protection and safety monitoring system and, therefore, the containment isolation function is not affected.

Chemistry and Materials Impacts During Normal Operation

According to TR-32, zinc addition has been demonstrated to change the oxide film on primary piping and components, significantly reducing occupational exposure (due to less nickel and cobalt in deposit) and the potential for CIPS. The applicant also stated that laboratory tests indicate a beneficial effect of zinc addition on the major materials in a PWR system because of the reduced corrosion rates and that operating industry experience has shown that up to 40 parts per billion can be added with no adverse effects. The applicant stated that the effect of zinc on the reactor coolant was calculated to be less than 0.2 pH units, which it considers negligible. The staff reviewed industry experience with zinc injection in operating plants and agrees that there is sufficient experience to support the conclusion that there is no deleterious effects on reactor coolant chemistry or reactor coolant pressure boundary materials at zinc injection concentrations up to the maximum limit proposed by the applicant. Although the beneficial effect of zinc addition on major materials at higher concentrations has not yet been fully established through laboratory tests, the reduction in occupational exposure and CIPS has been demonstrated through operating experience.

Post Accident Water Chemistry Impacts

Hydrogen generation caused by corrosion of reactive metals such as zinc and aluminum following a design-basis accident (DBA) is a concern that should be addressed according to

NUREG-0800 Section 6.1.1. However, according to TR-32, because zinc exists as a divalent cation (Zn^{+2}) in solution in the primary coolant and embedded in the corrosion film, hydrogen generation is not expected. The staff agrees that because zinc is added as zinc acetate salt rather than metallic zinc, the zinc would only exist in ionic form that cannot produce hydrogen as a corrosion reaction byproduct. Further, even if the zinc cations in solution could react to form hydrogen, the staff concurs that the amount of zinc is small and would not produce a significant amount of hydrogen.

In addition, given that the volume of reactor coolant is small compared to the borated water volume in the sump, the applicant stated that the effect of zinc on the sump pH following a DBA would also be negligible. The staff finds this statement reasonable due to the low concentration of zinc compared to the concentrations of buffer and boric acid in the sump water following a DBA.

Based on the above, the staff finds the applicant's evaluation of zinc addition on post accident chemistry to be acceptable because the evaluation is based on basic principles of chemistry and the quantity of zinc involved is small.

Fuel Corrosion and Crud Effects

According to TR-32, the addition of zinc to the RCS could result in additional crud deposit on the fuel cladding surface. The applicant performed oxide thickness measurements that showed the crud deposit was thin and the effect of the corrosion rate with zinc injection was statistically insignificant as compared to the corrosion rate without zinc injection. In response to RAI-TR32-07, the applicant provided data from 12 fuel surveillance campaigns, based on which it concluded that there were no observed adverse effects on the fuel cladding performance due to zinc addition. The staff reviewed the plant surveillance data for oxide thickness that were provided in the response to RAI-TR32-07 and agrees with the applicant's conclusion because there was no statistical difference in the measured oxide thickness for cladding with and without exposure to zinc in the coolant. Further, the staff's review of industry experience related to zinc impacts on fuel indicates there are no adverse effects for low- to medium-duty cores. The applicant indicated that the absence of deleterious effects on cladding will be confirmed through cycle-specific reload analyses with zinc addition. The staff identified Open Item OI-SRP9.3.6-SRSB-01 for the applicant to explain how cycle-specific reload analyses can confirm no adverse effect of zinc addition for the AP1000 with a high-duty core and why a fuel surveillance program is not needed to confirm the absence of adverse crud effects.

To provide further definition to assist the applicant in understanding the open item, the staff communicated the following questions to the applicant via an email dated October 23, 2009:

1. Is the AP1000 core design as described in DCD Revision 17 considered a high-duty core?

2. If the AP1000 is considered a high-duty core design, how will it be assured that there will not be problems with excessive crud buildup or uneven crud buildup in operating AP1000 plants? This answer may necessitate either operating experience that demonstrates that a fuel surveillance program is unnecessary, or a recommendation for a fuel surveillance program to be implemented (COL Item).

3. Explain how cycle-specific reload analyses would confirm that zinc would not have a significant effect on cladding corrosion.

4. Since one of the objectives of zinc addition is to reduce the potential for CIPS, will an evaluation of CIPS potential be performed as part of the cycle-specific reload analysis? If so, provide details of the evaluation and a relative comparison to operating plants with and without CIPS. Also, since zinc injection will initially increase the reactor coolant Ni concentration, explain in detail the zinc injection strategy to be employed to minimize the CIPS potential.

In a letter dated February 18, 2010, the applicant responded to Open Item OI-SRP9.3.6-SRSB-01 and specifically the 4 questions as follows:

1. The applicant stated that “According to EPRI HDCI [High-duty Core Index], AP1000 would be classified as a low to medium duty plant.” The applicant provided a table containing the parameters used to calculate the HDCI. The staff performed a confirmatory calculation using the same parameters and obtained the same result. The applicant further stated that “since in terms of boiling duty the AP1000 is approaching that of other Westinghouse high duty plants, we are conservatively treating AP1000 as a high duty plant. There are other currently operating PWRs that are higher duty and also use zinc addition, so AP1000 is bounded by current operating experience.”

The staff finds the response to Item 1 acceptable because a confirmatory calculation verified the HDCI for the AP1000, and because the applicant is conservatively treating the AP1000 core design as high-duty.

2. The applicant indicated that zinc addition will be employed to reduce RCS surface corrosion rates beginning from hot functional testing. The applicant also stated that experience with zinc addition in current PWRs following steam generator replacement indicates substantial benefits in reducing corrosion rates when zinc is applied to fresh metal surfaces such as those found following steam generator replacement. Papers on first cores show similar benefits will occur with AP1000, but right from the beginning of plant operation.

   The applicant also indicated that there have been several additional high-duty plants that began zinc addition since 2003, which were not all reflected in the EPRI Zinc Addition Guidelines cited by the staff. The applicant listed Callaway, Vogtle 1 and 2, Byron 2, Braidwood 2, South Texas 1 and 2, and Watts Bar 1 as high-duty plants that have successfully operated with zinc addition and no problems with crud deposition or fuel performance related to zinc. The applicant also stated that fuel examinations following zinc addition have been completed at numerous high-duty PWRs and continue to show no increase in cladding corrosion and no deleterious impact on fuel crud deposits.

   Finally the applicant stated that AP1000 will have a robust fuel inspection program looking not only at crud but other things using EPRI fuel reliability guidelines.

The staff finds the applicant’s response to Item 2 acceptable because:

a) Based on our review of industry experience related to zinc addition, the staff agrees that excessive nickel release should not occur if zinc addition starts during hot functional testing. This conclusion is supported by data from plants that started injecting zinc concurrently with steam generator replacement reported in EPRI

Report #1013420, “Pressurized Water Reactor Primary Water Zinc Application Guidelines,” of December 2006.

b) The applicant cited additional industry experience with zinc addition in high-duty cores that supports the applicant’s assertion that zinc addition will not cause increased CIPS risk in high-duty cores.

3. The applicant stated that zinc has been shown not to interact with zircaloy clad fuel and does not increase clad corrosion. The applicant further stated that reload-specific corrosion analyses do not need to be penalized due to zinc addition because as zinc began to be applied to higher duty cores additional fuel surveillance was undertaken to determine if any increased cladding corrosion was occurring. Finally the applicant stated that the surveillances have not shown any indication of enhanced clad corrosion for zinc application in these higher duty cores where crud deposits were present.

   Additionally, the applicant indicated that the cycle specific reload analysis described in the response to Item 4 will demonstrate that the reload designs should not result in excessively thick crud deposits.

The staff finds the applicant’s response to Item 3 acceptable because its review of operating experience related to zinc addition confirms the applicant’s claim that there are no adverse effects on fuel-cladding corrosion caused by zinc addition.

4. In response to the first part of Item 4, the applicant stated that a CIPS risk analysis is currently performed using EPRI guidelines and methods for every reload design performed in Westinghouse, and that this process will be performed as part of the initial core and each reload core analysis for AP1000. The applicant further stated that the VIPRE/BOA methods will be used as recommended in the EPRI AOA Guidelines (PWR Axial Offset Anomaly (AOA) Guidelines, Revision, 1008102, Final Report, June 2004, EPRI).

   In response to the second part of Item 4, the applicant indicated that no increase in reactor coolant nickel concentration is expected since zinc addition will start during hot functional testing; thus, the zinc will be incorporated into the corrosion films as they form on the fresh metal surfaces. According to the applicant, this is a more favorable situation compared to the addition of zinc to existing plants with mature corrosion films, which causes nickel to be displaced from the corrosion films. Therefore, the applicant’s response indicates they expect no increase in crud due to displacement of nickel.

The staff finds the response to the first part of Item 4 acceptable because the applicant will be using accepted industry computer codes for analysis of the crud and CIPS risk (VIPRE/BOA). This is consistent with the approach used for operating Westinghouse plants.

The staff finds the response to the second part of Item 4 acceptable because, based on its review of industry experience related to zinc addition; the staff agrees that excessive nickel release should not occur if zinc addition starts during hot functional testing. This conclusion is supported by data from plants that started injecting zinc concurrently with steam generator replacement reported in EPRI Report #1013420.

The staff finds that the applicant has adequately addressed potential fuel corrosion and crud effects of zinc addition because:

- The applicant has presented sufficient industry experience with zinc addition in reactors with high-duty cores to demonstrate that problems with cladding corrosion, excessive crud buildup, or CIPS are not expected.

- The applicant has proposed to use industry-accepted computer codes to model and predict crud formation, for each reload, to confirm that a problem will not occur with crud or CIPS.

Although the applicant did not propose to modify the DCD to include any of the information supplied in the open item response, or provide a COL information item to ensure the COL performs the activities described, the staff notes that there is no specific regulatory requirement for a plant to monitor, model or test for crud buildup or CIPS. Therefore, the proposed reload analyses and fuel surveillance program are not mandatory. The staff considers Open Item OI-SRP9.3.6-SRSB-01 resolved.

Based on the above evaluation, the staff concludes that the zinc addition into the RCS as an operational option, and the associated DCD changes associated with zinc addition discussed above, are acceptable.

<u>Modification to Boron Dilution Event</u>

In DCD Revision 17, the applicant proposed the following changes to DCD Section 9.3.6 associated with boron dilution events:

In DCD Revision 17, Section 9.3.6.3.7, “Chemical and Volume Control Systems Valves,” a sentence is added regarding the makeup line containment isolation valves, which are normally open motor-operated globe valves, to state that the valves close on a source range flux doubling signal to terminate possible unplanned boron dilution events. In DCD Section 9.3.6.7, “Instrumentation Requirements,” a change is also made to the “makeup isolation valves” to state that the two makeup isolation valves automatically close on a signal from the protection and safety monitoring system derived from source range doubling high-2 pressurizer level, high steam generator level, or a safeguards signal coincident with high-1 pressurizer level. In DCD Revision 17, Section 9.3.6.4.5.1, “Boron Dilution Events,” the CVS response to a boron dilution event is revised from “closing either one of two redundant safety-related, air-operated valves from the demineralized water system to the makeup pump suction” to “closing redundant safety-related valves, tripping the makeup pumps and/or aligning the suction of the makeup pumps to the boric acid tank.” The description of dilution events during shutdown is also revised to state that “the source range flux doubling signal is used to isolate the makeup line to the RCS by closing the two safety-related, MOVs, isolate the line from the demineralized water system by closing the two safety-related, air-operated valves and trip the makeup pumps.” This is a change from the statement in Revision 15 that “the source range flux doubling signal is used to isolate the line from the demineralized water system by closing the two safety-related, remotely operated valves. The three-way pump suction control valve aligns the makeup pumps to take suction from the boric acid tank and therefore stops the dilution.”

In TR-80, Item II.9 “Flux Doubling/Boron Dilution Modifications,” provides a rationale for the changes related to boron dilution events in DCD Section 9.3.6. The existing CVS design realigns the makeup pump suction from the demineralized water tank to the boric acid tank to terminate the potential boron dilution and to begin to reborate the RCS to restore shutdown margin. These actions would initially cause the boron dilution to continue because the volume of water in the makeup line path would still be unborated until borated water from the boric acid tank begin to reach the RCS. The function is therefore changed to close the makeup line isolation valves (as well as the demineralized water isolation valves) to terminate the event as soon as possible. Long term recovery from the event would then be accomplished using either a different flow path with a smaller unpurged volume or by using the makeup line after purging most of the unborated water in it. The staff finds that the revised boron dilution events description is consistent with the modifications on the CVS makeup isolation valves in DCD Sections 9.3.6.3.7 and 9.3.6.7. This is also consistent with the boron dilution events described in Section 15.4.6.1 and Sections 15.4.6.2.2 through 15.4.6.2.5 for boron dilution events during Modes 5 through mode 2, respectively. Therefore, the staff finds the changes in the AP1000 DCD Sections 9.3.6.3.7, 9.3.6.4.5.1, and 9.3.6.7 are acceptable.

In DCD Section 9.3.6.6.1.2, “Flow Testing,” the maximum makeup flow for the pump testing verification is changed from 757 Lpm to 662 Lpm (200 gpm to 175 gpm) with both pump operating. The change in the maximum makeup flow rate from 757 Lpm to 662 Lpm (200 gpm to 175 gpm) reflects the maximum flow rate through the cavitating venturi nozzle on the makeup pump discharge header. The CVS makeup pump testing is performed to verify that the maximum makeup flow with both makeup pumps operating is less than 662 Lpm (175 gpm). The staff finds that this maximum makeup flow rate is consistent with the assumptions of the boron dilution events analyzed in DCD Revision 17, Section 15.4.6, where the assumed unborated water flow rate is also changed from 757 Lpm to 662 Lpm (200 gpm to 175 gpm). The reduction of the maximum makeup flow to 662 Lpm (175 gpm) limits the unborated water flow rate to 662 Lpm (175 gpm) in the inadvertent boron dilution events and, thus, allows more time for isolation of the unborated water and termination of the events. Therefore, the staff finds that this change is acceptable.

In DCD Revision 17, Table 9.3.6-2, the following CVS nominal design parameters are changed: the letdown HX shell side and tube side design temperatures are changed from 93.3 °C (200 °F) and 343.3 °C (650 °F), respectively, to 65.5 °C (150 °F) and 315.5 °C (600 °F); the design flows of the mixed bed and cation bed demineralizers, and the reactor coolant filter are changed from 379 Lpm to 946 Lpm (100 gpm to 250 gpm); and the boric acid storage tank volume is changed from 264,979 L to 278,28 5 L (70,000 to 73,515 gallons). In RAI-SRP9.3.6-SRSB-02 the staff requested that the applicant provide the basis and justification for these changes to determine their acceptability. In its response dated January 26, 2009, the applicant provided the bases for these changes. The applicant states that the shell side temperature of the letdown HX cannot exceed 65.5 °C (150 °F) because shell side coolant is the CCS with a normal operating temperature of no higher than 37.8 °C (100 °F). The tube side temperature cannot exceed 315.5 °C (600 °F) as the purification flow is first cooled through the regenerative HX. The staff finds the tube side temperature acceptable because the purification flow is drawn from the RCS cold leg, which has a temperature lower than 315.5 °C (600 °F). The staff concludes that the changes of letdown HX shell side and tube side temperatures to 65.5 °C (150 °F) and 315.5 °C (600 °F), respectively, still maintain sufficient margin to the operating temperatures and are, therefore, acceptable.

The applicant states that the changes of the design flows from 379 Lpm to 946 Lpm (100 gpm to 250 gpm) for the demineralizers and the reactor coolant filters accommodate shutdown purification flows that could be as high as 810 Lpm (214 gpm) when the normal RNS provides the motive force for reactor coolant purification. The staff considers these design flow increases conservative changes that provide margin for the shutdown purification flow and are, therefore, acceptable. The applicant states that the boric acid storage tank increase in volume from 264,979 L to 278,285 L (70,000 to 73,515 gallons) represents the usable volume of the tank, which includes the volume to accommodate a shutdown to cold shutdown followed by refueling at the end of the fuel cycle, plus the volume needed for normal operation and operating margin, and this increased volume is calculated with updated inputs that more accurately represents the AP1000 design. Because this more accurately reflects the design information, the staff finds this change acceptable.

In DCD Revision 15, the CVS demineralizer resin flush line containment isolation thermal relief valve (CVS-PL-V042) was located outside of the containment and discharged to the WLS waste holdup tank. In DCD Revision 17, Figure 9.3.6-1 is revised to relocate CVS-PL-V042 to inside containment between the two containment isolation valves. This relief valve is provided to prevent overpressurization of the resin sluice line that is used to sluice resin from the mixed bed and cation bed demineralizers to the waste processing system. The staff reviewed this change and finds that the location of the relief valve inside containment does not affect the functional capability of the CVS, but provides a protection against release of potential radioactive products outside containment. Therefore, the staff concludes that the proposed change is acceptable.

9.3.6.3 Conclusion

The staff reviewed the changes to DCD Section 9.3.6 regarding the AP1000 CVS design as described in DCD Revision 17. Based on the evaluation described above, the staff concludes that these changes would not adversely impact the required AP1000 CVS functions, and that the requirements of GDC 1, 2, 5, 14, 29, 33, 35, 60, and 61 continue to be met. The proposed changes meet the criterion of 10 CFR 52.63(a)(1)(vii); in that they contribute to increased standardization of the certification information.

9.4 Air Conditioning, Heating, Cooling, and Ventilation System

In NUREG-1793, the staff approved Section 9.4, “Air Conditioning, Heating, Cooling, and Ventilation System,” of AP1000 DCD, Revision 15. In AP1000 DCD, Revision 17, the applicant proposed changes to this section, supported by TR-103.

The staff reviewed the changes to AP1000 DCD, Revision 15, Section 9.4, which are described in Revision 17. NUREG-1793 includes the regulatory basis for Section 9.4 of AP1000 DCD. The staff reviewed the proposed changes to DCD Section 9.4 against the applicable acceptance criteria in NUREG-0800 related to Section 9.4. Those changes that involve NRC review considerations as reflected in NUREG-0800 are described and evaluated in this section.

The specific criterion that applies to the changes evaluated in this section is 10 CFR 52.63(a)(1)(vii), which concerns the contribution to increased standardization of the certification information.

9.4.1 Nuclear Island Nonradioactive Ventilation System (VBS)

9.4.1.1 Summary of Technical Information

In Section 9.4.1.2.2, “Component Description,” the applicant proposed to change the humidifier description such that the design and rating of the VBS Humidifiers will be in accordance with ARI 640, “Commercial and Industrial Humidifiers.”

The DCD previously referenced standard ARI 620, “Self Contained Humidifiers for Residential Applications” in the design of the humidifiers. This was incorrect as ARI 620 states that the intended application of the humidifiers is typically for non-ducted applications, and is independent of a central air system. The AP1000 uses humidifiers in ducted central air applications; therefore, ARI 640, “Commercial and Industrial Humidifiers” is the correct specification, and has replaced ARI 620. This correction applies to VAS, VBS, health physics and hot machine shop heating, ventilation, and air conditioning (HVAC) system (VHS), turbine building ventilation system (VTS), and annex/auxiliary buildings nonradioactive HVAC system (VXS) systems.

In Section 9.4.1.2.3.1, “Main Control Room/Control Support Area HVAC Subsystem,” the applicant proposed various modifications to both the normal plant operation and abnormal plant operation sections.

In NUREG-1793, the staff approved a VBS HVAC system that has one heater in each air handler and one pair of temperature sensors to control the temperature in the control support area (CSA) and MCR areas. The airflow to each space is selected to properly cool each space at the summer design weather conditions. During winter conditions, cooling is required to maintain design conditions in some spaces, including the MCR, some electric/electronic equipment spaces, and the CSA computer rooms. Since the VBS system, as previously configured, could not heat some spaces and cool others simultaneously, additional heaters and temperature sensors have been added in the return ducting from the computer room for temperature control.

In Table 9.4-1 and Table 9.4.1-1, changes to the VBS leakage rates to MCR/CSA were proposed. The control logic depicted on the Figure 9.4.1-1 (sheet 4 of 7) of the DCD for the VBS fans serving the Class 1E Division B and D electrical rooms has been changed so that starting an air handling unit will start the chilled water system associated with that air handling unit. Previously, starting air handling unit MS03B sent a signal to the VWS to start chilled water pump MP02, which provides chilled water to air handling unit MS03D. In the same manner, starting air handling unit MS03D sent a signal to the VWS to start chilled water pump MP03, which provides chilled water to air handling unit MS03B. In both cases starting the air handling unit fails to start the correct water chiller and, therefore, the cooling system would not have operated correctly. The logic has been corrected so that starting air handling unit MS03B will start chilled water pump MP03 and starting air handling unit MS03D will start chilled water pump MP02; thus, starting each air handling unit will start the respective supporting pump.

9.4.1.2 Evaluation

The above mentioned DCD changes are technical improvements, corrections to design errors, or changes of facility descriptions. For the reasons discussed above, all of the changes are acceptable.

9.4.1.3 Conclusion

The NRC staff has reviewed the proposed changes to the VBS system and finds them acceptable. On the basis of the evaluation described in NUREG-1793 and this evaluation, the NRC staff concludes that the VBS system is acceptable and that the application for DC meets the requirements of Subpart B of 10 CFR Part 52 that are applicable and technically relevant.

9.4.2 Annex/Auxiliary Buildings Nonradioactive HVAC System (VXS)

9.4.2.1 Summary of Technical Information

In Section 9.4.2.1.2, “Power Generation Design Basis,” for the annex building nonradioactive HVAC system, there were some room rearrangements: Office areas, conference rooms, and security rooms and areas were added. A central alarm station and a security access area were deleted from the system and a security room in the mechanical equipment room was added.

In Section 9.4.2.2.1.1, “General Area HVAC Subsystem,” the “VXS General Area HVAC Subsystem” was expanded. This expansion would add two more supply air handling units and other equipment to provide ventilated air to personnel areas in the annex building outside the security area.

In Section 9.4.2.2.2, “Component Description,” the applicant changed the humidifier description such that the performance rating of the VAS Humidifiers will be in accordance with ARI 640.

9.4.2.2 Evaluation

The above mentioned DCD changes are technical improvements or changes of facility descriptions. For the reasons discussed above, all of the changes are acceptable.

9.4.2.3 Conclusion

The NRC staff has reviewed the proposed changes to the VXS system and finds them acceptable. On the basis of the evaluation described in NUREG-1793 and this evaluation, the NRC staff concludes that the VXS system is acceptable and that the application for DC meets the requirements of Subpart B of 10 CFR Part 52 that are applicable and technically relevant.

9.4.3 Radiological Controlled Area Ventilation System (VAS)

9.4.3.1 Summary of Technical Information

In Section 9.4.3.2.2, “Component Description,” the applicant proposed to change the humidifier description such that the performance rating of the VAS humidifiers would be in accordance with ARI 640 and Figure 9.4.3-1 would be revised accordingly.

9.4.3.2 Evaluation

The change to ARI 640 is evaluated in Section 9.4.1.

9.4.3.3 Conclusion

The NRC staff has reviewed the proposed changes to the VAS system and finds them acceptable. On the basis of the evaluation described in NUREG-1793 and this evaluation, the NRC staff concludes that the VAS system is acceptable and that the application for DC meets the requirements of Subpart B of 10 CFR Part 52 that are applicable and technically relevant.

9.4.7 Containment Air Filtration System (VFS)

9.4.7.1 Summary of Technical Information

In Section 9.4.7.1.2, the applicant proposed to specify a VFS design pressure of "< -0.125 in. water gauge."

9.4.7.2 Evaluation

This change is evaluated in Section 16.4.12 of this report.

9.4.8 Radwaste Building HVAC System (VRS)

9.4.8.1 Summary of Technical Information

In Section 9.4.8.1.2, "Power Generation Design Basis," the applicant proposed to add "Truck Staging Area" to the rooms/areas covered by the VRS with a specified temperature range.

9.4.8.2 Evaluation

The above mentioned DCD change is an acceptable design improvement.

9.4.8.3 Conclusion

The NRC staff has reviewed the proposed changes to the VRS system and finds them acceptable. On the basis of the evaluation described in NUREG-1793 and this evaluation, the NRC staff concludes that the VRS system is acceptable and that the application for DC meets the requirements of Subpart B of 10 CFR Part 52 that are applicable and technically relevant.

9.4.9 Turbine Building Ventilation System (VTS)

9.4.9.1 Summary of Technical Information

In Section 9.4.9.2.1.2, "Electrical Equipment and Personnel Work Area HVAC," the applicant proposed to provide details regarding the electrical equipment, south bay equipment, and personnel work area air conditioning subsystems including area temperature re-designation from 10.0 °C to 40.5 °C (50 °F to 105 °F) to 10.0 °C to 37.7 °C (50 °F to 100 °F). The following descriptive paragraph was also provided:

> The south bay equipment area HVAC system consists of two 50-percent capacity air handling units of about 7000 cfm capacity each. The air handling units are located on elevation 117'-6" of the turbine building between column 11 and 11.2. The temperature of the room is maintained by the thermostats that control the chilled water control valves for cooling and the integral face bypass dampers for heating. Outside air is mixed with the recirculation air to maintain a positive pressure.

In Section 9.4.9.2.2, "Component Description," the applicant proposed to change the humidifier description such that the design and rating of the VTS humidifiers will be in accordance with ARI 640.

9.4.9.2 Evaluation

The temperature change is acceptable because a lower maximum temperature is preferred for electrical equipment. The change to ARI 640 is evaluated in Section 9.4.1.

9.4.9.3 Conclusion

The NRC staff has reviewed the proposed changes to the VTS system and finds them acceptable. On the basis of the evaluation described in NUREG-1793 and this evaluation, the NRC staff concludes that the VTS system is acceptable and that the application for DC meets the requirements of Subpart B of 10 CFR Part 52 that are applicable and technically relevant.

9.4.10 Diesel Generator Building Heating and Ventilation System (VZS)

9.4.10.1 Summary of Technical Information

In Section 9.4.10.2.1.1, “Normal Heating and Ventilation System,” the applicant proposed to add the following paragraph:

> Electric unit heaters are provided in the diesel generator stairwell and security room to maintain the space at a minimum temperature.

9.4.10.2 Evaluation

The above mentioned DCD change is technically sound. The design change is acceptable.

9.4.10.3 Conclusion

The NRC staff has reviewed the proposed change to the VZS system and finds it acceptable. On the basis of the evaluation described in NUREG-1793 and this evaluation, the NRC staff concludes that the VZS system is acceptable and that the application for DC meets the requirements of Subpart B of 10 CFR Part 52 that are applicable and technically relevant.

9.4.11 Health Physics and Hot Machine Shop HVAC System (VHS)

9.4.11.1 Summary of Technical Information

In Section 9.4.11.1.2, “Power Generation Design Basis,” of the DCD the applicant proposed to add the “Security Room,” the “Elevator Machine Room” and the “Stairwell” to the VHS ventilation system coverage rooms/areas with specified temperature ranges.

In Section 9.4.11.2.2, “Component Description,” the applicant proposed to change the humidifier description such that the design and rating of the VHS humidifier will be in accordance with ARI 640.

9.4.11.2 Evaluation

The staff finds this change acceptable because the VHS ventilation system coverage has no safety significance. The change to ARI 640 is evaluated in Section 9.4.1.

9.4.11.3 Conclusion

The NRC staff has reviewed the proposed change to the VHS system and finds it acceptable. On the basis of the evaluation described in NUREG-1793 and this evaluation, the NRC staff concludes that the VHS system is acceptable and that the application for DC meets the requirements of Subpart B of 10 CFR Part 52 that are applicable and technically relevant.

9.5 Other Auxiliary Systems

9.5.1 Fire Protection Program

9.5.1.1 Summary of Technical Information

Section 9.5.1, "Fire Protection System" of the AP1000 DCD, Revision 15, was approved by the staff in NUREG-1793. In AP1000 DCD, Revision 17, the applicant has proposed to make the following change to Section 9.5.1:

1. In the AP1000 DCD, Revision 17, the applicant proposes to revise Section 9.5.1.8, alleviating the need for the COL applicant to submit additional information and to close out COL Action Items 9.5-5 and 9.5-8.

2. In Table 9.5.1-1, the applicant proposes to add carpeting into the MCR (e.g., for sound abatement or other human factors).

<u>Multiple Spurious Actuations</u>

Section 9A.2.7.1, "Criteria and Assumptions," of Appendix 9A, "Fire Protection Analysis," of the DCD, states the following with respect to the approach to evaluating multiple spurious actuations that result from fire-induced electrical shorts: "spurious actuations or signals resulting from the fire are postulated one-at-a-time (except for high/low pressure interfaces)." However, as noted in RG 1.189, "Fire Protection for Nuclear Power Plants," Revision 1, the "one-at-a-time" assumption for spurious actuations may not adequately address the potential risk attributed to fire as demonstrated by NRC and industry fire tests.

The specific criterion that applies to the changes referred to above is 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

9.5.1.2 Evaluation

In the AP1000 DCD, Revision 17, the applicant proposes to add carpeting into the MCR as allowed by RG 1.189, Regulatory Position 6.1.2. Although the DCD stated that the MCR carpeting issue is addressed in the fire protection analysis, the NRC staff noted that only the additional fire loading has been documented in the fire hazard analysis. Since the introduction of carpeting as proposed in DCD Revision 17 increases the fire duration in Fire Area 1242 AF 01 (MCR Complex) beyond 60 minutes, the current fire protection adequacy evaluation based primarily on the "light hazard" assumption for this fire area may no longer be valid. In addition, since the fire duration in Fire Zone 1242 AF 12401B increases to 75 minutes, which exceeds the 1-hour fire barrier rating between the two fire zones within the MRC Complex, the assumption that a fire is limited to one fire zone within the MCR Complex is no longer valid. Furthermore, while RG 1.189 references American Society for Testing and Materials (ASTM) D2859, "Standard Test Method for Flammability of Finished Textile Floor

Covering Materials," for establishing the acceptable flammability characteristics of the material, the applicant establishes compliance by referencing ASTM E-648, "Standard Test Method for Critical Radiant Flux of Floor-Covering Systems Using a Radiant Heat Energy Source," and National Fire Protection Association (NFPA) 253, "Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source," flame tests. In reviewing the above standards, the NRC staff cannot establish a direct correlation in the testing methods and acceptance criteria between ASTM D2859 and ASTM E-648 or NFPA 253.

In RAI-SRP9.5.1-SFPB-02, the staff requested that the applicant provide additional information to demonstrate that the alternative fire testing standards meet ASTM D2859 at the minimum. In addition, it was requested that the applicant revise the DCD and provide an evaluation that shows the additional fire loading does not impact the existing fire protection adequacy evaluation for the MCR Complex and it was requested that the applicant justify that the exclusion of a fixed fire suppression system in this fire area is still acceptable.

In a letter dated September 23, 2009, the applicant proposed several DCD revisions to address the information requested in RAI-SRP9.5.1-SFPB-02. The applicant included the testing standard used and revised Table 9.5.1-1 to indicate that the flammability characteristics of the carpeting are acceptable when tested to ASTM D2859. In addition, the applicant has stated that a revised combustible loading/fire severity calculation has been performed using a lower carpet quantity (weight per square foot), based on carpet vendor data, for carpeted areas and further reduced quantities to reflect areas not carpeted. Based on the new calculation, the applicant affirmed that the fire severity in the affected zone/area remains under the 1-hour fire duration, thus the "light hazard" assumption in the affected fire zone/area is maintained. Based on the above, the NRC staff determined that the applicant has adequately addressed the technical concerns in RAI-SRP9.5.1-SFPB-02. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Multiple Spurious Actuations

On February 19, 2009 and again on March 31, 2009, the NRC staff conducted audits of the applicant's fire hazards analysis supplemental report APP-FPS-G1R-002 and discussed the "one-at-a-time" assumption used in the report. The applicant stated that this assumption is not applied in supplemental report APP-FPS-G1R-002 or any other safe-shutdown analyses. The applicant further stated that by design, any unsafe plant conditions created by spurious equipment actuations (regardless of single or multiple spurious actuations) will be detected by the redundant safety instrumentation logics and will be mitigated by operators using the preferred safe-shutdown method or ultimately by the AP1000 passive safe-shutdown system. Since the applicant maintained that the "one-at-a-time" assumption is not used in the fire hazards analysis or any other safe-shutdown analysis, the NRC staff requested in RAI-SRP9.5.I-SFPB-01 that the "one-at-a-time" assumption be replaced with "multiple spurious actuations" assumption in applicable sections of the AP1000 DCD and that supplemental report APP-FPS-G1R-002 be referenced in the DCD. In a letter dated June 9, 2009, the applicant accepted the NRC staff's recommendation and proposed the above changes in the next revision of the DCD. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

9.5.1.2.1 Evaluation of COL Action Items

COL Action Item 9.5-5

In the AP1000 DCD, Revision 17, the applicant proposes to revise Section 9.5.1.8, alleviating the need for the COL applicant to submit additional information and to close out COL Action Item 9.5-5.

COL Action Item 9.5-5:

> The COL applicant will provide an analysis to demonstrate that operator actions that minimize the potential for spurious actuation of the automatic depressurization system (ADS) as a result of a fire can be accomplished within 30 minutes following detection of the fire, as well as the procedure for manual actuation of the fire water containment supply isolation valve to allow fire water to reach the automatic fire system in the containment maintenance floor.

This proposed change is supported by TR-45, "Operator Actions Minimizing Spurious ADS Actuation," APP-GW-GLR-027, Revision 1, dated June 2006, in which the applicant provided an analysis demonstrating that operator manual action can be accomplished within 30 minutes to minimize the potential for spurious automatic depressurization system (ADS) actuation in the event of a fire. The TR also stated that the procedure for the manual actuation of the valve to allow fire water to reach the automatic fire system in the containment maintenance floor has been written.

The ADS consists of four different stages of valves that are designed to open sequentially when actuated and to remain open for the duration of an automatic depressurization event. The sequential valves actuation logic relies on a combination of time delays and level indicators to prevent simultaneous opening of more than one stage at a time, and thus provides for a controlled depressurization of the RCS. Manual actuation switches are also provided in the MCR and on the remote shutdown console (RSC).

The applicant had previously asserted in the AP1000 DCD, and in subsequent responses to the staff's RAIs, that the inherent design of the ADS actuation logic, and the spatial separation of the manual activation switches in the MCR, made fire-induced spurious ADS actuation a highly unlikely event and therefore not a concern. However, the NRC staff has maintained that for certain plant areas, including the MCR, Division A Instrumentation and Control (I&C) Room, Division B I&C Room, Division C I&C Room, Division D I&C Room, Division A Penetration Room, and Division C Penetration Room, fire-induced spurious ADS actuation cannot be precluded due to the potential of multiple hot shorts and smoke-induced integrated circuit failures. Consequently, the applicant introduced post-fire operator actions as prescribed in TR45 to further minimize the probability of spurious ADS actuation in the above plant areas.

The staff initially had a concern regarding the feasibility and reliability of the proposed post-fire operator manual actions prescribed in TR-45 and issued RAI-TR45-006 in a letter dated March 30, 2007. In a letter dated July 13, 2007, the applicant responded to RAI-TR45-006 asserting that although spurious ADS actuation is undesirable, if ADS were to actuate as the result of a fire, the AP1000 plant would still be able to achieve and maintain post-fire safe shutdown. Also, the disabling of the ADS as proposed has no impact on the ability to achieve and maintain post-fire safe shutdown. Since the proposed post-fire operator manual actions are neither required for achieving and maintaining post-fire safe shutdown nor will create an adverse impact on the post-fire safe-shutdown capability, the staff concludes that these actions do not have to meet the feasibility and reliability criteria outlined in RIS 2006-10, “Regulatory Expectations with Appendix R Paragraph III.G.2 Operator Manual Actions.” Furthermore, these operator manual actions, aimed to minimize ADS actuations, have no adverse impact on the fire protection program.

In addition to providing the analysis supporting the minimization of spurious ADS actuation, TR-45 also provided that the applicant’s document, APP-GW-GJP-305, “AP1000 Fire Emergency Response,” includes steps for manual alignment of valves to allow fire water to reach the automatic fire system in the containment maintenance floor. This procedure, in addition to the above analysis, provided adequate information to satisfy COL Action Item 9.5-5.

<u>COL Action Item 9.5-8</u>

Section 9.5.1.8, “Special Protection Guidelines (Regulatory Position C.8 of BTP cmEB 9.5-1)” of the AP1000 DCD, Revision 15, was approved by the staff in the certified design. In the AP1000 DCD, Revision 17, the applicant proposes to revise Section 9.5.1.8, alleviating the need for the COL applicant to submit additional information and to close out COL Action Item 9.5-8. This proposed change is supported by TR-46, “Fire Resistance Test Data,” APP-GW-GLR-019, Revision 0, dated May 2006, in which the applicant provided the fire resistance test data for the concrete/steel composite building material selected for use in certain firefighting and safe shutdown access/egress routes, in particular the stairwell towers within the Auxiliary Building. COL Action Item 9.5-8:

> The COL applicant will provide 2-hour fire resistance test data in accordance with American Society for Testing and Materials (ASTM) Standard E-119 and NFPA 51 for the composite material selected for stairwell fire barriers.

Regulatory Position C.5.a.6 of Branch Technical Position (BTP) cmEB 9.5.1 specifies that “Stairwells outside primary containment serving as escape routes, access routes, for firefighting, or access routes to areas containing equipment necessary for safe shutdown should be enclosed in masonry or concrete towers with a minimum fire rating of 2 hours and self-closing Class B fire doors.” The AP1000 design, however, deviates from the above guideline by specifying concrete/steel composite material with an equivalent fire resistance rating of 2 hours in lieu of masonry or concrete for the auxiliary building stairway towers. The applicant, however, did not provide test reports to demonstrate that the designed concrete/steel composite configuration would meet the applicable regulation (GDC 3, “Fire Protection”) and the applicable guidance (BTP cmEB 9.5-1) requiring an equivalent level of safety of concrete or masonry. The responsibility to provide test data was deferred to the COL applicant. Consequently, the NRC staff assigned COL Action Item 9.5-8 requiring the COL applicant to provide fire resistance test data in accordance with ASTM E-119, “Standard Test Method of Fire Tests of Building Construction and Materials,” and NFPA 251, “Tests of Fire Endurance of Building Construction and Materials,” for the concrete/steel composite material.

TR-46 supported the close-out of COL Action Item 9.5-8 by providing the fire resistance test data for the concrete/steel composite material. TR-46 confirmed that test results from Factory Mutual Research Corporation’s Report J. I. 1R7Q3 successfully demonstrated at least a 2-hour fire resistance rating for the concrete/steel composite material as required by regulatory Position C.5.a.6 of BTP CMEB 9.5-1. This TR also confirmed that the fire resistance test was performed in accordance with ASTM E-119 and NFPA 251 as required per Section 3.1.6 of Generic Letter (GL) 86-10, “Implementation of Fire Protection Requirements.”

Based on the above, the staff concluded that the applicant has provided adequate information to demonstrate the adequacy of the concrete/steel composite material to provide a fire resistance equivalent to that of a 2-hour rated concrete or masonry barrier as specified in Regulatory Position C.5.a.6 of BTP CMEB 9.5-1. Accordingly, COL Action Item 9.5-8 can be closed.

9.5.1.3 Conclusion

The NRC staff finds that the applicant has adequately addressed the staff's concern regarding the additional combustible loading/fire severity in the MCR Complex. The NRC staff also finds that the applicant's proposed DCD revision to replace the fire-induced "one-at-a-time" assumption with the "multiple spurious actuations" assumption is acceptable. The staff also concludes that the applicant has provided adequate information to close COL Action Item 9.5-5 and COL Action Item 9.5-8.

Based on the evaluation above, the staff concludes that the proposed changes are acceptable because the AP1000 design continues to meet the applicable requirements and guidance in GDC 3, BTP CMEB 9.5-1 and 10 CFR 50.48. The proposed changes meet the criterion of 10 CFR 52.63(a)(1)(vii), because they contribute to increased standardization of the certification information.

9.5.2 Communications Systems

9.5.2.1 Summary of Technical Information

The staff has reviewed the amendments to Section 9.5.2 of the AP1000 DCD, in accordance with the acceptance criteria in NUREG-0800 Section 9.5.2, "Communications System."

In Section 9.5.2.2.3, "Private Automatic Branch Exchange (PABX) System," the applicant has proposed to change the PABX interface to communications system requirements with the following modifications:

The applicant states that the hotlines to specified locations (for example, dedicated communication lines with load dispatcher to support and coordinate the system gird) are as described in Section 9.5.2.5, "Combined License Information." The hotline circuits are dedicated channels that provide direct communication between the MCR and the headquarters, or other facilities, are as specified in Section 9.5.2.5.

Direct extensions from the PABX locations exterior to the plant is as dictated by Section 9.5.2.5.

In addition, the applicant has proposed to modify the requirements for commercial telephone lines that are provided by the local area telephone company. Specifically, the applicant specifies that the number of lines will be defined as required in Section 9.5.2.5.

9.5.2.2 Evaluation

The specific criterion that applies to the changes referred to above is 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

In RAI-SRP9.5.2-ICE-01, the staff requested additional information regarding the transfer of requirements from Section 9.5.2.2.3 to Section 9.5.2.5 for the COL applicant to address PABX interfaces to hotlines and direct extensions from the PABX locations exterior to the plant. In the July 31, 2008, response to the staff's request for additional information, the applicant provided justification for these modifications. The applicant states that the changes made in Section 9.5.2.2.3 were administrative as described in TR-130, "Editorial Format Changes Related to Combined License Applicant and COL Information Items," APP-GW-GLR-130, Revision 0 of June 2007. TR-130 states:

"Up through Revision 15 of the DCD, there were many instances where the text states, "...the Combined License applicant will...." or words exist stating something similar. The applicant has taken the position that in the "Combined License Information" sections in Tier 2 of the DCD, these words are appropriate. Having the words appear in other sections of the DCD, however, leads to confusion, especially when the COL applicant is attempting to incorporate by reference the DCD section (or subsection) into their individual COL application. As a result, the applicant has reviewed the DCD and has removed these types of phrases from Tier 2… "In no case is it the intent of Westinghouse to change the commitment that exists in DCD, as the changes are intended to be editorial."

9.5.2.3 Conclusion

The applicant states that the requirements in Section 9.5.2.2.3 have not been modified or removed nor have they been transferred to Section 9.5.2.5. As delineated in Section 9.5.2.5, the COL applicant will describe how it meets the requirements specified in Section 9.5.2. The staff finds this response acceptable. The staff verified that the modifications made in Section 9.5.2.2.3 are administrative and do not affect the requirements within the COL action items described in Section 9.5.2.5. The staff concludes that the changes made in Revision 19 of the AP1000 DCD do not impact the staff's conclusions within Section 9.5.2, "Communication Systems" of NUREG-1793 regarding the AP1000 communication system's compliance. The proposed changes meet the criterion of 10 CFR 52.63(a)(1)(vii); on the basis that they contribute to increased standardization of the certification information and are, therefore, acceptable.

9.5.4 Diesel Generator Auxiliary Support Systems

9.5.4.1 Summary of Technical Information

Section 9.5.4, "Standby Diesel Fuel Oil System" of the AP1000 DCD, Revision 15, was approved by the staff in NUREG-1793. In AP1000 DCD, Revision 17, the applicant has proposed to make the following changes to Section 9.5.4 of the certified design:

1. The applicant has proposed to delete the function of supplying diesel fuel oil to the auxiliary boiler. In the previously approved AP1000 DCD, Revision 15, the standby diesel fuel oil system supplied fuel oil to the auxiliary boiler.

2. The applicant has proposed to complete COL Information Item 9.5-12 of Table 1.8-2, which is addressed in Section 9.5.4.7 of the AP1000 DCD Revision 15 and states:

    > Combined License applicants referencing the AP1000 certified design will address the site-specific need for cathodic protection in accordance with NACE Standard RP-01-69 for external metal surfaces of metal tanks in contact with the ground.

3. The applicant has proposed to partially complete COL Item 9.5-13 of Table 1.8-2, which is addressed in Section 9.5.4.7 of the AP1000 DCD Revision 15 and states:

    Combined License applicants referencing the AP1000 certified design will address site-specific factors in the fuel oil storage tank installation specification to reduce the effects of sun heat input into the stored fuel, the diesel fuel specifications grade and the fuel properties consistent with manufacturers' recommendations, and will address measures to protect against fuel degradation by a program of fuel sampling and testing.

9.5.4.2 Evaluation

The staff reviewed all changes to the Standby Diesel Fuel Oil System (SDFOS) in the AP1000 DCD Revision 17 in accordance with the guidance in NUREG-0800 Section 9.5.4, "Emergency Diesel Engine Fuel Oil Storage and Transfer System." The regulatory basis for Section 9.5.4 of the AP1000 DCD is documented in NUREG-1793. The following evaluation discusses the results of the staff's review.

The specific criterion that applies to the changes referred to above is 10 CFR 52.63(a)(1)(vii), which concerns contribution to increased standardization of the certification information.

9.5.4.2.1 Delete the Function of Supplying Diesel Fuel Oil to the Auxiliary Boiler

In DCD Revision 17, the applicant changed Tier 1 Section 2.3.3, ITAAC Table 2.3.3-2; and Tier 2 pages 9.5-24 through 9.5-28, Table 9.5.4-1, Table 9.5.4-2, and Figure 9.5.4-1. The applicant deleted the function of supplying diesel fuel oil to the auxiliary boiler. In TR-114, "AP1000 Auxiliary Boiler Sizing and Design," APP-GW-GLN-114, Revision 0 of June 2007, the applicant states that utilities have reported operational problems due to fouling of the fuel in diesel boilers that sit idle for extended periods of time. Some have changed their auxiliary boilers to electric boilers. For AP1000, the applicant has proposed a design change from a diesel fired auxiliary boiler to an electric auxiliary steam boiler. The fuel oil pumps and fuel oil piping associated with the auxiliary boiler have been removed from the DCD. The staff finds this change does not affect the function of the SDFOS to supply diesel fuel oil to the standby DGs. The staff also finds that the statements regarding the auxiliary boiler fuel oil supply in Section 9.5.9 of NUREG-1793 are no longer applicable. Since the changes to the SDFOS, which are the removal of the portion that would supply the auxiliary boiler, do not affect the function to supply fuel oil to the standby DGs, the staff finds that the conclusions of NUREG-1793 regarding the acceptability of the SDFOS remain valid.

9.5.4.2.2 Resolution of COL Item 9.5-12

In Revision 17 to the AP1000 DCD, the applicant proposed to resolve COL Information Item 9.5-12 which addresses cathodic protection of diesel fuel oil storage tanks. COL Information Item 9.5-12 in the DCD is also discussed in NUREG-1793 as COL Action Item 9.5.9-1. The applicant submitted TR-120, "Cathodic Protection for Metal Tanks in Contact With the Ground," APP-GW-GLR-120, of 25 May, 2007, for staff review to close out COL Information Item 9.5-12. The proposed change will eliminate the need for COL applicants to address cathodic protection of diesel fuel oil storage tanks as stated in COL Information Item 9.5-12.

In Revision 15, Section 9.5.4.7 to the AP1000 DCD, COL Information Item 9.5-12 states:

> Combined License applicants referencing the AP1000 certified design will address the site-specific need for cathodic protection in accordance with NACE Standard RP-01-69 for external metal surfaces of metal tanks in contact with the ground.

This COL item refers to National Association of Corrosion Engineers (NACE International) Standard Recommended Practice RP0169, “Control of External Corrosion on Underground or Submerged Metallic Piping Systems,” which is referenced in RG 1.137, “Fuel-Oil Systems for Standby Diesel Generators.” Since the diesel fuel tanks proposed for the AP1000 are on grade rather than buried, TR-120 proposes to address the COL item based on an alternative to NACE International RP0169.

In Revision 17 of the AP1000 DCD, the applicant proposed to resolve COL Information Item 9.5-12 by addressing the cathodic protection of diesel fuel oil storage tanks in TR-120, Section 9.5.4.7 of the DCD was revised to add Section 9.5.4.7.1, which states:

> The Combined License information requested in this subsection has been completely addressed in APP-GW-GLR-120 (Reference 24), and the applicable changes are incorporated into the DCD. No additional work is required.
>
> The following words represent the original COL Information item commitment, which has been addressed as discussed above:
>
>> Combined License applicants referencing the AP1000 certified design will address the site-specific need for cathodic protection in accordance with NACE Standard RP-01-69 for external metal surfaces of metal tanks in contact with the ground.

According to Section 9.5.4.2.2.1 of the DCD, the fuel oil storage tanks are located on grade and will be erected on a continuous concrete slab contained within a concrete dike. The tanks will have no direct contact with the soil, and the design is intended to minimize the intrusion of groundwater and rainwater into the interface between the tank bottom and concrete foundation.

In its report, the applicant explained that because NACE International RP0169 applies to underground tanks and the AP1000 diesel tanks are above ground, this COL item is being addressed according to guidance in American Petroleum Institute (API) Recommended Design Practice 651 (API 651), “Cathodic Protection of Aboveground Storage Tanks.” The applicant quoted a portion of Section 5.3.3 in API 651 that indicates: (1) a properly designed concrete tank pad may be effective in eliminating external corrosion from the soil and the need for cathodic protection (CP); and (2) moisture may still collect between the tank bottom and pad, and CP is generally not an effective corrosion control method under these conditions. The corrosion protection proposed for these tanks is, therefore, based on a combination of keeping the tank bottom dry and coating it with an appropriate epoxy-urethane paint system.

Because cathodic protection of a structure relies on the flow of electrical charge (i.e., current) from external electrodes (anodes) to the structure (cathode), successful application of CP requires an electrolyte path between the anodes and the structure. (See, for example, “Cathodic Protection,” in Metals Handbook, Ninth Edition, Volume 13, ASM International, 1987.) For external protection, CP is normally used in a soil or aqueous environment in conjunction with an external coating on the structure; hence, current is needed only at coating defects that expose the underlying metal. For the AP1000 diesel tanks, the staff concludes CP would not be useful under the design conditions because the tank bottoms are expected to be dry. Any anticipated moisture accumulation causing partial or intermittent wetness would not be expected to cause significant corrosion of tanks utilizing a well designed and maintained coating system.

The staff notes that another NACE International Standard Recommended Practice, RP0193, "External Cathodic Protection of On-Grade Carbon Steel Storage Tank Bottoms," provides guidance similar to API 651:

> 5.7 On-grade tanks that are set on solid concrete or asphalt pad foundations generally require specialized measures for corrosion protection, because cathodic protection may be ineffective. In this circumstance, the external surface of the tank bottom should be coated. In all cases, steps should be taken to ensure that water does not migrate between the tank bottom and the pad.

The industry recommended practices cited by the applicant and by the staff indicate cathodic protection is not required for the on-grade diesel fuel storage tanks proposed for the AP1000, and the proposed resolution of COL Information Item 9.5-12 is, therefore, technically sound. Therefore, the staff found that the DCD changes, as proposed by the applicant in TR-120, are acceptable, and COL Information Item 9.5-12 is resolved. These DCD changes are generic and are expected for all COL applications referencing the AP1000 certified design. At this time, the NRC has not issued a COL for any AP1000 plant. Thus, the proposed changes incorporated into Revision 17 contribute to the increased standardization of the certification information in the AP1000 DCD.

The staff notes that the standby DGs and their support systems (e.g., fuel storage tanks) have no safety-related functions in the AP1000 passive plant design and, therefore, no nuclear-safety design basis. Hence, storage tank design features discussed above are not safety significant. NUREG-1793, which was written based on Revision 14 of the AP1000 DCD, stated this conclusion as follows:

> Based on its review, the staff determined that the DG and auxiliary boiler fuel oil system is a non-safety-related system and serves no safety-related function. Its failure does not lead to the failure of any safety systems. The staff, therefore, concludes that the requirements of GDC 2, 4, 5, and 17, and the guidance of SRP Section 9.5.4, do not apply.

9.5.4.2.3 COL Item 9.5-13

In Revision 17 to the AP1000 DCD, the applicant proposed to resolve the portion of COL Information Item 9.5-13, that addresses the need to reduce heat input to the fuel oil storage tanks from the sun. COL Information Item 9.5-13 in the DCD is also discussed in NUREG-1793 as COL Action Item 9.5.9-2, which is associated with ensuring the quality of diesel fuel oil. The applicant submitted TR-120 for staff review to close out COL Information Item 9.5-13. The proposed change will eliminate the need for COL applicants to address the site-specific requirement for reducing heat input to the fuel oil storage tanks from the sun. With respect to the other two parts of COL Information Item 9.5-13, the proposal is clear that addressing the fuel specifications grade, properties, and sampling/testing program remains the responsibility of the COL applicant.

In Revision 15, Section 9.5.4.7 to the AP1000 DCD, COL Information Item 9.5-13 states:

> Combined License applicants referencing the AP1000 certified design will address site-specific factors in the fuel oil storage tank installation specification to reduce the effects of sun heat input into the stored fuel, the diesel fuel specifications grade and the fuel properties consistent with manufacturers' recommendations, and will address measures to protect against fuel degradation by a program of fuel sampling and testing.

COL Information Item 9.5-13 addresses three separate issues: 1) reducing heat input to the tank from the sun; 2) specifying the proper fuel grade and properties based on the engine manufacturer recommendations; and 3) protecting against fuel degradation with a fuel sampling and testing program. The applicant proposes to partially resolve this COL item by closing out that portion of the COL item related to reducing heat input to the tank from the sun. COL Information Item 9.5-13 will remain open and COL applicants are required to specify the proper fuel grade and properties based on the engine manufacturer's recommendations, and provide measures to protect against fuel degradation with a fuel sampling and testing program.

In Revision 17 of the AP1000 DCD, the applicant proposed to partially resolve COL Information Item 9.5-13 by addressing heat input to the tank from the sun in TR-120. Section 9.5.4.7 and Table 1.8-2 of the DCD was revised to add Section 9.5.4.7.2, which states:

> 9.5.4.7.2 The Combined License information requested in this subsection has been partially addressed in APP-GW-GLR-120, (Reference 24), and the applicable changes are incorporated into the DCD. No additional work is required to address the information requested in this subsection as delineated in the following paragraph:
>
>> The epoxy-urethane paint color selected for the exterior of the standby diesel fuel oil storage tanks shall be white to minimize radiant sunlight heat transmission to the tank oil stored fuel volume.
>
> The following activities are to be addressed by the Combined License applicant:
>
>> Address the diesel fuel specifications grade and the fuel properties consistent with manufacturers' recommendations and the measures to protect against fuel degradation by a program of fuel sampling and testing.
>
> The following words represent the original Combined License Information item commitment, which has been addressed as discussed above:
>
>> Combined License applicants referencing the AP1000 certified design will address site-specific factors in the fuel oil storage tank installation specification to reduce the effects of sun heat input into the stored fuel, the diesel fuel specifications grade and the fuel properties consistent with manufacturers' recommendations, and will address measures to protect against fuel degradation by a program of fuel sampling and testing.

Heat input to the tank is addressed by stating that the color of the epoxy-urethane exterior coating will be white to minimize heat input to the tank contents. This approach is technically sound. For example, it is consistent with ASTM D-975, “Standard Specification for Diesel Fuel Oils,” – 07b, Section X3.7, which states reflective paint color should be used to prevent thermal degradation of the fuel oil.

With respect to the other two parts of COL Information Item 9.5-13, the proposal is clear that addressing the fuel specifications grade, properties, and sampling/testing program remains the responsibility of the COL applicant.

Based on the above, the staff finds that the portion of COL Information Item 9.5-13 that addresses reducing heat input to the tank from the sun is resolved. These DCD changes are generic and are expected for all COL applications referencing the AP1000 certified design.

9.5.4.3 Conclusion

Based on the above evaluation, the staff finds the applicant’s proposed design change from a diesel fired auxiliary boiler to an electric auxiliary steam boiler does not affect the function of the SDFOS to supply diesel fuel oil to the standby DGs and is, therefore, acceptable. The staff also finds that the applicant’s proposed resolution to COL Information Item 9.5-12 is consistent with applicable industry guidance and is, therefore, acceptable. The staff also finds that the applicant’s proposed partial resolution to COL Information Item 9.5-13 for reducing heat input to the tank from the sun is consistent with applicable industry guidance and is acceptable. The proposed changes meet the criterion of 10 CFR 52.63(a)(1)(vii) on the basis that they contribute to increased standardization of the certification information.

10. STEAM AND POWER CONVERSION SYSTEM

10.1 Introduction

Westinghouse Electric Company LLC (Westinghouse or the applicant) proposed to the U.S. Nuclear Regulatory Commission (NRC) an alternative design for its steam and power conversion (SPC) system in its technical report (TR)-86, “APP-GW-GLN-018, Revision 0, “Alternate Steam & Power Conversion Design,” dated February 8, 2007. On June 25, 2007, the applicant submitted Revision 1 to TR-86 and proposed a new standard design with a single turbine-generator and steam-cycle unit for all AP1000 plants. In Revision 17 to the AP1000 design control document (DCD), Tier 2, Section 10.2, “Turbine Generator,” the applicant incorporated all the changes associated with the new standard design.

The most significant differences between the designs that the NRC staff evaluated in NUREG-1793, “Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design,” issued September 2004, and the proposed new design of the main turbine-generator set are as follows:

(1) replacement of the mechanical overspeed protection with a diverse electrical overspeed trip;

(2) triplicate channels for turbine speed indication and turbine trip signal versus two redundant channels;

(3) three modes of turbine overspeed protection versus two modes;

(4) hydraulic trip manifold, which enables online testing;

(5) addition of 7th stage feedwater heaters;

(6) decrease in diameter from 137 centimeters (cm) (54 inch (in)) to 132 cm (52 in) for the low-pressure turbine last stage blade (LSB);

(7) addition of moisture extraction blades (MEB); and

(8) static excitation provided by solid-state thyristors versus brushless excitation.

In the AP1000 DCD, Tier 1, Section 2.4.2, Table 2.4.2-2, the applicant proposed adding an “emergency electrical overspeed trip device” as a component located in the turbine building.

In addition, AP1000 DCD, Section 10.2, includes the following proposed changes:

- In DCD Tier 2, Section 10.2.6, “Combined License Information on Turbine Maintenance and Inspection,” the applicant proposed revising the implementation timing for combined license (COL) Information Item 10.2.6. This was identified as COL Action Item 10.5-2 in Section 10.5 of Appendix F, “Combined License Action Items,” to NUREG-1793.

- In DCD Tier 2, Section 10.2.3.6, “Maintenance and Inspection Program Plan,” the applicant proposed revising the turbine valve testing intervals from quarterly to semiannually.

- In DCD Tier 2, Section 10.2, the applicant proposed a number of changes related to the layout and general arrangement in the turbine building as a result of replacing the original design with the alternative design, which includes an additional stage of feedwater heaters.

- In DCD Tier 2, Section 10.2.2.4, “Digital Hydraulic System Description”; Section 10.2.2.5, “Overspeed Protection”; and Table 10.2-2, “Turbine Overspeed Protection”; the applicant proposed revisions to reflect the replacement of the Toshiba Turbine Control System with an Ovation® Turbine Control System.

- In DCD Tier 2, Figure 10.2-1, “Turbine Generator Outline Drawing,” the applicant revised the drawing to provide consistency with the Toshiba Turbine-Generator Steam Cycle Design.

All other changes to Section 10.2 were determined by the staff to be editorial in nature and do not affect the conclusion in NUREG-1793 and are, therefore, acceptable.

10.2 Turbine Generator

The staff reviewed all changes to the turbine generator, in accordance with Section 10.2, “Turbine Generator,” of NUREG-0800, “Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants.” The new design of the turbine-generator system was evaluated against the requirements in Title 10 of the *Code of Federal Regulations* (10 CFR) Part 50, “Domestic licensing of production and utilization facilities.” Specifically, the design must meet the requirements of General Design Criterion (GDC) 4, “Environmental and Dynamic Effects Design Bases,” in Appendix A, “General Design Criteria for Nuclear Power Plants,” to 10 CFR Part 50, as they relate to protecting the structures, systems, and components (SSCs) that are important to safety from the effects of turbine missiles. GDC 4 provides guidance for the turbine overspeed protection system (with suitable redundancy and diversity) to minimize the generation of turbine missiles. NUREG-0800 Section 10.2.II, “Acceptance Criteria,” describes the specific criteria needed to meet the requirements of GDC 4. Also, the staff used NUREG-0800 Section 10.2.III, “Review Procedures,” to determine whether the preliminary design in the DCD meets the acceptance criteria in NUREG-0800 Section 10.2.II.

The staff focused its review on changes 1 through 4 identified above, COL Action Item 10.5-2, turbine valve testing, and the general layout arrangements, since these changes affect the protection of the turbine from overspeed conditions that could lead to the generation of turbine missiles. These items relate directly to the specific criteria described in Items 1 A and 1 C of NUREG-0800 Section 10.2.II that are necessary to meet the requirements of GDC 4, as they relate to the turbine overspeed protection and periodic testing of components while the unit is operating at rated load. Also, the staff reviewed changes 5 through 8 identified above and determined that these changes do not affect the safety conclusions in NUREG-1793.

For the purpose of this evaluation, the NRC refers to the design of the turbine-generator system provided in the AP1000 DCD, Revision 15, and evaluated in Section 10.2 of NUREG-1793, as the "original" design. The staff refers to the alternative Toshiba design in the proposed changes to the AP1000 DCD as the "new" design.

The safety design bases and power generation design bases for the turbine generator are the same for both the original and new designs. The turbine generator of the new design is designated as Model TC6F, with a diameter of 132 cm (52 in) for the low-pressure turbine LSB unit. The low-pressure turbine LSB in the original design had a diameter of 137 cm (54 in). DCD Tier 2, Table 10.2-1, identifies the design parameters of the new design. DCD Tier 2, Figure 10.3.2-2, provides the piping and instrumentation diagram containing the stop, control, intercept, and reheat valves. Also, the new design consists of a double-flow, high-pressure turbine; three double-flow, low-pressure turbines; and two external moisture separator/reheaters. The difference between the two designs is that the new design has two reheating stages, while the original design had only one.

The single direct-driven generator is cooled by hydrogen gas and de-ionized water (water-cooled in the original design). Other related system components include a turbine-generator-bearing lubrication system, a digital electrohydraulic control (D-EHC) system with supervisory instrumentation, a turbine steam-sealing system, overspeed protective devices, turning gear, a stator cooling-water system, a generator hydrogen and seal oil system, a generator carbon-dioxide system, a rectifier section, an excitation transformer, and a voltage regulator. The D-EHC system, the overspeed protective devices, and the excitation system in the new design differ from those in the original.

The turbine-generation foundation in both designs is a spring-mounted support system. The springs dynamically isolate the turbine-generator deck from the remainder of the structure in the range of operating frequencies.

The turbine-generator cycle is basically the same for both designs. Steam from each of the two steam generators enters the high-pressure turbine through stop valves and control valves (CVs). After expanding through the high-pressure turbine, exhaust steam flows through two external moisture separator/reheater vessels. The reheated steam flows through separate reheat stop and intercept valves in each of six reheat steamlines leading to the inlets of the three low-pressure turbines. Turbine steam extraction connections are provided for seven stages of feedwater heating (six stages in the original design). Moisture separation in the new design differs from the original; however, the difference does not affect the evaluation and the staff's conclusion in NUREG-1793.

10.2.1 Overspeed Protection

A D-EHC system and an emergency trip system provided overspeed protection in the original design. The D-EHC system opened a drainpath for the hydraulic fluid in the overspeed protection control header, if the turbine exceeded 103 percent of rated speed. As a result of the loss of fluid pressure in the header, the control and intercept valves closed.

The emergency trip system tripped the turbine if speeds exceeded 110 percent of the rated speed. The emergency trip system has an emergency trip control block, trip solenoid valves, a mechanical overspeed device, three test trip blocks with pressure sensors and test solenoid valves, rotor position pickups, speed sensors, and a test panel. The mechanical overspeed trip device consisted of a spring-loaded trip weight mounted in the rotor extension shaft.

In the new design, the two systems that provide overspeed protection, the D-EHC control system and the electrical overspeed trip system, differ from those in the original.

The new D-EHC has three modes of operation to protect the turbine generator against overspeed. The first is the intercept-valves control function, which initiates closure of the intercept valves when the error between the demand position signal and the actual position signal of the intercept valve exceeds the setpoint. The second mode is load unbalance, which operates at greater than or equal to 30-percent load rejection. It causes all control and intercept valves to close quickly. The third mode is the emergency overspeed trip. All CVs and intercept valves are fully closed quickly by the actuation of each fast-acting solenoid valve of the electrical overspeed trip system.

The electrical overspeed trip system consists of redundant processors, three speed channel circuits, and trip relays. An independent electrical overspeed system replaces the mechanical overspeed device of the original design. A trip of the system opens a drainpath for the hydraulic fluid in the emergency trip supply. A loss of fluid pressure in the trip header causes the main stop and reheat valves to close. Also, a relay trip valve in the connection to the emergency trip supply opens to drop the pressure in the relay emergency trip supply and cause the control and intercept valves to close.

The specific criteria that apply to the overspeed protection related changes include 10 CFR 52.63(a)(1)(vi), “Finality of standard design certifications,” in that the changes substantially increase overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security, and 10 CFR 52.63(a)(1)(vii), in that the proposed changes contribute to increased standardization of the certification information.

The following Sections 10.2.2 and 10.2.2.1 provide further details on the D-EHC and the electrical overspeed trip systems, respectively.

10.2.2 Digital Electrohydraulic Control System

AP1000 DCD, Section 10.2.2.4, “Digital Electrohydraulic System Description,” states that the turbine generator is equipped with a D-EHC system that combines the capabilities of redundant processors and high-pressure hydraulics to regulate steamflow through the turbine. The system provides the functions of speed control, load control, and automatic turbine control. A hydraulic system, independent of the bearing lubrication system, provides valve opening actuation in the D-EHC system. Upon reduction or relief of fluid pressure, springs provide valve-closing actuation. The system is designed so that loss of fluid pressure, for any reason, leads to valve closing and, consequently, a turbine trip. Steam valves are provided in an in-line configuration. The overspeed trip system trips the stop valves; the CVs are modulated by the control system and are actuated by the trip system.

The speed control function of the D-EHC master controller provides speed control, acceleration, and overspeed protection. The speed error signal is derived by comparing the desired setpoint with the actual speed of the turbine. A failure of one speed input generates an alarm. The failure of two or more speed inputs generates an alarm and trips the turbine.

The speed control function exists in triplicate channels. The master controller speed function also contains 110-percent and 111-percent overspeed trips. The 110-percent trip signal is sent to a fast-acting solenoid valve in the hydraulic trip manifold that actuates closure of the stop, control, intercept, and reheat valves. An independent emergency electrical trip is available at 111-percent turbine speed, as a backup to the 110-percent electrical overspeed trip.

The load control function of the D-EHC develops signals that are used to regulate unit load. Signal inputs are based on a proper combination of the speed error and actual load setpoints (turbine megawatt) to generate flow demand on the CVs.

The automatic turbine control provides start up and loading of the turbine generator. The automatic turbine control programs monitor the applicable limits and precautions. When the operator selects the automatic turbine control, the programs both monitor and control the turbine. The automatic turbine control is capable of performing the following activities:

- changing speed
- changing acceleration
- generating speed holds
- changing load rates
- generating load holds

The staff's evaluation finds that the D-EHC system combines the capabilities of redundant processors and high-pressure hydraulics to regulate steamflow through the turbine. The control system provides the functions of speed control, load control, and the automatic turbine control, which may be used either for control or for supervisory purposes, at the option of the plant operator.

The D-EHC system employs three electric speed inputs with signals that are processed in redundant processors. A hydraulic system that is independent of the bearing lubrication system provides valve-opening actuation. Upon reduction or relief of fluid pressure, springs and steam forces provide valve-closing actuation. The system is designed so that a loss of fluid pressure, for any reason, leads to valve closing and consequent turbine trip.

The staff discusses the acceptability of the redundancy and diversity functions of the new D-EHC system design below.

The overspeed trips for the turbine consist of a 110-percent electrical trip and a 111-percent independent emergency electrical trip. In DCD Tier 2, Section 10.2.2.4.1, the applicant stated that the independent emergency electrical trip was available at 111-percent turbine speed, as a backup to the 110-percent electrical overspeed trip.

The electrical overspeed trip system includes an online testable hydraulic manifold, speed sensors, a trip relay, independent power supplies, and a test panel. The emergency trip supply pressure is established when the master trip solenoid valves are closed. The valves are arranged in two channels for testing purposes. Both valves in a channel will open to trip the channel. Both channels must trip before the emergency trip supply pressure collapses to close the turbine steam inlet valves. Each tripping function of the electrical emergency trip system can be individually tested either by the operator or from the test panel, without tripping the turbine, by separately testing each channel of the appropriate trip function. The solenoid valves may be individually tested.

The 110-percent electrical overspeed trip system has triplicated (i.e., redundant) speed sensors, separate from the 111-percent emergency electrical overspeed trip speed sensors, that provide backup overspeed protection, and use the master trip solenoid valves in the master trip device to drain the emergency trip hydraulic supply. The hydraulic fluid in the trip and overspeed protection control headers is independent of the bearing lubrication system to minimize the potential for contamination of the fluid.

Separate instruments sense low bearing oil pressure, low electrohydraulic fluid pressure, and high condenser back pressure. Each assembly consists of triplicate pressure transmitters with instrument valves. Each assembly is arranged into three channels. If two of the three signals (pressure or vacuum) reach a trip setpoint, then the pressure sensors cause the master trip device to operate. A test device can check the trip function by simulating pressure to activate the trip outputs from the modules.

The mechanical overspeed device, evaluated in NUREG-1793, has been replaced with an independent, diverse electrical overspeed trip system. The electrical overspeed trip system consists of redundant processors, three speed channel circuits, and trip relays, as well as other protective functions, such as trip anticipations and power load unbalance detection. The overspeed controllers execute offline and online testing, both of which are conducted from the control room and require no technicians at the turbine. Offline testing is performed during startup and trips the turbine, based on an internal setpoint rather than actual turbine speed. Online testing is automatically executed through the internal injection of a ramping signal into all three independent speed channels at once. This test verifies the proper operation of the software, the hardware, and the components of the hydraulic trip manifold. Loss of one signal will neither cause nor prevent a trip; however, failure of two of the three channels will initiate a turbine trip.

Regarding redundancy, Westinghouse stated that its design achieves additional redundancy by using three speed channel circuits in the master controller of the D-EHC turbine control system. The master controller is the primary controller for starting, synchronizing, and megawatt-loading the turbine/generator. This emergency overspeed trip system residing in the master controller is redundant, independent, and diverse to the electrical overspeed trip system, as discussed above. Each speed channel also has its own independent tripping relays. Loss of one signal will neither cause nor prevent a trip. Further, Section 3.0, "Technical Background," of TR-86, Revision 1, states: "Both the electrical overspeed trip system and the emergency overspeed trip systems in the master controller meet the single-failure criterion and are testable when the turbine is in operation." However, the staff's review of the DCD markup could not find any commitment for either the electrical overspeed trip system or the emergency overspeed trip system in the master controller to meet the single-failure criterion. Item 1.A of NUREG-0800 Section 10.2 states that the overspeed protection system should meet the single-failure criterion and should be testable when the turbine is in operation. Therefore, in request for additional information (RAI)-SRP10.2-SBPA-01, the staff asked the applicant to provide additional information and justification for its claim that its design meets the NUREG-0800 guidance for the single-failure criterion.

In its response to RAI-SRP10.2-SBPA-01, in a letter dated June 20, 2008, the applicant stated that the detailed design of the emergency overspeed trip system for AP1000 is still being completed and that the overspeed protection system design will meet the NUREG-0800 guidance for the single-failure criterion. The applicant is to provide a date for the completed design. The staff had identified this as Open Item OI-SRP10.2-SBPA-01.

The applicant addressed the single failure criteria in its response to RAI-SRP10.2-SBPA-02, dated June 12, 2009. The response included a mark-up of DCD Tier 2, Section 10.2.2.5.3

stating that the overspeed protection system will function for abnormal conditions, including a single failure of any component or subsystem. The staff finds the DCD mark-up meets the NUREG-0800 guidance and is acceptable. Therefore, Open Item OI-SRP 10.2-SBPA-01 is considered closed. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

With respect to the diversity of overspeed protection, in an earlier request, in Item 3 of RAI-TR86-SBPB-01, the staff asked the applicant to compare the reliability of the proposed turbine overspeed protection capability to the reliability that is afforded by the diverse capability for existing plants. In its letter response dated July 27, 2007, the applicant stated: "Another degree of diversity is provided by the software based trip that takes the speed reading from the input/output (I/O) modules and applies control builder logic to determine the trip function which is then output via separate relay modules." The applicant's response did not specify whether this applies to the primary overspeed trip of 110 percent, or the emergency backup overspeed trip of 111 percent, or both. The staff could not find any further details on the software configuration for the overspeed trip system, either in the changes to the DCD identified in TR-86 or in the responses to other RAIs. The staff's concern is that, if both the 110-percent and 111-percent overspeed trips use the same software, a common-cause failure (CCF) could render both systems inoperable. Also, Item 2.A of NUREG-0800 Section III states that the defense-in-depth provided by the turbine-generator protection system to preclude excessive overspeeds should include diverse protection means. Therefore, with respect to diverse protection against CCF in its design, the staff asked the applicant, in RAI-SRP10.2-SBPA-02, to provide further details to show that it meets the NUREG-0800 guidance, as described above.

In response to RAI-SRP10.2-SBPA-02, the applicant stated that the original design approach was to use Ovation® speed detector module firmware for both trips in parallel with an Ovation® controller software-based logic that provides a level of redundancy and diversity. Now, the applicant has committed to implementing the two overspeed trips using diverse (hardware and software/firmware) electronic means (i.e., one of the trips will not be implemented using the Ovation® speed detector module), so that the 110-percent and 111-percent trips are not susceptible to a common-cause software failure that would render them both inoperable. The staff finds that this commitment meets the guidance described in Item 2.A of NUREG-0800 Section 10.2.III, which states: "The design of the in-depth defense provided by the turbine-generator protection system to preclude excessive overspeeds should include diverse protection means." The staff finds this acceptable; however, the staff's position is that the applicant should update the Tier 1 and Tier 2 sections of the DCD, with inspections, tests, analyses, and acceptance criteria (ITAAC), to confirm that the design acceptance criteria requiring diverse hardware, firmware, and software between the two overspeed trips are met. The staff had identified this as Open Item OI-SRP10.2-SBPA-02a.

Revision 3 of the applicant's response to RAI-SRP10.2-SBPA-02a, dated December 28, 2009, addresses Open Item OI-SRP10.2-SBPA-02a. The applicant provided a mark-up of DCD Tier 1 Table 2.4.2-1 (ITAAC) where Design Commitment 3 has been added, which addresses the applicant's commitment to provide adequate diversity between the two electrical overspeed trips. Design Commitment 3 states: "The trip signals from the two turbine electrical overspeed protection trip systems within the PLS are isolated from, and independent of, each other." For the inspections, tests, and analyses of this ITAAC, the applicant identified three subparts, which include: i) the system design review; ii) testing of the as-built system; and iii) an inspection to be performed for the existence of a report verifying that the two turbine electrical overspeed protection systems have diverse hardware and software/firmware. Further, the applicant described an associated acceptance criteria for each of these inspections, tests, and analyses, where the Acceptance Criteria 3.iii stating: "A report exists and concludes that the two electrical overspeed protection systems within the PLS have diverse hardware and software/firmware." The staff finds this ITAAC acceptable since it ensures that the two electrical overspeed protection systems consist of diverse hardware and software/firmware.

Additionally, in the same December 28, 2009 response, the applicant provided a mark-up of DCD Tier 2, Section 10.2.2.5.3, where it states that the 110 percent and 111 percent trip systems have diverse hardware and software/firmware to eliminate CCFs from rendering the trip functions inoperable. Also in the response, the applicant added Figure 10.2-2, "Emergency Trip System Functional Diagram," to the end of DCD Tier 2, Section 10.2, which shows schematically the diverse hardware and software/firmware of the overspeed trip systems. The staff finds the DCD Tier 1 and Tier 2 mark-ups and added Tier 2 Figure 10.2-2 acceptable as they meet the guidance in Item 2.A of NUREG-0800 Section 10.2.III. Therefore, Open Item OI-SRP 10.2-SBPA-02a is considered closed. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Also, in NUREG-0800 Section 10.2.III, Item 2.D, the guidance states: "An independent and redundant backup electrical overspeed trip circuit senses the turbine speed by magnetic pickup and closes all valves associated with speed control at approximately 112 percent of rated speed." However, the the applicant response to the above RAI does not state whether the electrical backup senses the turbine speed by magnetic pickup. The staff had identified this as Open Item OI-SRP10.2-SBPA-02b.

In its response to RAI-SRP10.2-SBPA-02, dated June 12, 2009, the applicant provided a mark-up of DCD Tier 2, Section 10.2.2.5.3 where it is stated that an independent and redundant backup electrical overspeed trip circuit senses the turbine speed by magnetic pickup and closes all valves associated with speed control at approximately 111 percent of rated speed. The staff finds the DCD mark-up acceptable as it meets the guidance in NUREG-0800 Section 10.2.III-2c. Therefore, Open Item OI-SRP 10.2-SBPA-02b is considered closed. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

In RAI-SRP10.2-SBPA-04, the staff asked the applicant to provide a timeframe for completion of the system design and submittal of an analysis of failure modes and effects; specifically, common-mode failures of the software for the 110-percent and 111-percent overspeed protection features. In response to RAI-SRP10.2-SBPA-04, the applicant stated that, based on its response to RAI-SRP10.2-SBPA-02 on the diversity of the two turbine overspeed trips provided for the 110-percent and the 111-percent speed points, an analysis would not be necessary; the staff finds this acceptable.

Further, NUREG-0800 Section 10.2.III, Item 2.B, states: "For normal speed-load control, the speed governor of the electrohydraulic control system fully cuts off steam at approximately 103 percent of rated turbine speed by closing the control and intercept valves." The original design included this provision, as shown in Table 10.2-2 in Revision 15 of the AP1000 DCD. However, for the new design, the applicant eliminated the 103-percent trip without providing any justification in the revised DCD or in TR-86, Revision 1. Therefore, in RAI-SRP10.2-SBPA-03, the staff asked the applicant to justify the elimination of the 103-percent trip.

In response to RAI-SRP10.2-SBPA-03, in a letter dated July 31, 2008, the applicant stated that the 103-percent trip value previously provided in Table 10.2-2 in Revision 15 of the DCD was not for a turbine-trip condition. The described condition was for the speed-control mode of the turbine-control system for a load reject event and a generator breaker open condition. The applicant eliminated the 103-percent value from DCD Table 10.2-2 because the Toshiba turbine valves and hydraulic system are not designed to fully close at the 103-percent rated speed. The CVs are closed at approximately 105 percent of rated turbine speed, and the intercept valves are closed at approximately 107 percent of rated speed. However, before these overspeed points are reached, the CVs and intercept valves begin to close at 101 percent of the rated turbine speed, as stated in DCD Table 10.2-2. The system is designed to prevent the peak transient of 108 percent of rated speed from being exceeded, as stated in the table. The applicant stated that this had not changed from DCD Revision 15—as speed is reduced, the valves will reopen and modulate as needed to achieve and maintain 100-percent rated speed. The staff accepts the applicant's response to RAI-SRP10.2-SBPA-03, for the reasons explained above, as well as the the applicant's explanation that it had eliminated the 103-percent value from DCD Table 10.2-2 because of the new Toshiba design.

In the changes to Tier 1 Section 2.4.2, Table 2.4.2-2 of the AP1000 DCD, the applicant added the emergency electrical overspeed trip device as a component located in the turbine building. This component, in conjunction with the electrical overspeed trip device (which is already listed in Tier 1 Table 2.4.2-2) provides the diversity and redundancy for the turbine overspeed trip function that are specified by NUREG-0800 Section 10.2. The staff agrees that the emergency electrical overspeed trip device is an important design feature that should be included in the Tier 1 design description for the main turbine system. Therefore, the addition of the emergency electrical overspeed trip device as a component located in the turbine building in Tier 1 Table 2.4.2-2 is considered to be acceptable.

10.2.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for design certification (DC) met the requirements of Subpart B, "Standard Design Certifications," to 10 CFR Part 52, "Licenses, certifications, and approvals for nuclear power plants," that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the changes the applicant proposed to the AP1000 turbine generator in the AP1000 DCD. The staff finds that incorporating the proposed changes does not adversely affect the ability of the turbine generator to meet the applicable acceptance criteria in NUREG-0800 Section 10.2. The staff also finds that the applicant has properly incorporated the design changes into the appropriate sections of the AP1000 DCD. Because the AP1000 turbine-generator design continues to meet all applicable acceptance criteria and the changes are properly documented in the updated AP1000 DCD, the staff finds that all of the changes to the AP1000 turbine generator are acceptable.

In addition, the changes establish the proposed Toshiba design as the single, standard design for all AP1000 plants. These DCD changes are generic and are expected to be included in all COL applications referencing the AP1000 certified design. At this time, the NRC has not issued a COL for any AP1000 plant. Thus, the proposed changes to the AP1000 DCD contribute to the increased standardization of the certification information in the AP1000 DCD.

10.2.5 Valve Control

10.2.5.1 Summary of Technical Information

NUREG-0800 Section 10.2, Criterion II.1.B, states that the applicant should provide turbine main steam stop and CVs and reheat steam stop and intercept valves to protect the turbine from exceeding set speeds, as well as to protect the reactor system from abnormal surges. To ensure that turbine overspeed is controlled within acceptable limits, the reheat stop and intercept valves should be capable of closure concurrent with the main steam stop valves (MSVs) or of sequential closure within an appropriate time limit. The valve arrangements and valve closure times should ensure that a failure of any single valve to close will not result in an excessive turbine overspeed in the event of a turbine-generator system trip signal.

10.2.5.2 Evaluation

The valve arrangement in the new design is basically the same as in the original design, with the following exception: The No. 2 and No. 4 stop valves in the new design have a bypass valve, which is controlled by an electrohydraulic servo actuator for CV warming. The closure time for all stop, control, reheat, and intercept valves is 0.3 seconds for both the new and the original design.

The specific criterion that applies to the change evaluated above is 10 CFR 52.63(a)(1)(vi) in that the change substantially increases overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security.

10.2.5.3 Conclusion

On the basis of its review, the staff finds that the design change is acceptable, because the availability and adequacy of the CVs in the AP1000 design conform to Criterion II.1.B and Criterion II.3 in NUREG-0800 Section 10.2.

10.2.8 Turbine Rotor Integrity

10.2.8.1 Summary of Technical Information

In the proposed changes to the AP1000 DCD, the applicant proposed an alternative SPC design that includes changing the design of the turbine rotors from a Westinghouse/Mitsubishi model to a Toshiba model. This evaluation addresses only the turbine-rotor design change. Revision 0 of TR-86, dated February 8, 2007, provided the technical justification for the proposed changes. Revision 1 of TR-86, submitted on June 25, 2007, established the Toshiba design as the single, standard turbine-rotor design for all AP1000 plants. In a letter dated July 12, 2007, the applicant submitted additional information on the TR. The staff evaluates the rotor design and probability of missile generation for the Toshiba turbine design below.

10.2.8.2 Evaluation

GDC 4 requires SSCs important to safety to be appropriately protected against environmental and dynamic effects, including the effects of missiles that may result from equipment failure. The staff reviewed the AP1000 DCD changes related to this section that ensure turbine-rotor integrity and a low probability that turbine-rotor failure will result in the generation of missiles.

In the proposed changes to AP1000 DCD, the applicant proposed a change to the design of the turbine rotors from a Westinghouse/Mitsubishi model to a Toshiba model. The Toshiba design includes two types of bucket (blade) fixations instead of side-entry blades, as in the Westinghouse/Mitsubishi design. The two types of fixations are an outside dovetail and a fork-type dovetail. The outside dovetail will be used in every stage of the high-pressure turbine and the fork-type dovetail will be used in the last two stages of the low-pressure turbine.

As a result of the design change, the applicant performed a new analysis of the missile generation probability for fully integral rotors of the Toshiba turbine-generator design. Westinghouse Commercial Atomic Power (WCAP)-16650-P, Revision 0, “Analysis of the Probability of the Generation of Missiles from Fully Integral Nuclear Low-Pressure Turbines,” issued February 2007, includes the methodology and results of the analysis. This report evaluates the probability of missiles resulting from four failure mechanisms: ductile burst from destructive overspeed, high-cycle fatigue cracking, low-cycle fatigue cracking, and stress-corrosion cracking. The staff reviewed the methodology used in WCAP-16650-P and its applicability to the Toshiba design. The applicant’s analysis concluded that an inspection interval of up to 24 years was sufficient to satisfy the requirement that the probability of missile generation be less than 1.0×10^{-5} per year. The applicant included conservative assumptions in its analysis for parameters, such as the stress required for ductile burst, the probability for stress-corrosion crack initiation, the probability of rotor overspeed, and the number of startup and shutdown cycles. In RAI-SRP10.2.3-CIB1-01, the staff requested additional information about the way in which the new missile probability analysis addressed high-trajectory missiles.

In a letter dated June 20, 2008, the applicant stated that the AP1000 design has a favorable turbine orientation that prevents turbine missiles from causing unacceptable damage to safety-related SSCs. The analysis in WCAP-16650-P demonstrates that for high-trajectory missiles, the probability of generating a missile from a burst turbine rotor (P1) is 10^{-5}. This meets the guidance in NUREG-0800 Section 3.5.1.3 of 10^{-4} for a favorable turbine orientation and 10^{-5} for an unfavorable turbine orientation. The staff finds this acceptable, because the the applicant’s analysis for high-trajectory missiles meets the guidance in NUREG-0800 Section 3.5.1.3.

The applicant also stated that the analysis in WCAP-16650-P applies only to high-trajectory missiles and that high-velocity, low-trajectory missiles cannot directly strike safety-related systems and components. However, the turbine generators at dual-unit sites must be considered unfavorably oriented, because safety-related systems and components are in the low-trajectory missile strike zone. Therefore, to address COL applications for dual-unit sites, the staff requested that the applicant provide a bounding turbine missile analysis for low-trajectory missiles or provide a COL action item that requires COL applicants to provide a turbine missile analysis for low-trajectory missiles at dual-unit sites. In a letter dated April 13, 2009, the applicant stated that WCAP-16650 also applies to low-trajectory turbine missiles for dual unit sites that have unfavorable orientation. However, the applicant did not provide justification for applying this analysis for low-trajectory turbine missiles, and did not address whether the analysis is dependent on missile trajectory. The staff identified this as Open Item OI-SRP10.2.3-CIB1-01.

In a letter dated September 22, 2009, the applicant provided further clarification of the applicability of WCAP-16650. The applicant stated that WCAP-16650-P determines the probability of generating a missile due to a burst turbine rotor, regardless of whether the missile is high-trajectory or low-trajectory. In addition, the applicant stated that the AP1000 DCD does not consider low-trajectory missiles for a single unit site. However, if a dual unit site is considered, the probability, P1, from WCAP-16650-P can be used to evaluate low-trajectory missiles. Therefore, the staff finds that since the angle of trajectory is not used in WCAP-16650-P for determining the total probability of generating a missile due to a burst turbine rotor, P1, the results of the analysis can be used for both low and high-trajectory missiles. The P1 result from WCAP-16650-P is then used to ensure that the probability of striking SSCs, P4, is less than 10^{-7} per the guidance of regulatory guide (RG) 1.115, “Protection Against Low-Trajectory Turbine Missiles,” Revision 1, and NUREG-0800 Section 3.5.1.3. On this basis, the staff finds the response acceptable; therefore, Open Item OI-SRP10.2.3-CIB1-01 is closed.

Based on the conservative assumptions incorporated into this analysis and the fact that the rotors will be inspected during plant operation at approximately 10-year intervals, the staff finds the methodology and results acceptable. The staff, therefore, finds the proposed rotor design changes acceptable, because they do not change the probability of missile generation for fully integral low-pressure rotors previously accepted by the NRC staff in NUREG-1793.

The staff reviewed the proposed changes to the AP1000 DCD. The changes establish the proposed design as the single, standard design for all AP1000 plants. These DCD changes are generic and are expected to be included in all COL applications referencing the AP1000 certified design. At this time, the NRC has not issued a COL for any AP1000 plant. Thus, the proposed changes contribute to the increased standardization of the certification information in the AP1000 DCD.

10.2.8.3 Conclusion

Based on the above evaluation, the staff concludes that the AP1000 design change is acceptable, because it meets the requirements of GDC 4 and does not change the probability of missile generation for fully integral rotors that the staff previously accepted. Furthermore, the staff finds that the conclusions regarding the proposed turbine-rotor design and the methodology for analyzing the probability of missile generation are expected to apply to all COL applications referencing the AP1000 DC. Therefore, the proposed DCD changes are acceptable, under 10 CFR 52.63(a)(1)(vii), on the basis that they contribute to the increased standardization of the DC information.

10.2.10 Valve Testing Intervals

10.2.10.1 Summary of Technical Information

Section 10.2.3.6 of the AP1000 DCD, proposed a decrease in the frequency of turbine-valve testing from every 3 months to every 6 months. To support this change, the applicant submitted TR WCAP-16651-P, Revision 0, “Probabilistic Evaluation of Turbine Valve Test Frequency,” issued February 2007. This report is similar to WCAP-15785, issued April 2002, with the same title, which used the same methodology to evaluate turbine-valve test frequency for the Westinghouse/Mitsubishi turbine design approved in Revision 15 of the AP1000 DCD. The methodology in WCAP-16651-P is based on an analysis of the operating experience with Toshiba Corporation nuclear steam turbines. The applicant introduced a proposed change to the DCD by replacing the word “quarterly” with “six-month” or “semi-annual” as follows:

> Turbine valve testing is performed at six-month intervals. The semi-annual testing frequency is based on nuclear industry experience that turbine-related

tests are the most common cause of plant trips at power. Plant trips at power may lead to challenges of the safety-related systems. Evaluations show that the probability of turbine missile generation with a semi-annual valve test is less than the evaluation criteria.

10.2.10.2 Evaluation

For the plant-specific turbine-rotor test data, the current COL Information Item 10.2-1 states that the COL holder "will have available plant-specific turbine rotor test data and calculated toughness curves that support the material property assumptions in the turbine rotor analysis." The applicant proposed to revise this information item by adding, to the end, the following time commitment: "prior to fuel load after the fabrication of the turbine." TR-6, "AP1000 As-Built COL Information Items" (APP-GW-GLR-021), Revision 0, issued June 2006, stated that an applicant cannot provide the as-built data at the time of the COL application. This justification is appropriate because the as-built material data for turbine rotors will not be available until the rotor material is procured for fabrication. In addition, the proposal to provide the as-built data before fuel load after the fabrication of the turbine is acceptable for reasons similar to those allowing the deferral of the maintenance and inspection program.

Regarding the proposal to extend the valve-test interval from 3 months to 6 months, the analysis in WCAP-16651-P showed that, for a favorably oriented turbine, the missile-probability criterion of 10^{-4} per year could be met, based on the operating experience with Toshiba turbines. In response to RAI-SRP10.2.3-CIB1-02, the applicant confirmed that the AP1000 turbine has a favorable orientation with respect to high-trajectory missiles. The analysis also concluded that the turbine-missile probability criterion of 10^{-5} per year could be met with a 6-month valve-test interval. This is significant because, for dual-unit sites, the turbine orientation is considered unfavorable with respect to low-trajectory missiles potentially striking safety-related systems and components. In response to RAI-SRP10.2.3-CIB1-02, the applicant provided clarifying information about the calculations used to determine the probability of missile generation, based on the frequency of valve tests.

The analysis presented in WCAP-16651-P, along with clarifying information provided in response to RAI-SRP10.2.3-CIB1-02, indicates that the existing operating experience for Toshiba turbines supports a missile generation probability of less than 10^{-5} per year, using 95-percent confidence-level values for the system separation frequency and valve-failure frequency. Therefore, based on the information provided, the staff concludes that the 6-month valve testing frequency meets the missile generation acceptance criteria for both favorable orientation (10^{-4} per year) and unfavorable orientation (10^{-5} per year).

However, the staff notes that an apparent error exists in Table 6-5 of WCAP-16651-P, Revision 0. Based on the equation given on page 18 of WCAP-16651-P, Revision 0, the staff's calculations indicated that, for a 6-month valve-test interval, the value of "probability of a turbine missile" for "1/Time Interval" was an order of magnitude lower than the value shown in Table 6-5. The value in Table 6.5 of Revision 0 does not support a six-month valve test frequency, and the staff identified this as Open Item OI-SRP10.2.3-CIB1-02. In a letter dated July 10, 2009, the applicant addressed this open item by submitting WCAP-16651-P, Revision 1. The applicant confirmed that the exponent in the probability value in Table 6-5 of Revision 0 was a typographical error. The corrected value in Table 6-5 of Revision 1 is consistent with the applicant's calculated value of the annual probability of a turbine missile that was used to support the six-month valve test interval. Therefore, Open Item OI-SRP10.2.3-CIB1-02 was closed.

10.2.10.3 Conclusion

Based on this evaluation, the staff concludes that the DCD changes meet the requirements of GDC 4 and thus are acceptable. The proposed DCD changes are acceptable, under 10 CFR 52.63(a)(1)(vii), on the basis that they contribute to the increased standardization of the certification information.

10.2.11 Turbine Rotor Maintenance and Inspection Program

10.2.11.1 Summary of Technical Information

The proposed changes to the AP1000 DCD revised COL Information Item 10.2-1 to change the timing for the COL holder to provide information on the turbine-rotor maintenance and inspection program from within 3 years of obtaining a COL until prior to fuel load. NUREG-1793 also discusses this information item under COL Action Item 10.5-2. TR-6 justified the revision to COL Information Item 10.2-1. The DCD changes also proposed a decrease in the frequency of turbine-valve testing from every 3 months to every 6 months.

In AP1000 DCD Tier 2, Revision 15, Section 10.2.6, COL Information Item 10.2-1 states the following:

> The Combined License holder will submit to the staff for review and approval within 3 years of obtaining a Combined License, and then implement a turbine maintenance and inspection program. The program will be consistent with the maintenance and inspection program plan activities and inspection intervals identified in Subsection 10.2.3.6. The Combined License holder will have available plant-specific turbine rotor test data and calculated toughness curves that support the material property assumptions in the turbine rotor analysis.

In the proposed changes to the AP1000 DCD, the applicant proposed a modification to COL Information Item 10.2-1 by changing the COL holder commitments to “prior to fuel load.” The proposed revision to DCD Tier 2, Section 10.2.6, states the following:

> The Combined License holder will submit to the NRC staff for review prior to fuel load, and then implement a turbine maintenance and inspection program. The program will be consistent with the maintenance and inspection program plan activities and inspection intervals identified in Subsection 10.2.3.6. The Combined License holder will have available plant-specific turbine rotor test data and calculated toughness curves that support the material property assumptions in the turbine rotor analysis prior to fuel load after the fabrication of the turbine.

10.2.11.2 Evaluation

GDC 4 requires that SSCs important to safety be appropriately protected against environmental and dynamic effects, including the effects of missiles that may result from equipment failure. The staff reviewed the AP1000 DCD changes related to this section that ensure turbine rotor integrity and a low probability of missile generation caused by turbine rotor failure.

COL Information Item 10.2-1 addressed two issues: the turbine maintenance and inspection program and the plant-specific turbine rotor test data. TR-6 proposed modifications to both commitments.

For the turbine maintenance and inspection program, TR-6 states the following:

> A turbine maintenance and inspection program that is consistent with the frequency in DCD Subsection 10.2.3 does not need further approval from the NRC. The testing and inspection frequency in DCD Subsection 10.2.3 are supported by evaluations that are based on operating and inspection program experience in operating power plants.

For the maintenance and inspection program, the applicant proposed that the current COL Information Item 10.2-1 replace the commitment “submit to the staff for review and approval within 3 years of obtaining a Combined License” with “submit to the NRC staff for review prior to fuel load.” With respect to the proposed change in valve-test frequency, the staff requested, in RAI-SRP10.2.3-CIB1-02, that the applicant clarify the analysis in WCAP-16651-P with respect to the evaluation criterion.

Since the deferral of the activities in the COL information item does not alter the design of the turbine, turbine valves, or connected piping systems, it will not affect turbine rotor integrity. Further, this change does not involve a test or experiment, does not affect design features associated with the mitigation of severe accidents, and does not alter barriers or alarms that affect security assessments of the AP1000. Therefore, the staff finds that the applicant revised COL Information Item 10.2-1 to be acceptable. This determination is also consistent with the acceptance criteria in NUREG-0800 Section 10.2.3, “Turbine Rotor Integrity.”

10.2.11.3 Conclusion

Based on this evaluation, the staff concludes that the DCD changes meet the requirements of GDC 4 and thus are acceptable. Furthermore, the staff finds that the TR-6 conclusions regarding the submittal and availability of COL holder information for a turbine-rotor maintenance and inspection program are generic and are expected to apply to all COL applications referencing the AP1000 DC. Therefore, the proposed DCD changes are acceptable, under 10 CFR 52.63(a)(1)(vii), on the basis that they contribute to the increased standardization of the certification information.

10.3 Main Steam Supply System

10.3.1 Main Steam Supply System Design

10.3.1.1 Summary of Technical Information

In NUREG-1793, the staff approved Section 10.3, “Main Steam Supply System (MSSS),” of the AP1000 DCD, Revision 15. In the proposed changes to the AP1000 DCD, the applicant proposed changes to this section, supported by the following Westinghouse reports: TR-86, “Alternate Steam and Power Conversion Design,” (APP-GW-GLN-018), Revision 1, issued June 25, 2007; TR-103, “Fluid System Changes” (APP-GW-GLN-019), Revision 2, dated January 29, 2008; and TR-125, “Corrections to Tier 1 ITAAC 2.2.4 and Tier 2 Section 3.6.1.3.3 and 10.3” (APP-GW-GLR-125), Revision 0, issued May 2007.

10.3.1.2 Evaluation

The staff reviewed the changes to AP1000 DCD, Section 10.3. NUREG-1793 includes the regulatory basis for Section 10.3 of the AP1000 DCD. The staff reviewed the proposed changes to DCD Section 10.3 against the applicable acceptance criteria in NUREG-0800 Section 10.3, “Main Steam Supply System.” Those changes that involve NRC review considerations as reflected in NUREG-0800 Section 10.3 are described and evaluated in this section. The specific criteria that apply to the MSSS design related changes include 10 CFR 52.63(a)(1)(vi) in that the changes substantially increases overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security, and 10 CFR 52.63(a)(1)(vii), in that the proposed changes contribute to increased standardization of the certification information. The results of the staff’s evaluation are provided as follows:

(1) Section 10.3.2.2.4, “Main Steam Isolation Valves,” Page 10.3-8:

The staff reviewed the applicant’s additional language stating that, on loss of electric power, the main steam isolation valves (MSIVs) remain in their current position. Since the closure of the MSIVs is credited for the mitigation of several design-basis transients and accidents, such as an inadvertent opening of a steam generator relief or safety valve, steam system piping failure, or steam generator tube rupture, the staff asked the applicant, in RAI-SRP10.3-SBPA-01, to evaluate the effect that maintaining the MSIVs in an open position after a loss of electrical power would have on the mitigation of these transients and accidents. Also, the staff asked the applicant to explain whether it had analyzed the events in DCD Chapter 15, “Accident Analyses,” with this MSIV fail-as-is logic.

In its response, dated July 18, 2008, the applicant clarified that the DCD statement, “On loss of electrical power the valves remain in their current position,” meant that the MSIVs would not close on loss of electric power to the actuator, since the solenoids are normally deenergized and closed. This is not to imply that the MSIVs will not close, once a steamline isolation signal is generated. As discussed in DCD Section 10.3.2.2.4, each MSIV is provided with a hydraulic/pneumatic actuator. The valve actuator consists of a hydraulic cylinder with a stored energy system to provide emergency closure of the MSIV. The energy to operate the valve actuator is stored in the form of compressed nitrogen contained in one end of the actuator cylinder. The MSIVs are normally maintained in an open position by high-pressure hydraulic fluid. For emergency valve closure, normally deenergized and closed redundant solenoids for each MSIV are energized, resulting in the high-pressure hydraulic fluid being dumped to a fluid reservoir and the compressed nitrogen closing the MSIV. Additionally, the applicant stated that the redundant solenoids for each MSIV are powered by separate divisions from the Class 1E direct current and uninterrupted power supply systems. Energizing either solenoid for each MSIV will close the MSIV. The loss of both redundant power sources is beyond the design basis of the plant.

Based on the above explanation, the staff finds the the applicant’s response acceptable for the following reasons:

- As described above, high-pressure hydraulic fluid in the actuators maintains the MSIVs open and, therefore, a loss of power will have no effect on the MSIV position. In addition, since the solenoids are normally deenergized, a loss of power will have no effect on their ability to keep the MSIVs open.

- To close the MSIVs during an emergency, the redundant solenoids powered by separate power sources will be used to dump the high-pressure fluid from the actuators. Since the solenoids are provided by two separate sources of power, the loss of an electric power source should have no effect on the MSIV position. Therefore, the staff finds the applicant's response acceptable, and the concern described in RAI-SRP10.3-SBPA-01 is resolved.

(2) Table 10.3.2-1, "Main Steam Supply System Design Data," Page 10.3-17:

The applicant modified the steam generator flow rates to conform to the new SPC design described in TR-86, Revision 1. In DCD Revision 15, the steamflow rate per steam generator was 3,396,535 kilograms per hour (kg/h) (7,488,000 pounds per hour (lb/h)) and the total steamflow rate was 6,793,069 kg/h (14,976,000 lb/h). In the revised DCD, the applicant changed the steamflow rate per steam generator to 3.40×10^6 kg/h (7.49×10^6 lb/h) and the total steamflow rate to 6.79×10^6 kg/h (14.97×10^6 lb/h). The staff reviewed these changes and determined that they are not significant and that they continue to meet all the acceptance criteria in NUREG-1793. Therefore, the staff considers these changes to be acceptable.

(3) Table 10.3.2-2, "Design Data for Main Steam Safety Valves," Page 10.3-18:

The staff reviewed the applicant's revisions to the set pressures and relieving capacities of the main steam safety valves (MSSVs). Since the MSSVs are credited for the mitigation of many design-basis transients and accidents, including overpressure protection of the heatup events, such as a loss of external electrical load and a turbine trip, the staff asked the applicant, in RAI-SRP10.3-SBPA-02, to provide additional information with respect to the effects of the revised MSSV set pressures and relieving capacities on the event analysis in Chapter 15. The staff also asked whether the applicant had performed the Chapter 15 event analysis with the revised MSSV setpoints and relieving capacities.

In its response, dated July 18, 2008, the applicant stated that it included the revised MSSV setpoints and capacities, as shown in Table 10.3.2-2 of the DCD, in its evaluation of the limiting Chapter 15 event analyses that were provided in its response to RAI-TR29-SRSB-01. The results of the evaluation provided in the response to RAI-TR29-SRSB-01 show that the effect of the changes to the MSSV parameters meets the acceptance criteria of the limiting Chapter 15 events and that the existing analysis is bounding.

Based on its review of the Chapter 15 event analyses, the staff finds that the applicant did include the revised MSSV setpoints and capacities in its evaluation of the limiting Chapter 15 event analyses. In addition, based on the results of the Chapter 15 event evaluation, the staff finds that the changes to the MSSV parameters meet the acceptance criteria of the limiting Chapter 15 events. Because the applicant performed the Chapter 15 event analyses with the revised MSSV setpoint pressures and relieving capacities and because the results remained within the acceptance criteria of the limiting Chapter 15 events, the staff's concern described in RAI-SRP10.3-SBPA-02 is resolved.

(4) Main Steam Piping and Instrumentation Diagrams (Safety-Related System), Pages 10.3-37 and 10.3-39 (Figure 10.3.2-1, two sheets):

The applicant revised the AP1000 DCD Tier 2, Figure 10.3.2-1, to be consistent with the applicant's proposed changes to DCD Tier 1, Section 2.2.4, "Steam Generator System," described in TR-125. This change pertains to the safety-related portion of the MSSS.

During an April 1, 2009, conference call, the staff asked the applicant to provide legible DCD Tier 2, Figures 10.3.2-1 and 10.3.2-2, and to incorporate the July 3, 2008, response to RAI-SRP 3.6.1-SBPA-01 into DCD Section 10.3.1.1. In a subsequent revision to the AP1000 DCD, the applicant made appropriate changes to the DCD, which resolves this issue.

(5) Main Steam Piping and Instrumentation Diagrams (Safety-Related System), Pages 10.3-37 and 10.3-39 (Figure 10.3.2-1, two sheets):

The applicant changed the system arrangement and configuration design in DCD Tier 2, Figure 10.3.2-1, to conform to TR-103.

During an April 1, 2009, conference call, the staff asked the applicant to provide legible Tier 2, Figures 10.3.2-1 and 10.3.2-2 and to incorporate the July 3, 2008, response to RAI-SRP3.6.1-SBPA-01 into DCD Section 10.3.1.1 In a subsequent revision to the AP1000 DCD, the applicant made appropriate changes to the DCD, which resolves this issue.

(6) Main Steam System Diagram, Page 10.3-41 (Figure 10.3.2-2):

The applicant modified the MSSS arrangement to conform to the new SPC design, as proposed in TR-86, Revision 1. The applicant's changes to sections, tables, and figures of the DCD support the specifics of the new design. The staff reviewed these changes and finds that they are modifications to the system arrangement and configuration design. The staff finds that these changes will have no impact on the ability of the MSSS to supply steam from the steam generator to the main turbine-generator system. The staff finds that the MSSS will continue to meet all of the acceptance criteria in NUREG-1793 and, therefore, the changes are acceptable.

(7) a) Section 10.3.1.1, "Safety Design Basis," Page 10.3-3:

The applicant added the turbine bypass valve and also changed the moisture separator reheater stop valves to moisture separator reheater 2nd stage steam isolation valves in the list of valves credited in a single failure analysis. These valves are credited in the analysis to mitigate the event for those cases in which the rupture of the main steam or feedwater piping inside containment is the postulated initiating event. These two changes conform to the applicant's response to RAI-SRP3.6.1-SBPA-01, which was found acceptable in Section 3.6.1 of this report.

b) Tier 1, Table 2.2.4-3, "Components which Provide Backup Isolation of the Steam Generator System," Page 2.2.4-15:

The applicant added two moisture separator reheater 2nd stage steam isolation valves to the list of components, which provide backup isolation of the steam generator system and deleted other components. The staff reviewed this design change and determined that it was made to be consistent with the change made in a) above. Therefore, the staff finds the change to be acceptable.

c) Section 10.3.4.2, "In-service Testing," Page 10.3-12:

The applicant revised the scope of the inservice testing (IST) program for the AP1000 reactor to replace the moisture separator reheater steam supply control valves, MSS-PL-V016A, MSS-PL-V016B, MSS-PL-V017A, and MSS-PL-V017B, with the moisture separator reheater 2nd stage steam isolation valves, MSS-PL-V015A and MSS-PL-V015B, in response to the design change described in a) above. The staff reviewed the revised IST program description for consistency with the design change. MSS-PL-V015A and MSS-PL-V015B have been included in AP1000 DCD Tier 2, Table 3.9-16, because the design change will have those valves perform a backup isolation function for the safety-related MSIVs in the AP1000 reactor design rather than MSS-PL-V016A, MSS-PL-V016B, MSS-PL-V017A, and MSS-PL-V017B. MSS-PL-V015A and MSS-PL-V015B are nonsafety related valves (without a specific safety-related leakage limitation) that are outside the scope of the IST requirements specified in 10 CFR 50.55a, "Codes and standards," and will be included in the IST program for the AP1000 reactor to augment their performance capability. Based on its review, the staff finds the revision to the IST program scope to be consistent with the design change described in a) above.

(8) Piping Material Changes to Section 10.3.2.2.1, "Main Steam Piping," Page 10.3-5; Table 10.3.2-3, "Description of Main Steam and Main Feedwater Piping," Page 10.3-19; Main Steam Piping and Instrumentation Diagrams (Safety-Related System) and Page 10.3-37 (Figure 10.3.2-1, "Main Steam Piping and Instrumentation Diagram (Safety-Related System) – Sheet 1 of 2):

The applicant changed the material used for the main steam piping and segments of the main feedwater line to low alloy steel to facilitate a design life of 60 years with respect to minimizing the effects of erosion/corrosion. In the certified design, carbon steel is the main steam piping material for some portions. The changes proposed in Revision 17 make P11 material (nominally 1.25 percent chromium and 0.5 percent molybdenum) the only material for main steam piping. The staff finds this material is acceptable because testing and operating experience have shown P11 is resistant to flow-accelerated corrosion (sometimes called erosion-corrosion) in main steam piping, including wet steam. Current industry guidance (Electric Power Research Institute (EPRI) NSAC-202L, "Recommendations for an Effective Flow-Accelerated Corrosion Program") allows P11 main steam components to be excluded from flow-accelerated corrosion inspection programs due to the flow accelerated corrosion resistance imparted by the chromium and, to a lesser extent, molybdenum.

(9) Section 10.3.3, "Safety Evaluation," Page 10.3-10:

The applicant changed from inline main steam line radiation monitors to adjacent-to-line radiation monitors.

The applicant made the change to Section 10.3.3 to be consistent with the detailed monitor description provided in DCD Section 11.5.2.3.1. DCD Section 11.5.2.3.1 has not changed from the DCD Revision 15 description of these monitors as "…adjacent to the steam lines." The staff concludes that both DCD sections are now consistent and that the change to Section 10.3 is acceptable. The staff provides additional evaluation of the main steam line monitors in Section 11.5.2.4 of this report.

(10) Table 10.3.2-2, "Design Data for Main Steam Safety Valves," Page 10.3-18:

In Table 10.3.2-2, the applicant changed the size of MSSV and added clarifying text. The MSSVs are designed to American Society of Mechanical Engineers (ASME) Code Section III, Class 2, seismic Category I. Based on the system's accumulation pressure of 3 percent, in accordance with Subsection NC-7512 of ASME Code, Section III, Division 1, 1989 Edition, Subsection NC, Class 2 components, the applicant increased the relieving capacity of MSSVs. The changes were made to ensure that the MSSV design meets the requirements and conforms to the ASME Code. The staff finds the changes acceptable.

(11) Table 10.3.2-4, "Main Steam Branch Piping (2.5-Inch and Larger) Downstream of MSIV," Page 10.3-20:

The applicant changed, in DCD Table 10.3.2-4: the size of the shutoff valves for the turbine bypass lines to the condenser from 30.5 cm (12 in) to 40.6 cm (16 in), the size of the shutoff valves for the reheating steam to moisture separator reheater lines from 30.5 cm (12 in) to 25.4 cm (10 in), and the numerical value for the maximum steam flow rate for these lines. The description of the shutoff valve and number of lines under the description column was also changed. Further, the size of the shutoff valve for the main steam supply to auxiliary steam system line was changed from 15.2 cm (6 in) to 25.4 cm (10 in).

As reflected in Table 10.3.2-4, the applicant made changes to the main steam branch piping, in order to meet the analyzed closure time for the MSIV backup isolation valves.

The applicant made changes to the main steam shutoff valves in Table 10.3.2-4 to support the change in the turbine generator design and to optimize the auxiliary steam supply system. The staff reviewed these design changes and determined that they are bounded by existing safety analysis because the shutoff valve closure times remain unchanged. The design will continue to meet all acceptance criteria in NUREG-1793. The staff finds the changes are acceptable.

10.3.1.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the applicant's proposed changes to the AP1000 MSSS. The staff finds that the applicant's proposed changes do not affect the ability of the AP1000 MSSS to meet the applicable acceptance criteria in NUREG-0800 Section 10.3. The staff also finds that the applicant properly incorporated the design changes into the appropriate sections of AP1000 DCD. Because the AP1000 MSSS design continues to meet all of the applicable acceptance criteria and the changes are properly documented in the updated AP1000 DCD, the staff finds that all of the changes to the AP1000 MSSS are acceptable.

10.4 Other Features

10.4.1 Main Condensers

10.4.1.1 Summary of Technical Information

In NUREG-1793, the staff approved Section 10.4.1, "Main Condenser," of the AP1000 DCD, Revision 15. In the proposed changes to the AP1000 DCD, the applicant proposed to make the following changes to Section 10.4.1 of the DCD.

In DCD Section 10.4.1.2, "System Description," Paragraph 2, the applicant revised the condenser tube material providing an option to the COL applicant to substitute "stainless steel" tubes for "titanium" tubes for fresh water cooled plants. The revised description reads as, "…..The condenser is equipped with titanium <u>or stainless</u> steel tubes. The titanium material provides good corrosion and erosion resisting properties. <u>Fresh water cooled plants do not require the high level corrosion and erosion resistance provided by titanium; therefore, 304L, 316L, 904L, or AL-6X may be substituted if desired.</u>" The revisions are indicated by the underlined text. The applicant added a corresponding note to Table 10.4.1-1, "Main Condenser Design Data." In addition, a second note added to Table 10.4.1-1 states that if one of the alternate tube materials (i.e., stainless steel) is used, the tubesheet will be carbon steel material with a cladding of the same material as the tubes. The certified design specified titanium or titanium-clad carbon steel as the tubesheet material.

10.4.1.2 Evaluation

The staff reviewed the proposed changes to AP1000 DCD, Section 10.4.1. The regulatory basis for AP1000 DCD, Section 10.4.1, is documented in NUREG-1793. The staff has reviewed the proposed changes to DCD Section 10.4.1 against the applicable acceptance criteria of NUREG-0800 Section 10.4.1, "Main Condensers."

The changes identified above are related to the material of the condenser tubes. Several stainless steel alloys (304L, 316L, 904L, and AL-6X) were added as alternatives to titanium condenser tube material for plants cooled by fresh water. The staff finds the use of stainless steel materials is acceptable because the corrosion of stainless steel in cooling waters is strongly related to the chloride content. Operating experience has shown that the stainless steels proposed by the applicant are suitable for condenser tubes in fresh water applications. For example, EPRI characterizes the corrosion resistance of these stainless steels as very good to excellent in fresh water (EPRI TR-102922, "High-Reliability Condenser Application Study," Final Report, November 1993). The corresponding change to allow the tubesheet to be carbon steel with a cladding of the same stainless steel as the tube material is also acceptable based on the operating experience referenced above.

10.4.1.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed Section 10.4.1, "Main Condensers," as documented in the AP1000 DCD, Revision 17. On the basis of its review, the staff finds that the design changes have been adequately incorporated into the appropriate sections of the AP1000 DCD, Revision 17. The staff also finds, based on operating experience with stainless steel condenser tubes, that the main condenser continues to meet all acceptance criteria as documented in NUREG-1793 and are, therefore, considered to be acceptable.

10.4.2 Main Condenser Evacuation System

10.4.2.1 Summary of Technical Information

In NUREG-1793, the staff approved Section 10.4.2, "Main Condenser Evacuation System," of the AP1000 DCD, Revision 15. In the proposed changes to the AP1000 DCD, the applicant revised Sections 10.4.2.2.1, "General Description"; and 10.4.2.2.2, "Component Description," to identify the circulating water system (CWS) as conceptual design information (CDI).

10.4.2.2 Evaluation

The staff reviewed all of the changes to AP1000 DCD, Section 10.4.2. The staff did not re-review descriptions and evaluations of Section 10.4.2 that were previously approved and that are not affected by the new changes.

The specific criterion that applies to the main condenser evacuation system related changes is 10 CFR 52.63(a)(1)(vii), in that the proposed changes contribute to increased standardization of the certification information.

NUREG-1793 includes the regulatory basis for Section 10.4.2 of the AP1000 DCD. The staff has reviewed the proposed changes to DCD Section 10.4.2 against the applicable acceptance criteria in NUREG-0800 Section 10.4.2.

The only change the applicant proposed to AP1000 DCD, Section 10.4.2, was to identify the CWS as CDI. The staff discusses the issue of identifying the CWS as CDI in Section 10.4.5 of this report. Since the changes made to DCD Sections 10.4.2.2.1 and 10.4.2.2.2 conform to the changes made to DCD Section 10.4.5 and do not adversely affect the main condenser evacuation system, the staff finds these changes to be acceptable.

10.4.2.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusion that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the proposed changes to AP1000 DCD, Section 10.4.2. The staff finds no changes except the two conforming changes identified above. On the basis of its review, the staff finds that the main condenser evacuation system continues to meet all of the acceptance criteria in NUREG-1793, and these changes are, therefore, acceptable.

10.4.3 Turbine Gland Seal System

10.4.3.1 Summary of Technical Information

In NUREG-1793, the staff approved AP1000 DCD, Revision 15, Section 10.4.3, "Gland Seal System." In the proposed changes to the AP1000 DCD, the applicant proposed changes to Section 10.4.3 of the DCD.

In AP1000 DCD, Section 10.4.3, the applicant made the following changes, which reflect the new single turbine-generator design (i.e., alternative SPC design) that is proposed in TR-86, Revision 1:

(1) Section 10.4.3.2.2, "System Operation," of the DCD, Revision 16:

AP1000 DCD, Revision 15, Section 10.4.3.2.2, stated that the sealing steam to the turbine shaft seals is supplied from either the auxiliary steam system or from the main steam system extracted ahead of the high-pressure turbine throttle valve. In the DCD Revision 17, the applicant revised Section 10.4.3.2.2 to refer to the "high-pressure turbine control valve."

In addition, DCD Section 10.4.3.2.2, Revision 15, stated that, at times other than initial startup, turbine-generator sealing steam is supplied from the auxiliary steam system or from main steam. In the DCD, Revision 17, the applicant modified paragraph 3 on page 10.4-7 to add "the MSV (main steam stop valve) and CV (control valve) gland steam leak-off" as an additional source of steam to the turbine gland seals.

(2) Section 10.4.3.5, "Instrumentation Applications," of the DCD, Revision 17:

The applicant removed the following sentence: "Pressure control valves are used to provide appropriate pressures to operate both the low and high pressure turbine steam seals."

10.4.3.2 Evaluation

The staff reviewed all of the proposed changes to AP1000 DCD, Section 10.4.3. The staff did not review descriptions and evaluations of Section 10.4.3 that were previously approved and that are not affected by the new changes.

NUREG-1793 includes the regulatory basis for Section 10.4.3 of the AP1000 DCD. The staff has reviewed the proposed changes to AP1000 DCD, Section 10.4.3, against the applicable acceptance criteria of NUREG-0800 Section 10.4.3, "Turbine Gland Sealing System."

The specific criterion that applies to the turbine gland seal system related changes is 10 CFR 52.63(a)(1)(vii), in that the proposed changes contribute to increased standardization of the certification information.

The staff finds that the changes to DCD Section 10.4.3.2.2 associated with specifying a high-pressure turbine CV and the addition of sealing steam supply from MSV and CV gland steam leakoff are conforming changes to the new design, in accordance with TR-86, Revision 1, and do not affect the staff's conclusion in NUREG-1793 that the gland seal system design meets the requirements of GDC 60, "Control of Releases of Radioactive Materials to the Environment," with respect to the design features in place to control releases of radioactive materials to the environment. Therefore, the staff finds these changes acceptable.

However, with respect to the removal of the pressure CVs from DCD Section 10.4.3.5, "Instrumentation Application," the applicant did not provide a basis for this change. Therefore, in RAI-SRP10.4.3-SBPA-01, the staff asked the applicant to explain and justify this deletion of the pressure-regulating valves.

In response to RAI-SRP10.4.3-SBPA-01, in its letter dated June 20, 2008, the applicant stated that the AP1000 gland seal system uses pressure-regulating valves to control steam pressure to the turbine glands. In the approved design, as described in the DCD, Revision 15, the high-pressure and low-pressure turbine glands used steam at different pressures and, therefore, had their own pressure-regulating valves to deliver their respective pressures. In the proposed changes to the DCD; however, the applicant changed its design to a single-pressure system, in which the high- and low-pressure turbine glands use the same steam pressure from a common gland seal steam supply header. Figure 10.4.3-1 of the DCD, Revision 17, includes the diagram depicting the gland seal steam piping and instrumentation. The gland seal steam header is supplied with steam from both the auxiliary steam and main steam systems, and the above-cited pressure-regulating valves are located in each of these systems upstream of the header. Based on the above discussion and a review of Figure 10.4.3-1, the staff finds the elimination of the gland seal steam dual-pressure system acceptable, since it is the new Westinghouse design and does not affect any safety-related systems or equipment. Therefore, the staff's concern described in RAI-SRP10.4.3-SBPA-01 is resolved.

10.4.3.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the proposed changes to Section 10.4.3of the AP1000 DCD. The staff finds that the changes with respect to specifying a high-pressure turbine CV, the addition of seal steam supply from MSV and CV gland steam leakoff, and other changes to the gland seal system design proposed in TR-86, Revision 1, do not affect the staff's conclusion in NUREG-1793 that the gland seal system design meets the requirements of GDC 60, with respect to the design features in place to control releases of radioactive materials to the environment. The proposed changes do not adversely affect the AP1000 turbine gland seal steam system.

10.4.4 Turbine Bypass System

10.4.4.1 Summary of Technical Information

In NUREG-1793, the staff approved Section 10.4.4, "Turbine Bypass System," of the AP1000 DCD, Revision 15.

In the proposed changes to the AP1000 DCD, the applicant proposed to clarify Section 10.4.4.2.2, "Component Description," regarding the manual use of the bypass valves during cooldown. The revised sentence reads: "…the low T_{avg} block can be manually bypassed for ~~one of~~ the bypass valves <u>that are designated as cooldown valves</u> to allow operation during plant cooldown." The addition is indicated by underlined text.

10.4.4.2 Evaluation

The staff reviewed the proposed changes to Section 10.4.4. The specific criterion that applies to the change is 10 CFR 52.63(a)(1)(vii), in that the proposed change contribute to increased standardization of the certification information.

The regulatory basis for AP1000 DCD, Section 10.4.4, is documented in NUREG-1793. The staff reviewed the proposed changes to DCD Section 10.4.4 against the applicable acceptance criteria of NUREG-0800 Section 10.4.4. The acceptability of the system design is based on meeting the following GDC as described in NUREG-0800:

- GDC 4, as it relates to the system being designated such that a failure of the system (due to a pipe break or system malfunction) does not adversely affect safety-related systems or components

- GDC 34, "Residual Heat Removal," as it relates to the ability to use the turbine bypass system for shutting down the plant during normal operations by removing residual heat without using the turbine generator

The change proposed by the applicant is considered a clarification and does not alter the ability of the system to manually bypass a T_{avg} block and allow operation of the bypass valves during plant cooldown. Therefore, the change is considered acceptable.

10.4.4.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and thatthe application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the proposed changes to Section 10.4.4, "Turbine Bypass System." On the basis of its review, the staff finds the turbine bypass system continues to meet all acceptance criteria as documented in NUREG-1793 and is, therefore, considered to be acceptable.

10.4.5 Circulating Water System

10.4.5.1 Summary of Technical Information

In NUREG-1793, the staff approved Section 10.4.5, "Circulating Water System," of the AP1000 DCD, Revision 15. In the proposed changes to the AP1000 DCD, the applicant proposed the following changes to Section 10.4.3.

In Section 10.4.5, the applicant identified CDI items related to the alternative SPC design proposed in TR-86, Revision 1. Additionally, as part of identifying the CDI information, the applicant revised Section 10.4.5 to include makeup water as an additional source to the CWS by stating the following:

> The CWS and/or makeup water from the raw water system supplies cooling water to the turbine building closed cooling water system (TCS) heat exchangers and the condenser vacuum pump seal water heat exchangers under varying conditions of power plant loading and design weather conditions.

The underlined text indicates the revision.

10.4.5.2 Evaluation

The staff reviewed the proposed changes to the CWS in the AP1000 DCD. The staff did not review descriptions and evaluations of Section 10.4.5 that were previously approved and that are not affected by the new changes. The specific criterion that applies to the changes is 10 CFR 52.63(a)(1)(vii), in that the proposed changes contribute to increased standardization of the certification information.

NUREG-1793 includes the regulatory basis for Section 10.4.5 of the AP1000 DCD. The staff has reviewed the proposed changes to DCD Section 10.4.5 against the applicable acceptance criteria of NUREG-0800 Section 10.4.5, “Circulating Water System,” and other applicable criteria.

Since the CWS system configuration and its components, such as circulating water pumps, cooling tower or heat sink, and piping and valves, are plant-specific items, the applicant identified these as CDI items. Further, the addition of makeup water to the CWS for the supply of cooling water to the turbine control system heat exchangers and the condenser vacuum pump seal water heat exchangers are plant-specific CDI items.

Therefore, the staff finds that the addition of makeup water and the identification of CDI items are changes to conform to the new design, in accordance with TR-86, Revision 1, and do not affect the staff’s conclusion in NUREG-1793 that the CWS design meets the requirements of GDC 4 with respect to the effects of discharging water that may result from a failure of a component or piping in the CWS. Therefore, the staff finds these changes to be acceptable.

10.4.5.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the proposed changes to Section 10.4.5. The staff finds that the addition of the makeup water system and the identification of the CDI items are acceptable, as they relate to the new design proposed in TR-86, Revision 1. Further, these revisions to Section 10.4.5 of the DCD, do not adversely affect the ability of the CWS to meet the requirements of GDC 4. On the basis of its review, the staff finds that the CWS continues to meet all of the acceptance criteria in NUREG-1793 and is, therefore, acceptable.

10.4.7 Condensate and Feedwater System

10.4.7.1 Summary of Technical Information

In NUREG-1793, the staff approved Section 10.4.7, "Condensate and Feedwater System," of the AP1000 DCD, Revision 15. The applicant proposed changes to Section 10.4.7 of the AP1000 DCD.

The applicant proposed the following four technical changes to the AP1000 DCD, three of which are supported by information in Westinghouse TRs:

(1) In Revision 17 to the AP1000 DCD, pages 10.4-21, 10.4-22, 10.4-26, and drawing page 10.4-71 (Figure 10.4.7-1, Sheet 3 of 4), the applicant proposed changing the number of high-pressure feedwater heater stages from one to two. The AP1000 DCD, Revision 15, designates the one high-pressure feedwater heater stage as feedwater heater number 6, with the stage consisting of two parallel feedwater heaters, numbers 6A and 6B. The AP1000 DCD, Revision 17, designates the additional stage feedwater heater number 7, with the stage consisting of two parallel feedwater heaters, numbers 7A and 7B. TR-86, Revision 1, documents the basis for this change.

(2) In the AP1000 DCD, Revision 17, page 10.4-25, the applicant changed text in the first and second paragraphs under the title "Low-Pressure Feedwater Heaters." The current text reads as follows:

> Except for the No. 1 feedwater heaters, the closed low-pressure feedwater heaters have integral drain coolers, and their shell side drains cascade to the next lower stage feedwater heater. The drains from the No. 1 heaters are dumped to their respective condenser shell.
>
> A drain line from each heater allows direct discharge of the heater drains to the condenser in the event the normal drain path is not available or flooding occurs in the heater.

The revised text reads as follows:

> The closed low-pressure feedwater heaters use drain coolers. The cascaded drains from the heaters are dumped to their respective condenser shell.
>
> A drain line from the heater allows direct discharge of the heater drains to the condenser in the event the normal drain path is not available or flooding occurs in the heater.

TR-86, Revision 1, documents the basis for this change. The applicant also incorporated this change in the AP1000 DCD, on drawing page 10.4-69 (Figure 10.4.7-1, Sheet 2 of 4), to show that the number 1 and number 2 feedwater heater drains dump into their respective condenser shells.

(3) In the AP1000 DCD, Revision 17, on page 10.4-73 (Figure 10.4.7-1, Sheet 4 of 4), the applicant proposed eliminating pressure transmitters PT043, PT044, and PT045, and

pressure instrument controllers PIC043, PIC044, and PIC045, and replacing them with PT042 and PC042. TR-103, Revision 2, documents this change.

(4) In the AP1000 DCD, Revision 17, on pages 10.4-69 and 10.4-71 (Figure 10.4.7-1, Sheets 2 and 3), the applicant apparently made a change to the arrangement of the deaerator feedwater heater and its associated storage tank.

10.4.7.2 Evaluation

The staff reviewed all changes to the condensate and feedwater system (CFS) in the AP1000 DCD. The staff did not re-review descriptions and evaluations of Section 10.4.7 that were previously approved and are not affected by the new changes. The specific criteria that apply to the CFS related changes include 10 CFR 52.63(a)(1)(vi) in that the changes substantially increases overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security, and 10 CFR 52.63(a)(1)(vii), in that the proposed changes contribute to increased standardization of the certification information.

NUREG-1793 includes the regulatory basis for Section 10.4.7 of the AP1000 DCD. The staff has reviewed the proposed changes to DCD Section 10.4.7 against the applicable acceptance criteria of NUREG-0800 Section 10.4.7, "Condensate and Feedwater System." The following evaluation discusses the results of the staff's review.

10.4.7.2.1 Condensate and Feedwater System—Addition of High-Pressure Feedwater Heater Stage 7

In TR-86, Revision 1, Section 1, the applicant stated that an alternative SPC design was presented in Revision 0 of TR-86 as DCD Chapter 10A, and that all standard AP1000 units built will now employ a single turbine-generator and steam-cycle design. The applicant proposed incorporating changes from DCD Chapter 10A as a single design for AP1000 and stated that one of the significant differences between the reference design and the alternative new design of the turbine-generator set is the addition of a seventh-stage feedwater heater. Because the alternative design of the turbine-generator set uses a seventh-stage high-pressure feedwater heater in its feedwater system design, and because the addition of the seventh-stage heater has no effect on CFS compliance with GDC 2, "Design Bases for Protection against Natural Phenomena"; GDC 4; GDC 44, "Cooling Water"; GDC 45, "Inspection of Cooling Water System"; and GDC 46, "Testing of Cooling Water System," the staff finds the addition of the second high-pressure feedwater heater to the AP1000 CFS design acceptable. The staff also finds that the addition of the seventh-stage heater does not result in a change to the CFS compliance with NUREG-0800 Section 10.4.7 in NUREG-1793.

10.4.7.2.2 Condensate and Feedwater System, Low-Pressure Feedwater Heater Stages 1 and 2 Drain to Their Respective Condensers

In TR-86, Revision 1, on page 52, the applicant proposed a design change for low-pressure feedwater heater stages 1 and 2 drains to dump directly into their respective condenser shells. This design change is part of the alternative SPC design described in Revision 0 of TR-86 as DCD Chapter 10A. Also, on page 60 of TR-86, Revision 1, the applicant proposed a similar change to DCD Figure 10.4.7-1 (Sheet 2 of 4), which has been changed schematically to show that the drains from low-pressure feedwater heaters 1A, 1B, 1C, 2A, 2B, and 2C dump into the respective condenser shells A, B, and C. The low-pressure feedwater heater stage 2 drain no longer cascades into feedwater heater stage 1. Because the alternative design of the turbine-generator set uses a different drainpath for the No. 2 low-pressure feedwater heater stage, which does not affect the safety-related functions of the CFS or its compliance with GDC 2, 4, 44, 45, and 46, the staff finds this design change to the AP1000 CFS acceptable. The staff also finds that the change to the heater drain system does not result in a change to the CFS compliance with NUREG-0800 Section 10.4.7 in NUREG-1793.

10.4.7.2.3 Condensate and Feedwater System Pressure Transmitters PT043, PT044, and PT045, and Pressure Instrument Controllers PIC043, PIC044, and PIC045 Replaced with PT042 and PC042

In TR-103, Revision 2, on page 7, the applicant proposed eliminating the control function shown in Figure 10.4.7-1 (Sheet 4 of 4) for PT-043–45, because the startup feedwater header pressure is no longer an input to the startup feedwater control system. In TR-103, the applicant further stated that all three pressure transmitters are no longer necessary, since they do not have a control function and pressure transmitters PT-044 and PT-045 have been deleted. Additionally, the applicant has revised Note 4 to reflect the updated control logic diagram APP-PLS-J1-143 and has deleted the statement in the note that mentions startup feedwater header pressure as an input to the control system. The applicant also made a change in Note 3 to indicate that control logic diagram APP-PLS-J1-114 has been updated and is now APP-PLS-J1-144.

Because the startup feedwater header pressure signal no longer provides input to the startup feedwater control system, and the new control logic does not affect the CFS compliance with GDC 2, 4, 44, 45, and 46, the staff finds this design change to the AP1000 CFS acceptable. Section 7.7.1.5 of this report reviews the acceptability of instrumentation and controls changes related to AP1000 DCD Sections 7.7.1.8.1, “Feedwater Control”; and 7.7.1.8.2, “Startup Feedwater Control.”

10.4.7.2.4 Figure 10.4.7-1 (Sheets 2 and 3) Revised To Show the ME 05 “Deaerator Feedwater Heater and Deaerator Storage Tank” as a Single Component

The approved DCD shows the deaerator and the deaerator storage tank as separate components. However, AP1000 DCD, Revision 16, Figure 10.4.7-1 (Sheets 2 and 3), shows the deaerator feedwater heater and the deaerator storage tank as a single component. Furthermore, Section 10.4.7.2.2, “Component Description,” of the DCD describes the deaerator as “a tray type, horizontal shell, direct contact heater located on top of a horizontal storage tank.” Since the design of the deaerator and the deaerator storage tank in the AP1000 DCD, Revision 16, differs from the approved design and from the component description provided in the DCD, the staff, in RAI-SRP10.4.7-SBPA-01, dated April 28, 2008, asked the applicant to explain why the design change is acceptable.

In its response, dated June 20, 2008, the applicant stated that there was no change to the function of the deaerator or the feedwater and condensate systems, and the confusion was a result of the various descriptions and pictorial representations of the deaerator used throughout the DCD. A more consistent representation of the deaerator in the DCD would have likely prevented the confusion. The deaerator vendor changed the previous vendor’s design, which used a deaerator storage tank with the deaerating heater mounted on top of the tank. The latest vendor’s standard design is functionally the same, but the deaerating heater is mounted inside the deaerator storage tank.

The applicant further stated that the differences between the two vendors' deaerator designs do not have any effect on the design or function of the feedwater and condensate systems. The applicant changed DCD Figure 10.4.7-1 (Sheets 2 and 3), as well as the text in DCD Section 10.4.7.2.2, to more accurately reflect the current vendor's deaerator.

In evaluating the applicant's response, the staff notes that the applicant indicated that the deaerator vendor had changed and that in the new vendor's design, the deaerator heater is mounted inside the deaerator storage tank, as opposed to being located on top of the tank, as was the case in the DCD revisions before Revision 16. However, while the new design is shown in the revised Figure 10.4.7-1, the deaerator description in Section 10.4.7.2.2 continues to describe the dearator as "a tray type horizontal shell, direct contact heater located on top of a horizontal storage tank." The deareator described in Section 10.4.7.2.2 of the DCD, and that shown in Figure 10.4.7-1, are not consistent, despite the applicant's claim in its response that it changed the text in DCD Section 10.4.7.2.2 to more accurately reflect the current vendor's deaerator. The staff found the DCD information on the deaerator to be inconsistent and the applicant's response to be insufficient, since the response includes an inaccuracy regarding the text in Section 10.4.7.2.2. In DCD Revision 17, Section 10.4.7.2.2, the applicant revised the text that describes the deaerator to reflect what is shown in Figure 10.4.7-1 of the DCD. On the basis of its review, the staff finds RAI-SRP10.4.7-SBPA-01 to be resolved.

10.4.7.3 Conclusion

The staff reviewed the applicant's proposed changes to the CFS. The staff finds that the applicant's proposed changes do not affect the ability of the AP1000 CFS to meet the applicable acceptance criteria. The staff also finds that the applicant properly incorporated the design changes into the appropriate sections of the AP1000 DCD. Because the AP1000 CFS design continues to meet all of the applicable acceptance criteria and the changes are properly documented in the updated AP1000 DCD, the staff finds that all of the changes to the AP1000 CFS are acceptable.

10.4.8 Steam Generator Blowdown System

10.4.8.1 Summary of Technical Information

The staff approved Section 10.4.8, "Steam Generator Blowdown System," of the AP1000 DCD, Revision 15, in the certified design. In the proposed changes to the AP1000 DCD, the applicant revised Section 10.4.8 of the certified design.

- In DCD Section 10.4.8.2.2, the system flow rates were increased by approximately 8 to 9 percent. In a letter dated July 30, 2009, the applicant explained that the flow rates were changed in order to reflect updated system design calculations. In addition, the words, "at standard conditions" were added after the flow rates.

- Three wording corrections were made for consistency with other parts of the DCD.

- A note was added to Figure 10.4.8-1. The note identifies the drawing as a functional arrangement that could have different internal details due to procurement requirements.

10.4.8.2 Evaluation

The staff reviewed the changes to the steam generator blowdown system identified in Section 10.4.8 of the AP1000 DCD. The staff did not review descriptions and evaluations of Section 10.4.8 that were previously approved and that are not affected by the new changes. The specific criteria that apply to the steam and generator blowdown system related changes include 10 CFR 52.63(a)(1)(vi) in that the changes substantially increases overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security, and 10 CFR 52.63(a)(1)(vii), in that the proposed changes contribute to increased standardization of the certification information.

NUREG-1793 includes the regulatory basis for Section 10.4.8 of the AP1000 DCD. The staff reviewed the proposed changes to the AP1000 DCD against the applicable acceptance criteria of NUREG-0800 Section 10.4.8, "Steam Generator Blowdown System," and other applicable criteria.

The staff finds the changes in flow rate values acceptable because they do not affect the amount of blowdown as a percentage of steam flow. Hence, the updated flow rates support the level of secondary-side water purification in the certified AP1000 design. Adding the phrase, "at standard conditions" is acceptable because it provides clarification to the flow-rate values.

The other wording changes were made for consistency with the design as documented in other parts of the DCD and are, thus, acceptable. The note added to Figure 10.4.8-1 is acceptable because it clarifies that there is flexibility in the as-built system without affecting the system functionality.

10.4.8.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the applicant's proposed changes to the AP1000 steam generator blowdown system. The staff finds that the applicant's proposed changes do not affect the ability of the steam generator blowdown system to meet the applicable acceptance criteria. Therefore, the staff finds that the proposed changes to AP1000 DCD, Section 10.4.8, are acceptable.

10.4.10 Auxiliary Steam System

The staff approved Section 10.4.10, "Auxiliary Steam System," of the AP1000 DCD, Revision 15, in the certified design. In the the proposed changes to the AP1000 DCD, the applicant proposed the following change to Section 10.4.10 of the certified design.

The applicant replaced the oil-fired boiler with an electric boiler. TR-114, "AP1000 Auxiliary Boiler Sizing and Design" (APP-GW-GLR-114), dated June 14, 2007, documents the basis for this change. The applicant deleted detailed design information for the oil-fired boiler and proposed some changes throughout Section 10.4.10 to reflect the changes addressed in TR-114.

The staff confirmed that all other changes in DCD Section 10.4.10 are editorial and do not require an evaluation.

10.4.10.1 Evaluation

The staff reviewed all changes identified in the AP1000 DCD. The staff did not review descriptions and evaluations of the auxiliary steam system in the AP1000 DCD, Revision 15, that were previously approved and that are not affected by the new changes. All technical changes in the DCD are supported by information presented in Westinghouse TRs. The specific criteria that apply to the auxiliary steam system related changes include 10 CFR 52.63(a)(1)(vi) in that the changes substantially increases overall safety, reliability, or security of facility design, construction, or operation, and the direct and indirect costs of implementation of the rule change are justified in view of this increased safety, reliability, or security, and 10 CFR 52.63(a)(1)(vii), in that the proposed changes contribute to increased standardization of the certification information.

NUREG-1793 includes the regulatory basis for Section 10.4.10 of the AP1000 DCD. In its previous evaluations of this section, the staff found that the current NUREG-0800 does not include a section specifically addressing the auxiliary steam system. The staff has determined that the acceptability of this system will be based on meeting the requirements of GDC 4. In other words, failure of the auxiliary steam system, as a result of a pipe break or malfunction of the system, should not adversely affect safety-related SSCs. The staff has reviewed the proposed changes to DCD Section 10.4.10 and discusses the results below.

The applicant replaced the oil-fired boiler with an electric boiler and submitted TR-114 to address the basis for this change. The applicant proposed a series of changes to DCD Section 10.4.10 to be consistent with the new electric boiler. These changes include the following:

- The applicant added text to DCD Section 10.4.10.1.2 to indicate that auxiliary steam supplements the main steam system during startup. This change provides additional information on system operation, has no impact on the auxiliary steam system and is, therefore, acceptable.

- The applicant deleted reference to “oil-fired boiler” and replaced it with “electric package boiler” in DCD Section 10.4.10.2.2. This is a conforming change to reflect the design change and is, therefore, acceptable.

- The applicant changed the nominal net output capacity from “at least 110,000 pounds per hour (49,900 kilograms per hour)” to “approximately 100,000 pounds per hour (45,360 kilograms per hour)” in DCD Section 10.4.10.2.2. This change has no impact on any safety-related SSC and, therefore, is acceptable.

- The applicant deleted the component description for the auxiliary boiler fuel-oil components from DCD Section 10.4.10.2.2. This is a conforming change to reflect the design change and, therefore, is acceptable.

10.4.10.2 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the application for DC met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

The staff reviewed the applicant's proposed changes to the AP1000 auxiliary steam system against GDC 4. The staff finds that the applicant's proposed changes do not affect the ability of the auxiliary steam system to meet the applicable acceptance criteria. The staff also finds that the applicant properly incorporated the design changes into the appropriate sections of the AP1000 DCD. The staff concludes that the AP1000 auxiliary steam system continues to meet all applicable acceptance criteria, and the proposed changes are properly documented in the updated AP1000 DCD; therefore, the staff finds that the proposed changes to AP1000 DCD, Section 10.4.10, are acceptable.

11. RADIOACTIVE WASTE MANAGEMENT

The AP1000 radioactive waste (radwaste) management systems control the handling and treatment of liquid, gaseous, and solid radwaste. These systems include the liquid radwaste system (WLS), the gaseous radwaste system (WGS), and the solid radwaste system (WSS). The WLS is designed to control, collect, process, store, and dispose of liquid radioactive wastes. The WLS is discussed in Section 11.2 of this report. The WLS contains holdup tanks, process pumps, and other processing equipment, including monitor tanks and appropriate instrumentation and controls. Ion exchange is the principal waste treatment process in the WLS.

The WGS collects, processes, and monitors gaseous releases. The WGS is discussed in Section 11.3 of this report. The WGS collects gaseous wastes that are potentially radioactive or hydrogen-bearing (i.e., those wastes resulting from degassing the reactor coolant and the contents of the reactor coolant drain tank (RCDT)), stores them for decay in charcoal delay beds, and subsequently releases them into the environment via the plant vent. The WSS controls the processing of solid wastes generated during reactor operation, as well as the packaging and storage of such processed wastes before shipment to a licensed disposal facility. The WSS is discussed in Section 11.4 of this report. The process and effluent radiological monitoring instrumentation and sampling systems, which are discussed in Section 11.5 of this report, detect and measure the radioactive materials in plant liquid and gaseous processes and effluent streams.

The U.S. Nuclear Regulatory Commission (NRC) staff reviewed the additional and amended information provided by the applicant using the guidance in Chapter 11 of NUREG-0800, “Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants,” Revision 3, issued March 2007. The NRC developed the original NUREG-1793, “Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design,” using the guidance from regulatory guide (RG) 1.70, “Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants,” Revision 3, issued November 1978. Therefore, this supplement follows the format of the original NUREG-1793.

The scope of this review includes Chapter 11, Sections 11.2 through 11.5 of Revision 16 and 17 of the AP1000 design certification amendment, Tier 2 and Tier 1, Chapter 2, Sections 2.3.10, “Liquid Radwaste System”; 2.3.11, “Gaseous Radwaste System”; and 3.5, “Radwaste Monitoring,” which includes the associated inspections, tests, analyses, and acceptance criteria (ITAAC). Section 11.1 did not include any technical changes in Revisions 16 and 17; therefore, the staff did not include Section 11.1 in this supplement.

This section describes the staff’s evaluation and findings of the AP1000 Design Control, Document (DCD), Revisions 16 and 17. The staff reviewed Revision 16 upon receipt; however, after review, the staff issued several requests for additional information (RAIs) and the applicant issued Revision 17 prior to the resolution of these RAIs. Hence, this review and evaluation encompasses both revisions.

11.2 Liquid Waste Management System

11.2.1 Summary of Technical Information

In the AP1000 DCD, the applicant proposed to make five technical changes as described below:

1) In AP1000 DCD Section 11.2, the applicant proposed to increase overall liquid waste holdup capacity and improve operational flexibility by adding three additional liquid waste monitor tanks (and associated pumps, piping, instruments, and valves). The applicant proposed to house the new tanks 56,781 liters (15,000 gallons) each in the radwaste buildings. The new tanks are identical to the three existing monitor tanks, which are housed in the auxiliary building. The applicant has documented these changes in Westinghouse TR-116, "Additional Liquid Radwaste Monitor Tanks and Radwaste Building Extension," APP-GW-GLN-116, Revision 0.

2) In AP1000 DCD Sections 11.2.1.2.4 and 11.2.1.3, the applicant added statements certifying compliance with Title 10 of the *Code of Federal Regulations* (10 CFR) 20.1406, "Minimization of contamination." These changes are documented in Westinghouse TR-98, "Compliance with 10 CFR 20.1406," APP-GW-GLN-098, Revision 0.

3) In AP1000 DCD Section 11.2, Figure 11.2-2, "Liquid Radwaste System Piping and Instrumentation Diagram, Sheet 1, the applicant proposed changing the figure to show the addition of a flow element to monitor letdown flow from the chemical and volume control system to the liquid waste system. The applicant documented this chemical and volume control system post accident monitoring system (PAMS) instrument modification in TR-118, "Chemical and Volume Control System PAMS Instrument Modifications," APP-GW-GLN-118, Revision 0.

4) In AP1000 DCD Sections 11.2.5.3 and 11.2.5.4, the applicant proposed updates to document the closure of combined license (COL) Information Items 11.2-3 and 11.2-4, respectively and as described in TR-48, "Identification of Ion Exchange and Adsorbent Media," APP-GW-GLR-008, Revision 0 and in TR-73, "Dilution and Control of Boric Acid Discharge," APP-GW-GLR-014, Revision 0.

5) In AP1000 DCD Section 11.2.3.3, 11.2.3.5 and 11.2.5.2, the applicant proposed changes related to the liquid effluent release requirements in 10 CFR Part 20, "Standards for protection against radiation," and 10 CFR Part 50, "Domestic licensing of production and utilization facilities."

The changes in Revision 17 to the AP1000 DCD reflect the responses to the RAIs from Revision 16.

The evaluation below discusses these changes and other information pertaining to NUREG-0800 acceptance criteria, provides an overview of the staff's RAIs, the applicant's responses, and the staff's evaluation of the responses.

11.2.2 Evaluation

The staff reviewed all technical changes and ITAAC to the liquid waste management system in accordance with NUREG-0800 Section 11.2, "Liquid Waste Management System" and all changes identified by change marks in the AP1000 DCD. In addition, the staff reviewed all changes to the liquid waste management system-based design description and ITAAC in AP1000 DCD Tier 1, Section 2.3.10.

11.2.2.1 Addition of Three Liquid Waste Monitor Tanks

In TR-116, the applicant proposed to add three additional liquid waste monitor tanks (and associated pumps, piping, instruments, and valves). The applicant proposed to house the new tanks, 56,781 liters (15,000 gallons) each in the radwaste building.

In AP1000 DCD Tier 2, Section 11.2, the staff noted that a potential exists for the quantity of radionuclides in the radwaste building portion of the liquid waste management system to exceed the A_1 value, thus requiring these structures, systems, and components (SSCs) to be designated as RW-IIa in accordance with RG 1.143, “Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light-Water-Cooled Nuclear Power Plants,” Revision 2. However, these SSCs were designated as RW-IIc in AP1000 DCD Tier 2, Section 1, Appendix 1A. In a September 9, 2008 letter, the applicant responded to the staff’s concern and provided an analysis to show that the concentrations will be less than the A_1 and A_2 levels. The applicant then modified Revision 17 of the AP1000 DCD to state that the contents of each monitor tank in the non-seismic radwaste building will be less that the A_1 and A_2 levels of 10 CFR Part 71, “Packaging and transportation of radioactive material,” Appendix A, “Determination of A_1 and A_2,” Table A-1, “A_1 and A_2 Values for Radionuclides.” The staff finds this response acceptable and RAI-SRP11.2-CHPB-06 is closed.

In AP1000 DCD Section 3.2, Table 3.2-3, Sheets 63 and 64, the staff noted that the additional equipment for the WLS was not included in the table, nor was the location of the added WLS components included in the Radwaste Building. Moreover, in Table 3.2-3, the applicant did not identify the new WLS piping interconnecting the Auxiliary and Radwaste Buildings and its classification. The applicant added the necessary information to the diagrams and table in Revision 17. The staff reviewed these changes and found them acceptable. RAI-SRP11.2-CHPB-07 is closed.

Based on the evaluation of AP1000 DCD Section 11.2 and the response to the RAI, the staff concludes that the applicant properly identified all design information related to the three additional liquid waste monitor tanks and associated equipment, and provided an adequate demonstration that design objectives for equipment necessary to control releases of radioactive effluents to the environment have been met in accordance with 10 CFR Part 50.34a, “Design objectives for equipment to control releases of radioactive material in effluents—nuclear power reactors.”

11.2.2.2 Documentation of Compliance with 10 CFR 20.1406

In TR-98, the applicant proposed to comply with the regulation by selection of design technology. Table TR98-1, “AP1000 Features Applicable to 10 CFR 20.1406” in TR-98 lists specific examples of how the AP1000 design complies with 10 CFR 20.1406 (Items 19, 22, 23, 24, 25, and 26). The staff reviewed the items listed in Table TR98-1 pertaining to the WLS and found that the applicant addressed the minimization of waste generation in 10 CFR 20.1406.

The staff issued regulatory guidance for 10 CFR 20.1406 in RG 4.21, “Minimization of Contamination and Radioactive Waste Generation: Life-Cycle Planning,” after Revision 16 but before the issuance of Revision 17. As such, the staff documented its review according to

RG 4.21 in Chapter 12. The staff finds that this change does not affect the design and performance aspects of the WLS.

11.2.2.3 Chemical and Volume Control System Post Accident Monitoring System Instrument Modifications

In AP1000 DCD Section 11.2, Figure 11.2-2, “Liquid Radwaste System Piping and Instrumentation Diagram” Sheet 1, the applicant changed the figure to include a flow element to monitor letdown flow from the chemical and volume control system to the WLS. The staff concluded that this change does not affect the design and performance aspects of the WLS and provides additional capabilities to monitor the flow to the WLS.

11.2.2.4 Closure of COL Information Item 11.2-3 and 11.2-4

In AP1000 DCD Sections 11.2.5.3 and 11.2.5.4, the applicant proposed updates to document the closure of COL Information Items 11.2-3 and 11.2-4, respectively as described in TR-48 and in TR-73. The applicant proposed that media selection should be a matter for the plant operator, and should not be identified at the COL application stage. The two reports, TR-48 and TR-73, describe this process and give justification to show that COL Information Items 11.2-3 and 11.2-4 should be deleted. For both of these applications, the staff considered that this media will be replaced multiple times throughout the operating life of the plant. Since these changes are operational in nature and do not affect the design and performance aspects of the WLS, the staff finds these changes acceptable.

11.2.2.5 Changes Related to the Effluent Release Requirements in Parts 20 and 50

Section 11.2.3.3, “Dilution Factor” in the AP1000 DCD, Revision 16 omitted compliance with the annual offsite dose limits of 10 CFR Part 50, “Domestic licensing of production and utilization facilities,” Appendix I, “Numerical Guides for Design Objectives and Limiting Conditions for Operation to Meet the Criterion ‘As Low as is Reasonably Achievable’ for Radioactive Material in Light-Water-Cooled Nuclear Power Reactor Effluents,” Section II.A. The DCD stated that the plant operator selected dilution flow rates to ensure compliance with the effluent concentration limits of 10 CFR Part 20 and any local requirements. Plant operators must also ensure that the annual releases are within the dose limits of 10 CFR Part 50, Appendix I, which in some situations may be the limiting case. Because of this omission, the staff issued an RAI requesting the applicant to incorporate Section II.A requirements. The applicant added this requirement to Revision 17. The staff reviewed this change and concluded that it was acceptable and closed RAI-SRP11.2-CHPB-01.

Section 11.2.3.5 in the AP1000 DCD, Revision 16 stated that the estimated doses from liquid effluents are site-specific and discussed in DCD Section 11.2.5. Section 11.2.5 only stated that the COL applicant will provide a site-specific cost-benefit analysis to address the requirements of 10 CFR Part 50, Appendix I, Section II.D regarding population doses due to liquid effluents. The COL applicant must also comply with the individual dose limits to members of the public in 10 CFR Part 50, Appendix I and 10 CFR 20.1301(e). Because of this omission, the staff issued an RAI requesting the applicant to incorporate the individual dose requirements of 10 CFR Part 20 and 10 CFR Part 50. The applicant added these requirements to Revision 17. The staff reviewed this change and concluded that it was acceptable and closed RAI-SRP11.2-CHPB-02.

The staff found an inconsistency between the estimated dose sections in Sections 11.2, “Liquid Waste Management System,” and 11.3, “Gaseous Waste Management System.” No individual doses were calculated for liquid effluents, but doses were calculated for gaseous releases. The staff issued an RAI asking the applicant to address this inconsistency. Revision 17 to the AP1000 DCD addressed this inconsistency by adding text that requires compliance with Section II.A of Appendix I to 10 CFR Part 50. The staff reviewed this change and concluded that it was acceptable and closed RAI-SRP11.2-CHPB-03.

11.2.2.6 Preoperational Testing Information

Section 11.2.4, “Preoperational Testing,” of the AP1000 DCD, Revisions 16 and 17 did not address the testing and inspection of ion exchange resin. The initial performance of the liquid radioactive waste system depends on the existence and performance of ion exchange resin in the ion exchange vessels. The applicant based the annual liquid effluent release of radioactivity estimated in Section 11.2 on assuming that the media provided a specific level of decontamination as listed in Table 11.2-5, “Decontamination Factors.” The applicant did not specify any preoperational testing and inspections to ensure that the resin is properly installed and performing to assumed levels at initial start up.

The staff issued RAI-SRP11.2-CHPB-05 requesting a statement in the DCD indicating that the applicant will confirm the presence of the correct amount of resin in the liquid radwaste system ion exchange vessels. On April 3, 2009, the applicant submitted a proposed revision to DCD Section 11.2.4.3. This revision stated that an inspection of the system would confirm that the applicant installed the proper volume of media into the appropriate components. The staff finds this confirmation acceptable. In a subsequent revision to the DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

11.2.2.7 Reactor Coolant System Effluents

In the AP1000 DCD, Revision 17, the applicant included additional operator actions when returning the contents of the monitoring tanks for further processing. When radioactivity exceeds operational targets, the operator is instructed to recirculate and sample the contents of the monitoring tanks. The staff reviewed this change and found it to be more specific and appropriate. Thus, the staff concluded that this change was acceptable.

11.2.2.8 Tier 1 Section 2.3.10, Liquid Radwaste System

The applicant added three additional WLS monitoring tanks and a letdown flow monitor to reflect the current design changes in Tier 1, Section 2.3.10. These are conforming changes and have no impact on the staff’s conclusion about the acceptability of the design of the WLS.

11.2.3 Conclusion

In NUREG-1793, Supplement 1, the staff documented its conclusion that the AP1000 design and DCD (up to and including Revision 15 of the DCD) were acceptable and that the applicant’s application for the design certification met the requirements of Subpart B to 10 CFR Part 52, “License, certifications, and approvals for nuclear power plants” that are applicable and technically relevant to the AP1000 standard plant design.

In the previous evaluation of AP1000 DCD, Section 11.2, “Liquid Waste Management System,” the staff identified acceptance criteria based on the design’s meeting relevant requirements in

10 CFR 20.1302, “Compliance with dose limits for individual members of the public,” as it relates to limits on doses to persons in unrestricted areas; 10 CFR 50.34a, as it relates to the inclusion of sufficient design information to demonstrate the design objectives for equipment necessary to control releases of radioactive effluents to the environment; 10 CFR Part 50, Appendix A, “General Design Criteria for Nuclear Power Plants” General Design Criteria (GDC) 60, “Control of Releases of Radioactive Materials to the Environment,” as it relates to the design of liquid waste management systems to control releases of liquid radioactive effluents; and GDC 61, “Fuel Storage and Handling and Radioactivity Control,” as it relates to the design of liquid waste management systems to ensure adequate safety under normal and postulated accident conditions.

The staff reviewed the applicant’s proposed changes to the AP1000 liquid waste management system. The staff concluded that the applicant’s proposed changes do not affect the ability of the AP1000 liquid waste management system to meet the applicable acceptance criteria in NUREG-0800 Section 11.2. The staff also concluded that the applicant had properly incorporated design changes into the appropriate sections of the AP1000 DCD. The staff determined that the AP1000 liquid waste management system continued to meet all applicable acceptance criteria and the applicant documented the changes in the updated AP1000 DCD. The staff also concluded that all of the changes related to the liquid waste management system design description and ITAAC as described in AP1000 DCD Tier 1, Section 2.3.10 are acceptable.

11.3 Gaseous Waste Management System

11.3.1 Summary of Technical Information

In the AP1000 DCD, Revision 17, the applicant proposed ten technical changes to the gaseous waste management system as supported by information presented in TR-48, TR-98, and TR-103, “Fluid System Changes” APP-GW-GLN-019, Revision 2. A description of each Revision 16 technical change is provided below:

1) The applicant demonstrated compliance with 10 CFR 20.1406 through the selection of design technology. This change is documented in TR-98. The applicant identified this change in AP1000 DCD, Revision 16, Tier 2, page 11.3-4.

2) The applicant completed COL Information Item 11.3.5.2 by providing the requested information in TR-48. The applicant has identified this change in AP1000 DCD, Revision 16, Tier 2, pages 11.3-4 and 11.3-11.

3) The applicant changed Figure 11.3-1, “Gaseous Radwaste System Piping and Instrumentation Diagram,” to update the drawing nomenclature. This change was documented TR-103. The applicant identified this change in AP1000 DCD, Revision 16, Tier 2, page 11.3-20.

4) On page 11.3-2 in the DCD section on water incursion (Section 11.3.1.2.2.2), the applicant added the automatic isolation of the guard bed inlet on high moisture separator level.

5) In the General Description (Section 11.3.2.1) on page 11.3-5, the applicant changed the temperature of the influent gas from 7 degrees Celsius (C) (45 degrees Fahrenheit (F)) to 4 degrees C (40 degrees F).

6) In the General Description (Section 11.3.2.1) on page 11.3-5 and in Section 11.3.2.3.3 on pages 11.3-7 and 11.3-8, the applicant reduced the capacity of each of the two activated carbon delay beds from 100 percent system capacity to 50 percent capacity.

7) In order to maintain a slight positive pressure in the WGS when the system is inactive, the applicant originally proposed to inject a small nitrogen flow into the system. In Revision 17, the applicant eliminated the nitrogen injection and relied on a closed discharge isolation valve to maintain positive pressure. The applicant documented this change in Section 11.3.2.2.1, "Normal Operation," on page 11.3-5.

8) The applicant previously stated that the gas leaving the moisture separator would be monitored for moisture content and a high alarm would alert the operator to a condition requiring attention. The applicant revised the design and operation of the system to monitor temperature and not moisture. The applicant documented this change in Section 11.3.2.2.1, "Normal Operation," on page 11.3-6 and in Table 11.3-2, "Component Data (Nominal) – Gaseous Radwaste System."

9) The applicant removed the Xenon and Krypton dynamic adsorption coefficients and holdup times from Table 11.3-1, "Gaseous Radwaste System Parameters," on page 11.3-12.

10) The applicant removed some of the parameter data and revised some of the remaining parameter values in Table 11.3-2, "Component Data (Nominal) – Gaseous Radwaste System" on page 11.3-13.

The evaluation below discusses these changes and other information pertaining to the NUREG-0800 acceptance criteria, provides an overview of the staff's RAIs, the applicant's responses, and the staff's evaluation of the responses.

11.3.2 Evaluation

The staff reviewed all technical changes to the WGS in accordance with NUREG-0800 Section 11.3, "Gaseous Waste Management System" and all changes identified by change marks in the AP1000 DCD. In addition, the staff reviewed all changes to the gaseous waste management system design description and ITAAC in AP1000 DCD, Tier 1, Section 2.3.11.

11.3.2.1 Compliance with 20.1406

In TR-98, the applicant proposed to comply with the regulation by the selection of design technology. Table TR-98-1 in TR-98 lists specific examples of how the AP1000 design complies with 10 CFR 20.1406 (Items 19, 22, 23, 24, 25, and 26). The staff reviewed the items listed in Table TR-98-1 pertaining to the WGS and found that the applicant addressed the minimization of waste generation in 10 CFR 20.1406.

The NRC staff issued regulatory guidance for 10 CFR 20.1406 in RG 4.21 after Revision 16 but before the issuance of Revision 17. As such, the staff documented its review according to RG 4.21 in Chapter 12. The staff finds that this change does not affect the design and performance aspects of the gaseous waste management system.

11.3.2.2 Completion of COL Item 11.3.5.2

The applicant addressed COL Information Item 11.3.5.2 by providing the requested information in TR-48. The applicant proposed that media selection should be a matter for the plant operator, and should not be identified at the COL application stage. The two reports, TR-48 and TR-73, describe this process and justify the deletion of COL Information Item 11.3.5.2. For both of these applications, the staff considered that this media was a consumable item, designed for replacement when expended. The media will be replaced multiple times throughout the operating life of the plant. For these reasons, the staff concluded that these changes are operational in nature and do not affect the design and performance aspects of the WGS.

11.3.2.3 Revision of Figure 11.3-1 Piping and Instrumentation Diagram

The applicant proposed a change to Figure 11.3-1, “Gaseous Radwaste System Piping and Instrumentation Diagram,” to update the drawing nomenclature. The staff concluded that the updated nomenclature did not affect the design or performance of the system and considered the change in nomenclature editorial.

11.3.2.4 Addition of Automatic Isolation of the Guard Bed Inlet on High Moisture Separator Level

In Section 11.3.1.2.2.2, “Water Incursion,” the applicant removed an automatic isolation of the guard bed inlet on high moisture separator level. The staff concluded that this change was acceptable because the system has an automatic isolation on temperature, a moisture separator, drain traps, and the guard bed. These all provide protection from wetting of the activated carbon delay beds. Activated carbon loses its retention properties when wet.

11.3.2.5 Temperature of the Influent Gas Changed From 7 °C (45 °F) to 4 °C (40 °F)

In Section 11.3.2.1, “General Description,” the applicant changed the outlet gas temperature from the gas cooler from about 7 °C (45 °F) to about 4 °C (40 °F). This change is small and conservative, and does not affect the conclusions in NUREG-1793. The staff found this change acceptable.

11.3.2.6 Reduced Capacity of Each of the Two Activated Carbon Delay Beds from 100 Percent System Capacity to 50 Percent Capacity

In Section 11.3.2.3.3, “Gaseous Radwaste System Tanks,” the applicant proposed to reduce each activated carbon delay bed capacity from 100 percent of the system capacity to 50 percent of the system capacity during design basis conditions. A single bed still provided adequate performance under normal conditions. The staff issued RAI-SRP11.3-CHPB-04 requesting additional information to verify compliance with NUREG-0800 Section 11.3, “SRP Acceptance Criteria,” Item 2 regarding the capacity of the system to meet the anticipated processing requirements of the plant.

On April 3, 2009, the applicant responded to RAI-SRP11.3-CHPB-04 and provided an analysis to determine the effects of operation with one charcoal delay bed out of service. The applicant used the PWR-GALE code to determine gaseous effluent releases assuming delay times for noble gases with only one delay bed in service. The applicant then compared the expected airborne concentrations and doses at the site boundary to those using the holdup times for two delay beds. The results of the analysis for the one delay bed showed that the effluent concentrations and doses at the site boundary increased by negligible amounts and were still well within the limits of 10 CFR Part 20, Appendix B, “Annual Limits on Intake (ALIs) and Derived Air Concentrations (DACs) of Radionuclides for Occupational Exposure; Effluent Concentrations; Concentrations for Release to Sewerage,” Table 2, and the design limits of Appendix I to 10 CFR Part 50.

The staff reviewed this analysis and concluded that the applicant used reasonable delay times and an approved computer code to simulate the performance of one delay bed. The staff found the response acceptable and RAI-SRP11.3-CHPB-04 is closed.

11.3.2.7 Elimination of the Nitrogen Injection and Reliance on a Closed Discharge Isolation Valve to Maintain Positive Pressure in WGS

In Section 11.3.2.2.1, the applicant used the discharge isolation valve to maintain the WGS at a positive pressure. In AP1000 DCD Section 11.3.2.3.4, “Remotely Operated Valves,” the applicant provided information regarding the nitrogen purge pressure control valve. The applicant stated that this valve maintains a small positive pressure in the WGS to prevent ingress of air during periods of low flow. Section 11.3.1.2.3.1, “Prevention of Hydrogen Ignition,” stated that the discharge isolation valve of the WGS is continuously pressurized with nitrogen to prevent ingress of air into the system from the discharge path. The staff concluded that this change is acceptable as a provision to preclude the ingress of air and does not affect the conclusions in NUREG-1793.

11.3.2.8 Monitoring Temperature Instead of Moisture of the Gas Leaving the Moisture Separator

In Section 11.3.2.2.1, “Normal Operation,” and Table 11.3-2, “Component Data (Nominal) – Gaseous Radwaste System of Instrument Indication and Alarms,” the applicant changed the monitored parameter of the gas leaving the moisture separator to temperature instead of moisture. The high temperature alarm indicates a reduced performance of the moisture separators and alerts the operator of an abnormal situation. Since this change performs the same function as the moisture alarm in the previous revisions, the staff finds this change acceptable.

11.3.2.9 Removal of the Xenon and Krypton Dynamic Adsorption Coefficients and Holdup Times from Table 11.3-1

In AP1000 DCD Table 11.3-1, “Gaseous Radwaste System Parameters,” the applicant removed the dynamic adsorption coefficients and holdup times for noble gases. With the removal of this information, the staff questioned the justification of the holdup times used to calculate the Krypton and Xenon releases in the gaseous effluents. In addition, the staff used these holdup times to conclude that no alteration in system operation would be necessary due to adverse meteorological conditions. The staff asked the applicant in RAI-SRP11.3-CHPB-04 to explain the reason for removing the coefficients and holdup times from the table.

On April 3, 2009, the applicant responded to the staff’s concern and stated that the dynamic adsorption coefficients and holdup times were removed from the table to avoid confusion. The applicant did not use these data in any analysis. Furthermore, these coefficients and holdup times are less conservative than what the applicant used to calculate the release of noble gases using the GALE code.

The staff confirmed that the applicant did not use these data in any analysis; therefore, any conclusions regarding effluent releases remain unchanged. Even using the more conservative dynamic coefficients and holdup times from the GALE code, the resulting concentrations and doses are low enough to provide an ample margin of safety should adverse meteorological conditions occur. The staff found the response acceptable and closed RAI-SRP11.3-CHPB-04.

11.3.2.10 Removal of Some of the Parameter Data and Revising Some of the Remaining Parameter Values in Table 11.3-2

The applicant revised AP1000 DCD Table 11.3-2, "Component Data (Nominal) – Gaseous Radwaste System" to reflect the performance of the current design. The changes include pump operating pressure, heat exchanger type, and heat exchanger operating temperature, pressure, and flow. These changes have been reviewed by the staff and have been found to be minor, do not affect the performance of the system to meet the design objectives and the conclusions in NUREG-1793, and are, therefore, acceptable.

11.3.2.11 Additional NUREG-0800 Section 11.3 Acceptance Criteria

The NRC staff noted that Section 11.3.3 was missing the consequence evaluation of a gaseous waste system leak or failure. The acceptance criteria in NUREG-0800 Section 11.3 are based on the availability of this information as part of the evaluation and relies on the approach specified in Branch Technical Position (BTP) 11-5. Based on the safety evaluation report (SER) for Revision 15, the applicant performed this analysis in response to an RAI, but the description of the analysis and results were not included in the AP1000 DCD. The staff issued RAI-SRP11.3-CHPB-02 requesting the inclusion of this analysis in the DCD.

On January 13, 2009, the applicant responded to RAI-SRP11.3-CHPB-02 stating that Section 11.2.2 will be revised to include the consequence analysis. The applicant committed to base its analysis on 1 percent fuel defects, 1-hour bypass of charcoal beds, 30 minute decay prior to release to the environment, and updated atmospheric dispersion factors. At that time, the applicant had not submitted the consequence analysis. This issue was tracked as an open item in the SER until the staff received and evaluated the resulting analysis.

On July 9, 2009, the applicant responded to RAI-SRP11.3-CHPB-02 Revision 1, with the requested analysis and proposed revisions to the AP1000 DCD. The applicant based its analysis on BTP 11-5, which included 1 percent fuel defects, 1-hour bypass of the charcoal beds, 30 minute decay prior to release to the environment, and updated atmospheric dispersion factors. The staff reviewed this response and determined that the applicant properly followed BTP 11-5. The staff independently verified the calculations. Based on the facts that the applicant's analysis properly followed BTP 11-5, the staff verified the results, and the results meet the acceptance criteria in BTP 11-5, the staff finds this response acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

11.3.2.12 Tier 1 Section 2.3.11, Gaseous Radwaste System

The applicant revised this section to indicate that the activated carbon delay beds will be designed to one-half seismic Category I instead of full seismic Category I. Since the WGS is not a safety-related system, the staff finds that this change is in accordance with RG 1.143 and is acceptable.

Additionally, in a letter dated January 20, 2010, the applicant also proposed Change Number 23 to AP1000 DCD, Tier 1 Section 2.3.11 removing all ITAAC concerning the seismic design loads of the equipment in the gaseous radioactive waste management system, specifically the carbon delay beds and the discharge isolation valve. In RAI-SRP11.3-CHPB-06, the staff questioned the basis for removing the ITAAC because these components have seismic design criteria that the applicant must inspect and test before operation.

In response to this RAI, the applicant reinstated the ITAAC for the gaseous waste management system and provided seismic design criteria. The staff reviewed this response and found that the ITAAC meet the inspection and testing recommendations in RG 1.143 and finds the response acceptable.

In a subsequent revision to the DCD, the applicant revised DCD Tier 1, Section 2.3.11, and Table 2.3.11-1 to include the appropriate ITAAC, which resolves this issue.

11.3.3 Conclusion

In NUREG-1793, Supplement 1, the staff concluded that the AP1000 design and DCD (up to and including Revision 15 of the DCD) was acceptable and that the application for the design certification met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

In the previous evaluation of the AP1000 DCD, Section 11.3, “Gaseous Waste Management System,” the staff identified acceptance criteria based on the design’s meeting relevant requirements in 10 CFR 20.1302, as it relates to limits on doses to persons in unrestricted areas; 10 CFR 50.34a, as it relates to the inclusion of sufficient design information to demonstrate the design objectives for equipment necessary to control releases of radioactive effluents to the environment; GDC 60, as it relates to the design of the gaseous waste management system to control releases of radioactive effluents; and GDC 61 as it relates to the design of the gaseous waste management systems to ensure adequate safety under normal and postulated accident conditions.

The staff reviewed the applicant’s proposed changes to the AP1000 gaseous waste management system as documented in the AP1000 DCD. The staff concluded that the applicant’s proposed changes do not affect the ability of the AP1000 gaseous waste management system to meet the applicable acceptance criteria in NUREG-0800 Section 11.3. The staff also concluded that the applicant had properly incorporated design changes into the appropriate sections of AP1000 DCD. The staff determined that the AP1000 gaseous waste management system continued to meet all applicable acceptance criteria and the applicant documented these changes in the updated AP1000 DCD. The staff also concluded that all of the changes related to the gaseous waste management system design description and ITAAC in AP1000 DCD Tier 1, Section 2.3.11 are acceptable.

11.4 Solid Waste Management System

11.4.1 Summary of Technical Information

In the AP1000 DCD, Revision 16, the applicant proposed to make changes to Section 11.4. The applicant proposed two technical changes that were supported by information presented in TR-98 and TR-103. The description of each technical change is provided below:

1) The applicant proposed to demonstrate compliance with 10 CFR 20.1406 through the selection of design technology. This change is documented in TR-98. The applicant has identified this change in the AP1000 DCD, Revision 16, Tier 2, on pages 11.4-3 and 11.4-14.

2) The applicant proposed to change the type of pump used for spent resin transfer. This change is documented in TR-103. The applicant has identified this change in the AP1000 DCD, Revision 16, Tier 2, Table 11.4-10, and on page 11.4-32.

The applicant made no additional technical changes in subsequent revisions to the AP1000 DCD. The evaluation below discusses technical changes provided in updated revisions to the AP1000 DCD, and provides an overview of the staff's RAIs, the applicant's responses, and the staff's evaluation of the responses.

11.4.2 Evaluation

The staff reviewed all changes to the solid waste management system as described in the AP1000 DCD in accordance with the guidance in NUREG-0800 Section 11.4, "Solid Waste Management System." The regulatory basis for Section 11.4 of the AP1000 DCD is documented in NUREG-1793. The following evaluation discusses the results of the staff's review. In addition, the staff reviewed the solid waste management system design description and ITAAC in AP1000 DCD Tier 1, Section 2.3.11 and identified no changes to this section.

11.4.2.1 Documentation of Compliance with 10 CFR 20.1406

In TR-98, the applicant proposed to comply with the regulation by the selection of design technology. Table TR98-1 in TR-98 lists specific examples of how the AP1000 design complies with 10 CFR 20.1406 (Items 19, 22, 23, 24, 25, and 26). The staff reviewed the items listed in Table TR98-1 pertaining to the solid waste management system and found that the applicant addressed the minimization of waste generation in 10 CFR 20.1406.

The NRC staff issued regulatory guidance for 10 CFR 20.1406 in RG 4.21 after the receipt of DCD Revision 16, but before the issuance of Revision 17. As such, the staff documented its review according to RG 4.21 in Chapter 12. The staff concluded that this change does not affect the design and performance aspects of the solid waste management system.

11.4.2.2 Spent Resin Transfer Pump

In TR-103, the applicant stated that utilities have reported operational problems due to wear of progressive cavity pumps, and the grinding of resin beads. The crushed beads are difficult to dewater and could create a storage problem. To remedy this situation, the applicant proposed to replace the progressive cavity pump with a material handling positive displacement pump. The staff concluded that this change does not affect the design of the WSS. The staff finds that the conclusions of NUREG-1793 regarding the acceptability of the WSS remain valid.

11.4.3 Conclusion

In NUREG-1793, Supplement 1, the staff concluded that the AP1000 design was acceptable and that the applicant's application for the design certification met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

In the previous evaluation of AP1000 DCD, Section 11.4, "Solid Waste Management System," the staff identified acceptance criteria based on the design's meeting the relevant requirements in 10 CFR 20.1302, as it relates to limits on dose to persons in unrestricted areas; 10 CFR 50.34a, as it relates to the inclusion of sufficient design information to demonstrate the design objectives for equipment necessary to control releases of radioactive effluents to the environment; GDC 60, as it relates to the design of waste management systems to control releases of radioactive effluents; and GDC 61, as it relates to the design of waste management systems to ensure adequate safety under normal and postulated accident conditions.

The staff reviewed the applicant's proposed changes to the AP1000 solid waste management system as documented in the the latest revision of the AP1000 DCD. The staff concluded that the applicant's proposed changes do not affect the ability of the AP1000 solid waste management system to meet the applicable acceptance criteria in NUREG-0800 Section 11.4. The staff also concluded that the applicant had properly incorporated design changes into the appropriate sections of the AP1000 DCD. The staff determined that the AP1000 solid waste management system continued to meet all applicable acceptance criteria and the applicant documented the changes in the updated AP1000 DCD. The staff also concluded that all of the changes related to the gaseous waste management system design description and ITAAC in AP1000 DCD Tier 1, Section 2.3.11 were acceptable. In addition, the staff reviewed the solid waste management design description and ITAAC in AP1000 DCD Tier 1, Section 2.3.11 and found no changes to this section.

11.5 Radiation Monitoring

This section describes the staff's evaluation and findings of the AP1000 DCD, Revisions 16 and 17. The staff reviewed Revision 16 upon receipt and after review issued several RAIs. Prior to resolving these RAIs, the applicant issued Revision 17 to the DCD. Hence, this review and evaluation encompasses both revisions.

11.5.1 Summary of Technical Information

In the AP1000 DCD, Revision 16, the applicant made changes to Section 11.5. In Revision 16, the applicant only made editorial changes by renaming the Technical Support Center to the Control Support Area. The staff reviewed these changes and found them to be editorial in nature.

In Revision 17, the applicant proposed the following five technical changes:

1) The applicant switched the radiation monitor for the service water blowdown from an offline monitor to an inline monitor. The applicant documented this change on pages 11.5-5 in Section 11.5.2.3.1.

2) The applicant eliminated the statement that it will follow the design guidelines of American National Standards Institute (ANSI) N13.1, "Sampling and Monitoring Releases of Airborne Radioactive Substances from the Stacks and Ducts of Nuclear Facilities" for the discharge radiation monitor of the turbine island vent. The applicant documented this change in Section 11.5.2.3.3 on page 11.5-11.

3) The applicant switched the radiation monitor for the liquid radwaste discharge from an offline monitor to an inline monitor. The applicant documented this change on pages 11.5-11 and 11.5-12 in Section 11.5.2.3.3.

4) The applicant made several changes to the monitors and specifications listed in Table 11.5-1. These changes included the following:

   - addition of two main steam line monitors for N-16
   - lowering the minimum and maximum of the nominal range of the steam generator blowdown monitors by an order of magnitude
   - adding the detection of Ar-51 and N-13 to the containment atmosphere monitors
   - lowering the minimum and maximum of the nominal range for the fuel handling building, auxiliary building, and annex building exhaust vents by an order of magnitude
   - changing the nominal range for the monitors of the main control room air supply duct, containment air filtration exhaust, health physics (HP) and hot machine shop exhaust, radwaste building exhaust, and the gaseous and liquid radwaste discharge

5) The applicant made several changes to the monitors and specifications listed in Table 11.5-2. These changes included the following:

   - the addition of a liquid and gaseous monitor for radwaste area 2
   - the addition of a containment area personal hatch monitor at maintenance elevation level 30.48 meters (m) (100.0 feet (ft))
   - specifying the location of the containment area monitor at operating deck – 41.22 m (135 ft, 3 inches (in))
   - removing the rail car bay area as a service area for monitor RMS-JE-RE013

The evaluation below discusses these changes and other information, and provides an overview of the staff's RAIs, the applicant's responses, and the staff's evaluation of the responses.

11.5.2 Evaluation

The staff reviewed the entire section and all technical changes to the radiation monitoring systems in accordance with NUREG-0800 Section 11.5, "Process and Effluent Radiological Monitoring Instrumentation and Sampling Systems." The staff reviewed the entire section and all changes identified by change marks in the AP1000 DCD.

11.5.2.1 Offline to Inline Monitors for Service Water and Radwaste Liquid Discharges

The change from offline to inline monitoring for the service water blowdown, liquid radwaste discharge, and the waste water discharge has the advantage of reducing the potential for liquid leaks, reducing the likelihood of equipment failure, and reducing areas within the system where radioactivity can accumulate and present exposure problems. For these reasons, the staff concluded that the change from offline to inline monitoring is acceptable.

11.5.2.2 Removal of Commitment to ANSI N13.1 for Turbine Vent Monitor

The applicant removed the commitment to follow ANSI N13.1 for the design of the monitoring system for the turbine island vent. This action raises a question about what design guidance the applicant would follow for this vent. NUREG-0800 Section 11.3 states that ANSI/HPS N13.1-1999 should be used. The staff issued RAI-SRP11.5-CHPB-02 and RAI-SRP11.5-CHPB-03 requesting that the applicant specify what design guidance it will follow.

On January 13, 2009 and March 23, 2009, the applicant responded to the RAIs by stating that since the turbine island vent monitor is an inline noble gas monitor and not a sample extraction monitor, ANSI N13.1 does not apply. The applicant then further stated that the monitor complies with ANSI N42.18-1980, "Specification and Performance of On-Site Instrumentation for Continuous Monitoring Radioactivity in Effluents."

The staff concluded that this response was acceptable given the fact that the 1980 version of ANSI N42.18 does not differ appreciably from the current version. on this basis, the staff closed RAI-SRP11.5-CHPB-02 and RAI-SRP11.5-CHPB-03.

11.5.2.3 Offline to Inline Monitors for Wastewater Discharge

The applicant changed the radiation monitor from an offline monitor to an inline monitor for the wastewater discharge. The staff concluded that the use of an inline monitor is preferable to an offline type. In addition, the applicant found an inconsistency between the descriptions of the action of the radiation monitor for the wastewater discharge between AP1000 DCD Sections 9.2.9 and 11.5.2. To make Section 11.5.2 consistent with the design description in Section 9.2.9, the applicant eliminated the statement that this monitor controls the basin transfer pumps. The staff concluded that this change is acceptable because Section 11.5 now reflects the actual design and function of the monitor originally described in Section 9.2.9.

11.5.2.4 Changes to Table 11.5-1

The staff reviewed the changes to Table 11.5-1. The staff found the changes acceptable for the following reasons:

- the additional monitors provide improved monitoring capabilities for the main steam line

- the addition of argon (Ar-51) and nitrogen (N-13 and N-16) monitoring in the containment atmosphere improve the monitoring capabilities of this system

- the steam generator blowdown monitors have improved sensitivity

- the fuel handling, auxiliary building, and annex building exhaust vent monitors have improved sensitivity

- the changes to the nominal ranges for main control room air supply duct, containment air filtration exhaust, HP and hot machine shop exhaust, radwaste building exhaust, and the gaseous and liquid radwaste discharge do not change the overall ability of the monitors to perform their intended function

11.5.2.5 Changes to Table 11.5-2

The staff reviewed the changes to Table 11.5-2. The staff concluded that the additional monitoring and location specificity improves the overall area monitoring and is thus acceptable. However, the staff required clarification on the change that removed the rail car bay area as a service area for monitor RMS-JE-RE013. This action seemed to leave the rail car bay area unmonitored. The staff issued RAI-SRP11.5-CHPB-04 to obtain clarification.

The applicant responded that it did not remove the monitor from the rail car bay area but renamed the area. The applicant proposed to revise the title of the area monitor to be consistent with the title of the area. This response is acceptable since the rail car area remains monitored.

In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

11.5.2.6 Additional NUREG-0800 Section 11.5 Acceptance Criteria

Section 11.5 states that the radiation monitoring system is designed in accordance with ANSI N13.1-1969. This standard was withdrawn and replaced in 1999 because the approach taken in the 1969 standard does not provide assurance that the sample in the effluent vent would be representative. The 1999 revision to ANSI N13.1 differs significantly from the earlier version in that it is now performance based. NUREG-0800 Section 11.5 (2007) uses the 1999 standard as acceptance criteria.

The 1969 standard does not provide assurance that the sample from the effluent vent is representative of the particulate matter and reactive vapors passing through the vent. The ability to obtain a representative sample is important since it supports the ability of the licensee to determine public and occupational exposure to radioactivity. The staff concluded that the applicant should use the new standard to ensure that the measurements are accurate. The staff issued RAI-SRP11.5-CHPB-01 to the applicant requesting a change to the newer standard.

On May 22, 2009, the applicant responded to the RAI by stating that committing to the 1999 standard would introduce an excessive degree of uncertainty into the detailed design and construction of the AP1000. To address the limitations of the 1969 standard the applicant proposed an alternative approach relying on best design practices and performance testing and criteria similar to the 1999 standard.

The staff reviewed the response and found that the applicant adopted all relevant performance tests and criteria in the 1999 standard. Once built, the applicant will test the system to ensure that it meets the performance objectives of the 1999 standard. The staff finds this response acceptable.

In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The staff also reviewed Change Number 45 to AP1000 DCD Tier 2 (proposed DCD Revision 18), Appendix 1A, Sections 3.1.4, 3.6.3.3, 5.2.5.3.3, and 11.5.2.3.1, and LCO 3.4.9

Sections B.3.4.7 and 3.4.9 and as a result issued RAI-SRP11.5-CHPB-05. The applicant subsequently provided sufficient information to demonstrate that the newly proposed Fluorine-18 (F-18) particulate radiation monitor (PSS-JE-RE027) is capable of detecting the AP1000 technical specifications for the reactor coolant system (RCS) leak rate. The discussion of the staff's review and analysis is included in Chapter 23 of this report, Section 23.F,"Changes to Reactor Coolant Pressure Boundary Leakage Detection."

Based on its review and independent verification, the staff concludes that the proposed monitor is sufficiently sensitive to detect the technical specification leak rate. In Revision 18 to the AP1000 DCD, the applicant made appropriate changes to the DCD text, which resolves this issue. On this basis, RAI-SRP11.5-CHPB-05 is resolved.

11.5.3 Conclusion

In NUREG-1793 and its Supplement 1, the staff documented its conclusion that the AP1000 design and DCD (up to and including Revision 15 of the DCD) was acceptable and that the applicant's application for the design certification met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

In its previous evaluations of AP1000 DCD, Section 11.5, "Radiation Monitoring," the staff identified acceptance criteria based on NUREG-0800 Section 11.5, "Process and Effluent Radiological Monitoring Instrumentation and Sampling Systems." The staff reviewed the AP1000 radiation monitoring and sampling systems for compliance with these requirements, as referenced in NUREG-0800 Section 11.5 and determined that the monitoring systems, as documented in AP1000 DCD, Revision 15, were acceptable because the design conformed to all applicable acceptance criteria.

The staff reviewed the applicant's proposed changes to AP1000 DCD Section 11.5. The staff concluded that the applicant's proposed changes did not affect the ability of the AP1000 radiation monitoring instrumentation and sampling systems to meet the applicable acceptance criteria in NUREG-0800 Section 11.5. The staff also concluded that the design changes have been properly incorporated into the appropriate sections of the AP1000 DCD. On the basis that the AP1000 monitoring system for process and effluents continues to meet all applicable acceptance criteria and the changes are properly documented in the updated AP1000 DCD, the staff concludes that all of the changes related to the system design of the AP1000 process and effluent radiation monitoring are acceptable.

12. RADIATION PROTECTION

12.1 Introduction

The AP1000 design control document (DCD) Tier 2, Chapter 12, "Radiation Protection," Revisions 16 and 17 include changes to the descriptions of the commitments pertaining to the radiation protection measures and programs of the AP1000 design, as described in NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design," issued September 2004. As such, this supplemental document to NUREG-1793 must be used in concert with the original issue of NUREG-1793 to completely understand the full evaluation of the AP1000 standard design.

In the AP1000 design certification amendment, the applicant provided additional information related to the Radiation Protection Program and the design features that will ensure that occupational radiation exposures are as low as is reasonably achievable (ALARA). It also provided information on related facility design changes submitted in various technical reports (TRs) potentially affecting the internal and external radiation exposures to station personnel, contractors, and the general population, resulting from plant conditions, including anticipated operational occurrences that will be within regulatory criteria. The staff of the U.S. Nuclear Regulatory Commission (NRC) reviewed the additional and amended information provided by the applicant, using the guidance in Chapter 12 of NUREG-0800, "Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants," Revision 3, issued March 2007. The NRC developed the original NUREG-1793 using the guidance from regulatory guide (RG) 1.70, "Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants," Revision 3, issued November 1978. Therefore, this supplement follows the format of the original NUREG-1793.

The scope of this review includes Chapter 12, Sections 12.1 through 12.5, Revision 17 of the AP1000 DCD, Tier 2 and Tier 1, and Section 3.5, "Radiation Monitoring," which covers the associated inspections, tests, analyses, and acceptance criteria (ITAAC).

Each section of this report describes the staff's evaluation and review results of the changes proposed in Chapter 12 of the AP1000 DCD, Revision 17. The staff reviewed Revision 16 upon receipt and after review issued several requests for additional information (RAIs); however, the applicant submitted Revision 17 prior to the resolution of these RAIs.

12.1.1 Compliance with Title 10 of the *Code of Federal Regulations* Part 20, "Standards for Protection Against Radiation"

The applicant has submitted several TRs with radiation protection implications that include references to industry standards and other regulatory guidance. The applicant's document, TR-98, "AP1000 COL Standard Technical Report Submittal of APP-GW-GLN-098, Revision 0, 'Compliance with 10 CFR 20.1406' " (APP-GW-GLR-017), references Title 10 of the *Code of Federal Regulations* (10 CFR) 20.1406, "Minimization of contamination." The applicant has documented changes to the radwaste building in TR-116, "Additional Liquid Radwaste Monitor Tanks and Radwaste Building Extension" (APP-GW-GLN-116), Revision 0. The applicant documented structural changes in TR-54, "Spent Fuel Storage Racks Structure/Seismic Analysis" (APP-GW-GLR-033), Revision 0, and a redesign of the reactor vessel (RV) head in

TR APP-GW-GLE-016, “Impact of In-Core Instrumentation Grid, Quicklocs and Changes to Integrated Head Package,” Revision 0.

12.1.2 Compliance with 10 CFR Part 52, “Licenses, Certifications, and Approvals for Nuclear Power Plants”

Based upon the discussion in Section 12.1 of NUREG-1793, the standardized power plant designer or combined license (COL) applicant will satisfactorily demonstrate that the radiation protection measures incorporated in the AP1000 program, as documented in the DCD, will offer reasonable assurance that, during all plant operations, the occupational doses will be maintained ALARA and within the limits of 10 CFR Part 20. The following sections present the basis for the staff’s conclusions.

12.2 Ensuring that Occupational Radiation Exposures Are As Low As Is Reasonably Achievable

12.2.1 Summary of Technical Information

This section addresses the design, construction, and operations policies to maximize the incorporation of both design and construction engineering practices and industry lessons learned to achieve the desired ALARA objectives.

The applicant revised two areas discussing the COL applicant’s management commitment and compliance with 10 CFR Part 20 and RG 1.8, “Qualification and Training of Personnel for Nuclear Power Plants”; RG 8.8, “Information Relevant to Ensuring that Occupational Radiation Exposures at Nuclear Power Stations Will Be as Low as Is Reasonably Achievable”; and RG 8.10, “Operating Philosophy for Maintaining Occupational Radiation Exposures as Low as Is Reasonably Achievable,” to reflect the plant’s staffing and organizational differences. These changes are editorial in nature and are incorporated in AP1000 DCD Section 12.1.3 as COL actions requiring the COL applicant to provide such information.

The staff determined that all changes in Revision 17 to DCD Section 12.1 are editorial, with the exception of the following item:

> In DCD Section 12.1.2.4, the applicant added statements certifying compliance with 10 CFR 20.1406. These changes are documented in Westinghouse TR-98, “Compliance with 10 CFR 20.1406” (APP-GW-GLN-098), Revision 0.

During its evaluation and confirmation, the staff identified insufficient information relating to the description of design features concerning the compliance with 10 CFR 20.1406. In the process of the staff developing RG 4.21, “Minimization of Contamination and Radioactive Waste Generation: Life-Cycle Planning,” issued June 2008 (formerly DG-4012), the applicant submitted TR-98. This report was intended to identify and justify standard changes to be incorporated in the DCD. Revision 17 to the AP1000 DCD has incorporated the information in the various sections of the DCD, including Chapters 9, 11, and 12. The implementation of the regulations in 10 CFR 20.1406 affects other structures, systems, and components (SSCs) described in the DCD. Even though this information was not described in the other DCD chapters, it was referenced in the response to RAI-SRP12.1-CHPB-01.

The evaluation below provides an overview of RAI-SRP12.1-CHPB-01, and discusses the applicant’s response and the staff’s evaluation of the response.

12.2.2 Evaluation

This section of the DCD lists specific equipment, as well as facility layout and general design considerations, for 10 CFR 20.1406. The description is substantial and provides examples of design features or considerations for meeting 10 CFR 20.1406. These design features appeared to be based on the draft guidance issued for public comment in the development of DG-4012. The staff has since published the guidance as RG 4.21, Revision 0.

The information presented in AP1000 DCD Tier 2, Sections 12.1 through 12.5, Revision 17, identifies some AP1000 general design features that would minimize the contamination of the facility and environment, as well as the generation of radioactive waste. Specifically, DCD Section 12.1.2.4 describes piping and fuel pool design features to comply with 10 CFR 20.1406. However, this information did not address design features that are unique to system designs or their locations in the plant, warranting more technical details. The applicant did not identify those that should be considered as COL action items. The staff asked the applicant to provide this information in RAI-SRP12.1-CHPB-01. In a letter dated September 9, 2008, the applicant described specific features that are incorporated into the AP1000 design to comply with the requirements of 10 CFR 20.1406 or referenced in TR-98, Revision 0, for the systems that were listed in RAI-SRP12.1-CHPB-01 (and for any other plant systems that may generate or transfer radioactive materials or waste).

The staff determined that the analysis provided by the applicant was insufficient because the applicant's response to RAI-SRP12.1-CHPB-01 and TR-98 failed to address specific information regarding compliance with 10 CFR 20.1406. Section 9.4, "Air-Conditioning, Heating, Cooling, and Ventilation System," covers design features for heating, ventilation, and air conditioning systems (HVAC). Additional information was needed concerning design features provided for these systems to prevent or minimize contamination of the environment. For example, whether there are provisions to monitor and collect condensate that may form at coolers or in HVAC ducts that may contain or potentially contain contamination. The staff issued RAI-SRP12.1-SPCV-01 and RAI-SRP12.1-SPCV-02 to request this information from the applicant. This was identified as an open item in the SER with open items and was tracked as Open Item OI-SRP12.1-CHPB-01.

In a letter dated August 19, 2009, the applicant submitted its response to RAI-SRP12.1-SPCV-01 (R1) and RAI-SRP12.1-SPCV-02 (R1). The applicant provided clarifying information regarding the AP1000 design features used to prevent and mitigate the spread of contamination due to HVAC operation or abnormal conditions. Information was provided in the applicant's response on the features to prevent water entry into HVAC ducting from the liquid radwaste system (WLS) and radioactive waste drain system (WRS). The applicant proposed to revise the following DCD sections: 9.4.3.2.1.1, "Auxiliary/Annex Building Ventilation Subsystem"; and 11.4.2.2.1, "Spent Resin Tanks." The staff concludes that the information provided describes the design features that will prevent and mitigate the spread of contamination through ventilation subsystems and is, therefore, appropriate. In a subsequent revision to the DCD, the applicant made an appropriate change to the DCD text; therefore, RAI-SRP12.1-SPCV-01 and RAI-SRP12.1-SPCV-02 and the associated Open Item OI-SRP12.1-CHPB-01 are resolved.

The staff also asked the applicant to provide information in RAI-TR98-CHPB-01, RAI-TR98-CHPB-02, and RAI-TR98-CHPB-03. In a letter dated December 19, 2007, the applicant described other specific design features that are incorporated into the AP1000 design to comply with the requirements of 10 CFR 20.1406 and that were referenced in TR-98, Revision 0. The applicant has not committed to RG 4.21, Revision 0, but has described the design features in the licensing basis, the referenced TR-98, and in the response to the aforementioned RAIs.

AP1000 DCD Tier 2, Revision 17, Chapter 12, identified some AP1000 general design features that would minimize the contamination of the facility and environment and would minimize the generation of radioactive waste. However, this information did not address design features that are unique to the auxiliary steam and condensate systems. Current generation plant operating experience has demonstrated that normal pressurized-water reactor (PWR) operation will likely result in detectable levels of tritium as well as other radionuclides in the condensate, auxiliary steam system, and boilers. This was identified as RAI-SRP12.1-CHPB-02. The applicant was requested to describe the design features and operating objectives related to the auxiliary steam and condensate transfer system leaks.

In a letter dated March 4, 2010, the applicant submitted its response to RAI-SRP12.1-CHPB-02. In its response, the applicant described that the outdoor piping from the hotwell to the condensate storage tank will be located above grade, such that leakage from the pipe could be detected in the conduct of routine site activities. When describing the interconnected steam and power systems located in the turbine building, the applicant described the collection of leakage via the waste water system and turbine building drains, which are directed to the turbine building sump. This sump requires routine sampling and analysis prior to the discharge into the environment. This is a requirement for the licensed facility operator to demonstrate compliance with the radiological effluent technical specifications (RETS) and Radiological Environmental Monitoring Program (REMP).

Additionally, the applicant described the plant hot water heating system heat exchangers as providing a barrier to the potential spread of contamination, in the event that the auxiliary steam system was to become contaminated by low levels of primary system leakage to the secondary side of the steam generators. The applicant proposed a revision to AP1000 DCD Section 12.1.2.4.1, “Piping,” which describes the configuration of the outdoor piping and collection of turbine building drains.

The staff reviewed the response provided by the applicant and found it to be acceptable in that the response provided a description of the design features provided to address minimization of contamination of the facility that were specifically not addressed in TR-98. The response provides adequate information, which would allow for timely identification of low activity leakage from these sources to preclude contamination of the site, facility or environment where an AP1000 site is located. The description provided addresses operating experience from the operating nuclear power plants, as discussed in DC/COL ISG-006, “Office of New Reactors Interim Staff Guidance on Evaluation and Acceptance Criteria for 10 CFR 20.1406 to Support Design Certification and Combined License Applications.” In a subsequent revision to the DCD, the applicant made an appropriate change to Tier 2, Section 12.1.2.4.1 of the DCD, which resolves this issue; therefore, RAI-SRP12.1-CHPB-02 is resolved.

12.2.3 Conclusions

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15) were acceptable and that the application for design certification met the requirements of Subpart B, “Standard Design Certifications,” to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design. Based on the information supplied by the applicant, as described above, the staff concludes that the AP1000 design features met the criteria of NUREG-0800 Section 12.1. These design features are intended to maintain individual doses (person-sievert (roentgen equivalent man) (rem)) and total doses to plant workers and to members of the public ALARA, while maintaining individual doses within the regulatory limits of 10 CFR Part 20.

Adding more detailed information to the DCD about the features for minimizing contamination increases standardization of the AP1000 design. Thus, these changes meet the finality criterion for changes in 10 CFR 52.63(a)(1)(vii).

The staff reviewed the applicant's proposed changes to the AP1000 radiation protection section describing activities that ensure that occupational radiation exposures are ALARA, as documented in DCD Section 12.1. The staff finds the applicant's proposed changes to DCD Section 12.1 to be acceptable.

12.3 Radiation Sources

12.3.1 Summary of Technical Information

The staff approved AP1000 DCD, Section 12.2, "Radiation Sources," Revision 15, in the certified design. This review addresses the compliance with 10 CFR Part 20 and General Design Criterion (GDC) 61, "Fuel Storage and Handling and Radioactivity Control," in Appendix A, "General Design Criteria for Nuclear Power Plants," to 10 CFR Part 50, "Domestic licensing of production and utilization facilities."

In the AP1000 DCD, Revision 17, the applicant proposed the following two technical changes with associated TR changes:

(1) In AP1000 DCD Section 11.2, the applicant proposed to increase the overall liquid waste holdup capacity and improve operational flexibility by adding three liquid waste monitor tanks (and associated pumps, piping, instruments, and valves). The applicant proposed to house the additional tanks, 56,775 liters (15,000 gallons) each, in the radwaste building. The new tanks are identical to the three existing monitor tanks, which are housed in the auxiliary building. The applicant documented these changes in TR-116, Revision 0.

(2) In AP1000 DCD Section 9.1.2.1, the applicant proposed to increase the overall capacity of the spent fuel pool (SFP) from storage locations for 619 fuel assemblies to locations for 884 fuel assemblies. The applicant documented these structural changes in TR-54, Revision 0. The applicant documented the heat loading analysis changes in TR-103, "Fluid System Changes" (APP-GW-GLR-019), Revision 2.

The evaluation below discusses these changes and missing information and provides an overview of the staff's RAI-SRP12.2-CHPB-01 and RAI-SRP12.2-CHPB-02, the applicant's response, and the staff's evaluation of the response.

12.3.2 Evaluation

Liquid Waste Hold-up Tank

The staff reviewed all technical changes to the radiation sources identified in the AP1000 DCD, Revision 17, in accordance with NUREG-0800 Section 12.2, “Radioactive Sources.” In addition, the staff reviewed the entire section to ensure that there was no missing information critical to providing adequate protection to public health and safety.

NUREG-1793 documents the regulatory basis for DCD Section 12.2, Revision 15. The staff has reviewed the proposed changes to DCD Section 12.2 against the applicable acceptance criteria in NUREG-0800 Section 12.2. The following evaluation discusses the results of the staff’s review.

In TR-116, the applicant proposed to add three liquid waste monitor tanks (and associated pumps, piping, instruments, and valves) and to house the additional tanks, 56,775 liters (15,000 gallons) each, in the radwaste building.

In its review of AP1000 DCD Section 12.2, the staff identified areas in which additional information was necessary to complete its evaluation of the applicant’s change (RAI-SRP12.2-CHPB-01). In DCD Tier 2, Section 11.2, the staff noted that a potential exists for the quantity of the radionuclides in the radwaste building portion of the liquid waste management system to exceed the A_1 value. The DCD states that, “The monitor tanks in the non-seismic radwaste building are used to store processed water. The radioactivity content of processed water in each tank will be less than the A_1 and A_2 levels of 10 CFR 71, Appendix A, Table A-1 (“A_1 and A_2 Values for Radionuclides”).”

In 10 CFR 71.4, “Definitions,” defines A_1 as the maximum activity of special form radioactive material permitted in a Type A package. A_2 is defined as the maximum activity of radioactive material, other than special form materials, low specific activity, and surface contaminated object material permitted in a Type A package.

The description of the radioactive sources listed for liquid waste tanks included in AP1000 DCD Section 12.2 did not indicate an increase in volume to approximately 170,325 liters (45,000 gallons) and hence an increase in the overall radioactivity that would thereby be a much larger source of occupational radiation to personnel in the radwaste building.

In Tier 2, Figure 12.3-1 (Sheet 14 of 16), “Radiation Zones, Normal Operation/Shutdown Radwaste Building EL 100’-0” indicates that the room (Room No. 50355) that the tanks will be located in is Plant Radiation Zone 1, which is defined by Figure 12.3-1 (Sheet 1 of 16) in Tier 2, as very low or no radiation sources: “Inside Controlled Area” and Outside “Restricted Area.” This is an area that will result in a dose rate of less than or equal to 2.5 microSieverts per hour (μSv/h) (0.25 millirem per hour (mrem/h)).

The applicant responded to the staff’s concerns in a letter dated September 9, 2008. The applicant agreed that the liquid waste tanks could alter the plant radiation zone assignment and that the issue should be re-analyzed. The affected area will be reclassified to a Plant Radiation Zone III. Plant Radiation Zone III is defined in AP1000 DCD Tier 2, Section 12.3, Figure 12.3-1, as being an area of low-to-moderate radiation sources; limited worker occupancy, with maximum design dose rates less than or equal to 150 μSv/h (15.0 mrem/h). The revised radiation zone reflects the potential increase in volume and hence the increased radioactivity stored in the liquid waste monitor tanks. Given the building design, tank thickness and potential radioactivity stored in the liquid waste monitor tanks, assigning the adjacent area as a Plant Radiation Zone III is appropriate. Based on the evaluation of the DCD information and the applicant's response to the RAI, the staff concludes that the applicant properly identified all design information related to the three additional liquid waste monitor tanks and associated equipment and provided an adequate demonstration that design objectives have been met for the contained source terms described in the DCD as the basis for radiation design shielding calculations and personnel dose assessment. Therefore, RAI-SRP12.2-CHPB-01 is resolved.

Spent Fuel Pool Capacity

In AP1000 DCD Section 9.1.2.1, "Design Basis," the applicant increased the overall capacity of the spent fuel storage from the proposed storage locations for 619 fuel assemblies to storage locations for 884 fuel assemblies. The staff noted that the additional fuel assemblies were not addressed in DCD Section 12.2.1.2.3, "Spent Fuel," nor included in Table 12.2-25, "Fuel Handling Area Airborne Radioactivity Concentrations." The potential addition of 265 fuel assemblies with 0.25 percent fuel defects would increase the airborne radioactivity. Moreover, Table 12.2-25, did not identify the basis of the parameters included in Table 12.2-24 for the number of fuel assemblies used in its calculations. The staff presented these concerns in RAI-SRP12.2-CHPB-02 and the applicant responded in a letter dated September 9, 2008. The air activity was based on a full core offload, with RV design head removal at 100 hours after shutdown; completion of core offload was determined to be 10 days (that is, 240 hours after shutdown); and the SFP purification system was assumed to be operating at 946 liters per minute (250 gallons per minute). Table 12.2-25 was based only on the core from the recent full offload and thus not affected by the increase in the number of fuel assemblies in the SFP. The applicant committed to completing a detailed review and revising the response, if necessary. This was tracked as Open Item OI-SRP12.2-CHPB-02 in the SER with open items.

In a letter dated September 25, 2009, the applicant submitted its response to Open Item OI-SRP12.2-CHPB-02, which provided a discussion that defined the basis and calculations made to assess the maximum airborne activity in the fuel handling area. Following the review of the calculations and additional information provided in the response, the staff concludes that the information in the applicant's response on the airborne activity based on a full core off-load is conservative and, therefore, appropriate. RAI-SRP12.2-CHPB-02 and the associated Open Item OI-SRP-12.2CHPB-02 are resolved.

12.3.3 Conclusions

In NUREG-1793 and its Supplement 1, the staff documented its conclusions that the AP1000 design and DCD (up to and including Revision 15 to the DCD) were acceptable and that the applicant's application for design certification met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

In its previous evaluations of the AP1000 DCD Section 12.2, the staff identified acceptance criteria based on the ability of the design to meet the relevant requirements in 10 CFR Part 20, as it relates to limits on doses to occupationally exposed persons in restricted areas, and in the requirements of GDC 61, as it relates to the information about radiation sources provided by the applicant.

The staff considers RAI-SRP12.2-CHPB-01 to be resolved, and has verified that the appropriate change was incorporated in Revision 17 to AP1000 DCD Tier 2, Figure 12.3-1, Sheet 14 of 16, room number 50355. Additionally, the staff considers Open Item OI-SRP12.2-CHPB-02 to be resolved and concludes that the applicant has committed to follow the guidelines of the RGs and staff positions set forth in NUREG-0800 Section 12.3.

12.4 Radiation Protection Design Features

12.4.1 Summary of Technical Information

The staff approved AP1000 DCD Section 12.3, “Radiation Protection Design Features,” Revision 15, in the certified design. This review addresses system design, performance aspects, and ITAAC only of the radiation protection design features.

The staff’s assessment of the revisions listed in Tier 2, Section 12.3, "Radiation Protection Design Features,” includes changes in Tier 1, Section 3.5, “Radiation Monitoring” (ITAAC) and Tier 2, Section 11.5, “Radiation Monitoring.” These changes do not affect the ITAAC scope and acceptance criteria.

In the AP1000 DCD, Revision 17, the applicant proposed to make the following three technical changes. The staff also identified additional changes related to the density of concrete used for shielding purposes and a description of the computer codes used for shielding calculations. These changes are described below:

(1) In AP1000 DCD Section 12.3.2.2.4, “Fuel Handling Area Shielding Design,” the applicant decreased the minimum water depth above the active fuel portion of the assembly. Spent fuel removal and transfer operations are performed under borated water to provide radiation protection and maintain subcriticality. Revision 15 of the AP1000 DCD stated that the minimum allowable water depths above active fuel in a fuel assembly during fuel handling were 3.05 meters (m) (10 feet (ft)) in the reactor cavity and in the SFP. This limits the dose to personnel on the spent fuel pool handling machine (SFHM) to less than 25 μSv/h (2.5 mrem/h) for an assembly in a vertical position. Normal water depth above the stored assemblies is about 7 m (23 ft), and for this depth the exposure to plant workers is insignificant. In DCD Revision 16, the minimum allowable water depth above active fuel in a fuel assembly during fuel handling was decreased to 2.89 m (9.5 ft). During the review of Revision 17 to DCD Tier 2, Section 12.3.2.2.4, the staff observed that the applicant decreased the overall minimum allowable water depth above active fuel in the reactor cavity and SFP to 2.67 m (8.75 ft) during fuel movement.

(2) In AP1000 DCD Section 12.3.1.1.2, “Common Facility and Layout Designs for ALARA,” and Section 12.3.5.1, “Administrative Controls for Radiological Protection,” the applicant added statements certifying compliance with 10 CFR 20.1406. TR-98, Revision 0, documented these changes. In the DCD sections, the applicant described general practices, such as to minimize the use of embedded pipes to the extent possible, consistent with maintaining radiation doses ALARA. In addition, to the extent possible, pipes will be routed in accessible areas, such as dedicated pipe routing tunnels or pipe trenches, which provide good conditions for decommissioning, and the number of passageways (doors) between the radiological controlled area and the environment has been minimized. When such doors are incorporated, systems of drains and floor and exterior concrete sloping are used to prevent (potentially radioactive) fluid from exiting the buildings, as well as to prevent surface water from entering the buildings. Because

of the potential for adsorption of contaminated fluids, another feature included minimizing the use of concrete block walls in the radiologically controlled areas of the plant. Where such walls are used, they are fully sealed at the ceiling or top of the block to prevent liquid incursion. The applicant added two COL information items where the COL applicant will, in accordance with 10 CFR 20.1406, establish a groundwater monitoring program beyond the normal radioactive effluent monitoring program and will establish a program to ensure documentation of operational events deemed to be of interest for decommissioning, beyond that required by 10 CFR 50.75, “Reporting and Recordkeeping for Decommissioning Planning.” This or another program will include remediation of any leaks that have the potential to contaminate groundwater.

(3) In AP1000 DCD Tier 2, Section 12.3.1.1.1, the applicant proposed changes to the integrated RV head package and quick-loc connectors. The staff noted that the applicant’s description included an integrated head package that combines the head lifting rig, control and gray rod drive mechanisms, lift columns, control rod drive mechanism cooling system, and power and instrumentation. In its review of DCD Sections 12.3 and 12.4, the staff identified areas that needed additional information to complete its evaluation of the applicant’s change including Figure 12.3-1 (Sheet 8 of 16), “Radiation Zones, Normal Operation/Shutdown Nuclear Island,” EL 135’-3” and Table 12-4-12, “Dose Estimate for Refueling Activities.” The description of the change lacked sufficient detail to determine the radiological impact on occupational exposure (RAI-SRP12.3-CHPB-01).

(4) In AP1000 DCD Section 12.3.2.2.9, the applicant decreased the overall assumed concrete density used for shielding design purposes in the spent fuel transfer canal and tube shielding from 147 pounds per cubic foot (lb/ft^3) to 140 lb/ft^3, without an analysis or description of the potential radiological effects.

(5) In AP1000 DCD Section 12.3.2.3, the applicant described computer codes used to determine design and operational dose rates. The DCD Reference 22 identified the point kernel code Microshield 4 as being a personal computer version with a menu guided user interface of the mainframe calculation code QAD. The staff requested additional information to support verification and validation of this computer code as it is used in the AP1000 DCD dose rate calculations.

12.4.2 Evaluation

The staff reviewed all technical changes to the radiation protection design features identified by change marks in the AP1000 DCD, Revision 17, in accordance with NUREG-0800 Section 12.3 - 12.4, “Radiation Protection Design Features.” Descriptions and evaluations of the radiation protection design features in the AP1000 DCD, Revision 15, that were previously approved are not affected by the new changes and were not re-reviewed by the staff. Information presented in the TRs support all technical changes in this section of the DCD.

The staff reviewed the Tier 1, Section 3.5, “Radiation Monitoring,” ITAAC. This section remained substantially unchanged, but the AP1000 DCD, Revision 17 enhanced the airborne radioactivity and area radiation monitors by adding monitors with multiple detectors and revising the title of selected area monitors. The staff’s evaluation of these Tier 1 changes is in Section 11.5 of this report. No additional technical evaluation was required for Section 12.3.4, “Area Radiation and Airborne Radioactivity Monitoring Instrumentation.”

NUREG-1793 documents the regulatory basis for AP1000 DCD Section 12.3, Revision 15. The staff has reviewed the proposed changes to DCD Section 12.3 against the applicable acceptance criteria of NUREG-0800 Section 12.3-12.4. The following evaluation discusses the results of the staff's review.

12.4.2.1 Fuel Handling Area Shielding Design

In AP1000 DCD Section 12.3.2.2.4, spent fuel removal and transfer operations are performed under borated water to provide radiation protection and maintain subcriticality. According to Revision 15 of DCD Tier 2, Section 12.3.2.2.4, minimum allowable water depths above active fuel in a fuel assembly during fuel handling are 3.05 m (10 ft) in the reactor cavity and SFP. This limits the dose to personnel on the SFHM to less than 25 μSv/h (2.5 mrem/h) for an assembly in a vertical position. Normal SFP water depth above the stored assemblies is approximately 7 m (23 ft); and, for this depth, the exposure to plant workers is insignificant. TR-121, Revision 0, documented several changes and, as a result, the NRC staff questioned the accuracy of the calculated exposure to workers adjacent to the fuel handling area. The response to RAI-SRP12.2-CHPB-02 clarified the issue raised by the NRC staff to show that it was not possible to maintain the original value of 3.05 m (10 ft) of water over the fuel assembly, given the design of the SFP and its handling equipment. The design drawings showed an actual value of 2.59 m (8.5 ft) of water above the active fuel portion of the fuel assembly. The changes submitted in TR-121 changed the water level in the SFP by 0.3 m (12 inches) to 2.89 m (9.5 ft), and dose rate calculations for this water depth showed that the dose to the SFHM operators would be 25 μSv/h (2.5 mrem/h) or less when moving an irradiated fuel assembly while standing on the SFHM. The applicant documented these changes in TR-121, Revision 0. The applicant also responded to the RAI related to TR-121 in a letter dated October 4, 2007, and described assumptions used in its calculations for the exposure of workers adjacent to the fuel handling areas (RAI-TR121-CHPB-01, RAI-TR121-CHPB-03, and RAI-TR121-CHPB-04). The applicant described the potential radiological effects and dose estimates associated with the change in the minimum water level over active fuel in the refueling area and the SFP.

During the review of Revision 17 to AP1000 DCD Tier 2, Section 12.3.2.2.4, the staff observed that the applicant again changed the overall minimum allowable water depth above active fuel in the reactor cavity and SFP from 2.89 m (9.5 ft) to 2.67 m (8.75 ft) during fuel movement. The applicant did not identify the basis of its parameters in Section 12.3.2.2.4 or the reason for this change. The staff issued RAI-SRP12.3-CHPB-02 to request an explanation for the Revision 17 changes to the minimum refueling and SFP water depth.

The staff reviewed the shielding calculation, APP-GW-N2C-006, Revision 2, "Spent Fuel Shielding Evaluation" (Alt Doc # CN-REA-05-55) referenced in the response to the staff's RAI-SRP12.3-CHPB-02. On the basis of this review, the staff had additional questions related to calculations performed for both 259 cm (102 inches(in)) and 267 cm (105 in) above the active portion of the fuel assembly and how the heights of 259 cm (102 in) and 267 cm (105 in) above the fuel assembly correspond to the minimum required water level in the SFP.

APP-GW-N2C-006 also provided the worst-case source, Case D (4.16E+12 γ–cc/sec) from a single fuel assembly at 259 cm (102 in) and 267 cm (105 in) below the water's surface. It appears from the information supplied in the referenced calculation that the source described in Case A (4.26E+12 γ–cc/sec) is more conservative based solely on the dose contribution from the single elevated fuel assembly in the SFP. The staff requested a clarification to determine the basis for selection of Case D versus Case A, as well as a description of design features/access controls to ensure that the dose to the refueling personnel on the fuel handling bridge deck are maintained ALARA during refueling operations. The staff identified this as Open Item OI-SRP12.3-CHPB-02 in the SER with open items.

In a letter dated July 20, 2009, the applicant submitted its revised response to RAI-SRP12.3-CHPB-02. The applicant indicated that the SFP bridge deck, with 2.54 centimeters (cm) (1 inch) of steel shield, would provide adequate shielding during irradiated fuel movement to maintain whole body exposures to personnel on the SFHM to less than 25 μSv/h (2.5 mrem/h). Calculations referenced by the applicant were reviewed and verified to demonstrate the adequacy of the design to maintain exposures ALARA and were found to be conservative. The staff concludes that the combination of shielding, configuration and SFP water level will maintain exposures ALARA, and is, therefore, acceptable. Therefore, both RAI-SRP12.3-CHPB-02 and the associated Open Item OI-SRP12.3-CHPB-02 are resolved.

12.4.2.2 Compliance with 10 CFR 20.1406

During its evaluation of Revision 17 to the AP1000 DCD, the staff identified insufficient information available on the description of design features concerning its compliance with 10 CFR 20.1406 (RAI-SRP12.1-CHPB-01). The staff was in the process of developing RG 4.21, when the DCD applicant submitted TR-98, Revision 0. The staff intended for its report to identify and justify standard changes to be incorporated into the DCD. Revisions 16 and 17 incorporated the information into the various sections of the DCD, including Chapters 9, 11, and 12. The implementation of 10 CFR 20.1406 affects other SSCs described in the DCD, but that information was not sufficiently described in the other DCD chapters. The design features discussed in DCD Section 12.3 and the COL information items, added as a result of TR-98, clarify some aspects of the applicant's compliance with 10 CFR 20.1406 but do not provide the description of the program consistent with the guidance in RG 4.21.

In TR-98, Revision 0, the applicant proposed to comply with the regulation by the selection of design technology. Table TR-98-1, "AP1000 Features Applicable to 10 CFR 20.1406," in TR-98 lists specific examples (Items 19, 22, 23, 24, 25 and 26 in the table) showing how the AP1000 design complies with the portions of 10 CFR 20.1406 dealing with minimizing the generation of waste. The staff has reviewed the items listed in Table TR-98-1 pertaining to the liquid radwaste system and finds that the applicant addressed the issue of minimization of waste generation in 10 CFR 20.1406. The applicant has not committed to RG 4.21, Revision 0, but has described the design features in the licensing basis for the AP1000 to meet 10 CFR 20.1406 requirements. The staff implemented 10 CFR 20.1406 and issued RG 4.21 after Revision 16 to the DCD but before Revision 17. Therefore, the staff is providing documentation requirements for following this RG in correspondence related to Chapter 12 for COL applicants.

In a letter dated September 9, 2008, the applicant described specific features that are incorporated into the AP1000 design to comply with the requirements of 10 CFR 20.1406 or are referenced in TR-98, Revision 0, for the systems that were listed in RAI-SRP12.1-CHPB-01 (and for any other plant systems that may generate or transfer radioactive materials or waste). The staff determined the analysis is sufficient because the responses to RAI-SRP12.1-CHPB-01, as well as TR-98, provide specific information about compliance with 10 CFR 20.1406, and the staff has determined that the applicant considered the applicable design criteria. (See also Section 12.2.2 of this report).

12.4.2.3 Addition of Integrated RV Head Package and Quick-Loc Connectors

In its review of AP1000 DCD Section 12.3, the staff identified areas that needed additional information to complete an evaluation of the applicant's proposed change (RAI-SRP12.3-CHPB-01). In Tier 2, DCD Section 12.3.1.1.1, the staff noted that the applicant's description includes an integrated RV head package that combines the head lifting rig, control and gray rod drive mechanisms, lift columns, control rod drive mechanism cooling system, and power and instrumentation cabling. The applicant also replaced the conventional top-mounted instrumentation ports/conoseal thermocouple arrangement with a combination thermocouple/incore detector system.

In Revision 17 to AP1000 DCD Tier 2, Figure 12.3-1 (Sheet 8 of 16), "Radiation Zones, Normal Operation/Shutdown Nuclear Island," EL 135′-3" indicates that the RV head stand area may be a Plant Radiation Zone V [less than or equal to 10 mSv/h (1 rem/h)] when the RV head is in the stand, which is defined by Figure 12.3-1 (Sheet 1 of 16). In Revision 15, the same drawing indicated that the area for the RV head stand would be a Plant Radiation Zone II [(less than or equal to 25 µSv/h (2.5 mrem/h)]. There were no supporting calculations to show that the integrated RV head package will result in a dose rate of less than or equal to the original RV head configuration, or to show how this change is ALARA.

Table 12.4-12, "Dose Estimate for Refueling Activities," did not change as a result of the addition of the design change implementing the integrated RV head package. The use of an integrated RV head, which has been installed at several current generation facilities, minimizes the time necessary to perform disassembly and reassembly of the RV during refueling outages.

The description of the change to include the integrated RV head package lacked sufficient information to determine if the containment area radiation zones are affected or if the implementation results in an increase or decrease in the refueling dose estimates. The staff identified this as Open Item OI-SRP12.3-CHPB-01 and was tracked in the SER with open items.

In a letter dated January 21, 2010, the applicant submitted its response to Open Item OI-SRP12.3-CHPB-01.

The applicant indicated that the integrated head package would result in several changes to the radiation zones associated with the upper level of containment and the head stand area. In addition, the applicant revised Table 12.4-12 to reflect a net positive effect concerning the reduction of total dose due to refueling processes. The staff concludes that revised exposure rates and total exposure are consistent with industry data and are appropriate. In a subsequent revision to the DCD, the applicant made an appropriate change to the DCD text; therefore, both RAI-SRP12.3-CHPB-01 and the associated Open Item OI-SRP12.3-CHPB-01 are resolved.

12.4.2.4 Concrete Density for Shielding Design

During the review of Revision 17 to AP1000 DCD Tier 2, Section 2.3.2.2.9, "Spent Fuel Transfer Canal and Tube Shielding," the staff observed that the applicant decreased the assumed overall concrete density for shielding design purposes from 2354.7 kilograms per cubic meter (kg/m^3)(147 lb/ft^3) to 2242.58 kg/m^3 (140 lb/ft^3). The applicant provided no discussion in DCD Chapter 12 (in Revision 17) describing the effect of an approximate 5-percent decrease in the assumed shielding density of the transfer tube on area radiation levels during fuel movement. With the reduction in the concrete density, the applicant did not identify the basis of the parameters included in Section 12.3.2.2.9 or the reason for the change.

The applicant did not describe the radiological exposure consequences for occupationally exposed personnel nor discuss the effect on radiation zoning. The staff asked the applicant to address these concerns in RAI-SRP12.3-CHPB-03. The staff identified this as Open Item OI-SRP12.3-CHPB-03 and was tracked in the SER with open items.

In a letter dated December 15, 2009, the applicant submitted its response to RAI-SRP12.3-CHPB-03.

The applicant indicated that additional dose calculations were performed and they resulted in redesignation of several radiation zones and two rooms being designated as High Radiation Areas. An additional room now will require access controls consistent with an area greater than 1 rem per hour. Regarding the information in the applicant's response on the changes in radiation zones and controls, the staff concludes that the information provided is consistent with regulatory requirements and guidance and is appropriate. In a subsequent revision to the DCD, the applicant made an appropriate change to the DCD text, which resolves this issue; therefore, both RAI-SRP12.3-CHPB-03 and the associated Open Item OI-SRP12.3-CHPB-03 are resolved.

12.4.2.5 Computer Codes Used for Shielding Calculations

In AP1000 DCD Section 12.3.2.3, the applicant described computer codes used to determine design and operational dose rates for the plant areas located on the AP1000 nuclear island. DCD Reference 22 in Section 12.3 identified the point kernel code, Microshield 4, as being a personal computer version with a menu-driven use interface of the mainframe calculation code QAD. The staff issued RAI-SRP12.3-CHPB-04 requesting additional information to support verification and validation of this computer code as it is used in the AP1000 DCD dose rate calculations.

In its December 15, 2009, response to the staff's RAI, the applicant stated that they had reviewed the AP1000 shielding calculations and updated the DCD to reflect the software used in the most recent shielding analyses of the plant. The applicant revised DCD Reference 22 to cite use of the updated Version 6.20 of the Microshield code. Microshield Version 6.20 is based upon data from the American National Standards Institute (ANSI) standard for gamma radiation attenuation and buildup (ANSI/American Nuclear Society (ANS)-6.4.3-1991, "Gamma-Ray Attenuation Coefficients and Buildup Factors for Engineering Materials") and is widely used in the nuclear industry. The applicant stated that they have verified this software code by comparing the software results from this code with the results for reference problems provided in ANSI/ANS-6.6.1-1979, "American National Standard for Calculation and Measurement of Direct and Scattered Gamma Radiation from LWR Nuclear Power Plants." While Microshield Version 6.20 is used for non-complex geometries, the applicant modified the DCD to state that they use Monte Carlo or discrete ordinate methods for radiation analysis for complex geometries. The staff finds the applicant's response to RAI-SRP12.3-CHPB-04 to be acceptable because the applicant modified the DCD to clarify and better describe the type of computer code software referenced to perform simple gamma radiation shielding calculations for the AP1000 design and also provided verification and validation of this code's output. Based on the applicant's response, RAI-SRP12.3-CHPB-04 is resolved.

12.4.3 Conclusions

Based on the evaluation of the AP1000 DCD information and response to RAI-SRP12.1-CHPB-01, and the resolution of Open Item OI-SRP12.1-CHPB-01 (see

Section 12.2.2), the staff concludes that the applicant properly identified design information related to its compliance with 10 CFR 20.1406 and provided an adequate demonstration that design objectives for equipment necessary to minimize contamination to the environment have been met, in accordance with 10 CFR Part 20.

Based on the evaluation of the DCD information in the applicant's response to RAI-SRP12.3-CHPB-02 and RAI-SRP12.3-CHPB-03, the staff concludes that the applicant has properly identified all design information related to its compliance with 10 CFR Part 20 and with GDC 61, and has provided an adequate demonstration that design objectives have been met for the spent fuel handling equipment, spent fuel transfer canal, and tube shielding necessary to minimize exposures and maintain personnel doses ALARA, in accordance with 10 CFR Part 20.

Based on the evaluation of the DCD information in the applicant's response to RAI-SRP12.3-CHPB-01, the staff concludes that the applicant provided a complete description of how the placement of the integrated RV head package and the revised and associated equipment in the containment building meet the acceptance criteria of NUREG-0800 Section 12.3 - 12.4.

Based on the evaluation of the DCD information in the applicant's response to RAI-SRP12.3-CHPB-04, the staff concludes that the applicant provided an adequate description of the computer codes used in the shielding calculations for the AP1000 DCD and revised the associated DCD Section 12.3.2.3 and Section 12.3.6 and as a result, meet the acceptance criteria of NUREG-0800 Section 12.3 - 12.4.

The staff's evaluation of the proposed changes (the addition of monitors with multiple detectors and the revision of the title of selected area monitors) in Tier 1, Section 3.5, "Radiation Monitoring," in Revision 17 of the DCD is in Section 11.5 of this report.

In NUREG-1793 and its Supplement 1, the staff documented its conclusion that the AP1000 design and DCD (up to and including Revision 15 to the DCD) were acceptable and that the applicant's application for design certification met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

In its previous evaluation of AP1000 DCD Section 12.3, the staff identified acceptance criteria based on the ability of the applicant's design to meet the relevant requirements in 10 CFR Part 20, as it relates to limits on doses to persons in restricted areas; 10 CFR Part 50, as it relates to the inclusion of sufficient design information to demonstrate the objectives for equipment facility design features, shielding, ventilation, area radiation, and airborne radioactivity monitoring instrumentation; and 10 CFR Part 70, "Domestic licensing of special nuclear material," as it relates to the design of radiation protection features to ensure adequate safety under normal and abnormal operating conditions. The staff reviewed the AP1000 design for compliance with these requirements, as referenced in NUREG-0800 Section 12.3 - 12.4, and determined that the design of the radiation protection features, as documented in the AP1000 DCD, Revision 15, was acceptable because it conformed to all applicable acceptance criteria.

The staff reviewed the applicant's proposed changes to the AP1000 radiation protection design features as documented in the AP1000 DCD, Revision 17. The staff finds that the applicant's proposed changes do not adversely affect the ability of the AP1000 design features to meet the applicable acceptance criteria. The staff also concludes that the applicant has properly incorporated the design changes into the appropriate sections of the AP1000 DCD. On the basis that the AP1000 radiation protection design features continue to meet all applicable acceptance criteria and that the updated AP1000 DCD properly documents the changes, the staff concludes that all of the changes related to the radiation protection features in the AP1000 system design are acceptable.

In addition, the radiation protection pertaining to the IHP and Quickloc connectors contribute to the increased standardization of this aspect of the AP1000 design. Therefore, these changes meet the finality criterion in 10 CFR 52.63(a)(1)(vii).

12.5 Dose Assessment

12.5.1 Summary of Technical Information

The staff approved DCD Section 12.4, “Dose Assessment,” in Revision 15 to the certified design. In Revision 17 to the AP1000 DCD there were no technical changes. This review addresses the anticipated occupational radiation exposure from normal operation and anticipated inspections and maintenance.

12.5.2 Evaluation

The staff reviewed all changes to the “Dose Assessment” section in accordance with NUREG-0800 Section 12.3 - 12.4. The staff also reviewed all changes in the AP1000 DCD, Revision 17. Information presented in the TRs support all changes in the DCD.

NUREG-1793 documents the regulatory basis for AP1000 DCD Section 12.4, Revision 15. The staff reviewed the proposed changes to DCD Section 12.4 against the applicable acceptance criteria in NUREG-0800 Section 12.3 - 12.4. The following evaluation discusses the results of the staff’s review.

12.5.2.1 Summary of Changes

The staff reviewed the applicant’s supporting documentation and determined that there were no supporting calculations that showed the integrated RV head package would result in a dose rate of less than or equal to the original RV head configuration, or that the change was ALARA. Table 12.4-12 did not reflect increased dose (person-sievert (person-rem)) as a result of the addition of the design change implementing the integrated RV head package. The use of an integrated head, which has been installed at several current generation facilities, minimizes the time necessary to perform disassembly and reassembly of the RV during refueling outages. The staff asked the applicant to address these issues in RAI-SRP12.3-CHPB-01. This was addressed as part of the applicant’s response to Open Item OI-SRP12.3-CHPB-01 and was found to be acceptable. (See also Section 12.4.2.3 of this report).

The staff concludes that COL Action Item 12.5-1 was not technical in nature and has not changed from the AP1000 DCD, Revision 15.

12.5.3 Conclusions

As described in Section 12.2 of this report, the response to Open Item OI-SRP12.3-CHPB-01 was found to be acceptable and the staff considers Open Item OI-SRP12.3-CHPB-01 to be resolved. In NUREG-1793 and its Supplement 1, the staff documented its conclusion that the

AP1000 design and DCD (up to and including Revision 15) were acceptable and that the applicant's application for design certification met the requirements in Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design. With the exception of the changes addressed in Open Item OI-SRP12.3-CHPB-01, none of the changes described alter or affect the dose assessment in Revision 15 to the AP1000 DCD. Therefore, the staff requires no technical evaluation of the changes described in DCD Tier 2, Section 12.4.

12.6 Health Physics Facilities Design

This section describes the staff's evaluation and findings of the AP1000 DCD, Revisions 16 and 17. The staff originally reviewed Revision 16 and issued several RAIs, but the applicant issued Revision 17 before the staff could close out the RAIs for the previous revision. This review and evaluation, therefore, encompasses both revisions.

12.6.1 Summary of Technical Information

The staff approved Section 12.6, "Health Physics Facilities Design," of the AP1000 DCD, Revision 15, in the certified design. In Revision 17 to the AP1000 DCD, the applicant proposed one change, described below, with associated TR changes. This review addressed system design and performance aspects only of the health physics facilities design.

In DCD Tier 2, Section 9.1.2, "Spent Fuel Storage," and Section 9.1.4, "Light Load Handling System," the applicant proposed to increase the minimum allowable water depth above the active fuel region in a fuel assembly to 2.89 m (9.5 ft) when an assembly is being transferred in a SFHM. The applicant stated that the proposed increase in minimum water depth was sufficient to ensure that the personnel radiation exposures would be limited to less than or equal to 25 μSv/h (2.5 mrem/h) on the SFHM. The applicant has documented these changes in TR-121, Revision 0.

12.6.2 Evaluation

The staff reviewed the technical changes to the health physics facilities design, in accordance with NUREG-0800 Section 12.3 - 12.4. The staff reviewed all changes identified by change marks in the AP1000 DCD, Revision 17. The information presented in the TRs support all of the technical changes in the DCD.

NUREG-1793 documents the regulatory basis for AO1000 DCD Section 12.5, Revision 15. The staff has reviewed the proposed changes to DCD Section 12.5 against the applicable acceptance criteria of NUREG-0800 Sections 12.3 - 12.4 and 12.5. The following evaluation discusses the results of the staff's review.

12.6.2.1 The Results of Spent Fuel Water Level and Dose

In TR-121, the applicant proposed to change the minimum required depth of water above the active fuel region in a fuel assembly to minimize the exposure from direct radiation to personnel operating equipment on the SFHM. In its review, the staff requested additional information providing the dose rate analysis that was based on an actual increase in the water level from approximately 2.59 m (8.5 ft) to 2.89 m (9.5 ft) above the actual fuel in a fuel assembly when in a SFHM. The applicant responded to the RAI related to TR-121 in a letter dated October 4, 2007, and described the assumptions used in its calculations for the exposure of workers adjacent to the fuel handling areas (RAI-TR121-CHPB-01, RAI-TR121-CHPB-03, and RAI-TR121-CHPB-04). The applicant described the potential radiological effects and dose estimates associated with the reduction of the minimum water level over active fuel in the refueling area and the SFP. Revision 16 to the AP1000 DCD incorporated these changes.

In its review of DCD Section 12.5, the staff identified areas in which the additional information provided by the applicant in a letter dated October 4, 2007, determined that the initial depth of water was in error. The SFHM design actually provided 2.59 m (8.5 ft) depth of water over the active fuel in a fuel assembly when initially proposed. In the applicant's response provided, the elevation of the top of the active fuel was unchanged since the SFP water level was increased by 0.3 m (12 inches). This was necessary to ensure that the exposure rates on the bridge deck (where operating personnel would normally be located) were less than 25 μSv/h (2.5 mrem/h). The information provided, and a review of the requisite guidance in NUREG-0800 Sections 12.3 - 12.4 and 12.5, and in RG 1.13, "Spent Fuel Storage Facility Design Basis," Revision 2, allowed the staff to complete its evaluation of the applicant's change. Further discussion on the water lever change is included in Section 12.4.2.1 of this report.

In DCD Tier 2, Section 9.1.4, the staff noted that a potential exists for the movement of active fuel above the required minimum water depth, if the applicant uses an auxiliary hoist in conjunction with a specialized spent fuel handling tool (SFHT) to reach the approximately 25 percent of the SFP rack spaces that are not accessible using the SFHM. The applicant's response to TR-121, RAI-SRP9.1.4-SBPB-04 describes this activity. The applicant's responses to the staff's RAI are discussed below.

Section 9.1.4.3.7 of the AP1000 DCD states that:

> The three fuel handling devices used to lift spent fuel assemblies are the refueling machine, fuel handling machine, and the spent fuel handling tool. Both the refueling machine and fuel handling machine contain positive stops which prevent the fuel assembly from being raised above a safe shielding height.

DCD Section 9.1.4.3.3 invokes the design of the refueling machine for the SFHM; DCD Section 9.1.4.3.1 states that, because of "mechanical or failure tolerant electrical interlocks or redundant electrical interlocks," the "refueling machine is restricted to raising a fuel assembly or core component to a height at which the water provides a safe radiation shield."

The latter statements imply that, when using the SFHT, there are no positive stops to prevent the fuel assembly from being raised above a safe shielding height. The SFHT with an auxiliary hoist will apparently be used for at least 25 percent of the SFP storage cells, based on the information in TR-121. In TR-121, Revision 0, the applicant stated the following:

> …due to the radius of the FHM manipulator mast and the proximity to the SFP walls, approximately 25 percent of the SFP storage cells cannot be serviced by the mast crane. Also, there are instances where fuel inspection and/or fuel repair require the fuel to be moved from the SFP storage racks to the designated fuel inspection or fuel repair workstation. These non-normal fuel transfer operations are performed using the Spent Fuel Handling Tool (SFHT). The SFHT is a long handled tool which latches onto the fuel assembly top nozzle via manually actuated grippers. Lifting of the SFHT and attached fuel assembly is performed using an auxiliary hoist on the FHM.

The DCD does not describe any interlocks related to the movement of fuel assemblies when using the auxiliary hoist.

In a letter dated June 26, 2008, the applicant submitted a response to RAI-SRP9.1.4-SBPB-04 on fuel handling equipment. The response stated that the refueling machine and the SFHM will contain positive stops to prevent the fuel assembly from being raised above a safe shielding point. The SFHT will only be used in conjunction with the refueling machine and the SFHM. The applicant's response also stated that it would revise AP1000 DCD Tier 1, Section 2.1.1, page 2.1.1-1, to limit the lift height of the refueling machine mast and SFHM mast to maintain the minimum required depth of water shielding. DCD Tier 1, Table 2.1.1-1, includes Item 5 of the ITAAC to describe the acceptance criteria for this design commitment. The staff's evaluation of this Tier 1 change is in Section 9.1.4 of this report.

12.6.2.2 Documentation of Compliance with 10 CFR Part 20

The staff finds that these changes do not affect the design and performance aspects of the health physics facilities, as previously reviewed in NUREG-1793, Section 12.6.

12.6.3 Conclusions

In NUREG-1793 and its Supplement 1, the staff documented its conclusion that the AP1000 design and DCD (up to and including Revision 15 to the DCD) were acceptable and that the applicant's application for design certification met the requirements of Subpart B to 10 CFR Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

In its previous evaluations of AP1000 DCD Section 12.5, regarding the health physics facilities design, the staff identified acceptance criteria based on the ability of the design to meet the relevant requirements in 10 CFR 20.1302, "Compliance with dose limits for individual members of the public," as it relates to limits on doses to persons in occupied areas, and GDC 61, as it relates to the design of spent fuel storage and handling to ensure adequate safety under normal and postulated accident conditions. The staff reviewed the AP1000 health physics facilities design for compliance with these requirements, as referenced in NUREG-0800 Section 12.5, and determined that the design of the health physics facilities, as documented in the AP1000 DCD, Revision 15, was acceptable because it conformed to all applicable acceptance criteria.

The staff reviewed the applicant's proposed changes to the AP1000 health physics facilities design as documented in the AP1000 DCD, Revision 17. The staff concludes that the applicant's proposed changes do not affect the ability of the AP1000 health physics facilities design to meet the applicable acceptance criteria. The staff also concludes that the applicant has properly incorporated the design changes into the appropriate sections of the AP1000 DCD, Revision 17. On the basis that the AP1000 health physics facilities design continues to meet all applicable acceptance criteria and the updated AP1000 DCD properly documents the changes, the staff concludes that all of the changes related to the system design of the AP1000 health physics facilities are acceptable.

13. CONDUCT OF OPERATIONS

13.3 Emergency Planning

13.3.1 Introduction

In Revision 17 to the AP1000 design control document (DCD), the applicant proposed changes to the annex building Technical Support Center (TSC). The specific DCD changes include: (1) renaming the TSC area in the annex building from the Main TSC Operations Area to the Control Support Area (CSA); (2) removing the identification of the specific TSC location from Tier 1 DCD information; (3) identifying the TSC location in the CSA as Tier 2; and (4) providing additional Tier 1 and Tier 2 DCD conforming changes to reflect the new TSC and CSA designations. The technical justification for the proposed changes is provided in technical report (TR)-107, "AP1000 Technical Support Center," APP-GW-GLR-107, Revision 1, dated June 14, 2007.

13.3.2 Regulatory Basis

Pursuant to Title 10 of the *Code of Federal Regulations* (10 CFR) 52.48, "Standards for review of applications," the Nuclear Regulatory Commission (NRC) staff reviewed the AP1000 DCD for compliance with the standards set out in 10 CFR 50.47(b)(8), "Emergency plans," and 10 CFR Part 50, "Domestic licensing of production and utilization facilities," Appendix E, "Emergency Planning and Preparedness for Production and Utilization Facilities," Section IV.E, as those standards are technically relevant to the proposed generic DCD changes for the TSC area. Associated TSC guidance is in NUREG-0800, "Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants," Sections 13.3, "Emergency Planning," and 14.3.10, "Emergency Planning – Inspections, Tests, Analyses, and Acceptance Criteria," NUREG-0654/FEMA-REP-1, Revision 1, "Criteria for Preparation and Evaluation of Radiological Emergency Response Plans and Preparedness in Support of Nuclear Power Plants," NUREG-0696, "Functional Criteria for Emergency Response Facilities," and Supplement 1 to NUREG-0737, "Requirements for Emergency Facilities." The specific criterion that applies to the changes evaluated in this section is 10 CFR 52.63(a)(1)(iii), in that the proposed changes reduce unnecessary regulatory burden and maintain protection to public health and safety and the common defense and security.

13.3.3 General Description of Facilities

The TSC provides an area and resources for use by personnel providing plant management and technical support to the plant operating staff during emergency evolutions. In addition, the TSC relieves operators of peripheral duties and communications not directly related to reactor system manipulations and prevents congestion in the control room. Revision 17 of the AP1000 DCD identifies the TSC as the Main TSC Operations Area (Room 40403) in the annex building at Elevation 117'-6", adjacent to the passage from the annex building to the nuclear island control room.

In Section 13.3, "Emergency Planning," of NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design," the staff evaluated the TSC information in Revision 15 of the AP1000 DCD and found that it meets the applicable regulatory requirements in 10 CFR 50.47(b)(8) and 10 CFR Part 50, Appendix E, Section IV.E.

10 CFR Part 52, "License, certifications, and approvals for nuclear power plants," Appendix D, "Design Certification Rule for the AP1000 Design," constitutes the standard design certification (DC) for the AP1000 design and incorporates by reference the associated generic DCD, which includes the Tier 1 and Tier 2 information.

As described in TR-107, the name of the AP1000 annex building TSC (i.e., Main TSC Operations Area) is changed to the CSA, and the DCD is modified to reflect the change. In addition, the identification of the specific TSC location is removed from Tier 1 DCD Section 3.1, "Emergency Response Facilities," and Table 3.1-1, "Inspections, Tests, Analyses, and Acceptance Criteria" (ITAAC). However, TR-107 does not affect the TSC functional requirements and criteria, which are retained and must be met regardless of its actual location. The changes are intended to facilitate a combined license (COL) applicant describing a site-specific location for its TSC, independent of the AP1000 annex building, without the need for an exemption to a Tier 1 AP1000 TSC location. These changes will also ease the NRC's review burden by eliminating the need for such individual COL applicants to apply for exemptions from the standardized DCD wording.

The changes in TR-107 provide flexibility, in that they will allow COL applicants who reference the AP1000 certified design to either use the CSA as the TSC (without departing from the DCD), or designate an alternative TSC location in accordance with the change process in 10 CFR Part 52, Appendix D, Section VIII. The CSA is designed so that it may be used as a TSC, if desired. The generic DCD Revision 17 location for the TSC is maintained in the annex building CSA, and was designated as Tier 2* information in DCD Tier 2, Section 18.8.3.5, "Technical Support Center Mission and Major Tasks," rather than Tier 1 information in DCD Section 3.1. The other DCD Tier 1 requirements associated with the TSC are unaffected by this change, and will be subject to the applicable Tier 1 change control process.

The staff's position is that the DCD Section 18.8.3.5 change should be to Tier 2, rather than Tier 2*. (A change from Tier 1 to Tier 2 would be governed by the same regulatory basis, described above, as a change from Tier 1 to Tier 2*.) This is because the NRC has previously used the Tier 2* designation for DCD information where there is a reasonable expectation of a change over the lifetime of the facility (e.g., a fuel change). The nature of the information is such that the NRC must review and approve the proposed change prior to the change being made. As another example, the Tier 2* designation would be appropriate for information relating to detailed design methodologies and evaluation criteria. Such examples could result in design changes where the safety of the completed design may not be readily apparent. In regard to the AP1000 DCD, once the TSC is built, it is unlikely that it will be moved. Thus, the staff concludes that the Tier 2 designation for the TSC location is more appropriate than Tier 2*. For a Tier 2 TSC DCD location designation, a proposed change to the TSC location (i.e., to a location other than the CSA) by an applicant (or licensee) would require a departure from the certified design.

The staff determined that the applicant must change the TSC location designations in the DCD from Tier 2* to Tier 2. The other DCD Tier 1 requirements associated with the TSC are unaffected by this change, and will be subject to the applicable Tier 1 change control process. The staff identified resolution of this issue as Open Item OI-TR107-NSIR-07. In its January 27, 2010, response to Open Item OI-TR107-NSIR-07, the applicant changed the TSC location designation in DCD Section 18.8.3.5 from Tier 2* to Tier 2, and reflected that change in Revision 19 of the AP1000 DCD. For the reasons discussed above, the staff finds the change acceptable, and Open Item OI-TR107-NSIR-07 is, therefore, resolved.

13.3.4 Conclusion

Based on the above evaluation, the staff concludes that the design changes in TR-107, which are reflected in Revision 19 of the AP1000 DCD, are acceptable because the TSC continues to meet the requirements in 10 CFR 50.47(b)(8) and Section IV.E of Appendix E to 10 CFR Part 50.

13.5 Plant Procedures

13.5.1 Summary of Technical Information

In Revision 19 to the AP1000 DCD, the applicant proposed to partially resolve COL Information Item 13.5-1 in TR-70, “Plant Operations, Surveillance, and Maintenance Procedures” (APP-GW-GLR-040), Revision 1 and in the DCD by addressing; normal operating, abnormal operating, emergency operating, refueling and outage planning, alarm response, administrative, maintenance, inspection, test, and surveillance procedures, as well as the procedures that address the operation of post-72-hour equipment. The COL applicant will address operational and maintenance programmatic issues to resolve COL Information Item 13.5-1.

13.5.2 Evaluation

NUREG-0800 Section 13.5.2.1 states that the applicant should describe its program for developing the operating procedures and that the staff will review the applicant's program for developing and implementing the operating procedures. The staff reviewed TR-70, Revision 1, and its associated references, and determined that it described a process to manage the development, review, and approval of these procedures, but did not clearly provide the requested description. The staff submitted request for additional information (RAI)-SRP13-COLP-01 to ask that the applicant clarify the program description for developing and implementing the operating procedures. In a letter dated July 29, 2008, the applicant stated that TR-70, Revision 1, described the program. Subsequent to the submission of TR-70, Revision 0, the staff met with the applicant to discuss procedure development issues related to the AP1000 design and to allow the staff an opportunity to audit a variety of AP1000 operations procedures. TR-70, Revision 1, addresses issues discussed in this meeting, as well as the concerns regarding NUREG-0711, “Human Factors Engineering Program Review Model,” issued February 2004, that were discussed and later addressed in the staff’s letter, “Summary of the April 11 and 12, 2007, Meeting to Discuss AP1000 Plant Operating Procedures,” dated May 11, 2007. Along with TR-70, Revision 1, the applicant submitted the “AP1000 Writer’s Guidelines for the Normal and Two-Column Format Procedures” (APP-GW-GJP-100 and 200). After reviewing the AP1000 Writer’s Guidelines, which clarified procedure development, the staff finds TR-70, Revision 1 acceptable because the applicant’s program description for developing and implementing the operating procedures meets the guidance in NUREG-0800 Section 13.5.2.1.

Similarly, with respect to the development of emergency operating procedures (EOPs), NUREG-0800 Section 13.5.2.1 states that the applicant should describe its program for developing EOPs, as well as the required content of the EOPs, and that the staff will review the applicant's program for developing and implementing the EOPs. The staff reviewed TR-70 and its associated references and determined that it described a process to manage the development, review, and approval of these procedures, but did not clearly provide the requested description. The staff submitted RAI-SRP13-COLP-02 to ask the applicant to describe the program for developing and implementing the EOPs. In a letter dated

July 29, 2008, the applicant stated that TR-70, Revision 1, described the program. Subsequent to the submission of TR-70, Revision 0, the staff met with the applicant to discuss procedure development issues related to the AP1000 design and to allow the staff an opportunity to audit a variety of the AP1000 operations procedures. TR-70, Revision 1, addresses issues discussed in this meeting, as well as the concerns regarding NUREG-0711 that were discussed and later addressed in the staff's letter dated May 11, 2007. Along with TR-70, Revision 1, the applicant submitted the "AP1000 Writer's Guidelines for the Normal and Two-Column Format Procedures" (APP-GW-GJP-100 and 200). After reviewing the AP1000 Writer's Guidelines, which clarified procedure development, the staff finds TR-70, Revision 1 acceptable because the applicant's program description for developing and implementing the EOPs meets the guidance in NUREG-0800 Section 13.5.2.1.

The staff reviewed DCD Section 13.5.1, which references TR-70, Revision 1, and its associated references, which the applicant submitted as a basis for closing this COL action item. During this review, the staff noted that the DCD addressed safety-related logic circuitry but did not specify which organization had responsibility for it. The staff submitted RAI-SRP13-COLP-03 and RAI-SRP13-COLP-04 to ask the applicant to specify which organization had responsibility for safety-related logic circuitry and freeze seals respectively. In a letter dated July 29, 2008, the applicant stated that it had responsibility for these issues, as described in TR-70, Revision 1. The staff finds this acceptable because the applicant's program for developing and implementing the operating procedures includes a complete description of the safety-related logic circuitry and freeze seals and thus meets the guidance in NUREG-0800 Section 13.5.2.1.

The staff reviewed DCD Section 13.5.1, which states that TR-70 partially addresses the requested COL information, which includes normal operating, abnormal operating, emergency operating, refueling and outage planning, alarm response, administrative, maintenance, inspection, test, and surveillance procedures, as well as the procedures that address the operation of post-72-hour equipment, and that the COL applicant will address operational and maintenance issues. The staff was not clear as to which operational and maintenance issues the COL applicant is responsible for or how they differ from those addressed in TR-70. The staff submitted RAI-SRP13-COLP-05 to ask the applicant to clarify these issues. In a letter dated July 29, 2008, the applicant stated that it was responsible for the development, review and approval of normal operating, abnormal operating, emergency operating, refueling and outage planning, alarm response, administrative, maintenance, inspection, test, and surveillance procedures, as well as the procedures that address the operation of post-72-hour equipment, and that the COL applicant was responsible for maintaining those procedures after their approval and acceptance, as well as for operator training in those procedures. The procedures developed and approved by the applicant are generic procedures. Site-specific procedures will be approved and maintained by the COL applicant. The staff finds this acceptable because the allocation for responsibility for developing and implementing the operating procedures meets the guidance in NUREG-0800 Section 13.5.2.1.

The staff reviewed DCD Section 13.5.1, which states that TR-70 submitted several reports to the staff. To the staff, the word "submit" means "docketed"; thus, this is not an appropriate word to use when referring to documents that have not been docketed. The staff submitted RAI-SRP13-COLP-06 to inform the applicant of this meaning. In a letter dated July 29, 2008, the applicant acknowledged the incorrect language and provided corrected text with amended language. The staff finds this acceptable because the applicant's program description now uses language that is clear and consistent with the staff's understanding.

13.5.3 Conclusion

Based on the above evaluation, the staff concludes that the AP1000 design changes are acceptable because they meet the guidance in NUREG-0800 Section 13.5.2.1. The proposed DCD changes are acceptable, pursuant to 10 CFR 52.63(a)(1)(vii), on the basis that they contribute to the increased standardization of the certification information.

13.6 Physical Security

13.6.1 Summary of Technical Information

This section of the AP1000 safety evaluation report (SER) documents the staff's review of the physical security aspects of the AP1000 DC application submitted to the NRC by the applicant.

In Revision 19 of the AP1000 DCD Tier 2, Section 13.6, the applicant describes the plant's physical security program, including those elements of physical protection and mitigative measures identified as being within the scope of the applicant's design. The description includes the required physical security elements of a DC application and references TRs that are part of the DC application, on physical protection and mitigative measures. It describes the design for protecting the plant against acts of radiological sabotage; specifically, the plant layout and protection of vital equipment are in accordance with 10 CFR 73.55, "Requirements for physical protection of licensed activities in nuclear power reactors against radiological sabotage," and applicable regulatory guidance. This safety evaluation (SE) incorporates the staff reviews of DCD Tier 2, Revision 19, Section 13.6; DCD Tier 1, Revision 19, Section 2.6.9, and Table 2.6.9-1; the applicant's RAI responses and the ITAAC for the physical security hardware and referenced safeguards TRs.

The applicant responded to several RAIs. The staff found all responses regarding regulatory requirements to be acceptable, including the applicant's responses to the RAIs associated with physical protection and the open items. All RAIs and open items are resolved and discussed in the SE that is designated as including safeguards information (SGI). The DCD and TRs identify vital equipment and vital areas; describe armed responder positions, physical security attributes (e.g., delay barrier(s) within the AP1000 design scope), their characteristics; and analyze adversarial scenarios for design-basis threats (DBTs). Because this information is security sensitive, the comprehensive physical protection SE includes SGI and is not available for public disclosure. Those persons with the correct access authorization and need-to-know may view the SGI version of the physical security SE, hereafter referred to as the "SGI SER of the AP1000," which is located in the NRC's Secure Local Area Network.

The applicant provided the design description and information related to physical protection in the following parts of the DCD: Section 13.6, Section 2.6.9, and referenced safeguards TRs.

In the AP1000 DCD Tier 1, Revision 19 and applicant RAI responses, Section 2.6.9 and Table 2.6.9-1, the applicant describes the design features and ITAAC for physical security hardware, and the design commitments for physical security hardware ITAAC within the scope of the AP1000 design.

In DCD Tier 2, Revision 19, Section 13.6, the applicant states that the "AP1000 Interim Compensatory Measures Report," the "AP1000 Enhancement Report," and the "AP1000 Safeguards Assessment Report" were separately submitted to establish the design of the AP1000 security systems.

In DCD Tier 2, Revision 19, Section 13.6.1, the applicant states that COL applicants referencing the AP1000 design will address site-specific information related to the "Physical Security Plan, Training and Qualification Plan and the Safeguards Contingency Plan," which are the responsibility of the COL applicant.

13.6.1.1 Summary of Technical Information - ITAAC

The applicant provided design-basis information, including associated tables and figures, in accordance with the selection criteria and methodology for developing DCD Tier 1 information, as described in DCD Tier 2, Section 14.3, to support ITAAC for the AP1000 structures, systems, and components (SSCs).

The applicant organized the DCD Tier 1 information in the systems, structures, and topical areas format shown in the DCD Tier 1 Table of Contents. Site-specific structures that are not within the scope of the certified design are to be addressed by the COL applicant that references the AP1000 certified design. Along with design and program descriptions of site-specific physical protection features, the COL applicant is required to address site security provisions during construction of new reactor(s) that is either inside or co-located to an existing PA. In addition, the COL applicant would address, as applicable, the controls and measures necessary for transitioning between new and existing physical protection systems and continue to maintain in effect the site security program and controls required for implementing the protective strategy for operating power reactors. ITAAC are addressed by both the DC and by the COL applicants incorporating its site-specific ITAAC to meet NRC requirements.

The design bases or supporting security analyses and assumptions related to the design descriptions of security-related features incorporated as AP1000 standard design are provided in SGI TR-94, "AP1000 Safeguards Assessment Report," APP-GW-GLR-066. The staff reviewed the DCD Tier 1 information provided by the applicant in accordance with NUREG-0800 Section 14.3.12, "Physical Security Hardware – Inspections, Tests, Analyses, and Acceptance Criteria" Revision 1, January 2010.

The applicant provided design descriptions and information related to physical protection systems or features in the following portions of the DCD and referenced TRs:

AP1000 DCD Tier 1, Chapter 2, "System Based Design Descriptions and ITAAC," Section 2.6.9, "Plant Security System," describes the design features and ITAAC for security hardware for the AP1000 design. Table 2.6.9-1, "Inspections, Tests, Analyses, and Acceptance Criteria" describes the design commitments for security hardware that are within the scope of the AP1000 design.

Tier 2, Chapter 1, Section 1.2, "General Plant Description," and Section 1.2.1, "Design Criteria, Operating Characteristics, and Safety Considerations," provide descriptions of the scope of the AP1000 design.

Tier 2, Chapter 13, "Conduct of Operations," Section 13.6, "Security," of the AP1000 describes physical protection systems or features incorporated as a part of the AP1000 standard design. Elements of a site-specific security program such as organization structure, training, operational program implementations, plant procedures, site-specific target sets, protective strategy, design features for security, and fitness for duty program are to be described by the COL applicant, along with an implementing schedule.

Section 14.2.9, “Preoperational Test Descriptions,” identifies tests to be completed prior to operating conditions. Section 14.2.9.1.14, “Class IE DC Power and Uninterruptible Power Supply Testing” and Section 14.2.9.4.13, “Plant Communications System Testing” addresses security components of plant’s lighting and intra-plant communications.

The applicant submitted TR-94, which describes the security measures credited in defending the AP1000 against a DBT in support of the application.

The applicant submitted TR-96, APP-GW-GLR-067, “AP1000 Interim Compensatory Measures Report,” that include information on compliance with the various sections of the Commission Order on Interim Compensatory Measures that was issued to NRC power reactor licensees on February 25, 2002.

The applicant submitted TR-49, APP-GW-GLR-062, “AP1000 Enhancement Report,” which describes design areas as physical security enhancements that will enhance the ability of a COL applicant to meet the general performance objective of 10 CFR 73.55.

The information found in these referenced reports is considered SGI and Official Use Only Security-Related Information and is protected in accordance with 10 CFR 2.390, “Public inspections, exemptions, requests for withholding,” and 10 CFR 73.21, “Protection of Safeguards Information: Performance Requirements.”

The applicant submitted, in Revision 19 of the AP1000 DCD and RAI responses, proposed changes to physical security hardware ITAAC in DCD Tier 1, Section 2.6.9, “Plant Security System.” As a result of the staff’s review, the applicant submitted additional proposed changes to DCD Tier 1, Section 2.6.9 in its responses to RAI-SRP14.3.12-NSIR-06 and RAI-SRP14.3.12-NSIR-07. The final proposed AP1000 physical security hardware ITAAC was provided in the response to RAI-SRP14.3.12-NSIR-07, Revision 1.

13.6.2 Regulatory Basis – Physical Security

The NRC’s regulations for protecting nuclear power reactors in 10 CFR Part 73, “Physical protection of plants and materials,” include specific security and performance requirements that, when implemented correctly, are designed to protect nuclear power reactors against acts of radiological sabotage, prevent the theft or diversion of special nuclear material, and protect SGI against unauthorized release.

Regulations in 10 CFR 73.1(a)(1), “Purpose and scope,” require the establishment of physical protection systems to protect special nuclear material against the DBT for radiological sabotage, and 10 CFR 73.55 describes the required physical protection for licensed activities. Pursuant to 10 CFR 50.34(c)(2), “Contents of applications; technical information,” and 10 CFR 52.79(a)(35)(i), “Contents of applications; technical information in final safety analysis report,” applicants must prepare and maintain security plans that describe the security-related actions they will take to protect their facilities against acts of radiological sabotage.

Subpart B of 10 CFR 52.47, “Contents of applications; technical information,” requires that information submitted for a DC include performance requirements and design information sufficiently detailed to permit an applicant to prepare procurement specifications and construction and installation specifications. According to 10 CFR Part 52.48, the NRC will review applications filed under 10 CFR Part 52 for compliance with the standards set forth in 10 CFR Part 73.

The AP1000 design descriptions, commitments, and acceptance criteria for the security features, including the plant's layout and protection of vital equipment, as described in the DC application, are based on meeting the relevant requirements of the following Commission regulations:

- 10 CFR Part 50
- 10 CFR Part 52
- 10 CFR Part 73, Appendix B, "General Criteria for Security Personnel"; Appendix C, "Nuclear Power Plant Safeguards Contingency Plans"; Appendix G, "Reportable Safeguards Events"; and Appendix H, "Weapons Qualification Criteria"
- 10 CFR 73.1(a)(1)
- 10 CFR 73.70(f), "Records"
- 10 CFR Part 74, "Material control and accounting of special nuclear material"
- 10 CFR 100.21(f), "Non-seismic site criteria"

In its review, the staff used NUREG-0800 Section 13.6.2 to complete its AP1000 physical security DC review. The following paragraphs in 10 CFR 73.55 include acceptance criteria related to the staff's review in accordance with NUREG-0800 Section 13.6.2:

- Section (e) – Physical barriers: The licensee shall locate vital equipment only within a vital area, which, in turn, shall be located within a protected area (PA), such that access to vital equipment requires passage through at least two physical barriers (as defined in 10 CFR 73.2, "Definitions") that perform their required function in support of the licensee's physical protection program. The physical barriers at the perimeter shall be separated from any other barrier designated as a physical barrier for a vital area within the PA. Isolation zones in outdoor areas adjacent to the physical barrier at the perimeter of the PA permit observation. An intrusion detection system detects penetration or attempted penetration of the PA barrier. Isolation zones and appropriate exterior areas within the PA are illuminated. The main control room has bullet-resistant external walls, doors, ceiling, and floors. Vehicle control measures, which include vehicle barrier systems, protect against the threat of assault by land vehicles.

- Section (g) – Access control: The licensee shall control all points of personnel and vehicle access into a PA; this includes providing equipment capable of detecting firearms, explosives, incendiary devices, or other items that could be used to commit radiological sabotage, or a visual and physical search, or both. Unoccupied vital areas are locked and alarmed with activated detection systems that annunciate in both the central alarm station (CAS) and secondary alarm station (SAS) upon intrusion into a vital area. The individual responsible for the last access control function (controlling admission to the PA) must be isolated within a bullet-resisting structure.

- Section (i) – Detection and assessment systems: All alarms required pursuant to this part must annunciate and display concurrently in at least two continuously staffed onsite alarm stations, at least one of which must be protected in accordance with the requirements of the CAS. The CAS must be inside the PA, and the interior must not be visible from the perimeter of the PA. The applicant must design and equip the continuously staffed CAS and SAS so that a single act cannot disable both. At least one alarm station must maintain the ability to detect and assess alarms, initiate and coordinate an adequate response to an alarm, summon offsite assistance, and provide command and control. The CAS shall be considered a vital area and be bullet resistant, and associated onsite secondary power supplies for alarm annunciators and nonportable communication equipment must be located within vital areas. Alarm devices and transmission lines must be tamper indicating and be self-checking. Alarm annunciation on CAS/SAS computer monitoring stations shall indicate the type of alarm and its location. All emergency exits from protected and vital areas shall be alarmed and secured by locking devices.

- Section (j) – Communication requirements: Each security officer or armed-response individual shall be capable of maintaining constant communications with an individual in each continuously manned alarm station. Conventional telephone and radio- or microwave-transmitted two-way voice communications shall be established with local law enforcement authorities.

- Section (n) – Maintenance, testing, and calibration: Each applicant shall develop test and maintenance provisions for intrusion alarms, emergency alarms, communications equipment, access-control equipment, physical barriers, and other security-related devices or equipment.

The staff, in its review, used the following regulatory guidance documents:

- Regulatory guide (RG) 1.91, "Evaluations of Explosions Postulated to Occur on Transportation Routes Near Nuclear Power Plants," issued February 1978

- RG 4.7, "General Site Suitability Criteria for Nuclear Power Stations," issued April 1998

- RG 5.12, "General Use of Locks in the Protection and Control of Facilities and Special Nuclear Materials," issued November 1973

- RG 5.65, "Vital Area Access Controls, Protection of Physical Security Equipment, and Key and Lock Controls," issued September 1986

- RG 5.7, "Entry/Exit Control for Protected Areas, Vital Areas, and Material Access Areas," Revision 1, issued May 1980

- RG 5.44, "Perimeter Intrusion Alarm Systems," Revision 3, issued October 1997

- Information Notice 86-83, "Underground Pathways into Protected Vital Areas, Material Access Areas, and Controlled Access Areas," dated September 19, 1986

- Regulatory Issue Summary 2005-04, "Guidance on Protection of Unattended Openings that Intersect a Security Boundary or Area," April 14, 2005

- "Nuclear Power Plant Security Assessment Format and Content Guide," Information Systems Laboratories, issued September 2007 (Agencywide Documents Access and Management System (ADAMS) Accession Number ML07030054)

- SAND 2007- 5591, "Nuclear Power Plant Security Assessment Technical Manual," Sandia National Laboratories, issued September 2007 (ADAMS Accession Number ML072620172)

The staff evaluates the following specific acceptance criteria for ITAAC:

- 10 CFR 73.1, as it relates to the prescribed requirements for the establishment and maintenance of a physical protection system and for protection against the DBT of radiological sabotage

- 10 CFR 73.55, as it relates to the requirements for physical protection against radiological sabotage of licensed activities in nuclear power reactors

- 10 CFR 73.70(f), as it relates to the requirements specific to alarm annunciation records

- 10 CFR 52.47(b)(1), which requires that a DC application include the proposed ITAAC that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria met, a plant that incorporates the DC will be built and operated in accordance with the DC; the provisions of the Atomic Energy Act of 1954, as amended (the Act); and NRC regulations

The COL applicant referencing a certified design is responsible for the site-specific security operational programs to meet the requirements in 10 CFR 50.34(c)(2) or 10 CFR 52.79(a)(35)(i) and 10 CFR 52.79(a)(36)(i), (ii), and (iii). This is satisfied, in part, by describing a physical protection system and administrative programs and procedures for implementing a site-specific protective strategy that demonstrates high assurance that the plant is protected against the DBT. The site-specific physical protection system must be reliable and available and must implement defense-in-depth to provide a high assurance of protection. The following specific and performance requirements describe the security operational programs and the physical protection system: 10 CFR Part 26, "Fitness for duty programs"; 10 CFR 73.55; 10 CFR 73.56, "Personnel access authorization requirements for nuclear power plants"; 10 CFR 73.57, "Requirements for criminal history records checks of individuals granted unescorted access to a nuclear power facility or access to Safeguards Information"; 10 CFR 73.70; 10 CFR 73.58, "Safety/security interface requirements for nuclear power reactors"; and 10 CFR Part 74. Regulations in 10 CFR 52.79(a)(36)(i) or 10 CFR 50.34(d) and Appendix C to 10 CFR Part 73 require COL applicants to submit the security program and planning for a safeguards contingency. The performance and specific requirements in Appendix B to 10 CFR Part 73 requires COL applicants to submit a training and qualification plan and implement the training and qualification requirements for readiness of security personnel and responders.

Within this context, the DC applicant must address those elements or portions of physical protection systems that are considered within the scope of the design. However, the DC applicant may include descriptions of security systems or hardware, with supporting technical bases that are beyond the physical configuration for the scope of the design, provided that it is clearly stated that they are within the scope of the DC.

The staff used NUREG-0800 Section 14.3.12, "Physical Security Hardware - Inspections, Tests, Analyses, and Acceptance Criteria," to review the applicant's ITAAC submittal. Section 13.6.3.1 of this SER documents the staff's evaluation of these DCD changes.

13.6.2.1 Regulatory Basis - ITAAC

The NRC regulation for protecting nuclear power reactors is provided in 10 CFR Part 73. The regulation includes specific security and performance requirements that, when adequately implemented, are designed to protect nuclear power reactors against acts of radiological sabotage, prevent the theft or diversion of special nuclear material, and protect safeguards information against unauthorized release.

The performance requirements for the physical protection of nuclear power reactors are provided in 10 CFR 73.1(a)(1), which bounds the adversarial characteristics of the DBT, and 10 CFR 73.55. Pursuant to 10 CFR 50.34(c)(2), 10 CFR 50.34(d), 10 CFR 50.54(p)(1), "Conditions of licenses," and 10 CFR 50.54(p)(2), 10 CFR 73.55(c)(4), and as referenced in 10 CFR Part 52, applicants are required to prepare and maintain security plans that describe the security-related actions that they will take to protect their facilities against acts of radiological sabotage.

10 CFR 52.47(b)(1) requires a DC applicant to contain the proposed ITAAC that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria are met, a plant that incorporates the DC is built and will operate in accordance with the DC.

Regulatory requirements and acceptance criteria related to physical protection systems or hardware are, in part, applicable to the DC (i.e., within scope of the design) or may only be applicable to a COL applicant (outside of a DC design scope) and are identified as follows, as specified in NUREG-0800 Section 14.3.12, "Physical Security Hardware – Inspections, Tests, Analyses, and Acceptance Criteria" Revision 1, January 2010.

The COL applicant is required to describe commitments for establishing and maintaining a physical protection system (engineered and administrative controls), organization, programs, and procedures for implementing a site-specific strategy that, if adequately implemented, provides a high assurance of protection of the plant against the DBT. The site-specific physical protection system described must be reliable and available and implement the concept of defense-in-depth protection in order to provide a high assurance of protection. The security operational programs and the physical protection system are required to meet specific and performance requirements of 10 CFR Part 26; 10 CFR Part 74; 10 CFR 73.55; 10 CFR 73.56; 10 CFR 73.57; and 10 CFR 73.70. The COL applicant's security program and planning for safeguards contingency are required to meet 10 CFR 50.34(d) and 10 CFR Part 73, Appendix C. The training and qualification program for readiness of security personnel and responders are required to meet performance and specific requirements of 10 CFR Part 73, Appendix B. Within this context, the DC applicant must address those elements or portion of physical protection systems or features that are considered within the scope of the certified portion of the design. The technical basis for physical protection hardware within the scope of the certified portion of the design provides the basis for ITAAC verification and closures. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves the list of ITAAC numbers. Therefore, all ITAAC numbers are consistent with NUREG-0800 Section 14.3.12.

13.6.3 Evaluation – Physical Security

The staff reviewed AP1000 DCD Tier 1, Revision 19, Section 2.6.9 and Table 2.6.9-1; and DCD Tier 2, Revision 19, Section 13.6, applicant RAI responses, and referenced safeguards TRs.

In its review of the referenced safeguards TRs, the staff identified areas in which it needed additional information to complete the review of the applicant's physical security design. The applicant responded to the staff's RAIs as discussed below.

The staff reviewed the applicant's submittals to determine if its consideration of physical security in the AP1000 design was acceptable.

The staff identified several RAIs relating to target sets for the purpose of reviewing the applicant's physical protection program. The applicant provided design details as background information to assist a licensee with the development of site-specific target sets analyses. The staff evaluated the applicant's responses, and found them to be acceptable for the DC review of the AP1000 physical protection program. The applicant stated in TR-94 that target sets were created to aid in the development of the AP1000 physical security system, and that final target sets will be developed by the COL applicant. Upon the completion of its review, the staff determined that the applicant adequately addressed regulations and the NUREG-0800 acceptance criteria that were identified as within the scope of their design.

Combined License Information Items

The staff reviewed the AP1000 description and commitment for the COL information item that COL applicants referencing the AP1000 certified design must address.

Acceptance Criteria

Pursuant to 10 CFR 52.47(b)(1), a DC applicant is required to submit the proposed ITAAC that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria met, a facility that incorporates the DC will be built and operated in accordance with the DC, the provisions of the Act, and the NRC's regulations.

In addition to ITAAC, the staff also reviewed the following information that was submitted by an applicant for the physical security design. The following information was provided by an applicant to meet the acceptance criteria identified in Section 13.6.2, "Regulatory Basis," for the physical security DC.

As required by 10 CFR 73.55(e)(9)(i), a DC applicant shall identify vital areas and a list of vital equipment, by location.

As required by 10 CFR 73.55(e)(9)(v) and (vi), a DC applicant shall identify the control room as a vital area and secondary power supply (for alarm annunciator equipment and nonportable communications) as within a vital area.

As required by 10 CFR 73.55(e)(9)(iii), a DC applicant shall provide the design of the locks and alarms of all unoccupied vital areas.

As required by 10 CFR 73.55(e)(5), a DC applicant shall provide the design describing the bullet resistance of the control room and the CAS.

As required by 10 CFR 73.55(g)(1)(i)(B), a DC applicant should identify locks used to protect the facility and special nuclear material as manipulative resistant.

<u>Evaluation of COL Information</u>

The staff evaluated the COL information item identified in its review of the AP1000 DC application and included in DCD Tier 2, Revision 19, Section 13.6.1. COL information items and applicant responses are those physical security requirements from the above six acceptance criteria that are either met partially or are not addressed by the DC applicant. The staff's evaluation determines whether the DC applicant adequately describes those physical security requirements so that a COL applicant would be able to address them during the COL licensing process. The DC applicant need not identify as COL information items those physical security elements required by regulation. However, for physical security elements partially met in the DC application, the DC applicant should explicitly identify which part of the requirement was met and which part the COL applicant referencing the design will be required to meet.

In the COL information item in DCD Section 13.6.1, the applicant states: Combined License applicants referencing the AP1000 certified design will address site-specific information related to the physical security, contingency, and training and qualification plans.

On the basis of the staff review, the COL information item appropriately addresses interface requirements between the referenced AP1000 physical protection system design and the COL applicant.

13.6.3.1 Evaluation – ITAAC

The applicant submitted the following ITAAC for detection and assessment hardware in Revision 17 of the AP1000 DCD Tier 1, Section 2.6.9, "Plant Security System," which addresses ITAAC consistent with NUREG-0800 Section 14.3.12. The numbering system below corresponds to the applicable elements of NUREG-0800 Section 14.3.12.

2. Physical barriers for the PA perimeter are not part of vital area barriers.

3. Isolation zones exist in outdoor areas adjacent to the physical barrier at the perimeter of the PA that allows 20 feet of observation on either side of the barrier. Where permanent buildings do not allow a 20-foot observation distance on the inside of the PA, the building walls are immediately adjacent to, or an integral part of, the PA barrier.

4. An intrusion detection system can detect penetration or attempted penetration of the PA barrier.

5. Isolation zones and exterior areas within the PA are provided with illumination to permit observation of abnormal presence or activity of persons or vehicles.

6. The external walls, doors, ceiling, and floors in the main control room, the CAS, and the last access control function for access to the PA are bullet resistant.

9. An access control system with numbered picture badges is installed for use by individuals who are authorized access to PAs without escort.

10. Vital areas are locked and alarmed with active intrusion detection systems that annunciate in the CAS and SAS upon intrusion into a vital area.

11. Security alarm annunciation occurs in the CAS and in at least one other continuously manned station not necessarily onsite.

14. Equipment exists to record onsite security alarm annunciation, including the location of the alarm, false alarm, alarm check, and tamper indication; and the type of alarm, location, alarm circuit, date, and time.

After the review of the ITAAC for detection and assessment hardware, the staff determined that the applicant submitted ITAAC within the DCD that are not within the scope of the DC, and that should be submitted as part of a COL application. In order to complete its review, in RAI-SRP14.3.12-NSIR-06, the staff requested that the applicant revise the physical security hardware ITAAC in Tier 1 of the DCD consistent with NUREG-0800 Section 14.3.12.

In its response to RAI-SRP14.3.12-NSIR-06, the applicant proposed to revise DCD Tier 1, Section 2.6.9 to delete any items that are outside the scope of the certified design. The applicant removed ITAAC Items 3, 4, and 9, which will be submitted by COL applicants. The applicant also removed ITAAC Item 2, as the PA barrier will be addressed by the COL applicant in an ITAAC that will be provided for the site-specific design elements of plant security. In addition, the applicant also revised Item 6.

As a result of changes to regulations for "Power Reactor Security Requirements," effective May 26, 2009, in RAI-SRP14.3.12-NSIR-07, the staff requested that the applicant submit revised AP1000 ITAAC that conform to the 10 CFR Part 73 Power Reactor Security Requirements Final Rule.

In its response to RAI-SRP14.3.12-NSIR-07, dated October 15, 2009, the applicant revised the AP1000 physical security hardware ITAAC to be consistent with the Power Reactor Security Requirements Final Rule of May 26, 2009. ITAAC Item 6 was revised to include the SAS. The applicant also revised ITAAC Item 11 to Item 11(a) and included the addition of video assessment capability and the SAS. In addition, the applicant added ITAAC Items 11(b) and 11(c) as follows:

11(b) The central and secondary alarm stations are located inside a protected area, and the interior of both alarm stations is not visible from the perimeter of the protected area.

11(c) The central and secondary alarm stations are designed and equipped such that, in the event of a single act, in accordance with the design basis threat of radiological sabotage, the design enables the survivability of equipment needed to maintain the functional capability of either alarm station to assess alarms and communicate with onsite and offsite response personnel.

Based on discussions at an RAI closed meeting on November 24, 2009 between the applicant and the staff, the applicant submitted revised AP1000 physical security hardware ITAAC in its Revision 1 response to RAI-SRP14.3.12-NSIR-07, dated December 16, 2009. The applicant revised ITAAC Item 6 to add the minimum bullet resistance for the Main Control Room, CAS, and SAS. In addition, the applicant revised ITAAC Item 11(a) to add that alarm annunciation and video assessment is displayed concurrently, and that video recording with real time playback capability can provide assessment of activities before and after each alarm. This revision of ITAAC Item 11(a) also reads on video image recording in ITAAC Item 4(b).

On the basis of its review, the staff finds the revised ITAAC for detection and assessment hardware to be acceptable because it is in conformance with the staff's definition of physical security hardware ITAAC that is within the scope of the DC, and the ITAAC are sufficient to verify that the hardware, as finally installed and constructed, will function as designed.

The applicant submitted the following ITAAC for delay or barrier design features in Revision 17 of the AP1000 DCD Tier 1, Section 2.69, "Plant Security System," which addresses ITAAC consistent with NUREG-0800 Section 14.3.12:

1.
    a) Vital equipment is located only within a vital area.
    b) Access to vital equipment requires passage through at least two physical barriers.

7. The vehicle barrier system is installed and located at the necessary stand-off distance to protect against the DBT vehicle bombs.

8. Access control points are established to:
    a) Control vehicle and personnel access into the PA.
    b) Detect firearms, explosives, and incendiary devices at the PA personnel access points.

13. Security alarm devices including transmission lines to annunciators are tamper-indicating and self-checking (e.g., an automatic indication is provided when failure of the alarm system or a component occurs, or when on standby power). Alarm annunciation shall indicate the type of alarm (e.g., intrusion alarms and emergency exit alarm) and location.

As a result of its review of the ITAAC for delay or barrier design features, the staff determined that the applicant submitted ITAAC within the AP1000 DCD that are not within the scope of the DC and that should be submitted as part of a COL application. In order to complete its review, in RAI-SRP14.3.12-NSIR-06, the staff requested that the applicant revise the physical security hardware ITAAC in Tier 1 of the DCD in accordance with NUREG-0800 Section 14.3.12.

In its response to RAI-SRP14.3.12-NSIR-06, the applicant proposed to revise the AP1000 DCD Tier 1, Section 2.6.9 by deleting ITAAC Items 8(a) and 8(b). The applicant indicated that ITAAC Items 8(a) and 8(b), access control points, would be submitted by the COL applicants.

As noted above, as a result of changes to regulations for "Power Reactor Security Requirements," effective May 26, 2009, in RAI-SRP14.3.12-NSIR-07, the staff requested that the applicant submit revised AP1000 ITAAC that conform to the 10 CFR Part 73 Power Reactor Security Requirements Final Rule.

In its response to RAI-SRP14.3.12-NSIR-07, the applicant revised the AP1000 physical security hardware ITAAC to be consistent with the Power Reactor Security Requirements Final Rule of May 26, 2009. The applicant revised ITAAC Item 13 to Item 13(a) and added ITAAC Item 13(b) to include the requirement for intrusion detection and assessment systems to provide visual display and audible annunciation of the alarm in both the CAS and SAS.

Based on discussions at an RAI closed meeting on November 24, 2009 between the applicant and the staff, the applicant submitted revised AP1000 physical security hardware ITAAC in its Revision 1 response to RAI-SRP14.3.12-NSIR-07. The applicant revised ITAAC Item 1(b) to state “Access to vital equipment requires passage through the vital area barrier.” Because the applicant considered the PA barrier outside of the design scope, it indicated that the requirement in 10 CFR 73.55(e)(9)(i) for two physical barriers would be the responsibility of COL applicants. The applicant added ITAAC Item 13(b) as follows:

> 13(b) Intrusion detection and assessment systems provide visual displays and audible annunciation of alarms in the central and secondary alarm station.

On the basis of its review, the staff finds the revised ITAAC for delay or barrier design features to be acceptable, because it is in conformance with the staff’s definition of physical security hardware ITAAC that is within the scope of the DC, and sufficient to verify that the hardware, as finally installed and constructed, will function as designed.

The applicant submitted the following ITAAC systems, hardware, or features facilitating security response and neutralization in Revision 17 to the AP1000 DCD Tier 1, Section 2.6.9, “Plant Security System,” which addresses ITAAC consistent with NUREG-0800 Section 14.3.12:

12. Secondary security power supply system for alarm annunciator equipment and non-portable communications equipment is located within a vital area.

15. Emergency exits through the PA perimeter and the vital area boundaries are alarmed.

16. The CAS and SAS:

    a) have conventional (landline) telephone service and other communication capabilities with local law enforcement authorities, and

    b) are capable of continuous communications with security personnel.

As a result of its review of the ITAAC systems, hardware, and changes to regulations for "Power Reactor Security Requirements,” effective May 26, 2009, the staff determined that the applicant submitted ITAAC within the AP1000 DCD that are not within the scope of the DC and that should be submitted as part of a COL application. In order to complete its review, in RAI-SRP14.3.12-NSIR-07, the staff requested that the applicant submit revised AP1000 ITAAC that address the 10 CFR Part 73 Power Reactor Security Requirements Final Rule.

In its original and Revision 1 responses to RAI-SRP14.3.12-NSIR-07, the applicant revised ITAAC Item 15 to include the requirement for emergency exits through the vital area boundaries to be equipped with a crash bar to allow for emergency egress.

The applicant also removed reference to emergency egress through the PA perimeter in ITAAC Item 15. As the applicant considers the PA barrier outside the design scope, it will be the responsibility of the COL applicant to complete the requirement in 10 CFR 73.55(e)(8)(iii) for emergency exits through the PA perimeter.

The applicant revised ITAAC Item 16(a) to include communication with the main control room, removed the phrase “other communication capabilities,” and added ITAAC Item 16(c) to include the requirement for continued operability of non-portable communications equipment in the CAS and SAS in the event of the loss of normal power, by independent power sources.

On the basis of its review, the staff finds the revised ITAAC for systems, hardware, and features to be acceptable, because it is in conformance with the staff’s definition of physical security hardware ITAAC that is within the scope of the DC, and sufficient to verify that the hardware, as finally installed and constructed, will function as designed.

The staff identified in its review of the proposed changes to the physical security hardware ITAAC in AP1000 DCD Tier 1 and Tier 2 as described below:

1. The external walls, doors, ceiling, and floors in the main control room, the CAS, and the SAS are bullet-resistant to at least Underwriters Laboratory Ballistic Standard 752, level 4.

3. Secondary security power supply system for alarm annunciator equipment and non-portable communications equipment is located within a vital area.

4. Vital areas are locked and alarmed with active intrusion detection systems that annunciate in the CAS and SAS upon intrusion into a vital area.

5.
   a) Security alarm annunciation and video assessment information is displayed concurrently in the CAS and the SAS, and the video image recording with real time playback capability can provide assessment of activities before and after each alarm annunciation within the perimeter barrier.

   b) The CAS and SAS are located inside the PA, and the interior of each alarm station is not visible from the perimeter of the PA.

   c) The CAS and SAS are designed and equipped such that, in the event of a single act, in accordance with the DBT of radiological sabotage, the design enables the survivability of equipment needed to maintain the functional capability of either alarm station to detect and assess alarms and communicate with onsite and offsite response personnel.

6. The vehicle barrier system is installed and located at the necessary stand-off distance to protect against the DBT vehicle bombs.

7.
   a) Vital equipment is located only within a vital area.
   b) Access to vital equipment requires passage through the vital area barrier.

8. Isolation zones and exterior areas within the PA area are provided with illumination to permit observation of abnormal presence or activity of persons or vehicles.

9. Emergency exits through the vital area boundaries are locked, alarmed and equipped with a crash bar to allow for emergency egress.

13.
   a) The CAS and SAS have conventional (landline) telephone service with the main control room and local law enforcement authorities.

   b) The CAS and SAS are capable of continuous communication with security personnel.

   c) Non-portable communication equipment in the CAS and SAS remains operable from an independent power source in the event of loss of normal power.

15.
   a) Security alarm devices including transmission lines to annunciators are tamper-indicating and self-checking (e.g., an automatic indication is provided when failure of the alarm system or a component occurs, or when on standby power). Alarm annunciation shall indicate the type of alarm (e.g., intrusion alarms and emergency exit alarm) and location.

   b) Intrusion detection and assessment systems concurrently provide visual displays and audible annunciation of alarms in the CAS and SAS.

16. Equipment exists to record onsite security alarm annunciation, including the location of the alarm, false alarm, alarm check, and tamper indication; and the type of alarm, location, alarm circuit, date, and time.

In DCD Tier 1, Revision 19, Table 2.6.9-1, Table 3.3-6, and Tier 2, Section 13.6, "Security," the applicant made appropriate changes that reflect the changes identified in RAI-SRP14.3.12-NSIR-07, Revision 1.

The staff concludes that the applicant has adequately described the Tier 1 physical security hardware ITAAC to be incorporated as part of the standard design. The applicant adequately described the plant layout and protection of vital equipment in accordance with the requirements of 10 CFR 73.55 and provided the technical bases for establishing a physical protection system for the protection against acts of radiological sabotage. The applicant has adequately described requirements specific to design for alarm annunciation records in accordance with 10 CFR 73.70(f). The applicant has provided adequate descriptions of objectives, prerequisites, test methods, data required, and acceptance criteria for security-related ITAAC for the certification the AP1000 design. Therefore, the staff concludes that the AP1000 ITAAC within the scope of NUREG-0800 Section 14.3.12 are necessary and sufficient to assure that with respect to these ITAAC, if the inspections, tests, analyses are performed and the acceptance criteria met, a facility referencing the certified AP1000 design has been constructed and will be operated in compliance with the DC and applicable regulations.

ITAAC Combined License Information Items

The staff reviewed the applicant's descriptions and commitments for COL action items for physical security hardware ITAAC that must be addressed by a COL applicant referencing the certified design.

In response to discussions with the staff at an RAI closed meeting on November 24, 2009, the applicant, in its Revision 1 response to RAI-SRP14.3.12-NSIR-07, proposed to include a COL action item in the next revision of the AP1000 DCD, Tier 2, Section 13.6.1, for the COL applicant to address the physical security hardware ITAAC listed above. The staff finds this to be acceptable and in conformance with the physical security hardware ITAAC requirements to protect against the DBT of radiological sabotage as stated in 10 CFR 73.1(a).

Based on its review of AP1000 DCD Tier 2, Section 13.6.2, the staff determined that the applicant has submitted an appropriate COL action item for physical security hardware ITAAC. The ITAAC that the applicant identified as the responsibility of the COL applicant meet the requirements of 10 CFR 52.47(b)(1) for a COL holder referencing the AP1000 design to build and operate in accordance with the DC, the provisions in the Atomic Energy Act and NRC regulations.

13.6.4 Conclusion

The staff finds that the applicant considered and provided descriptions of physical security systems or features in the standard AP1000 design to provide or facilitate the implementation of a physical protection system to protect against acts of radiological sabotage. The details of this information are provided in the SGI SER for the AP1000, which is stored in the automated database of the NRC's Secure Local Area Network Electronic Safe. The applicant adequately described the plant layout for physical protection and identifying vital equipment and areas, in accordance with the requirements of 10 CFR 73.55. The staff evaluated the technical bases and assumptions related to ITAAC for physical security hardware and found them to be adequate.

The applicant identified the generic issues in the following documents as being outside the scope of the AP1000 design: Generic letter (GL) 89-007, "Power Reactors Safeguards Contingency Planning for Surface Vehicle Bombs," dated April 28, 1989; GL 91-010, "Explosives Searches at Protected Area Portals," dated August 27, 1991; and GL 91-003, "Reporting of Safeguards Events," dated March 6, 1991. The staff has identified the generic issues in the above documents as outside the scope of the design and finds the applicant's approach acceptable. The staff's review of the design found that the applicant addressed Task Action Plan Item A-29, "Nuclear Power Plant Design for the Reduction of Vulnerability to Industrial Sabotage," in an acceptable method.

The staff finds that the applicant has provided reasonable assurance that the standard AP1000 design, if implemented correctly, will ensure adequate protection against acts of radiological sabotage. The applicant has provided sufficient physical security design information to support the issuance of an amendment to the AP1000 DC.

The staff reviewed AP1000 DCD, Tier 1, Section 2.6.9 and Tier 2, Section 13.6 and the applicant's responses to RAIs issued on Tier 1 and Tier 2 material, performed in accordance with NUREG-0800 Section 13.6.2, and NUREG-0800 Section 14.3.12 Revision 1 of January 2010. Based on its review, the staff determined that the applicant's selection criteria and methodology for the development of Tier 1 information are acceptable, that the implementation of this selection criteria and methodology is appropriate, and that the resultant ITAAC are adequate for verification that a facility referencing the AP1000 design has been constructed and will be operated in compliance with the DC and applicable regulations.

The staff finds that the applicant has adequately described the objectives, prerequisites, test methods, data required, and acceptance criteria for physical security hardware ITAAC for the certification of the AP1000 design.

14. VERIFICATION PROGRAMS

14.2 Initial Plant Test Program

14.2.9 Preoperational Test Abstracts

14.2.9.1 Introduction

Westinghouse (the applicant) has proposed significant changes to the following items in the AP1000 design control document (DCD) related to preoperational testing: (1) squib valves associated with passive core cooling (DCD Section 14.2.9.1.3); (2) control rod drive system (CRDS) (DCD Section 14.2.9.8); and (3) main alternating current (ac) power testing (DCD Section 14.2.9.2.15).

14.2.9.2 Evaluation

The Nuclear Regulatory Commission (NRC) staff sent the applicant a request for additional information (RAI) regarding the passive core cooling system test description in Section 14.2.9.1.3 of the AP1000 DCD. The NRC staff noted in RAI-SRP14.2-CQVP-10, that under the "General Test Methods and Acceptance Criteria," Item (t), the applicant described the testing of the squib valves as they relate to verification of the passive core cooling system safety injection function. The applicant stated that this test does not have to be performed in the plant. The applicant added this last sentence to the test abstract as part of Revision 16 of the AP1000 DCD. In the RAI, the staff requested that the applicant provide justification for this change. In its July 11, 2008, response to this RAI, the applicant stated that the last sentence of this section was added as an editorial change to clarify that this testing could be done without causing the risk of an actual safety injection into the core. Additionally, the applicant stated that the reliability of these valves could be verified without the valves actually being tested in the operating passive core cooling system.

The staff reviewed the applicant's response to this RAI and determined that this change does not affect the test of the squib valves consistent with regulatory guide (RG) 1.68, "Initial Test Programs for Water-Cooled Nuclear Power Plants," Revision 3, and the performance of these valves could be adequately verified through qualification testing. On this basis, the staff concludes that the passive core cooling system test adequately addresses proper operation of the squib valves and verifies adequate safety injection, and is, therefore, acceptable. This resolves RAI-SRP14.2-CQVP-10.

In RAI-SRP14.2-CQVP-9, the staff requested additional information regarding the CRDS test description in Section 14.2.9.1.8 of the AP1000 DCD, Revision 16. The staff noted that Section 14.2.9.1.8 of the AP1000 DCD, Revision 16, CRDS, stated that, as a prerequisite for the control rod drive mechanism cooling test, "the plant is at or near normal operating temperature and pressure, and <u>post-core</u> hot functional testing is in progress." The staff noted that the applicant added the word "post-core" to the test abstract as part of Revision 16 of the AP1000 DCD and asked that the applicant justify this change. In its July 11, 2008, response to this RAI, the applicant stated that the addition of the word "post-core" to modify the hot functional testing of the control rod drive mechanism was an editorial change to clarify the fact that this test can only occur after the core is loaded. The staff reviewed the applicant's response to this RAI and determined that this change clarifies the prerequisites of this test, does not affect the test abstract for the CRDS, and is consistent with the test recommended in

RG 1.68. Therefore, the staff finds this change to be acceptable. This resolves RAI-SRP14.2-CQVP-9.

In test abstract 14.2.9.2.15, "Main AC Power System Testing," the staff noted that the applicant included additional verification activities under "General Methods and Acceptance Criteria" for the bus transfer schemes as part of the test activities associated with the main ac power system. The applicant modified this test abstract to ensure that appropriate testing of the bus transfer schemes occurs during the preoperational phase of the initial test program. Section 8.3.1 of the AP1000 DCD provides details regarding the ac power system and the function of the bus transfer schemes.

The staff reviewed the applicant's proposed change to test abstract 14.2.9.2.15 and determined that this change provides a means to verify proper operation of the automatic and maintenance bus transfer schemes, does not affect the test of the main ac power system, and is consistent with the guidance in RG 1.68. On this basis, the staff concluded that the change is acceptable.

The staff notes that the applicant introduced several other changes to the preoperational test abstracts in Revision 17 of the AP1000 DCD. Upon review, the staff found that these changes were consistent with plant design changes and equipment naming conventions and have no significant impact on preoperational testing. Therefore, these changes are acceptable.

14.2.9.3 Conclusion

The staff reviewed the proposed changes to the preoperational test program described in Section 14.2.9 of the AP1000 DCD. Title 10 of the *Code of Federal Regulations* (10 CFR) Part 50, "Domestic licensing of production and utilization facilities," Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants," Section XI, "Test Control," requires that the applicant establish a test program which will ensure that all of the testing required to demonstrate that structures, systems, and components (SSCs) will perform satisfactorily in service, and will be performed in accordance with written test procedures which incorporate the requirements and acceptance limits in applicable design documents. On the basis of this review, the staff concludes that the proposed changes satisfy the requirements of Appendix B to 10 CFR Part 50, Section XI.

14.3 Tier 1 Information

14.3.2 Inspection, Test, Analysis, and Acceptance Criteria (ITAAC)

A number of changes to ITAAC were proposed in revisions to the AP1000 DCD. The staff's evaluations of the proposed changes to ITAAC (which are Tier 1 information) appear in those safety evaluation report (SER) sections where the subject SSCs are discussed. For example, with regard to changes in AP1000 DCD Tier 1, Table 2.1.1-1 concerning the fuel handling machine, these changes are evaluated in Section 9.1 of this report.

14.3.3 Design Acceptance Criteria (DAC)

Changes to design acceptance criteria (DAC) were proposed in Revisions 16 and 17 of the AP1000 DCD. The staff's evaluations of the proposed changes to DAC (which are Tier 1 information) appear in those SER sections where the subject SSCs are discussed. For example, the Tier 1 information found in AP1000 DCD Tier 1, Section 2.5.2, "Protection and Safety Monitoring Systems," Item 11, addresses the hardware and software development process for the design, testing and installation of instrumentation and control (I&C) equipment. Changes to this Tier 1 information are evaluated in Section 7.2 of this report.

14.3.5 Changes to Tier 1 Information

This section addresses the proposed changes to the AP1000 DCD Tier 1 information in the application for amendment to the design certification (DC), as supplemented. Tier 1 information includes the following:

- definitions and general provisions
- design descriptions
- ITAAC
- significant site parameters
- significant interface requirements

The Tier 1 information is derived from the AP1000 DCD Tier 2 information. This SER evaluates the proposed changes to the Tier 1 information in those SER sections in which the associated changes to the Tier 2 information are located, except as described below.

14.3.5.1 Evaluation

Section 1.1 of the AP1000 DCD Tier 1 provides the current definition of “as-built” as follows:

> As-built means the physical properties of a structure, system, or component (SSC) following the completion of its installation or construction activities at its final location at the plant site.

This definition will be used in implementing the ITAAC verification process. This definition intends that the determination of whether an SSC meets the acceptance criteria in the respective ITAAC be performed at its final, in-place location. This approach meets the intent of the ITAAC requirement in 10 CFR 52.97(b), “Issuance of combined licenses.”

In a letter dated June 13, 2008, the applicant submitted AP1000 DCD Impact Document APP-GW-GLE-007, Revision 0, “ITAAC Changes.” One of the proposed changes to the ITAAC would change the definition of “as-built.” The proposed change would add the following sentence to the definition of “as-built”:

> Determination of physical properties of the as-built structure, system, or component may be based on measurements, inspections, or tests that occur prior to installation provided that subsequent fabrication, handling, installation, and testing does not alter the properties.

This proposed change to the definition of “as-built” concerned the staff because the AP1000 ITAAC were developed with the expectation that verifications would be performed in the final, in-place location of the SSC. Also, the shipping, storage, handling, and installation performed after vendor fabrication and prior to the final, in-place location can damage an SSC. The staff raised these concerns during discussions with representatives of the Nuclear Energy Institute (NEI).

On August 1, 2008, NEI submitted NEI 08-01, Revision 0, “Industry Guidelines for ITAAC Closure Process under 10 CFR Part 52,” a draft of which was the basis for the proposed change to the definition of “as-built” in APP-GW-GLE-007, Revision 0. Section 3.1.4 of NEI 08-01 includes the following statement to clarify the definition of “as-built”:

> Many ITAAC require verification of “as-built” SSCs. However, some of these ITAAC will involve measurements and/or testing that can only be conducted at the vendor site due to the configuration of equipment or modules or the nature of the test (e.g., measurements of reactor vessel internals). For these specific items where access to the component for inspection or test is impractical after installation in the plant, the ITAAC closure documentation (e.g., test or inspection record) will be generated at the vendor site and provided to the licensee.

The staff understands that it may be impossible to perform some ITAAC verifications of an SSC in its final, in-place location. Therefore, the staff agrees with the NEI proposal to modify the definition of “as-built” with the clarification provided by the above statement and additional documentation demonstrating that subsequent fabrication, handling, installation, and testing did not alter the properties of the SSC.

In RAI-SRP14.3-NWE2-01, the staff requested that the applicant incorporate the above clarification into the AP1000 definition of “as-built” since it significantly restricts the completion of ITAAC at a vendor’s site. In its response to RAI-SRP14.3-NWE2-01, dated September 9, 2008, the applicant declined to incorporate the subject clarification into the definition of “as-built.” In a December 9, 2008, revised response to RAI-SRP14.3-NWE2-01, the applicant proposed to incorporate the subject clarification in Tier 2. The staff’s position is that this approach would provide too much latitude in application of the subject clarification and that the clarification should be incorporated into the definition itself in Tier 1 of the AP1000 DCD. This was identified as Open Item OI-SRP14.3-NWE2-01.

The industry and the NRC subsequently agreed to augment the NEI 08-01 definition of “as-built” to match the definition agreed to between the NRC and the industry at the December 17, 2009, Category 3 public meeting on ITAAC maintenance. The following definition is considered acceptable:

> **As-built** means the physical properties of a structure, system, or component following completion of its installation or construction activities at its final location at the plant site. In cases where it is technically justifiable, determination of physical properties of the as-built structure, system, or component may be based on measurements, inspections, or tests that occur prior to installation, provided that subsequent fabrication, handling, installation, and testing do not alter the properties.

In its February 19, 2010, response to RAI-SRP14.3-NWE2-01, the applicant adopted the above definition for use in Section 1.1 of Tier 1 of the AP1000 DCD. In addition, in the February 19, 2010, response the applicant indicated that, as the result of an extensive review of the ITAAC in Revision 17 of the AP1000 DCD, to ensure that those ITAAC utilizing the definition of the term “as-built” will be implemented consistent with the new definition, a number of changes to the ITAAC would be necessary. The staff has reviewed the proposed changes to the ITAAC that use the definition of “as-built” and concludes that these changes do not adversely affect inspectability or any technical aspect of the ITAAC and that these changes are acceptable.

The staff confirmed that Revision 19 to the AP1000 DCD contains the acceptable definition of “as-built” and associated ITAAC changes.

14.3.5.2 Conclusion

The proposed change to the DCD, to include the definition of “as-built” and associated changes to the ITAAC, are acceptable.

14.3.6 Design Acceptance Criteria/ITAAC Closure Process

In an April 1, 2010, Revision 1 response to Open Item OI-SRP3.12-EMB-4, the applicant proposed to include Appendix 14.3A in Tier 2, Chapter 14 of the AP1000 DCD as generic guidance for the resolution of DAC in the DCD. In a proposed Tier 2 Appendix 14.3A, the applicant discussed the options for resolving DAC following certification of the design: (1) through amendment of the DC rule; (2) through the combined operating license (COL) application review process; or (3) through ITAAC after COL issuance. For example, for the piping DAC, the applicant proposed that a COL information item be included in the DCD to resolve the piping design outside of the DC amendment. Closure of piping DAC is further discussed in Section 3.12 of this report.

The standard approach outlined above is voluntary on the part of each licensee referencing the standard AP1000 design. The process envisions an NRC review, inspection, or audit of the DAC completion that applies the “one issue, one review, one position” concept as discussed in RG 1.206, “Combined License Applications for Nuclear Power Plants.” Section C.III.5, to DAC resolution for the reference (first) AP1000 plant and to subsequent AP1000 plants. A COL applicant can apply this standard approach to each of the AP1000 design areas that include DAC (i.e., piping design, digital I&C design, and HFE design). When DAC applies, the process indicates the COL applicant is to provide ITAAC and closure schedule indicating the approach to be followed for the site. The staff finds that this standard approach is consistent with the NRC policy for a design-centered-review approach and the regulations and is, therefore, acceptable.

The staff confirmed that Revision 19 to the AP1000 DCD includes the acceptable standard approach.

14.4 Combined License Applicant Responsibilities

14.4.1 Test Specifications and Procedures

14.4.1.1 Introduction

In a letter dated September 22, 2006, and as supplemented in a letter dated May 11, 2007, the applicant submitted technical report (TR)-71A, APP-GW-GLR-037, “AP1000 Test Specifications and Procedures,” for NRC review and approval. The applicant requested resolution of COL Information Item 14.4-2 based on the information provided in TR-71A. Section 14.4 of the AP1000 DCD lists this COL information item and assigns the COL applicant the responsibility of providing test specifications and test procedures for preoperational and startup tests to the NRC for review and approval.

14.4.1.2 Evaluation

In Section 14.4.3 of the AP1000 DCD, Revision 15, the applicant assigned the responsibility for the development of preoperational and startup test specifications and procedures to the COL applicant. Specifically, COL Information Item 14.4-2 states the following:

> The COL applicant is responsible for providing test specifications and test procedures for the preoperational and startup tests, as identified in Section 14.2.3, for review by the NRC.

As part of Revision 16 to the AP1000 DCD, the applicant submitted TR-71A to address COL Information Item 14.4-2. TR-71A outlines the process to be used by the applicant to develop test specifications and draft procedures and provides a list of test specifications and test procedures to be provided in draft form by the applicant to the prospective COL holder.

TR-71A documents the development process for the preparation of 88 preoperational system test specifications and 59 startup test specifications, to be followed by 289 preoperational test procedures and 59 startup test procedures. However, TR-71A does not include the actual test specifications and test procedures for NRC review and approval.

The staff determined that COL Information Item 14.4-2 calls for the actual submittal of test specifications and test procedures by a COL holder to the NRC onsite inspectors for review and approval before as-built systems and plant features are tested in the field. Furthermore, the NRC inspection staff will need to review the actual test specifications and test procedures for components and systems to be tested to verify their acceptability before COL Information Item 14.4-2 can be categorized as resolved. Accordingly, resolution of COL Information Item 14.4-2 will be subject to the NRC's construction inspection program to allow for the necessary plant as-built inspections and walkdowns. On this basis, the staff concludes that COL Information Item 14.4-2 will remain open pending submittal of the required information by the COL holder.

The staff notes that Section 14.4.2 of Revision 17 of the AP1000 DCD includes the following statement:

> The Combined License information requested in this subsection has been partially addressed in APP-GW-GLR-037 (Reference 1), and the applicable changes incorporated into the DCD. Test specifications have been developed as indicated in Reference 1 and are available for NRC onsite review at Westinghouse's offices.

The above noted statement is inconsistent with the staff's conclusion; it should be deleted from the AP1000 DCD, and COL Information Item 14.4-2 should be modified to refer the responsibility for the information item to the COL holder. This was designated as Open Item OI-SRP14.2-CQVP-12.

In its September 30, 2009 response to Open Item OI-SRP14.2-CQVP-12, the applicant stated that it would remove reference to TR-71A in a revised version of the AP1000 DCD. The applicant also proposed to remove any references to TR-71A and to restore the text that would make the COL applicant responsible for providing the necessary information. The applicant included the proposed language to modify COL Information Item 14.4-2 in Enclosure 1 of the September 30, 2009 letter. The response to Open Item OI-SRP14.2-CQVP-12 is acceptable.

The staff confirmed that a subsequent revision to the AP1000 DCD includes the correct COL information item.

14.4.1.3 Conclusion

The staff reviewed the information submitted by the applicant in TR-71A to resolve COL Information Item 14.4-2 in Section 14.4 of the AP1000 DCD, Revision 16. On the basis of this review, the staff concludes that COL Information Item 14.4-2 cannot be resolved until after the issuance of the COL. Therefore, COL Information Item 14.4-2 will reflect that required information is to be provided by the COL holder.

14.4.2 Conduct of Test Program

14.4.2.1 Introduction

In a letter dated September 26, 2006, and as supplemented by letters dated May 24, 2007, and June 19, 2008, the applicant submitted TR-71B, APP-GW-GLR-038, "AP1000 Conduct of Test Program," for NRC review and approval. The applicant requested that COL Information Item 14.4-3 be resolved based on the information provided in TR-71B. Section 14.4.3 of the AP1000 DCD lists this COL information item as follows:

> The Combined License applicant is responsible for a startup administration manual (procedure), which contains the administrative procedures and requirements that govern the activities associated with the plant initial test program, as identified in subsection 14.2.3.

14.4.2.2 Evaluation

In Section 14.2.3.1 of the AP1000 DCD, Revision 15, the applicant provided a set of administrative requirements for the conduct of the initial test program. In addition, Section 14.4 of the AP1000 DCD, Revision 15, summarized the COL applicant responsibilities associated with the development of a startup administrative manual (SAM). COL Information Item 14.4-3 required applicants referencing the AP1000 DCD to provide administrative controls for the conduct of the initial test program in the form of a SAM.

As part of Revision 16 of the AP1000 DCD, the applicant submitted TR-71B to resolve COL Information Item 14.4-3. In reviewing TR-71B, the staff noted that the applicant provided a summary overview of the administrative process and program controls to be utilized in the conduct of the AP1000 startup test program at a licensed AP1000 operational plant site.

The staff also noted that TR-71B outlined basic functional relationships, responsibilities, activities, authority, and principles of conduct for the Joint Test Working Group and other organizational groups. Additionally, TR-71B presented a general and informative description of responsibilities and activities related to the testing of power plant equipment in the period between system turnover and plant acceptance.

On the basis of its review of TR-71B, the staff identified several areas that required additional information as presented in RAI-SRP14.2-CQVP-01 through RAI-SRP14.2-CQVP-08 and RAI-SRP14.2-CQVP-11. To this end, the staff requested that the applicant enhance the proposed program description and amplify the administrative requirements in TR-71B consistent with the guidance in RG 1.68 and Section 14.2, "Initial Plant Test Program—Design Certification and New License Applicants," of NUREG-0800, "Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants." Specifically, the staff requested that the applicant provide not only a list of activities that will be controlled during the conduct of the initial test program, but also a description of how these activities will be implemented and controlled. The staff also requested that the applicant justify the use of references to other documents in TR-71B that were not currently under review by the staff. In addition, the staff provided the applicant a set of administrative controls that needed to be described as part of the development of the AP1000 SAM.

In its June 19, 2008, response, the applicant provided Revision 2 of TR-71B. The staff reviewed Revision 2 of TR-71B and noted that the applicant had revised the organizational structure in charge of the initial test program and enhanced the description of the administrative controls for the startup testing phase of the initial test program. The applicant also provided partial responses to some of the RAIs and, in certain areas, did not provide a response at all. The applicant stated in its response letter that Revision 2 of TR-71B incorporated the responses to the RAIs and that the initial test program was developed in conformance with RG 1.68, Revision 2, issued August 1978, and Section 14.2 of NUREG-0800, Revision 2, issued July 1981, which is the certified design regulatory basis.

Because COL applicants are incorporating TR-71B by reference in their applications, the staff determined that the applicant's responses created a conflict between the information provided by the applicant and that required to be submitted by COL applicants. In addition, the staff determined that COL Information Item 14.4-3 calls for the actual submittal of a SAM describing the methods and practices that would govern the initial test program at AP1000 sites. This SAM should provide controls for the conduct of the initial test program consistent with the general criteria in RG 1.68, Revision 3, and Section 14.2 of NUREG-0800, Revision 3. On this basis, the staff determined that the existing content and structure of TR-71B does not meet the guidance applicable to COL applicants.

Since the applicant has not provided the necessary information consistent with COL Information Item 14.4-3, the staff concludes that COL Information Item 14.4-3 will remain open in the AP1000 DCD pending submittal of the required information by COL applicants referencing the AP1000 design.

The NRC staff notes that Section 14.4.3 of Revision 17 of the AP1000 DCD includes the following statement:

> The Combined License information requested in this subsection is partially addressed in APP-GW-GLR-038, (Reference 2), and the applicable changes are incorporated into the DCD.
>
> The program management description for the process to develop the AP1000 Startup Administrative Manual is delineated in APP-GW-GLR-038, (Reference 2).

The above-noted statement is inconsistent with the NRC staff's conclusions; it should be deleted from the DCD, and COL Information Item 14.4-3 should be restored to the original COL information item commitment noted in Section 14.4.3 of Revision 15 of the AP1000 DCD. This was identified as Open Item OI-SRP14.2-CQVP-13.

In its September 30, 2009 response to Open Item OI-SRP14.2-CQVP-13, the applicant stated that it would remove reference to TR-71B in a revised version of the AP1000 DCD. The applicant also proposed to remove any references to TR-71B and to restore the text that would make the COL holder responsible for providing the necessary information. The applicant included the proposed language to modify COL Information Item 14.4-3 in Enclosure 1 of the September 30, 2009 letter. The response to Open Item OI-SRP14.2-CQVP-13 is acceptable. The staff confirmed that a subsequent revision to the AP1000 DCD contains the correct COL information item.

14.4.2.3 Conclusion

On the basis of its review of TR-71B, the staff concludes that it lacks the elements that are necessary for a SAM. Furthermore, it is inconsistent with the guidance provided in RG 1.68, Revision 3, and Section 14.2, Revision 3, of NUREG-0800. Therefore, COL Information Item 14.4-3 will remain a responsibility of the COL applicant.

14.4.3 First-Plant-Only and Three-Plant-Only Tests

14.4.3.1 Introduction

In a letter dated June 5, 2006, the applicant submitted TR-6, "AP1000 As-Built COL Information Items," for NRC review and approval. TR-6 identified COL information items that required as-built information or conditions to be completed.

In its request, the applicant proposed a change to COL Information Item 14.4-6, "First-Plant-Only and Three-Plant-Only Tests," in order to clarify that the test requirements apply to a COL holder rather than a COL applicant.

14.4.3.2 Evaluation

COL Information Item 14.4-6 is associated with tests that must be completed only on the first plant or the first three plants. For COL Information Item 14.4-6, the following revision was underlined in TR-6:

> [The COL applicant or holder for the first plant and the first three plants will perform the tests listed in subsection 14.2.5. For subsequent plants, the COL applicant or licensee shall either perform the tests listed in subsection 14.2.5 or shall provide a justification that the results of the first-plant-only tests or first-three-plant tests are applicable to subsequent plants.]*
>
> The Combined License holder will perform the tests or provide the information defined above prior to fuel load.

The staff concluded that a COL holder can only perform these tests after the plant is essentially complete. The staff found this change to COL Information Item 14.4-6 acceptable for five preoperational tests of the nine tests described in AP1000 DCD Section 14.2.5, "Utilization of Reactor Operating and Testing Experience in the Development of Test Program." However, the staff also found that the following tests described in DCD Section 14.2.5 are performed after initial fuel load and during the low-power and power ascension test phase:

- Section 14.2.10.3.6, "Natural Circulation"
- Section 14.2.10.3.7, "Passive Residual Heat Removal Heat Exchanger"

- Section 14.2.10.4.6, “Rod Cluster Control Assembly Out-of-Bank Measurements”
- Section 14.2.10.4.22, “Load Follow Demonstration”

On the basis of this finding, the staff requested that the applicant revise COL Information Item 14.4-6 to state that the COL holder will perform these tests after initial fuel load and during the low-power and power ascension test phase of the initial test program.

In its February 1, 2007, letter, the applicant revised TR-6 and COL Information Item 14.4-6 to read as follows:

> The Combined License holder(s) for the first AP1000 plant (or first three plants) available for testing will perform the tests defined during the preoperational and startup testing as identified in Subsections 14.2.9 and 14.2.10. Combined License holders referencing the results of the tests will provide the report as necessary. The schedule for providing this information will be provided prior to preoperational testing.

The change proposed by the applicant clarifies the COL holder’s responsibility, in contrast to the previous assignment of responsibility to either the COL applicant or holder, for performing first-plant-only or three-plant-only tests or providing suitable justification for not performing these tests before the start of preoperational testing.

On this basis, the staff determined that this revision to COL Information Item 14.4-6 is acceptable.

14.4.3.3 Conclusion

The staff reviewed the information submitted by the applicant in TR-6 and concluded that the changes adequately clarified the timing of the testing of first-plant-only and three-plant-only tests. On the basis of this review, the staff concludes that the changes proposed by the applicant are acceptable.

15. TRANSIENT AND ACCIDENT ANALYSES

15.1 Introduction

In Chapter 15, "Accident Analyses," of the design control document (DCD), Westinghouse, (the applicant), described the safety analyses of various design-basis transients and accidents. The results of these analyses demonstrate conformance of the AP1000 design with the acceptance criteria. The acceptance criteria for the design-basis events are based on meeting the relevant requirements and general design criteria (GDC) specified in Appendix A, "General Design Criteria for Nuclear Power Plants," to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 50, "Domestic licensing of production and utilization facilities." The specific acceptance criteria for each event appear in NUREG-0800, "Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants," issued March 2007. The acceptance criteria include GDC 10, "Reactor Design," pertaining to the specified acceptable fuel design limits, and GDC 15, "Reactor Coolant System Design," pertaining to the design conditions of the reactor coolant pressure boundary (RCPB). These criteria ensure that these limits are not exceeded during any conditions of normal operation, including anticipated operational occurrences (AOOs). For postulated loss-of-coolant accidents (LOCAs), the applicant analyzed various break sizes and locations to show compliance with the emergency core cooling system (ECCS) performance acceptance criteria specified in 10 CFR 50.46, "Acceptance criteria for emergency core cooling systems for light-water nuclear power reactors."

Various sections and tables in Section 15.0 of the DCD describe the transient and accident events analyzed in Chapter 15 and the computer codes used and assumptions made in the safety analyses of these events. The assumptions relate to the design plant conditions, initial conditions, protection and safety monitoring system (PMS) setpoints and time delays to the reactor trip functions, the actuation of engineered safety features (ESFs), and the plant systems and components available for the mitigation of transients and accidents.

The proposed changes to the DCD include numerous changes to Section 15.0. The sections below describe the specific changes and their evaluation by the staff of the U.S. Nuclear Regulatory Commission (NRC).

15.1.0.3 Plant Characteristics and Initial Conditions Assumed in the Accident Analyses

15.1.0.3.1 Power Measurement Uncertainty

The initial conditions assumed in the existing Chapter 15 safety analyses include a ±2-percent allowance for the power calorimetric error. In DCD, Section 15.0.3.2, "Initial Conditions," Table 15.0-2, "Summary of Initial Conditions and Computer Codes Used (Sheets 1–5)" (Footnote a), and Table 15.0-5, "Determination of Maximum Power Range Neutron Flux Channel Trip Setpoint, Based on Nominal Setpoint and Inherent Typical Instrumentation Uncertainties," now include the following sentence:

> The main feedwater flow measurement supports a 1 percent power uncertainty; use of a 2 percent power uncertainty is conservative.

The applicant also changed the initial thermal power assumed for the large-break LOCA analysis in Table 15.0-2 from 3,468.0 megawatts thermal (MWt) to 3,434.0 MWt. Based on the

AP1000 rated thermal power of 3,400 MWt, the initial thermal power of 3,434 MWt represents a 1-percent allowance for the power calorimetric error.

15.1.0.3.1.1 Evaluation

The review guidance in NUREG-0800 Section 15.0 states that the reviewer ensures that the application specifies the permitted fluctuations and uncertainties with reactor system parameters and assumes the appropriate conditions, within the operating band, as the initial condition for transient analysis. For analyses of postulated LOCAs, Appendix K, "ECCS Evaluation Models," to 10 CFR Part 50 specifies that an assumed power level lower than 1.02 times the licensed power level may be used, provided the proposed alternative value has been demonstrated to account for uncertainties resulting from errors in power-level instrumentation.

The existing Chapter 15 safety analyses for all transients and accidents assume the rated thermal power with a calorimetric error of 2.0 percent as the initial condition. The DCD continues to assume the 2 percent power uncertainty for all events except for the large-break LOCA; for this event, it assumes the rated thermal power with a 1 percent power uncertainty as the initial condition. The AP1000 DCD does not describe the instrumentation or methodology used for the main feedwater flow measurement, nor does it provide a basis to support the claimed 1 percent power uncertainty.

In its response to request for additional information (RAI)-SRP-15.0-SRSB-02, the applicant stated that the AP1000 will use the proven application of high-accuracy ultrasonic feedwater flow measurement and high-accuracy feedwater temperature measurement to affect a high-accuracy plant calorimetric. AP1000 licensees will calculate the plant calorimetric uncertainty and verify that the actual plant instrumentation performance is bounded by the design value of 1 percent calorimetric uncertainty. For traceability, Section 15.0.15, "Combined License Information," will include the following combined license (COL) information item:

> 15.0.15.1 Following selection of the actual plant operating instrumentation and calculation of the instrumentation uncertainties of the operating plant parameters prior to fuel load, the Combined License holder will calculate the primary power calorimetric uncertainty. The calculations will be completed using an NRC acceptable method and confirm that the safety analysis primary power calorimetric uncertainty bounds the calculated values.

The applicant will also revise DCD Table 1.8-2, "Summary of AP1000 Standard Plant Combined License Information Items," to include COL Item 15.0-1, "Documentation of Plant Calorimetric Uncertainty Methodology," as an action item for the COL holder.

The staff notes that the NRC has approved high-accuracy ultrasonic feedwater measurement instrumentation that can achieve a 1 percent power measurement uncertainty, and this instrumentation has been used as a basis for power uprates for operating plants. The staff concludes that COL Information Item 15.0.15.1 and COL Item 15.0-1 provide acceptable vehicles for the COL license holder to confirm its selected instrumentation for the main feedwater measurement, with the power calorimetric measurement uncertainty bounded by the 1 percent power uncertainty assumed in the large-break LOCA analysis.

In a subsequent revision to the AP1000 DCD, the applicant incorporated COL Information Item 15.0.15.1 in DCD Section 15.0.15 and COL Item 15.0-1 in Table 1.8-2.

15.1.0.3.1.2 Conclusion

Based on the above evaluation, the staff finds that COL Item 15.0-1 and COL Information Item 15.0.15.1 provide acceptable vehicles to confirm the 1-percent power uncertainty assumed in the large-break LOCA analysis. The uncertainty pertaining to the initial condition of the power level is, therefore, properly addressed, consistent with NUREG-0800 Section 15.0 and Appendix K to 10 CFR 50.46 regarding LOCAs. Therefore, the staff concludes that the above proposed changes are acceptable

15.1.0.3.2 Axial Power Shape

Section 15.0.3.3, "Power Distribution," in Revision 15 of the DCD states that the axial power shape used in the departure from nucleate boiling (DNB) calculation is the 1.55 chopped cosine, as discussed in Section 4.4 for transients analyzed at full power. In Revision 17 of the DCD, the applicant changed "the 1.55 chopped cosine" to "a chopped cosine."

15.1.0.3.2.1 Evaluation

Section 4.4.4.3.2, "Axial Heat Flux Distributions," of the DCD states that the reference axial shape used in establishing core DNB limits (that is, overtemperature ΔT protection system setpoints) is a chopped cosine with a peak-to-average value of 1.61. The staff finds that the applicant made the proposed change in Section 15.0.3.3 of the DCD to eliminate the specific mention of the 1.55 chopped cosine in order to correct the inconsistency with the value given in Section 4.4.4.3.2 of the DCD. The staff concludes that the proposed change is acceptable because the Chapter 15 safety analyses for the transients were performed with the axial power shape described in DCD Section 4.4.4.3.2.

15.1.0.3.2.2 Conclusion

The staff has reviewed the proposed change in Section 15.0.3.3 of the DCD to eliminate the specific value of 1.55 for the chopped cosine axial power shape. Based on the above evaluation, the staff concludes that this proposed change is acceptable because the applicant made it in order to correct an inconsistency with the value specified in DCD Section 4.4.4.3.2, which was referenced in DCD Section 15.0.3.3.

15.1.0.6 Protection and Safety Monitoring System Setpoints and Time Delays to Trip Assumed in Accident Analyses

15.1.0.6.1 Change of "High-1" to "High-2" Containment Pressure for "S" Signal or Engineered Safety Feature Actuation

Revision 17 of the DCD changes Table 15.0-4a, "Protection and Safety Monitoring System Setpoints and Time Delay," from having the "S" signal trip function on high-1 containment pressure to its functioning on high-2 containment pressure. In addition, in Table 15.0-6, "Plant Systems and Equipment Available for Transient and Accident Conditions (Sheet 1 of 5)," the applicant changed the ESF actuation function credited for the steam system piping failure, feedwater system pipe break, and LOCA events from high-1 containment pressure to high-2 containment pressure.

15.1.0.6.1.1 Evaluation

The applicant made the change from “high-1” to “high-2” containment pressure in DCD Tables 15.0-4a and 15.0-6 for the “S” signal trip function and the ESF actuation function credited in the safety analyses, respectively, in order to be consistent with Technical Specification (TS) Table 3.3.2-1, “Engineered Safeguards Actuation System Instrumentation,” which indicates that the safeguard actuation function 1.b is “containment pressure—high 2.” Although the applicant changed the term “high-1 containment pressure” to “high-2 containment pressure,” the value of the setpoint assumed in the safety analyses is not changed, and therefore the safety analyses are not affected. Since this is merely a change in terminology for consistency, the staff concludes that this change is acceptable.

15.1.0.6.1.2 Conclusion

Under 10 CFR 50.36, “Technical specifications,” the plant TS must specify the limiting safety system settings of automatic protective devices. TS Table 3.3.2-1 for the AP1000 specifies the “Containment Pressure—High 2” trip setpoint for the safeguard actuation function. The staff finds the proposed change from “high-1” to “high-2” containment pressure in DCD Tables 15.0-4a and 15.0-6 to be acceptable because the applicant has made it in order to be consistent with the terminology used in the AP1000 TS, without changing the setpoint value or safety analyses.

15.1.0.6.2 Changes to Pressurizer Water Level Setpoints

In DCD Table 15.0-4a, the applicant changed the limiting setpoint for actuation of passive residual heat removal (PRHR) on the high-3 pressurizer water level from 80 percent of span to 76 percent of span. It also changed the chemical and volume control system (CVS) isolation on the high-2 pressurizer water level from 67 percent of span to 63 percent of span, and the CVS isolation on the high-1 pressurizer water level coincident with “S” signal from 30 percent of span to 28 percent of span.

15.1.0.6.2.1 Evaluation

The applicant changed the high-3, high-2, and high-1 pressurizer water level setpoints because of a design change in pressurizer dimensions. As described in technical report (TR)-36, APP-GW-GLR-016, Revision 0, “AP1000 Standard Combined License Technical Report, AP1000 Pressurizer Design,” the applicant has changed the AP1000 pressurizer dimensions to accommodate the space constraint. This dimensional change reduces the height and increases the diameter of the pressurizer but maintains the same overall pressurizer volume. Therefore, in DCD Table 15.0-4a, the setpoints assumed in the safety analyses for the high-3, high-2, and high-1 pressurizer water levels change from 80 percent, 67 percent, and 30 percent to 76 percent, 63 percent, and 28 percent, respectively, to maintain the same water volumes of the corresponding setpoints. The applicant also revised the high pressurizer water level setpoints in TS Tables 3.3.1-1 and 3.3.2-1, respectively, to be consistent with the revised assumed measurement instrumentation uncertainties accounted for in the safety analysis.

In its response to RAI-TR36-012, the applicant reanalyzed Chapter 15 limiting events using the changed dimension and the revised setpoints. The results show no or minimal effects on the Chapter 15 events, and the applicable acceptance criteria for each event continue to be met. Therefore, the staff concludes that these changes are acceptable.

15.1.0.6.2.2 Conclusions

Based on the above evaluation, the staff finds that the applicant has made the proposed changes to the high-3, high-2, and high-1 pressurizer water level setpoints in DCD Table 15.0-4a and in TS Tables 3.3.1-1 and 3.3.2-1 to accommodate the pressurizer dimension change without changing the corresponding water volume. The staff concludes that these changes are acceptable because the applicant's reanalyses of the Chapter 15 limiting events using the revised dimension and setpoints show no more than minimal effects, and the applicable acceptance criteria for each event analyzed continue to be met.

15.1.0.6.3 Change to the Limiting Setpoint of the Boron Dilution Block on the Source Range Flux Doubling Function

In DCD Table 15.0-4a, the applicant changed the limiting setpoint of the boron dilution block on the source range flux multiplication (doubling) function from "1.6 over 50 minutes" to "3.0 over 50 minutes."

15.1.0.6.3.1 Evaluation

The safety analyses of the boron dilution events during shutdown operation credit the boron dilution block on the source range flux multiplication function (DCD Section 15.4.6, "Chemical Volume and Control System Malfunction that Results in a Decrease in the Boron Concentration in the Reactor Coolant"). In DCD Table 15.0-4a, the applicant changed the terminology for the boron dilution block from "source range flux multiplication" to "source range flux doubling." In Section II.9, "Flux Doubling/Boron Dilution Modifications," of TR-80, APP-GW-GLR-080, "Mark-up of AP1000 Design Control Document Chapter 7," Revision 0, the applicant discussed the change for the setpoint of the source range flux doubling signal for the boron dilution block. The source range flux doubling signal is used for protection against boron dilution events during shutdown operation. If the source range neutron flux were to increase and exceed the setpoint because of a decrease in boron concentration in the reactor coolant, the boron dilution protection functions would be actuated. The applicant stated that an analysis of the source range flux doubling setpoints indicates that there is a significant likelihood that the setpoints could lead to inadvertent actuation of the boron dilution protection actions when the plant is shut down and the flux doubling function is active, even in the absence of actual changes in core neutron multiplication. This occurs because of the variability inherent in counting a discrete random process such as the leakage of neutrons from the reactor core, especially at relatively low count rates. Therefore, Revision 16 of the DCD changed the nominal setpoint from 1.6 over 50 minutes to 2.2 over 50 minutes to reduce the likelihood of inadvertent actuation of the boron dilution protection functions during normal operation.

DCD Section 15.4.6 provides the safety analyses of boron dilution events resulting from CVS malfunction during various modes of operation. The analyses for dilution during cold shutdown (Mode 5), safe shutdown (Mode 4), hot standby (Mode 3), and startup (Mode 2) take credit for the source range flux doubling signal with the increased setpoint that isolates the makeup flow to the reactor coolant system (RCS) from the demineralized water storage tank. The results indicate that automatic protective actions initiate to minimize the approach to criticality and maintain the plant in a subcritical condition.

In Revision 17 of the DCD, TS Table 3.3.2-1, the trip setpoint for function 15.a also specifies the source range flux doubling setpoint of 2.2 over 50 minutes for ESF actuation system function 15, boron dilution block. The staff questioned the value used in the safety analysis with the consideration of instrumentation uncertainties. In its response to RAI-SRP15.0-SRSB-01, the applicant stated that the safety analysis cases reported in DCD Section 15.4.6 support a setpoint of 3.0 over 50 minutes to mitigate the boron dilution event in Modes 3, 4, and 5. It further stated that DCD Table 15.0-4a should also report this value of 3.0 as the setpoint assumed in the safety analysis. The applicant has incorporated this change in DCD, Table 15.0-4a. In its response to RAI-SRP15.4.6-SRSB-02, the applicant stated that the boron dilution analyses performed for Modes 3, 4, and 5 documented in Revision 17 of the DCD, Section 15.4.6, assumed a safety analysis setpoint for the boron dilution protection system of 3.0 over 50 minutes with acceptable results (i.e., the automatic protective actions terminate the boron dilution event and maintain the plant in a subcritical condition). Therefore, the staff concludes that the change in Table 15.0-4a of the DCD, of the limiting setpoint of the boron dilution block on source range flux doubling to 3.0 over 50 minutes, is consistent with the assumption in the safety analysis and, therefore, is acceptable.

Regarding the TS nominal setpoint of 2.2 over 50 minutes, the applicant stated that it has estimated the major factors that contribute to the measurement uncertainty of the boron dilution algorithm. To ensure that the neutron count integrals are as large as possible, the design features include placing the source range neutron detectors outside the reactor vessel along the cardinal axes of the reactor core with the highest neutron leakage, and increasing the counting interval from 60 seconds to 120 seconds in the algorithm. The applicant presumes that the 36 percent difference between the value assumed in the accident analysis and the setpoint selected will bound the value determined when final plant design inputs are available. The staff notes that in DCD Tier 1, Section 2.5.2, "Protection and Safety Monitoring System," Table 2.5.2-8, "Inspections, Tests, Analyses and Acceptance Criteria," design commitment item 10 specifies that the PMS setpoints are determined using a methodology that accounts for loop inaccuracies, response testing, and maintenance or replacement instrumentation. If the measurement uncertainty after the final instrumentation installation is not bounded by the 36-percent allowance, the nominal setpoint would be revised accordingly. Therefore, the staff concludes that there is adequate assurance that the nominal setpoint specified in the TS is consistent with the safety analysis setpoint and the measurement uncertainty.

15.1.0.6.3.2 Conclusion

Based on the above evaluation, the staff concludes that the proposed change of the source range flux doubling setpoint from "1.6 over 50 minutes" to "3.0 over 50 minutes," in DCD Table 15.0-4a is acceptable because this change is consistent with the assumption made in the safety analysis of the boron dilution events with acceptable results.

15.1.0.6.4 Deletion of P-8 Interlock and Replacement with P-10

In Revision 17 of the DCD, the applicant deleted the "High neutron flux, P-8" reactor trip interlock from Table 15.0-4a, and in Table 15.0-6 it changed the permissive interlock for the power range high flux, low-flow trip function credited for the "startup of an inactive reactor coolant pump at incorrect temperature" event from P-8 to P-10.

15.1.0.6.4.1 Evaluation

The power range nuclear power P-8 interlock permits a reactor trip on low flow or reactor coolant pump (RCP) high bearing water temperature in a single loop. In TR-80, the applicant provided the rationale for the deletion of the high neutron flux P-8 interlock from the PMS. As stated in TR-80, Section II.7, "Low Reactor Coolant Flow Reactor Trip Logic Modifications," the

AP1000 is not licensed for N-1 operation and, therefore, the design of the PMS is not required to account for this requirement. The applicant also deleted the P-8 interlock from DCD Table 7.2-3, "Reactor Trip Permissives and Interlocks," and TS Table 3.3.1-1, trip function 10, reactor coolant flow—low, and function 11, RCP bearing water temperature—high. Therefore, the deletion of P-8 from DCD Table 15.0.4a is consistent with the reactor trip logic and TS. The staff concludes that the deletion of the P-8 interlock from DCD Tables 15.04a and 7.2-3 and TS Table 3.3.1-1 is acceptable because the P-8 interlock is not needed for the AP1000 design.

In Revision 15 of the DCD, one of the reactor trip functions used for the "startup of an inactive reactor coolant pump at an incorrect temperature" event is the low-flow trip with P-8 interlock. In Revision 17, the applicant changed the P-8 interlock credited for this event to the P-10 interlock. As discussed above, the applicant deleted the P-8 interlock because the AP1000 is not licensed for N-1 loop operation. The power range nuclear power P-10 interlock, which has a lower setpoint than the P-8 interlock (10 percent and 48 percent power for P-10 and P-8, respectively), performs the same function of allowing reactor trip on low coolant flow or RCP high bearing water temperature in multiple loops that the P-8 interlock performs for single loop. Since the P-10 interlock has lower setpoint than the P-8 interlock, the replacement of the P-8 with the P-10 interlock is conservative because it would permit the reactor to be tripped at a lower power for this event. The staff also requested that the applicant confirm that safety analyses of transient events that take credit for the P-8 interlock have been reanalyzed with the P-10 interlock. The staff agrees with the applicant's response to RAI-SRP15.3.1-SRSB-01 that the replacement of the P-8 with the P-10 interlock will improve the results of the non-LOCA safety analysis, including for loss-of-flow events, at lower power since the reactor will now be tripped by a partial or completed loss of flow down to 10 percent power.

In DCD TS Table 3.3.1-1, the applicant replaced the P-8 interlock with the P-10 interlock for trip function 10, reactor coolant flow—low, and function 11, RCP bearing water temperature—high. The staff concludes that the change to DCD Table 15.0-6 to replace the P-8 interlock with the P-10 interlock is acceptable because it is consistent with the reactor trip logic and the TS.

15.1.0.6.4.2 Conclusion

The staff has reviewed the proposed changes to the DCD for the removal of the power range nuclear power reactor trip P-8 interlock and replacement with the P-10 interlock where applicable. The staff finds these changes conservative and acceptable because the P-10 interlock has a lower setpoint than the P-8 interlock, and the safety analyses of non-LOCA events credited with this interlock would continue to show compliance with GDC 10 and 15 without exceeding the specified acceptable fuel design limits and the RCS pressure boundary design limit.

15.1.0.6.5 Changes in Valve Opening Time Delay

In DCD Table 15.0-4a, the applicant changed the time delay for the automatic depressurization system (ADS) Stage 1 actuation on core makeup tank (CMT) low level signal from 20 seconds to 30 seconds for the control valve to begin to open. It also changed the ADS Stage 4 actuation on CMT low-low level signal from 30 seconds to 2 seconds for the squib valve to begin to open. In Table 15.0-4b, the applicant changed the closure time of the CVS makeup isolation valves from 10 to 30 seconds, and in Table 15.6.5-10, it also changed the control valve actuation and opening times for ADS Stages 1, 2, 3, and 4. It added a note to these tables, stating the following:

The valve stroke times reflect the design basis of the AP1000. The applicable DCD Chapter 15 accidents were evaluated for the design basis stroke times. The results of this evaluation have shown that there is a small impact on the analysis and the conclusions remains valid. The output provided for the analyses is representative of the transient phenomenon.

15.1.0.6.5.1 Evaluation

In RAI-SRP15.0-SRSB-04, the staff asked the applicant to clarify the relationship among the 2-second delay time of the ADS Stage 4 squib valves specified in Table 15.0-4a and the opening time delay sequences for Substage A and Substage B of ADS Stage 4 described in DCD Section 7.3.1.2.4, “Automatic Depressurization System Actuation,” and the ADS Stage 4 actuation time delay assumed in the safety analyses. In its response to RAI-SRP15.0-SRSB-04, the applicant provided the following explanation. In the small-break LOCA analysis in DCD Section 15.6.5.4B, ADS Stage 4 was actuated from the coincidence of CMT level less than the low-2 setpoint, low RCS pressure, and a preset time delay following an open signal initiation for the ADS Stage 3 depressurization valves. The 2-second time delay for ADS Stage 4 actuation on CMT low-2 level identified in Table 15.0-4a represents the accident analysis delay time assumed specifically for the squib valve to begin to open. The accident analysis assumes the 2-second signal processing delay after the CMT low-2 level is reached or the preset time delay after the ADS Stage 3 depressurization valve open signal is generated, whichever is later. This explanation clarifies that the ADS-4 opening time assumed in the safety analysis is for the ADS-4 Substage A depressurization valve opening time, and the Substage B depressurization valve will open after the Stage A valve with a delay time specified in DCD Table 15.6.5-10.

The applicant also identified in its response to RAI-SRP15.0-SRSB-04 the following inconsistencies in Revision 17 of the DCD, Chapters 7 and 15, which need to be revised:

- Section 7.3.1.2.4 states that ADS Stage 2 actuation is interlocked with ADS Stage 1, and ADS Stage 3 actuation is interlocked with ADS Stage 2. However, no such interlocks exist and, therefore, Section 7.3.1.2.4 requires revision.

- Table 15.0-4a indicates an ADS Stage 1 actuation on CMT low-level signal delay time of 30 seconds. This should be revised to 32 seconds, consistent with DCD Table 15.6.5-10, as it includes a 30-second programmable delay time with a 2-second signal proceeding delay.

- DCD Table 15.0.4b incorrectly lists Table 15.6.5-13 for the ADS valve opening times. The ADS valve opening times actually appear in Table 15.6.5-10.

- Table 15.6.5-10 should be modified to add two notes: (1) a description of the interlock of CMT low-2 level, as well as 128 seconds after the ADS Stage 3 actuation signal is generated for initiation of ADS-4 Substage A valves; and (2) that the valve opening time of ADS Stage 4 valves includes an “arm-fire” processing delay.

In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Because the PMS and equipment actuation delay times assumed in the safety analyses for various design-basis events may differ from the valve stroke time design-basis values listed in DCD Tables 15.0-4a, 15.0-4b, and 15.6.5-10, the staff asked the applicant to list the PMS and equipment with the delay times assumed in the Chapter 15 safety analyses that differ from the design-basis values specified in these tables and to evaluate the impact of the inconsistencies in delay time assumptions on the affected events. In its response to RAI-SRP15.0-SRSB-05, the applicant listed the PMS actuation functions and valves with different delay times. The list includes the ADS Stage 1 and Stage 4 actuations on CMT low level signals; the ADS Stage 1, 2, 3, and 4 control (depressurization) valves; and the CVS makeup isolation valves. The events analyzed with different delay times include boron dilution, inadvertent CVS actuation, loss of normal feedwater events analyzed with different CVS makeup isolation valve delay times, and the small-break LOCA and inadvertent operation of the ADS with different ADS valve opening time delays. The applicant evaluated the effects of the inconsistencies on the safety analyses of the affected events.

The design-basis stroke time for the CVS makeup isolation valves is 30 seconds, but the safety analyses for the inadvertent CVS actuation (DCD Section 15.5.2) and loss of normal feedwater (DCD Section 15.2.7) events assume a 12-second valve closure (which includes a 2-second microprocessor delay and 10-second closure time). Based on the CVS makeup flow rate assumed in the analysis, an additional 20 seconds in the makeup valve isolation time would increase the makeup flow into the RCS by about 0.425 cubic meters (m^3) (15 cubic feet (ft^3)). For these two events, there is sufficient available margin between the pressurizer volume and the maximum pressurizer water volume (see DCD Figures 15.5.2-5 and 15.2.7-6, respectively) to accommodate this water volume without changing the conclusion that the minimum DNB ratio remains above the design-limit value and the RCS pressure remains below 110 percent of the design value. For the boron dilution events, the applicant’s response to RAI-SRP9.3.6-SRSB-01 provides an evaluation. The longer makeup valve closure time results in no adverse effect for the boron dilution events occurring during Mode 1 and 2 operations because the purge volume of the CVS is not sufficient to return the reactor to criticality. For the events occurring during Mode 3, 4, and 5 operations, the safety analyses described in DCD Sections 15.4.6.2.2 through 15.4.6.2.4 assume a makeup valve closure time of 28 seconds, and there is sufficient margin to accommodate the 2-second delay in the valve closure time.

The only non-LOCA event affected by the ADS is an inadvertent operation of the two ADS Stage 1 trains event, since all other non-LOCA events do not model the ADS valves. The existing analysis described DCD Section 15.6.1 for the inadvertent operation of the ADS Stage 1 valve event assumed a 25-second stroke time, compared to the design-basis value of 40 seconds. As shown in DCD Figure 15.6.1-7, the minimum DNB ratio occurs around 22 seconds, which is before the ADS valves are fully open. Therefore, the longer valve stroke time has no effect on the analysis result and the existing analysis remains valid.

Since the primary role of the ADS is to mitigate a small-break LOCA, the staff asked the applicant to evaluate the effects of changes in the ADS valve stroke times on the small-break LOCA analysis. In response to RAI-SRP5.4.6-SRSB-01, the applicant evaluated the effects of the changes in the ADS Stage 1, 2, and 3 stroke times, as well as the ADS Stage 4 time delay change from 30 seconds to 2 seconds, on the small-break LOCA analysis described in DCD Section 15.6.5.4B, “Small-break LOCA Analyses.” The evaluation includes inadvertent ADS actuation, a 2-inch cold leg break, and a direct vessel injection (DVI) break. The results show minimal effects on the safety analysis and that the core remains covered in all cases; thus, the design continues to comply with the acceptance criteria for the ECCS specified in

10 CFR 50.46. Therefore, the staff concludes that the changes in the ADS valve actuation and stroke times specified in DCD Tables 15.0-4a and 15.6.5-10 are acceptable.

It should be noted that in Revision 17 of the DCD, Tier 1, Section 2.1.2, "Reactor Coolant System," and Section 2.3.2, "Chemical and Volume Control System," the applicant proposed to change the acceptance criteria for the opening times after receipt of a signal from the PMS of the remotely operated ADS Stage 1, 2, and 3 valves (RCS-V001A/B, RCS-V002A/B, and RCS-V003A/B) and the CVS makeup isolation valves (V090 and V091) specified in Tables 2.1.2-4 and 2.3.2-4, "Inspections, Tests, Analyses, and Acceptance Criteria," for the RCS and CVS, respectively. The staff finds that the revised values are acceptable because they are consistent with the values described in DCD Tier 2, Tables 15.0-4b and 15.6.5-10.

15.1.0.6.5.2 Conclusion

Based on the above evaluation, the staff concludes that the proposed changes in DCD Tables 15.0.4a, 15.0.4b, and 15.6.5-10, regarding the delay times of the ADS valves and CVS makeup isolation valves are acceptable because they produce insignificant changes in the results of the analyses for the affected design-basis events, and the acceptance criteria in GDC 10, GDC 15, and 10 CFR 50.46 continue to be met.

15.1.0.6.6 Changes Pertaining to Steam Generator Tube Rupture Analysis

In Revision 17 of the DCD, the applicant made the following changes to Table 15.0-4a:

- Change the high-2 steam generator limiting setpoint from 100 percent to 95 percent of the narrow range level span.

- Add an entry for CMT actuation on pressurizer low-2 water level with a time delay of 2.0 seconds.

15.1.0.6.6.1 Evaluation

In its response to RAI-SRP15.0-SRSB-06, the applicant confirmed that it made these changes to clarify the DCD documentation in areas identified during the AP1000 DCD review process. The changes do not represent new assumptions or results and are consistent with the assumptions credited in the existing Chapter 15 safety analyses. The change of the high-2 steam generator limiting setpoint from 100 percent to 95 percent of the narrow range level span is consistent with the steam generator tube rupture analysis provided in DCD Section 15.6.3. Other events used 100 percent of the narrow range level span, but the steam generator tube rupture analysis provides the limiting setpoint. The addition of the CMT actuation on pressurizer low-2 water level with a time delay of 2 seconds is also consistent with the steam generator tube rupture analysis, which credits this signal. The staff, therefore, concludes that these changes are acceptable.

15.1.0.6.6.2 Conclusion

Based on the above evaluation, the staff concludes that the proposed changes in DCD Table 15.0-4a pertaining to the steam generator low-2 setpoint and CMT actuation are acceptable because they are made merely for clarification of the DCD documentation and do not represent new assumptions in the steam generator tube rupture analysis.

15.1.0.8 Plant Systems and Components Available for the Mitigation of Accident Effects

15.1.0.8.1 Change to Chemical and Volume Control System Makeup Suction Isolation for Boron Dilution Mitigation

In DCD Table 15.0-6, “Plant Systems and Equipment Available for Transient and Accident Conditions,” the applicant changed the equipment credited for the “chemical and volume control system malfunction which results in a boron dilution” event from “low insertion limit annuciators” to “CVS to RCS isolation valves, makeup pump suction isolation valves, from the demineralized water transfer and storage system.”

15.1.0.8.1.1 Evaluation

For the event of boron dilution resulting from CVS malfunction, the AP1000 design takes credit for the source range flux doubling signal (as discussed in Section 15.1.0.6.3 above), which will automatically isolate the unborated water source for boron dilution protection. Revision 17 of the DCD changes the CVS makeup valve realignment for boron dilution protection. The applicant revised DCD Section 9.3.6.4.5.1, “Boron Dilution Events,” to state that the CVS is designed to address a boron dilution accident by closing redundant safety-related valves, tripping the makeup pumps, or aligning the suction of the makeup pumps to the boric acid tank, or all three. It revised Section 9.3.6.3.7, “Chemical Volume and Control System Valves,” to state that these normally open, motor-operated makeup line containment isolation valves close on a source range flux doubling signal to terminate possible unplanned boron dilution events. The applicant also revised Section 7.3.1.2.14, “Boron Dilution Block,” to state the following:

> In the event of an excessive increasing rate of source range flux doubling signal, the block of boron dilution is accomplished by closing the chemical and volume control system makeup isolation valves and closing the makeup pump suction valves to the demineralized water storage tanks. This signal also provides a non-safety trip of the makeup pumps. These actions terminate the supply of potentially unborated water to the reactor coolant system as quickly as possible.

Therefore, the staff finds that the change in Table 15.0-6 regarding the use of CVS makeup pump suction isolation valves for the mitigation of boron dilution is consistent with the CVS design. As discussed in Section 15.2.4.6 of this report regarding boron dilution events occurring during Mode 3, 4, and 5 operations, this design change would terminate the boron dilution event sooner and has no safety significant effect on the consequence of the boron dilution events. Therefore, the staff concludes that this change is acceptable.

15.1.0.8.1.2 Conclusion

Based on the above evaluation, the staff concludes that the change in DCD Table 15.0-6, regarding the change to close the makeup line isolation valves for the termination of boron dilution events is acceptable because it reflects the CVS design change, has no significant effect on the consequence of boron dilution events, and the applicable GDC continue to be met.

15.1.0.8.2 Other Changes for Clarification

In Revision 17 of the DCD, the applicant made the following changes to Tables 15.0-6 and 15.0-8:

- Add the main steam isolation valves (MSIVs), startup feedwater isolation, and accumulators credited for the analyses of the inadvertent opening of a steam generator safety valve and steam system pipe failure events (DCD Sections 15.1.4 and 15.1.5).

- Add the steam generator safety valves for the analysis of the inadvertent operation of the CMT during power operation (DCD Section 15.5.1).

- Add the low steamline pressure ESF actuation functions for the analysis of the CVS malfunction that increases reactor coolant inventory (DCD Section 15.5.2).

- Add the low pressurizer level ESF actuation function for the analysis of the steam generator tube rupture (DCD Section 15.6.3).

- Add an entry to specify that the sample line isolation valves are credited for the failure of small lines carrying primary coolant outside containment (DCD Section 15.6.2).

- Revise the footnote to Table 15.0-8 pertaining to the MSIV backup valves from stating “moisture separator reheat steam supply control valve” to “moisture separator reheater 2nd stage steam isolation valves.”

15.1.0.8.2.1 Evaluation

In its response to RAI-SRP15.0-SRSB-06, the applicant confirmed that it made these changes merely to clarify the DCD documentation in areas identified during the AP1000 DCD review process. The changes are made to be consistent with the assumptions credited in the corresponding DCD sections in existing Chapter 15 safety analyses, and they do not represent new assumptions or results.

15.1.0.8.2.2 Conclusion

The staff has reviewed the above changes in DCD Tables 15.0-6 and 15.0-8. The staff concludes that these changes are acceptable because they are made merely for clarification of the DCD documentation and do not represent new assumptions or affect the results in the existing Chapter 15 safety analyses.

15.1.0.12 Component Failures

In Revision 17 of the DCD, the applicant proposed to delete the following paragraph in Section 15.0.12.1, pertaining to operator action error:

> A single incorrect or omitted operator action in response to an initiating event is also considered as an active failure. The error is limited to manipulation of safety related equipment and does not include thought process errors that could potentially lead to common cause or multiple errors.

15.1.0.12.1 Evaluation

In Revision 2 of response to RAI-SRP15.0-SRSB-03 dated July 8, 2010, the applicant stated that while the Chapter 15 safety analyses do meet the intent of the statement in DCD Section 15.0.12.1, the statement was originally removed to prevent confusion about the operator action assumptions made for in the DCD safety analyses. There were no changes to the safety analysis assumptions as a result of the removal of this statement. Based on a review of the statement in DCD Section 15.0.12.1, it is determined that the deleted statement will be returned to the DCD, with the punctuation of the statement updated as follows:

> A single incorrect or omitted operator action in response to an initiating event is also considered as an active failure; the error is limited to manipulation of safety related equipment and does not include thought process errors that could potentially lead to common cause or multiple errors.

Therefore, except for the editorial change in the above statement, no change is made to the certified DCD Revision 15 pertaining to operator actions. The staff finds it acceptable.

15.1.0.12.2 Conclusion

As discussed above, the applicant has determined to retain the statement in the certified DCD Revision 15 pertaining to operator actions, except for an editorial change. This is acceptable. In a subsequent revision to the AP1000 DCD, the applicant incorporated this change in the DCD text, which resolves this issue.

15.2 Transients and Accident Analysis

15.2.2 Decrease in Heat Removal by the Secondary System (DCD Tier 2, Section 15.2)

15.2.2.6 Loss of Alternating Current Power to the Plant Auxiliaries (DCD Tier 2, Section 15.2.6)

In Revision 17 of the DCD, Section 15.2.6.2.1, "Method of Analysis," the applicant added the statement that "the main feedwater flow measurement supports a 1-percent power uncertainty; use of a 2-percent power uncertainty is conservative." In addition, it deleted the statement from the assumption used in the analysis that "conservative PRHR heat exchanger heat transfer coefficients (low) associated with the low flow rate caused by the reactor coolant pump trip are assumed."

15.2.2.6.1 Evaluation

The acceptance criteria for the design-basis events are based on meeting the relevant requirements and GDC specified in Appendix A to 10 CFR Part 50. The specific acceptance criteria for this event appear in NUREG-0800. These acceptance criteria include GDC 10 and GDC 15, which require that the specified acceptable fuel design limits and the design conditions of the RCPB, respectively, are not exceeded during any conditions of normal operation, including AOOs.

DCD Section 15.2.6, "Loss of Power to the Plant Auxiliaries," describes the analysis of the loss of power to the plant auxiliaries caused by a complete loss of offsite grid, accompanied by a turbine-generator trip. Section 15.2.2.6 of NUREG-1793, "Final Safety Evaluation Report

Related to Certification of the AP1000 Standard Design," described the staff's evaluation of this event for compliance with the relevant acceptance criteria. Therefore, the evaluation in this document is limited to the effects of the proposed changes on compliance with the relevant acceptance criteria.

As stated in Section 15.1.0.3.1 of this report, the confirmation of 1-percent power uncertainty will be performed through COL Item 15.0-1. However, the changes have no effect on the analysis of the loss of alternating current power to the plant auxiliaries because the analysis assumes 2-percent power uncertainty. In addition, the applicant deleted the conservative PRHR heat exchanger heat transfer coefficient to provide more accurate information consistent with the existing analysis of the event. The staff concludes that these changes have no effect on the existing analysis of the event, which continues to show compliance with the relevant acceptance criteria; therefore, the changes are acceptable.

15.2.2.6.2 Conclusion

Based on the above evaluation, the staff concludes that the revisions proposed by the applicant to the DCD, Section 15.2.6.2.1, do not represent new assumptions and have no effects on the existing safety analysis, and the design continues to comply with the relevant requirements of GDC 10 and GDC 15. Therefore, the staff concludes that the proposed DCD changes are acceptable.

15.2.2.7 Loss of Normal Feedwater Flow (DCD Tier 2, Section 15.2.7)

Revision 17 of the DCD added the following statement to Section 15.2.7.2.1, "Method of Analysis," regarding the assumptions used in the analysis: "The main feedwater flow measurement supports a 1 percent power uncertainty; use of a 2-percent power uncertainty is conservative." The applicant also made editorial changes to Table 15.2-1 to correct the time sequence of the loss of normal feedwater flow event; these changes have no effect on the analysis.

15.2.2.7.1 Evaluation

The acceptance criteria for the design-basis events are based on meeting the relevant requirements and GDC specified in Appendix A to 10 CFR Part 50. The specific acceptance criteria for this event appear in NUREG-0800. These acceptance criteria include GDC 10 and GDC 15, which require that the specified acceptable fuel design limits and the design conditions of the RCPB, respectively, are not exceeded during any conditions of normal operation, including AOOs.

DCD Section 15.2.7, "Loss of Normal Feedwater Flow," describes the analysis of the loss of normal feedwater flow. Section 15.2.2.7 of NUREG-1793 described the staff evaluation of this event for compliance with the relevant acceptance criteria. Therefore, the evaluation in this document is limited to the effects of the proposed changes on compliance with the relevant acceptance criteria.

As stated in Section 15.1.0.3.1 of this report, the confirmation of 1-percent power uncertainty will be performed through COL Item 15.0-1. However, the change has no effect on the analysis of the loss of normal feedwater flow because the analysis assumes 2 percent power uncertainty. Therefore, the staff concludes that this change is acceptable.

15.2.2.7.2 Conclusion

Based on the above evaluation, the staff finds that the revisions proposed by the applicant to the DCD, Section 15.2.7, do not represent new assumptions and have no effects on the existing safety analysis, and the design continues to comply with the relevant requirements of GDC 10 and GDC 15. Therefore, the staff concludes that the proposed DCD changes are acceptable.

15.2.2.8 Feedwater System Pipe Break (DCD Tier 2, Section 15.2.8)

Revision 17 of the DCD changes Section 15.2.8.1, "Identification of Causes and Accident Description," to include the high-3 pressurizer water level as a condition for a reactor trip. The applicant also added the statement, "Method of Analysis," that "the main feedwater flow measurement supports a 1 percent power uncertainty; use of a 2 percent power uncertainty is conservative," to Section 15.2.8.2.1.

15.2.2.8.1 Evaluation

The acceptance criteria for the design-basis events are based on meeting the relevant requirements and GDC specified in Appendix A to 10 CFR Part 50. The specific acceptance criteria for this event appear in NUREG-0800. These acceptance criteria include GDC 10 and GDC 15, which require that the specified acceptable fuel design limits and the design conditions of the RCPB, respectively, are not exceeded during any conditions of normal operation, including AOOs.

DCD Section 15.2.8, "Feedwater System Pipe Break," describes the analysis of feedwater system pipe break. Section 15.2.2.8 of NUREG-1793 described the staff evaluation of this event for compliance with the relevant acceptance criteria. Therefore, the evaluation in this document is limited to the effects of the proposed changes on compliance with the relevant acceptance criteria.

In its response to RAI-SRP15.0-SRSB-06, the applicant stated that it added the high-3 pressurizer water level as a reactor trip actuation condition in order to provide more accurate information in the DCD to be consistent with the existing safety analysis assumption. The staff finds the change acceptable since it does not represent a new assumption and has no effect on the analysis result.

As stated in Section 15.1.0.3.1 of this report, the confirmation of 1 percent power uncertainty will be performed through COL Item 15.0-1. However, the change has no effect on the analysis of the feedwater system pipe break because the analysis assumes 2 percent power uncertainty. Therefore, the staff concludes that this change is acceptable.

15.2.2.8.2 Conclusion

Based on the above evaluation, the staff finds that the revisions proposed by the applicant to the DCD, Section 15.2.8, do not represent new assumptions and have no effect on the existing safety analysis, and the design continues to comply with the relevant requirements of GDC 10 and GDC 15. Therefore, the staff concludes that the proposed DCD changes are acceptable.

15.2.3 Decrease in Reactor Coolant System Flow Rate (DCD Tier 2, Section 15.3)

15.2.3.1 Partial Loss of Forced Reactor Coolant Flow (DCD Tier 2, Section 15.3.1)

In DCD, Section 15.3.1, the applicant proposed to change the power range nuclear power reactor trip permissive from the P-8 interlock to the P-10 interlock for protection against the partial loss of forced reactor coolant flow event.

15.2.3.1.1 Evaluation

The acceptance criteria for the design-basis events are based on meeting the relevant requirements and GDC specified in Appendix A to 10 CFR Part 50. The specific acceptance criteria for this event appear in NUREG-0800. These acceptance criteria include GDC 10 and GDC 15, which require that the specified acceptable fuel design limits and the design conditions of the RCPB, respectively, are not exceeded during any conditions of normal operation, including AOOs.

DCD Section 15.3.1 describes the safety analysis of the partial loss of forced reactor coolant flow event. Section 15.2.3.1 of NUREG-1793 described the staff evaluation of this event. Therefore, the evaluation in this document addresses the staff evaluation of the proposed change described in Revision 17 of the DCD.

DCD Section 15.3.1.1, “Identification of Causes and Accident Description,” describes the cause and progression of the partial loss of forced reactor coolant flow event (i.e., trip of one RCP). The low primary coolant flow reactor trip signal provides protection against this event. Revision 15 of the DCD stated that above permissive P8, low flow in either hot leg actuates a reactor trip, and between approximately 10 percent power (permissive P10) and the power level corresponding to P8, low flow in both hot legs actuates a reactor trip. Revision 17 of the DCD revises this to state that above permissive P10, low flow in either hot leg actuates a reactor trip.

As discussed in Section 15.1.0.6.4 of this report, Revision 17 of the DCD deletes the P-8 interlock because the P-8 interlock, which permits reactor trip on low flow or RCP high bearing temperature in a single loop, is not needed for the AP1000 since it is not licensed for N-1 loop operation. In Revision 17 of the DCD, the applicant deleted the P-8 interlock from Table 7.2-3, “Reactor Trip Permissives and Interlocks.” Therefore, the P-8 permissive interlock is changed to P-10 interlock for the low-flow trip function. The P-10 interlock also replaces the P-8 interlock in TS Table 3.3.1-1, trip function 10, reactor coolant flow—low, and function 11, RCP bearing water temperature—high. Therefore, the change to replace the P-8 interlock with the P-10 interlock is consistent with the reactor trip logic and TS. As stated in its response to RAI-SRP15.3.1-SRSB-01, the change from the P-8 interlock to the P-10 interlock will improve the results of the loss-of-flow events at lower powers since the reactor will now be tripped at the P-10 setpoint of 10-percent power, compared to the P-8 setpoint of 48 percent power. As a result of replacing the P-8 permissive with P-10, the reactor trip with low flow in both hot legs when the power level is between approximately 10 percent (permissive P-10) and that corresponding to permissive P8 (48 percent) is not necessary. The staff concludes that the change to DCD Section 15.3.1.1 is acceptable.

15.2.3.1.2 Conclusion

Based on the above evaluation, the staff finds that the revisions proposed by the applicant to the DCD, Section 15.3.1, to replace the P-8 interlock with the P-10 permissive interlock are conservative relative to the existing safety analysis, and the design continues to comply with the relevant requirements of GDC 10 and GDC 15. Therefore, the staff concludes that the proposed DCD changes are acceptable.

15.2.3.2 Complete Loss of Forced Reactor Coolant Flow (DCD Tier 2, Section 15.3.2)

In DCD, Section 15.3.2, the applicant proposed to change the power range nuclear power reactor trip permissive from the P-8 interlock to the P-10 interlock for protection against the complete loss of forced reactor coolant flow event.

15.2.3.2.1 Evaluation

The acceptance criteria for the design-basis events are based on meeting the relevant requirements and GDC specified in Appendix A to 10 CFR Part 50. The specific acceptance criteria for this event appear in NUREG-0800. These acceptance criteria include GDC 10 and GDC 15, which require that the specified acceptable fuel design limits and the design conditions of the RCPB, respectively, are not exceeded during any conditions of normal operation, including AOOs.

DCD Section 15.3.2, “Complete Loss of Forced Reactor Coolant,” describes the safety analysis of the complete loss of forced reactor coolant flow event. Section 15.2.3.2 of NUREG-1793 described the staff evaluation of this event. Therefore, the evaluation in this document addresses the staff evaluation of the proposed change described in Revision 17 of the DCD.

DCD Section 15.3.2.1, “Identification of Causes and Accident Description,” describes the cause and progression of the complete loss of forced reactor coolant flow event (i.e., trip of all four RCPs). The low primary coolant flow reactor trip signal provides protection against this event. Revision 15 of the DCD stated that above permissive P8, low flow in either hot leg actuates a reactor trip, and between approximately 10 percent power (permissive P10) and the power level corresponding to P8, low flow in both hot legs actuates a reactor trip. Revision 17 of the DCD revises this to state that above permissive P10, low flow in either hot leg actuates a reactor trip.

Section 15.2.3.1 of this report discusses the staff evaluation that concludes that the replacement of the P8 permissive interlock with the P10 interlock for the low reactor coolant flow is acceptable. This same conclusion applies to the complete loss of forced reactor coolant flow. Therefore, the staff concludes that the change to DCD Section 15.3.2.1 is acceptable.

15.2.3.2.2 Conclusion

Based on the above evaluation, the staff finds that the revisions proposed by the applicant to the DCD, Section 15.3.2, to replace the P-8 interlock with the P-10 permissive interlock are conservative relative to the existing safety analysis, and the design continues to comply with the relevant requirements of GDC 10 and GDC 15. Therefore, the staff concludes that the proposed DCD changes are acceptable.

15.2.4 Reactivity and Power Distribution Anomalies (DCD Tier 2, Section 15.4)

15.2.4.1 Uncontrolled Rod Cluster Control Assembly Bank Withdrawal from a Subcritical or Low-Power Startup Condition (DCD Tier 2, Section 15.4.1)

In DCD, Section 15.4.1.1, the applicant proposed to change the high nuclear flux rate reactor trip. This trip function is actuated when the positive rate of change of neutron flux on two out of four nuclear power range channels indicates a rate above a preset setpoint. Previously, this trip function could be manually bypassed after the coincident two out of four nuclear power range channels were manually reset. The applicant proposed to no longer allow the manual bypass of the trip function after the manual reset of the coincident two out of four nuclear power range channels.

15.2.4.1.1 Evaluation

GDC 10 requires that the reactor core and associated coolant, control, and protection systems be designed such that specified acceptable fuel design limits are not exceeded during normal operation, including the effects of AOOs. Control rod withdrawal is an AOO. The fuel cladding is the first barrier of protection against radioactive release. Meeting GDC 10 ensures that the fuel cladding integrity is not challenged during this AOO.

GDC 13, "Instrumentation and Control," requires the provision of instrumentation that is capable of monitoring variables and systems over their anticipated ranges to ensure adequate safety, and the provision of controls that can maintain these variables and systems within prescribed operating ranges. Meeting GDC 13 ensures that the appropriate controls are provided to maintain these variables and systems within the prescribed operating ranges.

GDC 17, "Electric Power Systems," requires that an onsite electric power system and an offsite electric power system be provided to permit functioning of structures, systems, and components (SSCs) important to safety. The safety function for each system (assuming the other system is not functioning) shall be to provide sufficient capacity and capability to ensure that specified acceptable fuel design limits and design conditions of the RCPS are not exceeded as a result of AOOs. Meeting GDC 17 ensures that the fuel cladding integrity is not challenged during an uncontrolled control rod assembly withdrawal in conjunction with a loss of onsite or offsite power.

GDC 20, "Protection System Functions," requires that the protective system automatically initiate the operation of the reactivity control system to ensure that fuel design limits are not exceeded as a result of AOOs. The withdrawal of a control assembly significantly impacts local fuel pin power and could lead to cladding failure. Measures are required to ensure that an abnormal rod withdrawal is detected and automatically terminated before fuel design safety limits are violated. Meeting GDC 20 ensures that cladding integrity is not challenged during this AOO.

GDC 25, "Protection System Requirements for Reactivity Control Malfunctions," requires that the reactor protection system be designed to ensure that specified acceptable fuel design limits are not exceeded for any single malfunction of the reactivity control system, such as accidental withdrawal of control rods. A failure of the reactivity control system that would create an unmitigated withdrawal of a control assembly could lead to cladding failure. Meeting GDC 25 ensures that a power transient fostered from a reactivity addition as a result of a single failure of the reactivity control system will be detected and terminated before challenging the fuel cladding integrity.

The staff has reviewed the proposed change by the applicant to no longer allow the manual bypass of the high nuclear flux rate reactor trip function after the manual reset of the coincident two out of four nuclear power range channels. Since the proposed change would no longer allow manual bypassing of the trip function, the proposed change has no effect on the analysis results for the control rod withdrawal from subcritical transient. Therefore, the staff concludes that this proposed change is acceptable.

15.2.4.1.2 Conclusion

Based on the above evaluation, the staff concludes that the AP1000 design change is acceptable because it continues to meet the requirements of GDC 10, GDC 13, GDC 17, GDC 20, and GDC 25.

15.2.4.3 Rod Cluster Control Assembly Misalignment (DCD Tier 2, Section 15.4.3)

In DCD, Section 15.4.3.1, the applicant proposed to delete a sentence pertaining to a specific operator action upon the inoperability of the rod deviation alarm to be consistent with the TS. The resolution of the rod position indicator channel is ±5 percent of span (±7.5 inches). A deviation of any rod cluster control assembly (RCCA) from its group by twice this distance (10 percent of span or 15 inches) does not cause power distributions greater than the design limits. The deviation alarm alerts the operator to rod deviation with respect to the group position in excess of 5 percent of span. The applicant proposed to delete the sentence from the application that states, “If the rod deviation alarm is not operable, the operator takes action as required by the Technical Specification.” However, the following paragraph in the application states that if one or more of the rod position indicator channels are out of service, operating instructions are followed to verify the alignment of the nonindicated RCCAs and the operator also takes action as required by the TS.

15.2.4.3.1 Evaluation

GDC 10 requires that the reactor core and associated coolant, control, and protection systems be designed such that specified acceptable fuel design limits are not exceeded during normal operation, including the effects of AOOs. Control rod withdrawal is an AOO. The fuel cladding is the first barrier of protection against radioactive release. Meeting GDC 10 ensures that the fuel cladding integrity is not challenged during this AOO.

GDC 13 requires the provision of instrumentation that is capable of monitoring variables and systems over their anticipated ranges to ensure adequate safety, and the provision of controls that can maintain these variables and systems within prescribed operating ranges. Meeting GDC 13 ensures that the appropriate controls are provided to maintain these variables and systems within the prescribed operating ranges.

GDC 20 requires that the protective system automatically initiate the operation of the reactivity control system to ensure that fuel design limits are not exceeded as a result of AOOs. The withdrawal of a control assembly significantly impacts local fuel pin power and could lead to cladding failure. Measures are required to ensure that an abnormal rod withdrawal is detected and automatically terminated before fuel design safety limits are violated. Meeting GDC 20 ensures that cladding integrity is not challenged during this AOO.

GDC 25 requires that the reactor protection system be designed to ensure that specified acceptable fuel design limits are not exceeded for any single malfunction of the reactivity control system, such as accidental withdrawal of control rods. A failure of the reactivity control system that would create an unmitigated withdrawal of a control assembly could lead to cladding failure. Meeting GDC 25 ensures that a power transient fostered from a reactivity addition as a result of a single failure of the reactivity control system will be detected and terminated before challenging the fuel cladding integrity.

In its response to RAI-SRP15.4.3-SRSB-01, the applicant stated that it revised the sentence, "If the rod deviation alarm is not operable, the operator takes action as required by the Technical Specifications," in Revision 16 of the DCD, Section 15.4.3.1, to be consistent with TS 3.1.4 and 3.1.7. The applicant also stated that neither of these TS or any other TS require the rod deviation alarm to be operable. The applicant also added that Revision 3 of the DCD revised TS 3.1.4 and 3.1.7 to be consistent with NUREG-1431, "Standard Technical Specifications—Westinghouse Plants," Revision 2, issued April 2001. NUREG-1431, Revision 2, removes the rod deviation alarm since it serves as indication only and does not directly relate to the limiting conditions for operation. This is documented in TSTF-110, "Delete SR frequencies based on inoperable alarms," Revision 2. AP1000 TS 3.1.4 does require that all shutdown and control rods shall be operable and that individual indicated rod positions shall be within 12 steps of their group step counter demand position. Surveillance Requirement (SR) 3.1.4.1 requires that individual rod positions are verified within alignment limit every 12 hours. The applicant stated that performing this verification every 12 hours provides a history that allows the operator to detect that a rod is beginning to deviate from its expected position. In addition, the specified frequency takes into account other rod position information that is continuously available to the operator in the main control room (MCR) so that during actual rod motion, deviations can immediately be detected. According to the applicant, the digital rod position indication system and the bank demand position indication system make rod position information continuously available to the operator in the MCR. TS 3.1.7 requires the digital rod position indication system and the bank demand position indication system to be operable. The digital rod control system maintains a count of steps taken by each rod group and, based on this information, a digital readout of the demanded bank position is provided and the demanded and measured rod position signals are displayed in the MCR. An alarm is generated whenever an individual rod position signal deviates from the other rods in the bank by a preset limit. The applicant verifies that the alarm is set with appropriate allowance for instrument error and within sufficiently narrow limits to prevent exceeding core design hot channel factors.

The staff has reviewed the proposed change by the applicant to delete the need for operator action if the rod deviation alarm is not operable. Based on its review, the staff finds that this revision does not affect the safety analysis of the RCCA misalignment events described in DCD Section 15.4.3, and the design continues to comply with the relevant requirements. Therefore, the staff concludes that this proposed change is acceptable.

15.2.4.3.2 Conclusion

Based on the above evaluation, the staff concludes that the AP1000 design change is acceptable because it continues to meet the requirements of GDC 10, 13, 20, and 25.

15.2.4.6 Chemical and Volume Control System Malfunctions that Result in a Decrease in the Boron Concentration in the Reactor Coolant (DCD Tier 2, Section 15.4.6)

The applicant proposed to revise Section 15.4.6 in the areas related to the CVS design modifications associated with the mitigation of boron dilution events. These modifications include the alignment of the makeup pump suction, and flux doubling boron dilution block and CVS isolation pertaining to boron dilution events occurring during Mode 3, 4, and 5 operations. In addition, the applicant made changes regarding the dilution flow rates, RCS mixing volume, and critical and shutdown boron concentrations for Mode 3, 4, and 5 operations.

15.2.4.6.1 Evaluation

The acceptance criteria for the design-basis events are based on meeting the relevant requirements and GDC specified in Appendix A to 10 CFR Part 50. The specific acceptance criteria for this event appear in NUREG-0800. These acceptance criteria include GDC 10 and GDC 15, which require that the specified acceptable fuel design limits and the design conditions of the RCPB, respectively, are not exceeded during any conditions of normal operation, including AOOs; and GDC 13 and GDC 26, "Reactivity Control System Redundancy and Capability," pertaining to appropriate instrumentation and reactivity control system redundancy and capability.

DCD Section 15.4.6 describes the safety analysis for the boron dilution event. Section 15.2.4.6 of NUREG-1793 described the staff evaluation of this event for compliance with relevant acceptance criteria. Therefore, the evaluation in this document is limited to the effects of the proposed changes on compliance with the relevant acceptance criteria.

In Section 15.4.6.1, "Identification of Causes and Accident Description," the applicant proposed to modify the description of boron dilution events and the general mitigation method to be consistent with the CVS design changes for boron dilution mitigation described in DCD Section 9.3.6, "Chemical Volume and Control System." The existing design currently realigns the makeup pump suction from the demineralized water tank to the boric acid tank to terminate the potential boron dilution, and to begin to reborate the RCS to restore shutdown margin. These actions would initially cause the boron dilution to continue because the volume of water in the makeup line path would still be unborated until borated water from the boric acid tank began to reach the RCS. The function was changed to close the makeup line isolation valves (as well as the demineralized water isolation valves) or trip the makeup pumps to terminate the event as soon as possible. Long-term recovery from the event would then be accomplished using either a different flowpath with a smaller unpurged volume or by using the makeup line after purging most of the unborated water in it. The applicant also proposed several text changes along with the logic changes that are required to implement this modication.

The staff reviewed the applicant's proposed change related to the realignment from the demineralized water tank to the boric acid tank as well as isolation of the makeup flow to the RCS for the termination of boron dilution events in Modes 3, 4, and 5. Since the proposed change would terminate the boron dilution event sooner and has no safety-significant effect on the transient, the staff finds this change acceptable. The text changes associated with the realignment are, therefore, acceptable.

In DCD, Section 15.4.6.2, the applicant proposed to delete text that states that in the event of an inadvertent boron dilution transient during Mode 3, 4, and 5 operations, the source range nuclear instrumentation detects "an increase of 60 percent of" the neutron flux and replace it with generic text reading “a sufficiently large increase in” the neutron flux. In its response to RAI-SRP-15.4.6-SRSB-01, the applicant explained that in Revision 15 of the DCD, the use of the phrase “an increase of 60 percent” reflected the 1.6 multiplier (over 50 minutes) setpoint reported in DCD Table 15.0-4a. In Revision 16 of the DCD, and supplemented by TR-80, the applicant proposed to change the multiplier from 1.6 to 2.2 (which would now be an increase of greater than 60 percent). The applicant stated that it reanalyzed the event and verified that an increase in the nominal setpoint from 1.6 to 2.2 demonstrates acceptable results and would reduce the likelihood of an inadvertent actuation of the boron dilution protection functions during normal operation.

The applicant changed Revision 16 of the DCD, Table 15.0-4a, to reflect the proposed 2.2 multiplier. The applicant stated that it decided to remove the text in DCD Section 15.4.6 referencing a specific flux increase value in order to simplify any potential future revisions to the text in the event of a subsequent change in the safety analysis setpoint. By reporting the actual numerical value in DCD Table 15.0-4a, the document completely defines the magnitude of the flux increase modeled in the safety analysis; therefore, the applicant stated that there is no need to repeat that same information in multiple locations within the text. The staff has reviewed the applicant’s justification for replacing the text referencing “an increase of 60 percent” with generic text reading “a sufficiently large increase.” Since DCD Table 15.0-4a will provide a specific value to quantify the phrase, “a sufficiently large increase,” this change is acceptable.

However, in its responses to both RAI-SRP-15.4.6-SRSB-01 and RAI-SRP15.0-SRSB-01, the applicant proposed to increase the multiplier again from 2.2 to 3.0. In its response to RAI-SRP15.0-SRSB-01, the applicant stated that the safety analysis cases reported in DCD Section 15.4.6 support a setpoint of 3.0 over 50 minutes to mitigate the boron dilution event in Modes 3, 4, and 5. However, DCD Section 15.4.6 and TR-80 only discuss the increase from 1.6 to 2.2 and do not mention an increase to 3.0. The applicant submitted Revision 17 of the DCD, Table 15.0-4a, which includes the new proposed flux rate setpoint of 3.0, but the staff asked the applicant to provide additional information regarding the 3.0 multiplier. In response to RAI-SRP15.4.6-SRSB-02, the applicant confirmed that the boron dilution analyses performed for Modes 3, 4, and 5 documented in Revision 17 of the DCD, Section 15.4.6, assumed a safety analysis setpoint for the boron dilution protection system of 3.0 over 50 minutes, and analysis results for all cases are acceptable. The applicant also justified why the 36-percent allowance between the safety analysis and TS nominal setpoints of 3.0 and 2.2 over 50 minutes is sufficient to bound the actual value determined when final plant design inputs are available. The staff reviewed the applicant’s response confirming that the boron dilution analyses documented in Revision 17 of the DCD, Section 15.4.6, assumed a safety analysis setpoint for the boron dilution protection system of 3.0 over 50 minutes, and it finds this change acceptable. The staff also reviewed the applicant’s justification that the 36-percent allowance between the safety analysis and TS nominal setpoints of 3.0 and 2.2 is sufficient to bound the actual value determined when the final plant design inputs are available, and it finds this explanation acceptable.

Additionally, in DCD, Section 15.4.6.2, the applicant proposed changes to the dilution flowrate, RCS water volume, critical and shutdown boron concentrations, and automatic protective actions initiation time for Mode 3, 4, and 5 operations. The applicant proposed these changes in order to be consistent with the TS, DCD Section 9.3.6, and the assumed conditions for the inadvertent boron dilution event. In its response to RAI-SRP15.4.6-SRSB-03, the applicant provided additional explanation for the changes in the RCS water volumes for different modes of operation. The applicant stated that it recalculated the RCS water volumes using the latest geometric data available, taking into consideration the design changes made up to this point.

These design change refinements result in a change of less than 5 percent for Mode 3 and of less than 8 percent for Mode 5. The Mode 4 RCS volume is the same volume as was assumed in the Mode 3 boron dilution calculation and no credit is taken for the upper head volume in the assumed active mixing volume in the Mode 3, 4, and 5 calculations. The staff reviewed the applicant's rationale for the changes in RCS water volumes for different modes of operation and concludes that these changes are acceptable.

15.2.4.6.2 Conclusion

The staff reviewed the proposed changes described in DCD, Section 15.4.6, regarding the CVS design modifications associated with the mitigation of boron dilution events. Based on the above evaluation, the staff concludes that the AP1000 design changes are acceptable because the analyses of boron dilution events continue to meet the requirements of GDC 10, 13, 15, and 26.

15.2.4.8 Spectrum of Rod Cluster Control Assembly Ejection Accidents (DCD Tier 2, Section 15.4.8)

DCD Section 15.4.8, "Spectrum of Rod Cluster Control Assembly Ejection Accidents," describes the RCCA ejection events resulting from mechanical failure of control rod mechanism pressure housing. For assemblies initially inserted, the consequences include a rapid reactivity insertion together with an adverse core power distribution, possibly leading to localized fuel rod damage. Although mechanical provisions have been made to render this accident extremely unlikely, the applicant has provided its analysis of the consequences of such an event. The applicant has considered plant systems and equipment, discussed in DCD Tier 2, Section 15.0.8, that are available to mitigate the effects of the event, and it determined that no single active failure in these systems or equipment adversely affects the consequences of the events.

Revision 17 of the DCD removes the longitudinal and circumferential failures described in Sections 15.4.8.1.1.5 and 15.4.8.1.1.6, respectively. These changes are supported by APP-GW-GLE-016, "Impact of In-core Instrumentation Grid, Quicklocs and Changes to Integrated Head Package (IHP)," Revision 0.

15.2.4.8.1 Evaluation

Revision 17 of the DCD removes the failure mechanisms outlined in Sections 15.4.8.1.1.5 and 15.4.8.1.1.6 because of a design change to the upper internals. TR APP-GW-GLE-016 provides a technical description of these changes, but the technical justification for removing the failure mechanisms was unclear.

The staff sent RAI-SRP15.4.8-SRSB-01 to the applicant to ask for more information as to why the failure mechanisms previously covered in DCD Sections 15.4.8.1.1.5 and 15.4.8.1.1.6 are no longer considered. In its response to RAI-SRP15.4.8-01, the applicant stated that it removed the failure mechanisms from Sections 15.4.8.1.1.5 and 15.4.8.1.1.6 because Section 3.9.4.1.1 covers RCCA failure mechanisms, and these methods were no longer considered credible. The RAI response further explains that the hypothetical failure of a RCCA housing described in DCD Section 15.4.8 is a rapid positive reactivity insertion independent of the specific failure mechanism; therefore, DCD Sections 15.4.8.1.1.5 and 15.4.8.1.1.6 are not needed.

The staff reviewed the RAI response and agrees that as long as the analysis continues to evaluate a rapid positive reactivity insertion resulting from an ejected rod, the requirements of

GDC 28, “Reactivity Limits” (as detailed in regulatory guide (RG) 1.77, “Assumptions Used for Evaluating a Control Rod Ejection Accident for Pressurized Water Reactors,” issued May 1974, and NUREG-0800 Sections 15.4.8 and 4.2), are met. Therefore, the staff concludes that the proposed change is acceptable.

15.2.4.8.2 Staff Position Related to the Revision of NUREG-0800 Section 15.4.8

In Section 15.2.4.8 of NUREG-1793, the staff provided a safety evaluation of the RCCA ejection analysis in accordance with NUREG-0800 Section 15.4.8, “Spectrum of Rod Ejection Accidents (PWR),” Revision 2, issued July 1981. The AP1000 analysis results of the RCCA ejection events initiated at hot full power and at hot zero power demonstrated that the calculated values of the hot spot radially averaged fuel enthalpy are well within the acceptance criterion of 280 calories per gram specified in NUREG-0800 Section 15.4.8, Revision 2.

After the AP1000 design certification (DC) rulemaking, the NRC revised NUREG-0800 Section 15.4.8. Revision 3 of NUREG-0800 Section 15.4.8, issued in March 2007, specifies that the number of failed fuel rods used in the radiological evaluation for the rod ejection events be calculated considering the failure mechanisms addressed in NUREG-0800 Section 4.2. Appendix B, “Interim Acceptance Criteria and Guidance for the Reactivity Initiated Accidents,” to NUREG-0800 Section 4.2, Revision 3, specifies that, for the reactivity-initiated accidents such as rod ejection accidents in pressurized-water reactors (PWRs), the total number of fuel rods that must be considered in the radiological assessment is equal to the sum of all of the fuel rods failing either: (1) the high cladding temperature failure criteria specified; or (2) the pellet-cladding mechanical interaction cladding failure criteria specified.

In 10 CFR 52.47(a)(9), “Contents of applications; technical information,” the NRC specifies that for applications for light-water reactor (LWR) nuclear power plants, the technical information in the application shall include an evaluation of the standard plant design against the NUREG-0800 revision in effect 6 months before the docket date of the application. In addition, 10 CFR 52.63(a)(1), “Finality of standard design certifications,” specifies that notwithstanding any provision in 10 CFR 50.109, “Backfitting,” while a standard DC rule is in effect under 10 CFR 52.55, “Duration of certification,” or 10 CFR 52.61, “Duration of renewal,” the Commission may not modify, rescind, or impose new requirements on the certified information, whether on its own motion or in response to a petition from any person, unless the Commission determines in a rulemaking that the change meets one of seven criteria. In 10 CFR 52.79(a)(41), “Contents of applications; technical information in final safety analysis report,” the NRC specifies that for applications for LWR nuclear power plant COLs, the technical information in the final safety analysis report (FSAR) shall include an evaluation of the facility against the NUREG-0800 revision in effect 6 months before the docket date of the application. In addition, 10 CFR 52.98(c)(1), “Finality of combined licenses; information requests,” specifies that if the COL references a certified design, then changes to or departures from information within the scope of the referenced DC rule are subject to the applicable change processes in that rule. Section VIII, “Processes for Changes and Departures,” in Appendix C, “Design Certification Rule for the AP600 Design,” and Appendix D, “Design Certification Rule for the AP1000 Design,” to 10 CFR Part 52, “Licenses, certifications, and approvals for nuclear power plants,” specifies the processes for changes and departures from the Tier 1, Tier 2, and Tier 2* information, respectively, in the certified design. For example, Section VIII.B.6 specifies that an applicant or licensee who references this appendix may not depart from Tier 2* information without NRC approval.

Accordingly, the staff determined that the AP600 and AP1000 certified standard designs, which the NRC certified before 2007, are not required to comply with Revision 3 of NUREG-0800 Sections 15.4.8 and 4.2, issued March 2007. For COL applicants or licensees who reference the AP1000 or AP600 certified designs, the staff will review any change or departure from the certified design that requires prior NRC approval as specified in Section VIII of Appendices C and D to 10 CFR Part 52, respectively.

The staff will evaluate the reactivity-initiated accidents such as rod ejection accidents based on the acceptance criteria in effect 6 months before docketing the amendment request, such as the interim acceptance criteria specified in Appendix B to NUREG-0800 Section 4.2, Revision 3, if a change or departure in fuel design or other aspects is proposed that requires a reevaluation of final safety evaluation report Chapter 4, “Reactor,” or Chapter 15, “Transient and Accident Analysis.”

15.2.4.8.3 Conclusion

The staff concludes that the RCCA ejection analysis meets the acceptance criteria specified in NUREG-0800 Section 15.4.8, Revision 2, which were in effect for the AP1000 DC application. Therefore, the RCCA ejection analysis in the DCD is acceptable and can be used by COL applicants referencing the AP1000 standard design. However, the staff will evaluate the RCCA ejection accident based on the acceptance criteria in effect 6 months before docketing the amendment request, such as the interim acceptance criteria specified in Appendix B to NUREG-0800 Section 4.2, Revision 3, if a change or departure in fuel design or other aspects is proposed that requires a reevaluation of final safety evaluation report Chapters 4 or 15.

15.2.5 Increase in Reactor Coolant System Inventory (DCD Tier 2, Section 15.5)

13.2.5.1 Inadvertent Operation of the Core Makeup Tanks during Power Operation (DCD Tier 2, Section 15.5.1)

The applicant proposed to revise Section 15.5.1.2 by deleting the sentence, “No single active failure in any of these systems or equipment adversely affects the consequences of the accident.”

15.2.5.1.1 Evaluation

The acceptance criteria for the design-basis events are based on meeting the relevant requirements and GDC specified in Appendix A to 10 CFR Part 50. The specific acceptance criteria for this event appear in the NUREG-0800. These acceptance criteria include GDC 10 and GDX 15, which require that the specified acceptable fuel design limits and the design conditions of the RCPB, respectively, are not exceeded during any conditions of normal operation, including AOOs.

In Section 15.5.1.2, the applicant proposed to delete the following sentence:

> No single active failure in any of these systems or equipment adversely affects the consequences of the accident.

As stated in DCD Section 15.5.1.2, regarding the PMS actuations for the mitigation of the event, the PRHR heat exchanger removes the core decay heat. The worst single failure assumed is the failure of one of the two parallel isolation valves in the outlet line of the PRHR heat exchanger to open. Therefore, the single active failure is assumed in the safety analysis. In its response to RAI-SRP15.5.1-SRSB-02, the applicant clarified that it deleted this sentence to remove contradictory information, and the change has no effect on the existing safety analysis assumptions or methodology. Therefore, the staff concludes that this change is acceptable.

15.2.5.1.2 Conclusion

Based on the above evaluation, the staff finds that the revisions proposed by the applicant to DCD, Section 15.5.1, to delete a contradicting statement are acceptable because there is no effect on the existing safety analysis, and the design continues to comply with the relevant requirements of GDC 10 and GDC 15.

15.2.5.2 Chemical and Volume Control System Malfunction that Increases Reactor Coolant Inventory (DCD Tier 2, Section 15.5.2)

The applicant proposed to revise Section 15.5.2, “Chemical and Volume Control System Malfunction That Increases Reactor Coolant Inventory,” by deleting the sentence, “No single active failure in any of these systems or equipment adversely affects the consequences of the accident.”

15.2.5.2.1 Evaluation

The acceptance criteria for the design-basis events are based on meeting the relevant requirements and GDC specified in Appendix A to 10 CFR Part 50. The specific acceptance criteria for this event appear in NUREG-0800. These acceptance criteria include GDC 10 and GDC 15, which require that the specified acceptable fuel design limits and the design conditions of the RCPB, respectively, are not exceeded during any conditions of normal operation, including AOOs.

In Section 15.5.2.2, the applicant proposed to delete the following sentence:

> No single active failure in any of these systems or equipment adversely affects the consequences of the accident.

As stated in DCD Section 15.5.2.2, regarding the PMS actuations for the mitigation of the event, the PRHR heat exchanger removes the core decay heat. The worst single failure assumed is the failure of one of the two parallel isolation valves in the outlet line of the PRHR heat exchanger to open. Therefore, the single active failure is assumed in the safety analysis. In response to RAI-SRP15.5.1-SRSB-02, the applicant clarified that it deleted this sentence to remove contradictory information, and the change has no effect on the existing safety analysis assumptions or methodology. Therefore, the staff concludes that the change is acceptable.

15.2.5.2.2 Conclusion

Based on the above evaluation, the staff finds that the revisions proposed by the applicant to DCD, Section 15.5.2, to delete a contradicting statement to be acceptable because there is no effect on the existing safety analysis, and the design continues to comply with the relevant requirements of GDC 10 and GDC 15.

15.2.6 Decrease in Reactor Coolant System Inventory (DCD Tier 2, Section 15.6, Excluding Section 15.6.5)

15.2.6.1 Inadvertent Opening of a Pressurizer Safety Valve or Inadvertent Operation of the Automatic Depressurization System

The applicant proposed to revise Section 15.6.1, “Inadvertent Opening of a Pressurizer Safety Valve or Inadvertent Operation of the ADS,” to change the motor-operated valve stroke times for the ADS valves for Stages 1–3.

15.2.6.1.1 Evaluation

The acceptance criteria for the design-basis events are based on meeting the relevant requirements and GDC specified in Appendix A to 10 CFR Part 50. The specific acceptance criteria for this event appear in the NUREG-0800. These acceptance criteria include GDC 10 and GDC 15, which require that the specified acceptable fuel design limits and the design conditions of the RCPB, respectively, are not exceeded during any conditions of normal operation, including AOOs.

In Section 15.6.1.1, “Identification of Causes and Accident Description,” the applicant proposed the following changes to the motor-operated valve stroke times for ADS valves during this event:

- Change the ADS Stage 1 design opening time from 25 seconds to 40 seconds.
- Change the ADS Stage 2 and 3 design opening times from 70 seconds to 100 seconds.

The applicant also proposed to add the following paragraph to clarify the effects of the proposed times above on the analysis results:

> The valve stroke times shown in Chapter 15 tables (input/assumptions) reflect the design basis of the AP1000. The accidents addressed in this section were evaluated for these design basis valve stroke times. The results of this evaluation have shown that there is a small impact on the analysis and the conclusions remain valid. The output provided in this section for the analyses is representative of the transient phenomenon.

The staff reviewed DCD, Section 15.6.1, and concludes that the proposed changes provide additional clarification and do not have a safety significant effect on the existing safety analysis of the event. Therefore, the proposed changes are acceptable.

15.2.6.1.2 Conclusion

Based on the above evaluation, the staff finds that the addition of the above paragraph in DCD, Section 15.6.1, only provides clarification and does not have a significant effect on the existing safety analysis. Therefore, the staff concludes that the proposed change is acceptable because the relevant requirements of GDC 10 and GDC 15 continue to be met.

15.2.6.5 Loss-of-Coolant Accident (DCD Tier 2, Section 15.6.5)

15.2.6.5.2 Large Breaks (DCD Tier 2, Section 15.6.5.4A)

In Revision 17 of the DCD, the applicant extensively revised Section 15.6.5.4A, “Large-Break LOCA Analysis Methodology and Results.” In Revision 15 of the DCD, the applicant performed the best estimate large-break loss-of-coolant accident (BELOCA) analysis using the WCOBRA/TRAC code to calculate thermal-hydraulic transients in the RCS during a postulated large-break LOCA, and it used the HOTSPOT program to calculate the effects of local models on the calculated peak cladding temperature (PCT). The uncertainties associated with the plant input parameters and states, such as initial fluid conditions in the reactor core system and the ECCS boundary conditions, were treated with a response surface method described in Westinghouse Commercial Atomic Power (WCAP)-12945-P-A, “Code Qualification Document [CQD] for Best Estimate LOCA Analysis,” Revision 2, issued 1998. In Revision 17 of the DCD, the applicant continued to use the WCOBRA/TRAC and HOTSPOT computer codes for the BELOCA thermal-hydraulic and hot fuel rod analyses. However, it used the Automated Statistical Treatment of Uncertainty Method (ASTRUM) for the statistical treatment of uncertainties, replacing the existing CQD response surface method. The NRC has reviewed and approved ASTRUM, documented in WCAP-16009-P-A, “Realistic Large Break LOCA Evaluation Methodology Using the Automated Statistical Treatment of Uncertainty Method,” issued 2005. Consistent with the CQD methodology, ASTRUM follows the steps of the Code Scaling, Applicability, and Uncertainty methodology. ASTRUM differs from the CQD methodology primarily in the statistical technique used for uncertainty treatment. ASTRUM uses a nonparametric statistical technique applied directly to a random sample of outputs, for example, the PCT, the maximum local oxidation (MLO), and the core-wide oxidation (CWO). These sample outputs are computed by applying Monte Carlo sampling of the inputs to the WCOBRA/TRAC and HOTSPOT calculations. The uncertainties and biases remain the same as in the CQD methodology.

In support of the revised BELOCA analysis in Revision 17 of the DCD, Section 15.6.5.4A, the applicant submitted APP-GW-GLE-026, “Application of ASTRUM Methodology for Best-Estimate Large-Break Loss-of-Coolant Accident Analysis,” Revision 1, issued 2009, which provides a detailed description of the revised analysis.

The staff used NUREG-0800 Section 15.6.5, “Loss-of-Coolant Accidents Resulting from Spectrum of Postulated Piping Breaks within the Reactor Coolant Pressure Boundary,” and RG 1.157, “Best-Estimate Calculations of Emergency Core Cooling System Performance,” issued May 1989, to guide its evaluation of this revised BELOCA analysis.

15.2.6.5.2.1 AP1000 BELOCA Analysis Code Applicability Evaluation

The BELOCA analysis uses the WCOBRA/TRAC code to calculate the effects of initial conditions, power distributions, and global models, and it uses the HOTSPOT code to calculate the effects of local models. The WCOBRA/TRAC code, described in WCAP-12945-P-A, is Westinghouse’s best estimate thermal-hydraulic computer code to evaluate the RCS response to a postulated large-break LOCA. Westinghouse developed the code consistent with the guidance provided in RG 1.157 to calculate thermal-hydraulic conditions in the RCS during blowdown and reflood of a LOCA. The code includes the features needed to satisfy the requirements of 10 CFR 50.46(a)(1)(i). The BELOCA analysis of the AP600 standard design used the WCOBRA/TRAC code. Section 21.6.3 of NUREG-1512, “Final Safety Evaluation Report Related to Certification of the AP600 Standard Design,” described the staff’s review of the application of WCOBRA/TRAC for the AP600 application. Revision 15 of the DCD used the "2000 Formulation" of WCOBRA/TRAC referenced in WCAP-15644-P, "AP1000 Code Applicability Report," Revision 2, issued 2004. This is the version approved in the analysis of the AP600 site safety analysis report, with the subsequent discretionary and nondiscretionary changes that Westinghouse reported to the NRC in 1998, 1999, and 2000, as presented in Appendix A to WCAP-15644-P, Revision 2. Section 21.6.3 of NUREG-1793 described the staff evaluation of WCOBRA/TRAC applicability to the AP1000 BELOCA.

The approved WCOBRA/TRAC code version used in the ASTRUM evaluation model described in WCAP-16009-P-A is WCOBRA/TRAC Mod 7, Revision 6, which is different from the 2000 Formulation of WCOBRA/TRAC used in Revision 15 of the DCD. The WCAP-16009-P-A code version includes the discretionary and nondiscretionary changes reported through the 10 CFR 50.46 reporting process.

The HOTSPOT program is a one-dimensional conduction code that models a portion of a fuel rod at the PCT or burst location and takes into account fuel relocation following a burst during a large-break LOCA. In the axial node where fuel rod burst is predicted to occur, the fuel relocation model in HOTSPOT is used to account for the likelihood that additional fuel-pellet fragments from above that elevation may settle into the burst region. Sections 25.4.2.3 and 25.4.2.4 of WCAP-12945-P-A describe the HOTSPOT model, application, and assessment. HOTSPOT uses a simple physical model that allows the effects of uncertainties to be calculated directly by running the model with parameter values that vary randomly according to specified distributions. The parameter uncertainties for the local models consider the power rates, fuel and cladding properties, metal-water reaction rates, and heat transfer coefficients.

15.2.6.5.2.1.1 WCOBRA/TRAC and HOTSPOT Code Modifications

Revision 17 of the DCD uses WCOBRA/TRAC (M7AR7_AP) and HOTSPOT (6.1) as the current code versions for the AP1000 revised BELOCA analysis. These versions differ from the earlier versions used in Revision 15 of the DCD and WCAP-16009-P-A because of additional code modifications identified through 10 CFR 50.46 reporting. For completeness, Appendix A to APP-GW-GLE-026 identifies a total of 35 changes through 10 CFR 50.46 reporting since 1998.

Appendix B to WCAP-16009-P-A identified 19 of the 35 changes and formed the bases for the acceptance of WCOBRA/TRAC Mod 7A, Revision 6, for BELOCA analyses. The applicant evaluated each of the changes and concluded that each error and its correction, or discretionary change did not have a significant impact on the WCOBRA/TRAC results and did not affect the prior assessments and uncertainties. The NRC evaluated these in its safety evaluation report for WCAP-16009-P-A. The agency concluded that these corrections were reasonable and effectual and found them to be acceptable. The remaining 16 changes were incorporated into WCOBRA/TRAC (M7AR7_AP) and HOTSPOT 6.1, the current code versions used for AP1000 BELOCA analyses.

Of the 16 changes, 10 are discretionary changes involving either: (1) enhanced input/output, corrections to output edits, or improvement in the automation of running the code cases; or (2) corrections to errors involving an option, model, code, or a code application that was not used for experiment simulations. The applicant evaluated each of these changes and concluded that each discretionary change did not have a significant impact on the WCOBRA/TRAC results and did not affect the prior assessments and uncertainties.

One of the nondiscretionary changes concerned an input error resulting in incomplete solution matrix (see 10 CFR 50.46 letter LTR-NRC-04-17, dated March 25, 2004). Two plant-specific calculations were found to be affected by this error. The applicant confirmed that correction of the error did not change the fundamental LOCA transient characteristics (e.g., blowdown cooling and reflood turnaround timing and behaviors). The reference double-ended guillotine break was used to develop the PCT assessments for each plant. The test simulation affected by this error was also corrected, and the transient calculation repeated. It was found that the error correction had no significant effect on the calculation results, and the prior validation conclusions remain valid. The correction is used for the AP1000 BELOCA analyses.

The second nondiscretionary change concerned Inconel 690 material properties capability (see 10 CFR 50.46 letter LTR-NRC-04-17). The material properties were revised in 2000, but the annual 10 CFR 50.46 report did not include the change. This capability was reported to correct that omission. The Inconel 690 material properties are only used for replacement steam generator analyses where the tube material has changed. The analyses directly reflect the effect of the material properties.

The staff identified the following three nondiscretionary changes with the potential to affect any of the prior code assessment and uncertainty results, and that have an effect on the AP1000 BELOCA analyses:

(1) Revised Blowdown Heatup Uncertainty Distribution

This nondiscretionary change was reported in a Westinghouse 10 CFR 50.46 letter LTR-NRC-05-20, dated April 11, 2005. This error was previously reported in a Westinghouse letter, LTR-NRC-04-11, dated February 3, 2004. As a result of input errors in the loss-of-fluid test (LOFT) facility model used to compare the predicted PCT to the test data to determine this distribution, revised analyses were performed with the version of WCOBRA/TRAC available at that time. As a result of the reanalysis with the modeling error corrections, revised blowdown heatup heat transfer multipliers were developed and the revised cumulative distribution function (CDF) was programmed into the new version of HOTSPOT. The applicant estimated the PCT effect of the revised blowdown heatup CDF by calculating the impact on the reference transient for representative two-, three-, and four-loop plants. The estimates bounded all of the 95th percentile HOTSPOT results. The applicant also made plant-specific estimates of the effect of the revised overall code uncertainty for blowdown for those plants that track the blowdown period.

The applicant identified the errors in the LOFT analyses in its response to RAI-SRP15.6.5-SRSB-03. The most important input error was the flag for the fuel rod gap pressure calculation, which was erroneously set to the steady-state option during the transient calculation. With this flag, the critical heat flux calculation was skipped and the transition to film boiling was only a result of the depletion of liquid from the core region. This was the primary input error that impacted the blowdown heatup heat transfer multiplier distribution. Other modeling aspects of the accumulator and break noding were also updated for consistency with the final, approved version of WCAP-12945-P-A, the one-dimensional pipe to three-dimensional vessel connection input was corrected, and errors in the choked flow flag applied to selected components were corrected.

The development of the blowdown heatup heat transfer multipliers and the resulting revised CDF were consistent with the previously approved methods used in WCAP-12945-P-A. The AP1000 ASTRUM analysis uses this revised CDF for the blowdown heatup heat transfer multipliers, consistent with an ASTRUM analysis of a standard Westinghouse PWR.

(2) Improved Automation of End of Blowdown Time

This discretionary change was reported in 10 CFR 50.46 letters LTR-NRC-05-20 and LTR-NRC-06-8, dated March 16, 2006. The automated selection of the end of blowdown time was first modified by replacing the criterion of 276 kilopascal (kPa) (40 pounds-force per square inch absolute (psia)) with a selection based on the time at which the system pressure stops decreasing. It was again modified by replacing the criterion related to when the system pressure stops decreasing with a selection based on the time when the collapsed liquid level in the lower plenum reaches a minimum and begins to increase again. The redefinition of the end of blowdown is a discretionary change. It has no impact on the WCOBRA/TRAC results and does not affect the prior assessments and uncertainties.

In its response to RAI-SRP15.6.5-SRSB-04, the applicant confirmed that the AP1000 BELOCA ASTRUM analysis used the improved automated method to define the end of blowdown based on the time at which the collapsed liquid level in the lower plenum reaches a minimum and begins to increase again. The time at which the collapsed liquid level is at its absolute minimum is selected as the end of blowdown time. For large double-ended guillotine breaks, similar results are obtained whether the end of blowdown is defined by RCS pressure criteria or at the time the lower plenum collapsed liquid level reaches a minimum. For the smaller breaks sampled in the ASTRUM analyses, the improved definition based on the lower plenum collapsed liquid level is more applicable than the historical pressure criterion. The ASTRUM analyses use a consistent definition of end of blowdown as the time at which the lower plenum collapsed liquid level is at its absolute minimum; this definition is applied for all runs.

(3) HOTSPOT Fuel Relocation

This nondiscretionary change was reported in 10 CFR 50.46 letter LTR-NRC-08-24, dated May 15, 2008. It was discovered that the effect of the fuel relocation on the local linear heat rate was being calculated correctly in accordance with the approved model, but then canceled out later in the coding. The HOTSPOT fuel-relocation error was an error in code logic that does not affect the approval of the fuel-relocation model. The applicant evaluated the impact of this error in letter DCP/NRC2074, "10 CFR 50.46 Report for the AP1000 Standard Plant Design," dated February 15, 2008. The impact was estimated to be ∆ 0 °Celsius (C) (∆ 0 °Fahrenheit (F)) during the blowdown phase and ∆ 38.9 °C (70 °F) during the reflood phase of the accident. The HOTSPOT fuel relocation error is a nondiscretionary change. It has no impact on the WCOBRA/TRAC results and does not affect the prior assessments and uncertainties. The AP1000 BELOCA analyses use the corrected logic.

The applicant has incorporated all of the 10 CFR 50.46 discretionary and nondiscretionary changes into the current versions of the WCOBRA/TRAC (M7AR7_AP) and HOTSPOT 6.1 codes. The discretionary changes were shown not to have a significant impact on the

WCOBRA/TRAC results and did not affect the prior assessments and uncertainties. The nondiscretionary changes addressed and corrected known errors.

15.2.6.5.2.1.2 WCOBRA/TRAC Code Validation

The phenomena identification ranking table for large-break LOCAs, provided in WCAP-15644-P, Revision 2, and NUREG-1793, indicates that the main difference between the AP1000 and operating PWRs is the DVI. Similar to validation performed for the AP600 design documented in WCAP-14171 and WCAP-14172 (nonproprietary), "WCOBRA/TRAC Applicability to AP600 Large-Break Loss-of-Coolant Accident," Revision 2, additional validation was performed to examine code capability of WCOBRA/TRAC (M7AR7_AP) to model the AP1000 DVI into the downcomer. Appendix B to APP-GW-GLE-026 documents the DVI assessment calculations. Researchers validated the DVI injection by comparing the code calculations with the tests carried out on the Cylindrical Core Test Facility and the Upper Plenum Test Facility.

Calculations for the Cylindrical Core Test Facility Test 78, Run 58, showed a reasonable prediction of the thermal-hydraulic behavior with WCOBRA/TRAC (M7AR7_AP). The filling of the core and downcomer were in reasonable agreement with the data, and the calculated core level was slightly overpredicted and the downcomer level underpredicted. The maximum clad temperatures in the core were also reasonably predicted at most elevations, and they tended to be overpredicted for the higher power rods. Overall, the applicant's evaluation indicated that the WCOBRA/TRAC M7AR7_AP calculations adequately captured the thermal-hydraulic effects associated with downcomer injection, with results similar to those for the AP600.

Calculations for the Upper Plenum Test Facility Test 21, Phases A, B-I, and B-II/III, also showed that the WCOBRA/TRAC (M7AR7_AP) code reasonably and conservatively predicted the downcomer bypass phenomenon, with results similar to those for the AP600.

The applicant's assessments demonstrated that the end-of-bypass remains conservatively calculated. They also demonstrated that the PCT predictions from WCOBRA/TRAC (M7AR7_AP) remain conservative at higher fuel rod elevations and in higher power rods, and essentially best estimate at lower elevations.

Based on its review, the staff concludes that WCOBRA/TRAC (M7AR7_AP) conforms to the guidance provided in RG 1.157 and is acceptable for AP1000 BELOCA analyses to demonstrate compliance with the 10 CFR 50.46 criteria.

15.2.6.5.2.2 WCOBRA/TRAC Nodalization Model for AP1000 Best Estimate Large-Break Loss-of-Coolant Accident Analyses

Appendix C to APP-GW-GLE-026 describes the WCOBRA/TRAC nodalization model for AP1000 BELOCA analyses. The nodalization model was developed using the methodology established in WCAP-12945-P-A. The major portion of a BELOCA analysis involves generating the plant-specific vessel and loop model for the WCOBRA/TRAC analyses. The vessel model, in particular, requires detailed information regarding the reactor pressure vessel internals. The AP1000 nodalization was also compared to the available modeling guidance presented in WCAP-16009-P-A.

15.2.6.5.2.2.1 Reactor Coolant System Loop Model

The AP1000 WCOBRA/TRAC RCS loop model (Figure C-3 in APP-GW-GLE-026) uses 75 components and 87 junctions to model the RCS loops and the passive safety systems, including the vessel module and the interface junctions between the one-dimensional loop components and the three-dimensional vessel module. The model includes the four cold legs, the two hot legs, the two steam generators, and the pressurizer.

The two passive safety injection system loops are modeled separately, complete with the CMT and balance line and the accumulator. The model also includes the in-containment refueling water storage tank (IRWST), the sump connections into the DVI lines, the PRHR, and the ADS.

The ADS modeling is simplified and excludes ADS Stages 1, 2, and 3, located on the top of the pressurizer, because ADS Stage 1 is actuated by a low-level signal from the CMTs, whose flow is effectively shut off by the actuation of accumulators. The CMT liquid level is expected to remains above the ADS Stage 1 actuation setpoint throughout the AP1000 BELOCA cladding temperature excursion, even though CMT injection begins again later in the transient. Therefore, ADS Stages 1, 2, and 3 are not expected to actuate during a large break until long after the PCT is calculated to occur. ADS Stage 4, located on the hot legs, is modeled because the limiting WCOBRA/TRAC case is extended beyond the fuel rod quench time until the CMT liquid level decreases to the low-2 setpoint that actuates the ADS Stage 4 valves and IRWST injection.

The RCS loop model also includes one-dimensional PIPE components, which model the thimble tube bypass in the low-power, support column/open hole, and guide tube assemblies. The inclusion of these components is consistent with the approved modeling of the thimble tube bypass in standard Westinghouse PWRs.

WCAP-16009-P-A describes the cold leg break nodalization used to model the break type (guillotine or split) and size.

It should be noted that Revision 17 of the DCD increased the inside diameter of the pressurizer and decreased the vessel height. However, the internal free volume of the pressurizer and the water volume, at power, remain unchanged (refer to APP-GW-GLR-016) and, therefore, have no effect on the WCOBRA/TRAC loop model. However, the decrease in the pressurizer vessel height results in the changes to the high-3, high-2, and high-1 pressurizer water level setpoints shown in DCD Table 15.0.4a. In addition, in letter DCP/NRC2074, the applicant reported that the pressurizer surge-line resistance used in the DCD Revision 15 WCOBRA/TRAC model was in error. This error has been corrected in this WCOBRA/TRAC model.

15.2.6.5.2.2.2 Reactor Pressure Vessel and Internals Model

For the AP1000 17x17 fuel, each fuel bundle contains 264 fuel rods, 24 thimble tubes, and 1 instrumentation tube. The AP1000 reactor pressure vessel model includes five fuel rod groups, based on the upper internal region design and power levels. Rod 1 represents a single fuel rod, the hot rod, which has the highest power in the core and is located in the hot assembly. Rod 2 represents the remaining 263 fuel rods in the hot assembly. It has a power equivalent to the hot assembly average fuel rods and represents an assembly located beneath a support column. Rod 3 represents the 15,576 fuel rods in the medium-power assemblies located beneath support-column/open-hole channels. Rod 4 represents the 18,216 fuel rods in the medium-power assemblies located beneath guide-tube channels. Rod 5 represents the 7,392 fuel rods in the peripheral assemblies in the low-power channel.

The location of the vertical section boundaries relative to the reactor pressure vessel structures and internals were chosen consistent with the approved AP600 WCOBRA/TRAC model described in WCAP-14171, Revision 2; NUREG-1512; and WCAP-14601, "AP600 Accident Analyses—Evaluation Models," Revision 2, with the elevations appropriate for the AP1000 design.

The model includes changes to reflect the following design changes to AP1000 reactor internals described in WCAP-16716-NP, "AP1000 Reactor Internals Design Changes," Revision 2, issued May 2007:

- relocation of radial support keys and tapered periphery on the lower core support plate (LCSP)
- addition of a flow skirt in the lower reactor vessel head
- addition of four neutron panels, attached to the outside surface of the core support barrel

The applicant has processes that identify plant configuration changes that could potentially impact safety analyses. It used these internal processes, along with internal processes for assessing evaluation model changes and errors, to identify the need to assess the impacts on LOCA analyses.

As shown in Appendix C to APP-GW-GLE-026, the downcomer region used six azimuthal sectors, as compared to four for the reference model in WCAP-16009-P-A, to account for the DVI lines, similar to the AP600 model. The two additional sectors span two of the four neutron panels, with the remaining two neutron panels falling on gaps (centered between two azimuthal sectors).

The following describes each of the three design changes in detail:

(1) Radial Support Keys/Tapered Periphery on the LCSP

The change to the AP1000 LCSP relocated the four lower radial support keys for the core barrel from the current location of 45 degrees from the cardinal axes to the cardinal locations, which eliminates the potential for interference with the core shroud attachment studs and nuts at the 45-, 135-, 225-, and 315-degree locations. The radial supports keys are now physically aligned with the locations of the cold leg nozzles.

In its response to RAI-SRP15.6.5-SRSB-06, the applicant provided a detailed description of the revised LCSP region modeling for the AP1000 WCOBRA/TRAC model. The metal volume of the LCSP was accounted for in the lower plenum channel. The radial keys were modeled in the downcomer channels to reflect the physical location of the radial keys consistent with the vessel volumes represented by the downcomer channels. One radial key was modeled in each of the two downcomer channel stacks connected to the DVI lines. One half of a radial key was modeled in each of the four downcomer channel stacks connected to the cold legs. The fraction of the radial key in each of these downcomer channels was averaged across the channel because the WCOBRA/TRAC code was not designed to reflect more detailed azimuthal modeling than that specified by the user through the nodalization and lateral gap connections. The momentum area and loss coefficients were adjusted to calibrate the steady-state pressure drop consistent with the modeling approach used for standard plants and the resolution of the WCOBRA/TRAC model nodalization. The AP1000 ASTRUM steady-state calculation confirmed that the steady-state acceptance criteria, specified in WCAP-16009-P-A, Table 12-6, "Criteria for Acceptable Steady-State," were met. The vessel pressure drop and the vessel inlet nozzle to mid-core pressure drop were benchmarked against hydraulic calculations to be within the acceptance criteria.

(2) Lower Reactor Vessel Head Flow Skirt

One of the design changes to the AP1000 reactor internals involved the addition of a flow skirt in the lower reactor vessel head to obtain a more uniform core inlet flow distribution that meets specifications established by the Westinghouse fuel group. The applicant provided a detailed description of the flow skirt region modeling for the AP1000 WCOBRA/TRAC model in response to RAI-SRP15.6.5-SRSB-07. The metal volume of the flow skirt was accounted for in the lower plenum channel. The radial flow area through the flow skirt holes and between the top of the flow skirt and the bottom of the LCSP was reflected in the gaps that connect the downcomer channels to the lower plenum channel. The AP1000 ASTRUM steady-state calculation confirmed that the steady-state acceptance criteria, specified in WCAP-16009-P-A, Table 12-6, were met. The vessel pressure drop and the vessel inlet nozzle to mid-core pressure drop were benchmarked against hydraulic calculations to be within the acceptance criteria. The applicant determined that the core inlet flow distribution assumptions that formed the basis of the original fuel thermal-hydraulic calculations remain valid.

(3) Neutron Panels

Neutron panels were attached to the outside diameter of the core support barrel to maintain the end-of-life reactor vessel fluence values at less than the maximum allowed in RG 1.99, "Radiation Embrittlement of Reactor Vessel Materials," Revision 2, issued May 1988. The panels reduce the reactor vessel fluence at the circumferential locations that have the highest fluence values and provide a relatively rigid structure with a smaller downcomer cross-sectional area than a full cylinder. The neutron panels are located at four circumferential locations where fuel assemblies are closest to the reactor vessel (the 0-, 90-, 180-, and 270-degree locations). The DVI lines are located at 0 and 180 degrees, and the hot leg nozzles are located at 90 and 270 degrees. Each neutron panel covers about 30 degrees circumferentially and extends over the entire length of the active core region (4.27 m (14 ft)). The neutron panels are contoured to minimize the impact on the downcomer annulus flow area reduction and to reduce the probability of vortex generation in the downcomer.

The applicant provided a detailed description of the neutron panel modeling for the AP1000 WCOBRA/TRAC model in response to RAI-SRP15.6.5-SRSB-09. The neutron panels were modeled in the downcomer channels to reflect the physical location of the neutron panels consistent with the vessel volumes represented by the downcomer channels. One neutron panel was modeled in each of the two downcomer channel stacks connected to the DVI lines. One half of a neutron panel was modeled in each of the four downcomer channel stacks connected to the cold legs. The fraction of the neutron panel in each of these downcomer channels was averaged across the channel because the WCOBRA/TRAC code was not designed to reflect more detailed azimuthal

> modeling than that specified by the user through the nodalization and lateral gap connections. The azimuthal flow areas were modeled as the flow area away from the neutron panels, and the friction factor for azimuthal flow reflects the flow between two walls, consistent with the modeling approach for standard plants. The metal mass of the neutron panels was modeled as an unheated conductor in the appropriate channels. This is an acceptable approach for capturing the effects of the neutron panels in the downcomer, including the calculation of downcomer boiling, and is consistent with the modeling of neutron panels in standard two-loop, three-loop, or four-loop Westinghouse PWRs.

15.2.6.5.2.2.3 Previous WCOBRA/TRAC Modeling Limitation

The AP600 safety evaluation in NUREG-1512, on the acceptability of the AP600 WCOBRA/TRAC model, imposed limitations that require an applicant to address the sensitivity of the CMT and residual heat removal system modeling parameters that are not included in the uncertainty methodology in the event that either the blowdown or reflood phase PCT exceeds 941 °C (1725 °F) for any reason. The applicant addresses this by repeating the study that identifies the PCT sensitivity to CMT/PRHR elimination and adding the blowdown and reflood PCT impacts as a bias to their respective 95 percent PCT results. Section 15.2.6.5.2 of NUREG-1793 also discussed this limitation. Revision 17 of the DCD, Section 15.6.5.4A.5, states that previous AP1000 sensitivity calculations evaluated the sensitivity of the CMT and PRHR to modeling relative to a baseline case. The results show that the calculated PCTs for both the cases, in which the CMT and the PRHR, respectively, were isolated from the rest of the AP1000, were lower than the PCT of the baseline case. In RAI-SRP15.6.5-SRSB-12, the NRC asked the applicant to clarify whether the sensitivity studies for the proposed AP1000 model include the MLO and CWO sensitivities. In its response, the applicant performed sensitivity studies for the CMT and PRHR with the model described in Appendix C to APP-GW-GLE-026. The WCOBRA/TRAC PCT results of the CMT inoperable study showed a temperature decrease of Δ 21 °C (38 °F) when compared to the reference case. The results of the PRHR inoperable study showed a temperature increase of Δ 1.1 °C (Δ 2 °F) when compared to the reference case. However, to perform the PRHR study, the maximum allowable time step had to be reduced by 0.0001 second to execute the case, and a revised reference case was also run with the reduced time step. The revised reference case resulted in a decreased PCT of Δ 3.3 °C (Δ 6 °F) as compared to the original reference case. The applicant concluded that the effect of PRHR inoperability was minimal. Since the AP1000 shows significant margin to the MLO and CWO limits, the staff concludes that no penalties need to be applied to the analysis results for assuming that the safety-related equipment does not operate.

In Attachment 2 to APP-GW-GLE-026, the applicant described the following revisions to Revision 17 of the DCD, Section 15.6.5.4A.5, “Large-Break LOCA Analysis Results,” to incorporate the results of these studies:

> The large break LOCA analysis complies with the restrictions in Reference 32 [WCAP-16009-P-A]. AP1000 sensitivity calculations evaluated the sensitivity to modeling of the CMT and PRHR relative to the reference transient configuration. A case in which the CMT was isolated from the rest of the AP1000 was analyzed, and the calculated PCT was lower than the PCT of the reference transient configuration. Also, a case in which the PRHR was isolated from the rest of the AP1000 was analyzed, and the calculated PCT was 1 ºC (2 °F) higher than the reference transient configuration.

This is acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

In summary, the AP1000 ASTRUM BELOCA model was developed consistent with the modeling guidelines presented in WCAP-16009-P-A. Therefore, the staff concludes that the AP1000 ASTRUM BELOCA model using WCOBRA/TRAC (M7AR7_AP) conforms to the guidance provided in RG 1.157 for evaluation models needed to demonstrate compliance with the acceptance criteria in 10 CFR 50.46.

15.2.6.5.2.3 ASTRUM AP1000 Best Estimate Large-Break Loss-of-Coolant Accident Analysis

15.2.6.5.2.3.1 ASTRUM Applicability to AP1000 Best Estimate Large-Break Loss-of-Coolant Accident Evaluation

ASTRUM uses a nonparametric statistical technique applied directly to a random sample of outputs, for example, the PCT, the MLO, and the CWO. These sample outputs are computed by applying Monte Carlo sampling of the inputs to the WCOBRA/TRAC calculations. With this approach, a simple singular statement of uncertainty in the form of a tolerance interval for the numerical acceptance criteria of 10 CFR 50.46 can be developed. Once the desired tolerance level is defined, the number of Monte Carlo code runs required to construct the tolerance interval that meets the desired level of safety can be computed. ASTRUM is based on a 95/95 tolerance level to demonstrate compliance with the 10 CFR 50.46 criteria. This tolerance level requires 124 WCOBRA/TRAC runs.

A confidence interval covers a population parameter with a stated confidence, that is, a certain proportion of the time. A fixed proportion of the population can also be covered with a stated confidence, called a tolerance interval. The endpoints of a tolerance interval are called tolerance limits. An application of tolerance intervals involves comparing specification limits with tolerance limits that cover a specified proportion of the population. The 95/95 statement is interpreted to mean that there is a 95 percent probability that 95 percent of the random output variable population falls within the specified tolerance limits. The maximum and minimum value of the samples of the output variables are used to define the limits. The results obtained with ASTRUM are taken to mean that there is at least a 95 percent confidence that the limiting PCT, MLO, and CWO from the sample exceed the true 95th percentile.

ASTRUM replaced the original CQD response surface method, described in WCAP-12945-P-A, to combine the uncertainties with a direct Monte Carlo sampling method. In the application of CQD methodology to AP1000, the uncertainties in the initial fluid conditions in the RCS and the ECCS boundary conditions were bounded in a direction to maximize the PCT. The model uncertainty component addressed uncertainties in the code models that affected the overall system transient (global models), as well as those that only affected the hot rod (local models). WCOBRA/TRAC was used to calculate the effects of initial conditions, power distributions, and global models, and HOTSPOT was used to calculate the effects of local models. Biases and uncertainties, resulting from the assumption that the initial conditions, the power distribution, and the model uncertainty components were linearly combined, were quantified and taken into account. The CQD methodology calculates the final PCT uncertainty distribution by a combination of response surface equations and Monte Carlo sampling. ASTRUM considers the same plant parameters, but each parameter is randomly sampled for each case. The 95/95 PCT is established using nonparametric order statistics.

With ASTRUM, the number of runs is fixed (124 runs for three outcomes—PCT, MLO, and CWO) and is independent of the number of uncertainty attributes considered in the sampling process. The uncertainty parameters are directly sampled instead of using the bounding approach of the CQD methodology.

ASTRUM retains the distinction between global and local variables. However, in ASTRUM, only a single HOTSPOT calculation is performed for each WCOBRA/TRAC run, instead of the multiple HOTSPOT runs with the CQD methodology used to obtain the local model PCT distribution. The HOTSPOT calculation is now a single calculation where the local uncertainties are set at their values by random sampling from their respective distributions. This is consistent with the Monte Carlo approach, where each uncertainty parameter is randomly sampled from the respective distribution for each simulation, which comprises a WCOBRA/TRAC and a HOTSPOT calculation.

The NRC reviewed the ASTRUM uncertainty methodology and found it to be acceptable for meeting the regulatory requirements of 10 CFR 50.46, as described in the staff evaluation of WCAP-16009-P-A. The AP1000 BELOCA analyses for Revision 17 of the DCD use the previously approved global model uncertainties and biases, as well as the local model uncertainties and biases, including the revised blowdown heatup transfer multiplier. The ASTRUM uncertainty methodology is independent of the physical system being modeled and is equally applicable to the AP1000 BELOCA analyses to demonstrate compliance with the requirements of 10 CFR 50.46.

15.2.6.5.2.3.2 Application of ASTRUM to the AP1000 Best Estimate Large-Break Loss-of-Coolant Accident Evaluation

The ASTRUM uncertainty methodology, used for the AP1000 BELOCA analysis for Revision 17 of the DCD, independently samples the uncertainties of the global models, local models, power distribution, and initial and boundary conditions for each of 124 runs over the same ranges of uncertainty and distributions as in the CQD methodology. The sampled uncertainties become inputs to each of the 124 WCOBRA/TRAC calculations.

The WCOBRA/TRAC thermal-hydraulic boundary conditions for the hot rod are input to the local model uncertainties calculation performed with HOTSPOT. The limiting PCT, MLO, and CWO may come from the same case or as many as three different cases. With ASTRUM, each parameter is assumed to be independent of the other two parameters. This assumption is conservative since the MLO and the CWO depend on the cladding temperature (time at temperature).

The WCOBRA/TRAC studies were performed for the AP1000 BELOCA to determine the sensitivities to some of the major plant parameters. These studies included effects of ranging the steam generator tube plugging, ranging the relative power in the low-power assemblies, loss of offsite power coincident with the break initiation, and the break location. The results were used to identify bounding conditions for these parameters, which were then used in the uncertainty calculations.

APP-GW-GLE-026, Table E-1, "Summary of Plant Physical Description, Initial Conditions, Power Distribution, and Global Model Uncertainty Application in CQD Methodology, AP1000 DCD Methodology, and ASTRUM Methodology as Applied to the AP1000," compares the plant physical models, initial conditions, power distributions, and global model uncertainties between the CQD method used in Revision 15 of the DCD and ASTRUM used in Revision 17. The values were referenced to the appropriate information in WCAP-16009-P-A.

DCD Table 15.0-4a provided the PMS setpoints and time delay assumed in the accident analyses. As described in Section 15.2.6.5.2.2 of this report, the safety system related to pressurizer water level high-3, high-2, and high-1 setpoints in DCD Table 15.0-4a are consistent with the revised pressurizer dimensions described in APP-GW-GLR-016.

Revision 17 of the DCD, Table 15.6.5-4, provides the major plant parameter assumptions used in the BELOCA analysis. These plant parameters were developed consistent with the guidance provided in WCAP-16009-P-A. The uncertainty distributions for the global models, local models, power-related parameters, and initial and boundary conditions appear in Tables 1, 2, 3, and 4, respectively, of APP-GW-GLE-026. These distributions are consistent with Tables 1-7, 1-8, 1-10, and 1-11, respectively, of WCAP-16009-P-A. The blowdown heatup heat transfer multiplier was modified to correct modeling inconsistencies and input errors in the WCOBRA/TRAC LOFT deck, as described in Section 15.2.6.5.2.1 of this report.

The initial reactor core power of less than 1.01x3400 MWt assumed a calorimetric uncertainty of 1 percent. This is consistent with DCD Table 15.0-2, which lists the initial thermal power output assumed for the large-break LOCA analysis as 3,434 MWt. As stated in the staff safety evaluation in Section 15.1.0.3.1.1 of this report, the applicant will revise DCD Section 15.0.15 to include COL Information Item 15.0.15.1, which requires the COL holder to calculate the primary power calorimetric uncertainty before fuel load to confirm that the safety analysis primary power calorimetric uncertainty bounds the calculated value. Therefore, the staff finds the use of 1 percent initial core power uncertainty acceptable.

The ranges of the parameters were compared to the TS limiting conditions for operation. The accumulator water temperature is ranged based on AP1000 expected values from 10 °C (50 °F) to 48.9 °C (120 °F), which is consistent with the TS 3.6.5, “Containment Air Temperature,” limiting condition for operation for an operable containment.

The accumulator pressure range between 4619 kPa (670.0 psia) and 5280 kPa (765.8 psia) was inconsistent with TS 3.5.1, SR 3.5.1.3, which specifies the accumulator pressure range between 4392 kPa and 5302 kPa (637 and 769 pounds-force per square inch gauge (psig)). In addition, Table 15.6.5-4 did not include the accumulator water volume range. In its response to RAI-SRP15.6.5-SRSB-13, the applicant indicated that the incorrect accumulator pressure and water volume ranges were assumed in the AP1000 BELOCA ASTRUM analysis, and a reanalysis of the top 10 HOTSPOT PCT cases from the ASTRUM run set was performed to evaluate the impact of the incorrect pressure and water volume ranges. Maintaining the seed values used in the original ASTRUM analyses, the accumulator pressures and liquid volumes for the top 10 HOTSPOT cases were determined based on the original sampling for each run and the revised ranges. The evaluation showed that the PCT, MLO, and CWO results reported in APP-GW-GLE-026 remained valid for the revised TS ranges. The applicant assessed a 0-degree PCT penalty for this set of closely related errors. It must be noted that Figure 27, “HOTSPOT PCT Versus Effective Break Area Scatter Plot for All 124 Cases,” in APP-GW-GLE-026 would likely show some changes in the PCT values for some cases if the complete set of 124 runs were to be reanalyzed with the correct accumulator pressure and water volume ranges. However, the overall conclusions for the limiting break would still be applicable.

The applicant also committed to update Table 15.6.5-4 of the DCD to make the accumulator pressure range and the accumulator water volume ranges consistent with TS 3.5.1, SR 3.5.1.3 and SR 3.5.1.2, respectively. In a subsequent revision to the DCD, the applicant incorporated this change in the DCD.

The percentage of steam generator tube plugging is based on the bounding case (10 percent), and DCD Table 5.1-3, “Thermal-Hydraulic Parameters (Nominal),” provides the nominal RCS thermal-hydraulic parameters for this case. The average RCS temperature (T_{AVE}) listed in Table 15.6.5-4 is consistent with DCD Table 5.1-3 for this level of plugging. The hot assembly location, under a support column, is bounding based on the design of the reactor vessel upper core region internals. The pressurizer location, in the intact loop, is bounding based on AP1000 WCOBRA/TRAC sensitivity calculations.

The single-failure assumption is the failure of one CMT isolation valve to open. During a large-break LOCA, the CMT is actuated by the ”S” signal, but the CMT flow is shut off upon accumulator actuation and resumes at the end of accumulator injection. This limiting single failure affects the safety injection flow delivery when the CMT begins to inject toward the end of accumulator injection.

One of the plant parameter assumptions is that the offsite power remains available during the LOCA transient. In its response to RAI-SRP15.6.5-SRSB-14, the applicant provided an offsite power availability/unavailability sensitivity analysis using the AP1000 BELOCA model. It confirmed that the offsite-power-available assumption remains limiting in the AP1000 ASTRUM analysis, because of the effect of RCP operation on the downflow cooling during the blowdown period. With loss of offsite power, the RCPs trip coincident with the break and begin to coast down. With offsite power available, the RCPs continue to run until they are automatically tripped. As a result, more fluid flows from the upper plenum into the hot leg in the broken loop, and less fluid reverses flow from the hot leg of the intact loop into the upper plenum. Therefore, less fluid in the upper plenum is available for blowdown cooling. In the case of a loss of offsite power, the liquid downflow into the hot assembly was observed during blowdown; however, there was no observed downflow of liquid into the hot assembly at the upper core plate with offsite power available. The downflow cooling in the case of a loss of offsite power results in increased blowdown cooling and lower PCT.

The containment backpressure is specified at a bounding minimum value, consistent with the WCAP-16009-P-A methodology. The containment pressure is specified at the break location as an input table. The AP1000 ASTRUM analysis followed the approved WCAP-16009-P-A methodology for determining the conservative containment backpressure approved for standard Westinghouse PWRs. The reference transient was used to establish the containment pressure response that was applied as a boundary condition in the uncertainty analysis calculations. The inputs to the containment pressure calculation were biased to obtain a conservative (low) pressure transient.

The peak linear heat rate, expressed in terms of total heat flux hot channel factor, F_Q, was compared to AP1000 DCD Table 4.3-2, “Nuclear Design Parameters (First Cycle),” and was found to be consistent with the design data. The hot rod assembly power, expressed in terms of nuclear enthalpy rise hot channel factor, $F_{\Delta H}$, was increased from 1.65 to 1.75. In its response to RAI-SRP15.6.5-SRSB-17, the applicant clarified that it increased $F_{\Delta H}$ in the AP1000 ASTRUM analysis in order to provide increased margin for the core design. The hot assembly average integrated power (P_{HA}) was correspondingly increased to 1.683 from 1.586. The hot assembly average integrated power is 4 percent lower than the hot rod integrated power, consistent with the standard value applied in the approved ASTRUM, WCAP-16009-P-A. DCD Figure 15.6.4A-13 shows the axial power distribution in terms of normalized power integrals in the bottom third of the core and middle third of the core, which is consistent with the treatment in WCAP-16009-P-A.

Only cold leg breaks were analyzed because the hot leg break location was found to be nonlimiting for the BELOCA methodology. ASTRUM explicitly accounts for the effect of break type, and various break types and sizes, such as double-ended cold leg guillotine (DECLG) and split breaks, are assumed to have an equal chance of being sampled. The break size and type were sampled consistent with this methodology. The applicant addressed the limiting break type analysis in its response to RAI-SRP15.6.5-SRSB-14. Before performing the detailed ASTRUM uncertainty analyses, confirmatory calculations were performed to identify the limiting settings for some of the major plant parameters. The results of these calculations were used to define the reference transient case. The applicant found that the important thermal-hydraulic characteristics of the AP1000 during a large-break LOCA were consistent with those observed in conventional Westinghouse three-loop plant analyses. The AP600 large-break LOCA phenomena identification ranking table indicated that the only high-ranking area of difference between the AP600 and a standard three-loop plant with respect to a large-break LOCA was the delivery of emergency core cooling water through the AP600 DVI lines (see the WCAP-14171, Revision 2, and WCAP-15644, Revision 2, WCOBRA/TRAC code applicability reports for the AP600 and the AP1000, respectively). The applicant's experience with BELOCA analyses has shown that, for three-loop plants, either a split break or a double-ended guillotine break may be limiting. The reference transient configuration was determined from simulations of nominal DECLG breaks consistent with the approved ASTRUM for conventional three-loop plants (WCAP-16009-P-A).

For Revision 15 of the DCD, the limiting large-break LOCA analyzed with the CQD methodology was determined to be a DECLG break. In Revision 17, the combination of uncertainty parameters sampled in the ASTRUM analysis resulted in the limiting break being a split break, which is the limiting case for both PCT and MLO. Figure 27 of APP-GW-GLE-026 depicts this result and provides the PCT scatter plot showing the impact of the effective break area on the HOTSPOT PCT analysis.

DCD Section 15.6.5.4A.6 describes the limiting PCT/MLO split break case from the AP1000 ASTRUM analysis with the results shown in Figures 15.6.5.4A-1 through 15.6.5.4A-12. Figure 15.6.5.4A-2 shows that the HOTSPOT PCT occurs during the reflood phase. In its response to RAI-SRP15.6.5-SRSB-14, The applicant confirmed that the AP1000 remains reflood limited and that the design changes did not result in the limiting PCT moving to the blowdown time period. The applicant inspected the 124 ASTRUM calculations. In 100 runs, the PCT occurred during reflood. The applicant then inspected the characteristics of the 24 runs in which the PCT occurred during blowdown. These 24 runs were significantly nonlimiting, with the WCOBRA/TRAC PCTs less than 649 °C (1200 °F). The effective break areas sampled for 21 of these calculations were less than 1.0 times the cold leg area, and one was a split break with an effective break area greater than 2.0. The peaking factor and power shape parameters sampled in the remaining two cases contributed to the low PCTs in these calculations. Overall, the early PCT peak in these 24 runs was attributed to the run-specific combinations of sampled parameters, particularly the sampled break areas for the majority of the runs. The applicant determined that the ASTRUM runs in which the calculated PCT peaks occurred early in the transient resulted from the combination of sampled parameters for those runs and not the AP1000 design changes.

DCD Table 15.6.5-6, "Best-Estimate Large-Break Sequence of Events for the Limiting PCT/MLO Case," provides the time line for the sequence of events for the limiting BELOCA. The containment high-2 pressure (156 kPa (22.7 psia or 8 psig)) is assumed to occur 2.2 seconds after the initiation of the break because the massive size of the break causes an immediate, rapid pressurization of the containment. This assumption of 2.2 seconds is consistent with the time delay for the "S" signal on high-2 containment pressure for a large-break LOCA specified in DCD Table 15.0-4a. In its response to RAI-SRP15.6.5-SRSB-15, the applicant addressed the acceptability of the assumed containment response to the BELOCA spectrum. The 2.2-second assumption overestimates the time to reach the containment pressure high-2 setpoint for a nominal DECLG large-break LOCA. The applicant's calculations with assumptions biased to obtain a conservatively low pressure transient show the containment pressure to be more than 165 kPa (24 psia), as compared to the 156 kPa (22.7 psia or 8 psig)) high-2 setpoint, at 2.2 seconds after the break. While 2.2 seconds may not allow enough time to reach the high-2 containment pressure setpoint for the smallest breaks sampled as part of ASTRUM because of the reduced mass and energy release, these smaller break sizes were found to be nonlimiting for the AP1000 as shown in APP-GW-GLE-026, Figure 27.

DCD Section 15.6.5.4A.5 states that local and core-wide cladding oxidation values have been determined using the methodology approved in WCAP-16009-P-A. The detailed CWO calculation procedure described in Section 11.6-2 of WCAP-16009-P-A would require a series of <u>W</u>COBRA/TRAC runs based on the oxidation value from the limiting hot assembly rod case, but with varying power levels for the other runs in the series to account for lower power assemblies in other core regions. For the AP1000, the applicant chose to apply the limiting case hot assembly rod oxidation value to the entire reactor core. In its response to RAI-SRP15.6.5-SRSB-18, the applicant clarified that the method used to evaluate the limiting CWO is a conservative approach and in accordance with the procedure used for standard ASTRUM analyses. The results of the 124 cases were ranked by the <u>W</u>COBRA/TRAC-calculated hot assembly average volumetric oxidation from highest to lowest. The case with the maximum hot assembly average volumetric oxidation was examined. In the AP1000 ASTRUM analysis, this was case "run015" with a hot assembly oxidation of 0.2 percent. Since this oxidation was substantially lower than the regulatory CWO limit of 1 percent, a detailed calculation of the CWO was not necessary for the AP1000. By definition, the CWO fraction is less than the hot assembly average volumetric oxidation because the many lower power assemblies present in the reactor core will have lower average volumetric oxidation than the hot assembly. The application of the limiting hot assembly rod oxidation value to the entire core is conservative and acceptable.

15.2.6.5.2.4 Summary of the Best Estimate Large Break Loss-of-Coolant Accident Analysis Results

The results of the AP1000 BELOCA ASTRUM analyses, based on the 124 <u>W</u>COBRA/TRAC and HOTSPOT runs, identify the limiting PCT/MLO split break. DCD Table 15.6.5-8 summarizes the AP1000 ASTRUM BELOCA results and shows the calculated 95th percentile PCT to be 1003 °C (1837 °F), the MLO to be 2.25 percent, and the limiting CWO to be 0.2 percent. Table 15.6.5-8 also indicates that the core remains coolable and the core remains cool in the long term. The core coolable geometry is generally satisfied when calculated PCT and MLO are within the associated acceptance criteria. The post-LOCA long-term core cooling, as described in DCD Section 15.6.5.4C, "Post-LOCA Long-Term Cooling," is not affected by the application of ASTRUM and continues to show compliance with 10 CFR 50.46 acceptance criteria. Therefore, the BELOCA analysis results show a high level of probability that the following criteria of 10 CFR 50.46 will be met:

- The calculated PCT will not exceed 1204 °C (2,200 °F).
- The calculated maximum cladding oxidation will not exceed 17 percent of the total cladding thickness before oxidation.
- The calculated total amount of hydrogen generated from the chemical reaction of the cladding with water or steam will not exceed 1 percent of the amount that would be generated if the entire cladding metal surrounding the fuel (excluding the cladding surrounding the plenum volume) were oxidized.
- The calculated changes in core geometry are such that the core remains amenable to cooling.
- After successful initial operation of the ECCS, the core temperature will be maintained at an acceptably low value, and the decay heat will be removed for the extended period of time required by the long-lived radioactivity remaining in the core.

The calculated results for the AP1000 BELOCA meet the acceptance criteria of 10 CFR 50.46 and are, therefore, acceptable.

15.2.6.5.2.5 Conclusion

Based on the above evaluation, the staff concludes that the BELOCA analysis using the WCOBRA/TRAC code and the ASTRUM statistical uncertainty treatment methodology described in Revision 17 of the DCD demonstrates compliance with the acceptance criteria of 10 CFR 50.46 and, therefore, is acceptable. In a subsequent revision to the AP1000 DCD, the applicant made appropriate changes to the DCD text, which resolves this issue.

15.2.7 Post-Loss-of-Coolant Accident Long-Term Cooling (DCD Tier 2, Section 15.6.5.4C)

DCD Section 15.6.5.4C did not change; however, the NRC is reviewing the long-term cooling analyses and supporting documentation submitted for resolution of COL Item 6.3.8.2 related to Generic Safety Issue (GSI)-191, “Assessment of Debris Accumulation on PWR Sumps,” for the AP1000, together with the GSI-191 issues addressed in Section 6.2.1.8, “Adequacy of IRWST and Containment Recirculation Screen Performance.” For consistency, the staff’s evaluation and conclusion regarding post-LOCA long-term cooling for the AP1000 appear with the GSI-191 discussion in Section 6.2.1.8 of this report.

15.3 Radiological Consequences of Accidents

In DCD Tier 2, Chapter 15, the applicant performed radiological consequence assessments of the following seven design-basis accidents (DBAs), using the hypothetical set of atmospheric dispersion factors (χ/Q values) provided in DCD Tier 1, Table 5.0-1, “Site Parameters”; DCD Tier 2, Table 2-1, “Site Parameters”; DCD Tier 2, Table 15A-5, “Offsite Atmospheric Dispersion Factors (χ/Q) for Accident Dose Analysis”; and Table 15A-6, “Control Room Atmospheric Dispersion Factors (χ/Q) for Accident Dose Analysis:

(1) LOCA
(2) fuel-handling accident (FHA)
(3) main steamline break accident outside of containment
(4) RCP shaft seizure accident
(5) failure of small lines carrying primary coolant outside containment
(6) rod cluster assembly ejection accident, and
(7) steam generator tube rupture accident

The applicant concluded in DCD Tier 2, Revision 15, that the AP1000 design will provide reasonable assurance that the radiological consequences resulting from any of the above DBAs will fall within the offsite dose criterion specified in 10 CFR 50.34(a)(1) and the control room operator dose criterion specified in GDC 19, “Control Room,” of Appendix A to 10 CFR Part 50. In NUREG-1793, the staff performed independent radiological consequence analyses for all of the DBAs listed above and verified the applicant’s assessments.

In September 2008, the applicant submitted Revision 17 of the DCD, as a part of its application to amend the AP1000 DC rule in Appendix D to 10 CFR Part 52. In Revision 17, the applicant requested the following four standard changes to the Chapter 15 of the certified AP1000 DCD, Revision 15:

(1) increase in the assumed decay time in the FHA dose analysis from 24 hours to 48 hours to provide increased radioactive decay of short-lived fission products before the handling of irradiated fuel assemblies

(2) increase in the aerosol removal duration in the containment from 15.5 hours to 24 hours from the initiation of a DBA

(3) revisions to some of the hypothetical offsite and control room χ/Q values, and

(4) changes to the MCR emergency habitability system (VES) operation

The applicant proposed these changes in accordance with the change criterion in 10 CFR 52.63(a)(1)(vii) in that the changes contribute to increased standardization of the certification information.

Subsequent to the submittal of the AP1000 DCD Revision 17, on November 3, 2008, the applicant proposed to add a first-of-a-kind passive control room air filtration line to the MCR VES. This design change is intended to allow the VES to meet the dose acceptance criterion specified in GDC 19 with an allowable control room unfiltered air inleakage of 25.5 cubic meters per hour (m^3/hr) (15 cubic feet per minute (ft^3/min)), which includes 8.5 m^3/hr (5 ft^3/min) for ingress/egress. Section 6.4 of this report provides the staff’s evaluation of the MCR VES, including the proposed design changes.

These changes will alter the calculated radiological doses in the control room for the above DBAs analyzed in the certified AP1000 DCD, Revision 15, and will revise some of the χ/Q values listed as site parameters in the following tables:

- DCD Tier 1, Table 5.0-1, “Site Parameters”

- DCD Tier 2, Table 2-1, “Site Parameters”

- DCD Tier 2, Table 15A-5, "Offsite Atmospheric Dispersion Factors (χ/Q) for Accident Dose Analysis"
- DCD Tier 2, Table 15A-6, "Control Room Atmospheric Dispersion Factors (χ/Q) for Accident Dose Analysis"

Revision 17 of the DCD, Section 2.3.4, evaluates the proposed changes to the hypothetical short-term accident χ/Qs, and Table 2.3.4-1 lists the accident χ/Q values used as site parameters.

15.3.1 Evaluation

15.3.1.1 Fuel-Handling Accident Decay Time Increase

In Revision 15 of the DCD, Section 15.7.4, "Fuel Handling Accident," the applicant analyzed the radiological consequences of a postulated FHA inside containment and in the fuel-handling area inside the auxiliary building, assuming that a single fuel assembly that has undergone 24 hours of decay time is dropped. This decay time provides for radioactive decay of short-lived fission products to reduce the radiological consequences of a release for the design-basis FHA. Even though the applicant analyzed the FHA using a decay time of 24 hours in Revision 15 of the DCD, the applicant had conservatively specified a 100-hour decay time in Revision 15 of the DCD, Chapter 16, TS 3.9.7, "Decay Time." The longer decay time would result in further reduction of radiological consequences of the FHA than the applicant calculated in the FHA radiological consequences analysis in Revision 15 of the DCD.

As discussed in NUREG-1793, the staff reviewed the applicant's analysis and performed an independent confirmatory radiological analysis for the postulated FHA. The staff's results agree with the applicant's values. Both the applicant's and the staff's results met the relevant dose acceptance criteria at the exclusion area boundary (EAB), low-population zone (LPZ), and control room. Based on its review, the staff finds the applicant's analysis of the FHA to be acceptable and that the dose criteria in 10 CFR 50.34(a)(1) and GDC 19 are met.

In Revision 17 of the DCD, the applicant proposed to change the minimum decay time to 48 hours from the 24 hours assumed in Revision 15 of the DCD and in NUREG-1793. This change will provide additional radioactive decay of short-lived fission products, which would result in a lesser amount of radioactive material available for release and, therefore, lower dose results for the radiological consequence assessment for the postulated FHA. Revision 17 of the DCD, Section 15.7.4, discussed the revised FHA analysis assuming a 48-hour decay time. The staff verified that the only changes to the analyses were related to the change in decay time and the changes in the hypothetical χ/Q values discussed below in Section 15.3.1.3.

The staff finds that the change in the FHA radiological consequence analysis ensures that the decay time assumption in the analysis is consistent with the minimum decay time value proposed for the AP1000 TS and results in lower control room and offsite doses than previously found acceptable for Revision 15 of the DCD. Therefore, the staff finds that the proposed change to the TS decay time is acceptable with respect to the radiological consequences of DBAs. The resulting doses off site and in the control room continue to meet the dose acceptance criteria in RG 1.183, "Alternative Radiological Source Terms for Evaluating Design Basis Accidents at Nuclear Power Reactors," issued July 2000, and NUREG-0800

Section 15.0.3 for the DC review. The applicant's revised FHA dose analyses show that the dose criteria in 10 CFR 50.34(a)(1), 10 CFR 52.47(a)(2)(iv), and GDC 19 would be met with the change in minimum decay time before fuel movement. The applicant revised the decay time requirement in Revision 17 of the DCD, TS 3.9.7, to 48 hours from 100 hours to be consistent with the revised FHA analysis. The staff finds that the proposed change to the TS is supported by the FHA analysis and, therefore, is acceptable.

15.3.1.2 Aerosol Removal Duration in Containment

In Table 15.6.5-3,"Radiological Consequences of a Loss-of-Coolant Accident with Core Melt," of Revisions 15 and 17 of the DCD, the applicant provided the LPZ doses as 0.238 sievert (Sv) and 0.234 Sv (23.8 and 23.4 roentgen equivalent man (rem)) total effective dose equivalent (TEDE), respectively. In RAI-SRP15.6.5-RSAC-01, the staff asked the applicant to explain the discrepancy in these two LPZ doses, since none of the analysis assumptions given in the certified Revision 15 appear to have changed in Revision 17. In its response, the applicant stated that the analyses in Revision 17 of the DCD took full credit for aerosol removal for the first 24 hours (rather than for 15.5 hours as in Revision 15), using the removal coefficients presented in Appendix 15B to Revision 15 of the DCD. This resulted in a small decrease in the LPZ dose to 0.234 Sv (23.4 rem) TEDE. The staff had previously found the aerosol removal coefficients credited for the first 24 hours in Appendix 15B to Revision 15 of the DCD to be acceptable. Revision 17 did not change any of the aerosol removal coefficients in Appendix 15B. The staff finds that the response to RAI-SRP15.6.5-RSAC-01 is acceptable; therefore, this RAI is closed and the changes to the assumed duration of the aerosol removal in containment are acceptable.

15.3.1.3 Offsite and Control Room χ/Q Values

15.3.1.3.1 Control Room χ/Q Values

In Revision 16 of the DCD, the applicant increased the control room χ/Q values from those specified in Revision 15. In Revision 17, the applicant proposed a change in the control room isolation logic so that the increased χ/Q values in Revision 16 could be maintained, with two exceptions.

The χ/Q values for the heating, ventilation, and air conditioning (HVAC) intake at the ground level containment release points in the 2–8-hour and 8–24-hour intervals are reduced for the LOCA with the nuclear island nonradioactive ventilation system in supplemental filtration mode.

In addition, in Revision 17 of the DCD, the applicant: (1) revised the control room χ/Q values for plant vent/passive containment system air diffuser and ground level containment releases to the control room HVAC intake and Annex Building door; and (2) added new control room χ/Q values for condenser air removal stack releases to the HVAC intake and Annex Building door. Revision 17 of the DCD, Table 2.3.4-1, lists these revisions. Section 2.3.4 of this report provides the staff's evaluation and acceptance of these revisions.

15.3.1.3.2 Offsite χ/Q Values

Revision 17 of the DCD does not change the offsite χ/Q values provided in Revision 15.

15.3.1.4 Offsite and Control Room Doses

15.3.1.4.1 Offsite Doses

The applicant has not changed the radiological doses calculated for the postulated LOCA from those in Revision 15 of the DCD, except for the small decrease for the LPZ dose evaluated in Section 15.3.1.2 of this report. For the radiological consequences of DBAs other than the LOCA, the applicant used the higher and more restrictive χ/Q values provided in Revision 17 of the DCD (compared to those χ/Q values used in Revision 15), while still meeting the dose acceptance criteria. The staff verified and confirmed the applicant's revised offsite doses for the DBAs other than the LOCA. The radiological consequence analyses for the five remaining DBAs (other than the LOCA and FHA as discussed above) have not changed in Revision 17 of the DCD from those described in Revision 15.

Therefore, the DBA analyses in Revision 17 of the DCD used two sets of χ/Q values, one for the LOCA and the other for the DBAs other than the LOCA, although Table 15.A-5 shows only one set of χ/Q values used or LOCA. In its response to RAI-SRP15.6.5-RSAC-02, the applicant stated that Table 15A-5 of a future DCD revision will include these two sets of χ/Q values.

Subsequently, the applicant indicated during the November 3, 2008, meeting with the staff that it will use the same offsite χ/Q values for all DBAs in future DCD revisions to avoid having two sets of χ/Q values, one for the LOCA and another for the DBAs other than the LOCA. In a subsequent revision to the AP1000 DCD, the applicant revised the offsite doses for all DBAs except the LOCA, which resolves this issue.

15.3.1.4.2 Control Room Doses

In Revision 17 of the DCD, the applicant also proposed to modify the control room isolation to include switching to the main control room VES on the pressurizer low-pressure signal. In the LOCA dose analysis, this modification results in actuation of the VES by the time core activity releases start at 10 minutes with leak-before-break approval. In addition, the applicant proposed an effective unfiltered air inleakage assumption of 2.55 m^3/hr (1.5 ft^3/min) into the control room based on a total inleakage of 8.5 m^3/hr (5 ft^3/min), with credit taken for purging of the vestibule door volume and the incomplete mixing of the vestibule and control room volumes with outside air following ingress/egress.

During the November 3, 2008, meeting with the staff, the applicant presented the addition of a new passive control room air filtration line to the VES. This design change is intended to allow the VES to meet the dose acceptance criterion specified in GDC 19 with an allowable unfiltered air inleakage of 15 ft^3/min instead of the assumption of 5 ft^3/min total unfiltered inleakage as discussed above.

To evaluate the revised control room passive filtration design, the staff performed an independent radiological consequence dose calculation for the control room and audited the applicant's dose calculations with the new passive control room air filtration line to the VES. Based on this review of the applicant's analyses, the staff verified that the control room habitability system and the technical support center design in the AP1000 DCD, Revision 17, as modified in RAI response dated May 24, 2010, meet the dose acceptance criteria specified in GDC 19 and NUREG-0800 Section 15.0.3.

The staff previously stated that upon completion of the review and acceptance of this new passive control room air filtration line to the VES, the staff will complete its independent radiological consequence dose calculations for the control room to verify that the control room habitability system and the technical support center (TSC) designed in the AP1000 DCD meet the dose acceptance criteria specified in GDC 19 and NUREG-0800 Section 15.0.3. This was Open Item OI-SRP15.3-1-RSAC-01. With completion of staff's review and an independent dose calculation as discussed above, Open Item OI-SRP15.3-1-RSAC-01 is closed.

Section 6.4 of this report gives the staff's evaluation and acceptance of the new passive control room air filtration line.

15.3.2 Conclusion

Based on the above evaluation, the staff concludes that the proposed DCD changes provide reasonable assurance that the radiological consequences resulting from any of the DBAs will fall within the dose acceptance criteria specified in NUREG-0800 Section 15.0.3, 10 CFR 52.47(a)(2), GDC 19, and Paragraph IV.E.8 of Appendix E to 10 CFR Part 50 for the EAB, LPZ, and control room. The staff further concludes that Revision 17 of the DCD also provides reasonable assurance that the AP1000 TSC will meet radiological consequences criteria specified in NUREG-0737, "Clarification of TMI Action Plan Requirements," Supplement 1 and in NUREG-0800 Section 15.0.3.

16. TECHNICAL SPECIFICATIONS

16.1 Introduction

Chapter 16.0, “Technical Specifications,” of the AP1000 design control document (DCD), provides the AP1000 generic technical specifications (GTS) in accordance with Title 10 of the *Code of Federal Regulations* (10 CFR) 50.36, “Technical specifications.” Each operating license issued by the Commission is required to include technical specifications (TS) that set forth the safety limits (SLs), limiting safety system settings (LSSSs), limiting conditions for operation (LCOs), and other limitations on facility operation deemed necessary for the protection of public health and safety. 10 CFR 50.36(a)(2) requires, among other things, that each applicant for design certification (DC) include in its application proposed GTS for the portion of the plant that is within the scope of the DC application. For the AP1000 design, these are accepted as documented in 10 CFR Part 52, “License, certifications, and approvals for nuclear power plants,” Appendix D, “Design Certification Rule for the AP1000 Design,” and NUREG-1793, “Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design.”

10 CFR 52.47(a)(11), “Contents of applications; technical information,” and 10 CFR 52.79(a)(30), “Contents of applications; technical information in final safety analysis report,” states that a DC applicant and a combined license (COL) applicant respectively are to propose TS prepared in accordance with 10 CFR 50.36 and 10 CFR 50.36a, “Technical specifications on effluents from nuclear power reactors.” COL applicants that reference a certified design are to propose plant-specific technical specification (PTS), including the GTS approved during the DC review. The COL applicant may propose deviations from the certified generic TS prior to issuance of the COL by requesting an exemption from the associated 10 CFR Part 52 appendix that codifies the certified design. A holder of a COL may propose changes to the TS in accordance with 10 CFR 50.90, “Application for amendment of license, construction permit, or early site permit,” in order to adopt approved changes to the standard technical specification (STS) when such changes apply.

This safety evaluation report (SER) chapter documents the U.S. Nuclear Regulatory Commission (NRC) staff review of the amended GTS proposed by the DC applicant for the AP1000 design and their associated Bases. The review is for completeness and correctness in regard to NRC requirements and guidance, and for consistency with related portions of the DCD. The TS are derived from the analyses and evaluations in the DCD.

16.2 Summary

The AP1000 design employs passive safety-related systems that rely on gravity and natural processes, such as convection, evaporation, and condensation. The AP1000 GTS were modeled after Revision 2 of NUREG-1431, “Standard Technical Specifications: Westinghouse Plants.” In some cases, the applicant developed TS beyond those in the STS to account for the advanced passive design features of the AP1000. In many instances, the AP1000 system design functions are similar to those of operating pressurized-water reactors (PWRs), even though the components and systems are new. The amendment to the AP1000 DC affects the following sections of the AP1000 GTS and Bases:

- Section 1

- Section 2
- Sections 3.1 through 3.9
- Section 4
- Section 5

The AP1000 GTS include reviewer's notes stating conditions that a COL applicant (or licensee) must satisfy in order to complete a particular GTS provision (e.g., incorporation of an NRC-approved methodology into a plant's licensing basis, or a staff determination that a licensee's probabilistic risk assessment (PRA) program is of adequate quality).

In some instances, detailed design information, equipment selection, instrumentation settings, or other information needed to establish appropriate TS and Bases was not provided during the review of the AP1000 DC or the amendment to the AP1000 DC. This information is identified in Chapter 16 of the DCD and in the GTS and Bases and will be included in the PTS by the applicant for a COL. Locations for the addition of this information are signified in the GTS by square brackets [ ] to indicate that the COL applicant must provide plant-specific values or alternative text.

As parts of the amendment to the AP1000 DC, the applicant proposed to complete some of the bracketed COL information items. Technical report (TR)-74A (APP-GW-GLR-064), "AP1000 Generic Technical Specifications Completion," Revisions 0 and 1, were submitted to document these changes.

The remaining changes to the AP1000 GTS are either results of modifications to the plant equipment designs or are to resolve inconsistency between various TS requirements and their supporting information in the associated TS Bases. Revisions 0 and 1 to TR-74C (APP-GW-GLN-075), "AP1000 Generic Technical Specifications for Design Changes," were submitted to document these changes.

The applicant also submitted TR-134 (APP-GW-GLR-134), "AP1000 DCD Impacts to Support COLA Standardization," to document any supplemental changes to the AP1000 GTS that were not included in TR-74A or TR-74C.

This SER addresses changes to the AP1000 DCD, since Revision 15. These revisions were prepared using the guidance in NUREG-0800, "Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants," and to the extent applicable for the DC, using regulatory guide (RG) 1.206, "Combined License Applications for Nuclear Power Plants," as a guide for format and content.

Inspections, Tests, Analyses, and Acceptance Criteria (ITAAC): There are no ITAAC for this area of review.

TS: TS are provided in DCD Tier 2, Chapter 16.

16.3 Regulatory Basis

16.3.1 Regulatory Requirements

The relevant requirements of the NRC's regulations for this area of review, and the associated acceptance criteria, are given in Chapter 16 of NUREG-0800, and are summarized below.

Review interfaces with other NUREG-0800 sections can be found in Chapter 16 of NUREG-0800.

Section 182a of the Atomic Energy Act of 1954 (AEA), as amended, requires that applicants for nuclear power plant operating licenses will state:

> such technical specifications, including information of the amount, kind, and source of special nuclear material required, the place of the use, the specific characteristics of the facility, and such other information as the Commission may, by rule or regulation, deem necessary in order to enable it to find that the utilization of special nuclear material will be in accord with the common defense and security and will provide adequate protection to the health and safety of the public. Such technical specifications shall be a part of any license issued.

In 10 CFR 50.36, the NRC established its regulatory requirements related to the content of TS. In doing so, the NRC placed emphasis on those matters related to the prevention of accidents and the mitigation of accident consequences. As recorded in the Statements of Consideration, 33 *Federal Register* (*FR)* 18610, "Technical Specifications for Facility Licenses; Safety Analysis Reports," (December 17, 1968), the NRC noted that applicants were expected to incorporate into their TS "...those items that are directly related to maintaining the integrity of the physical barriers designed to contain radioactivity." Accordingly, 10 CFR 50.36(c) requires that TS include: (1) SLs and LSSSs, (2) LCOs, (3) surveillance requirement (SRs), (4) design features, and (5) administrative controls.

10 CFR 50.36(c)(2)(ii) requires that an LCO be established in TS for each item meeting one or more of the following four criteria:

- Criterion 1 - Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary (RCPB).

- Criterion 2 - A process variable, design feature, or operating restriction that is an initial condition of a design basis accident (DBA) or transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

- Criterion 3 - A structure, system, or component that is part of the primary success path and which functions or actuates to mitigate a design basis accident or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

- Criterion 4 - An SSC shown by operating experience or a probabilistic safety assessment to be significant to public health and safety.

In accordance with 10 CFR Part 50, "Domestic licensing of production and utilization facilities," Appendix A, "General Design Criteria for Nuclear Power Plants," General Design Criteria (GDC) 17, "Electric Power Systems"; GDC 21, "Protection System Reliability and Testability"; GDC 34, "Residual Heat Removal"; GDC 35, "Emergency Core Cooling"; GDC 38, "Containment Heat Removal"; GDC 41, "Containment Atmosphere Cleanup"; and GDC 44, "Cooling Water," those SSCs shown to be significant to public health and safety need to have sufficient independence, redundancy, and testability to perform their safety functions assuming single failure.

10 CFR 50.36a, requires that TS include procedures for control of radioactive effluents.

10 CFR 52.47(a)(11) requires that a DC applicant propose TS prepared in accordance with 10 CFR 50.36 and 10 CFR 50.36a.

16.3.2 Regulatory Guidance

The relevant NRC requirements for TS and Bases reviews, and the associated acceptance criteria, are given in Chapter 16 of NUREG-0800. They are summarized below. Areas of review that interface with other NUREG-0800 sections can also be found in Chapter 16 of NUREG-0800.

For the reasons discussed in detail below, the acceptance criteria adequate to meet the above requirements are included in the STS documents. The STS for PWRs are in three NRC NUREGs. For each NUREG, Volume 1 includes the TS and Volume 2 includes the associated TS bases. The STS include bases for SLs, LSSSs, LCOs, and associated action and SRs. The NUREGs for the STS for PWRs are as follows:

- NUREG-1430, “Standard Technical Specifications Babcock and Wilcox Plants”
- NUREG-1431, “Standard Technical Specifications Westinghouse Plants”
- NUREG-1432, “Standard Technical Specifications Combustion Engineering Plants“

The STS reflect the results of a detailed review of the application of the Interim Policy Statement criteria to generic system functions, which were published in a “Split Report” issued to the nuclear steam supply system vendor owners groups in May 1988. The STS also reflect the results of extensive discussions concerning various drafts of STS so that the application of the TS criteria and the Writer's Guide would consistently reflect detailed system configurations and operating characteristics for all reactor designs. As such, the generic Bases presented in the NUREGs provide an abundance of information regarding the extent to which the STS present the requirements necessary for protecting public health and safety.

On July 22, 1993, the NRC issued its Final Policy Statement (58 FR 39132), expressing the view that satisfying the guidance in the policy statement also satisfies Section 182a of the AEA and 10 CFR 50.36. In the final policy statement, the NRC described the safety benefits of the STS and encouraged licensees, to the extent applicable to use the STS for PTS amendments and for complete conversions to improved TS. Major revisions to the STS were published in 1995 (Revision 1), 2001 (Revision 2), and 2004 (Revision 3).

The format and content for GTS and Bases prepared for a DC should use STS and applicable Bases to the extent possible, notwithstanding design-specific characteristics. As is appropriate, deviation from the STS, as well as design-specific characteristics, should be technically justified by an applicant and reviewed in detail by the NRC prior to approval.

16.3.3 Other Guidance

The June 2005 “Writer’s Guide for Plant-Specific Improved Technical Specifications,” prepared by the Technical Specifications Task Force (TSTF), provides specific guidance for the preparation of PTS. The purpose of the guide is to provide guidance on the format and content of the improved TS and to promote consistency in content, format, and style.

Design/plant-specific risk insights were developed by the staff for use during the review of AP1000 applications and are provided in a risk insights report. The risk insights were developed using information from the AP1000 DCD and AP1000 PRA. The risk insights were used to identify areas that warranted more detailed review and to identify equipment and systems that met Criterion 4 in 10 CFR 50.36(c)(2)(ii).

16.3.4 Applicable Generic Communication

The following generic communications issued by the NRC are TS-related and require consideration when developing TS and associated bases:

- Generic letter (GL) 88-016, "Removal of Cycle-Specific Parameter Limits from Technical Specifications," October 3, 1988

- GL 91-004, "Changes in Technical Specification Surveillance Intervals to Accommodate a 24-Month Fuel Cycle," April 2, 1991

- GL 96-003, "Relocation of the Pressure Temperature Limit Curves and Low Temperature Overpressure Protection System Limits," January 31, 1996

- GL 03-001, "Control Room Habitability," June 12, 2003

- GL 06-001, "Steam Generator Tube Integrity and Associated Technical Specifications," January 20, 2006

The following NRC generic safety issues (GSI) are TS-related and require consideration when developing TS and associated Bases:

- GSI-78, "Monitoring of Fatigue Transient Limits for Reactor Coolant System"
- GSI-120, "On-Line Testability of Protection Systems"

16.4 Evaluation

The staff reviewed and evaluated the GTS and Bases to verify their accuracy and completeness. The staff also reviewed the GTS to confirm the appropriateness of the restrictions imposed by the GTS to ensure that an operating AP1000 will operate within its SLs and LSSSs, as described in the final safety analysis report (FSAR). The GTS must ensure that a plant designed and constructed in accordance with the AP1000 design will be operated so as to maintain the validity of the analyses in the FSAR during the operating lifetime of the plant. In particular, the GTS must require an AP1000 licensee to take specified actions, up to and including shutting down the plant, if one or more SSCs are not functioning as designed, such that the plant may not respond as predicted in the FSAR, including the accident analyses in FSAR Tier 2, Chapter 15. In addition, the GTS must include provisions to govern every SSC that meets one or more of the four criteria in 10 CFR 50.36(c)(2)(ii).

As described in more detail below, the staff verified the adequacy of the GTS primarily by comparing them with the STS developed for the operating fleet of power reactors. The staff developed each of these sets of STS by generically applying the criteria of 10 CFR 50.36(c)(2)(ii) to the SSCs included in the respective designs. Whether any set of STS is adequate to govern the operation of a particular power reactor cannot be determined without an evaluation of the TS as applied to the SSCs of the particular plant, considering the design as a whole. Currently, 75 of the 104 units of the operating fleet of nuclear plants use the STS, in whole or in part; the majority of these units use the Westinghouse STS in NUREG-1431.

While the staff has not approved the STS on a generic basis, it has implicitly approved them on a case-by-case basis through staff review of license amendment requests in which licensees of currently operating reactors have proposed to incorporate STS provisions in the existing custom technical specification (CTS) in their operating licenses. Some amendments have involved adoption of applicable STS on an item-by-item basis, while others have involved entire conversions of a plant's CTS to improved TS incorporating most, if not all, of the STS applicable to the particular design involved. The staff has evaluated and confirmed the adequacy of the model STS to ensure that particular plant SSCs will be operated in accordance with the analyses in individual plant FSARs in the context of these amendment requests. In addition, licensees of currently existing plants have employed STS pursuant to amendment requests granted by the NRC to govern the operation of their plants, and the staff has not identified any adverse effect on plant safety due to the adoption of the STS. Accordingly, the STS can be used as a model for the GTS to govern the operation of SSCs to the extent the AP1000 SSCs are similar in design and function to those governed by the STS. Use of the STS as guidance for the evaluation of the GTS in this manner allows the staff to determine whether the operation of SSCs in accordance with the GTS will assure that the analyses in the FSAR for these SSCs remain valid during plant operation. In view of its 2 Loop PWR design and the similar functions of many of its SSCs to the SSCs of a Westinghouse 4 Loop design, the Westinghouse STS in NUREG-1431 can be applied as guidance in evaluating most of the AP1000 GTS.

The staff evaluated each of the changes in the respective TS sections listed below. The applicant committed to making the changes in the final version of the AP1000 DCD that are identified in the AP1000 DCD, Revision 17. In a subsequent revision (Revision 18) of the AP1000 DCD, the applicant included these changes. In the review of confirmatory items in Revision 18, some conforming changes to the TS were identified. In addition, a number of editorial corrections were found. This resulted in several DCD changes for Chapter 16 that are included in Revision 19.

The staff did not review sections of the AP1000 GTS and Bases that were unaffected by the changes proposed in the AP1000 DCD. The technical evaluation for the sections that were not affected by the amendment can be found in NUREG-1793.

16.4.1 Use and Application

Section 1.0 of the AP1000 GTS includes definitions of terms used in the context of plant TS, and examples to illustrate the applications of logical connectors, completion times for required actions, and frequencies for SRs. Changes to AP1000 GTS Section 1.0 are as follows:

- In TS Section 1.1, the applicant proposed changes to the definition of "SHUTDOWN MARGIN," which is used in conjunction with TS Sections 3.1.1, 3.1.4, 3.1.5 and 3.1.6, to clarify how the gray rod cluster assemblies (GRCA) will be accounted for in the calculation of SHUTDOWN MARGIN. In request for additional information (RAI)-SRP16-CTSB-01, the staff requested additional details regarding this change. In its response, dated November 11, 2008, the applicant provided the requested information including a markup of changes to TS Section 1.1 in AP1000 DCD, Revision 17. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue. Section 16.4.3.1 below provides the staff's evaluation of proposed changes to TS Section 3.1.

- In addition, the staff noted that an error in TS Section 1.4 had not been corrected in accordance with the NRC approved TSTF-485, "Correct Example 1.4-1," which corrects Example 1.4-1, Revision 0. RAI-SRP16-CTSB-02 was issued to the applicant for its correction. In its response, dated December 2, 2008, the applicant agreed to revise TS Section 1.4 in a future DCD revision. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant adhered to the definitions for terms, logical connectors, conventions for completion times, and frequency requirements as provided in the Westinghouse STS. In addition, AP1000 GTS Section 1 and its Bases do not include any "bracketed information" or "Reviewer's Notes." Therefore, the staff finds that Section 1.0 of the AP1000 GTS is acceptable.

16.4.2 Safety Limits

Section 2.0 of the AP1000 DCD GTS and Bases include requirements for SLs, to ensure that the fuel design limits are not exceeded during steady state conditions, normal operational transients and anticipated operational occurrences.

The specifications provided in Section 2.0, which include the reactor core SLs and the reactor coolant system (RCS) pressure SL, are consistent with the STS and are found acceptable by the staff. Changes to AP1000 GTS Section 2.0 are as follows:

- In RAI-SRP16-CTSB-66, the staff asked the applicant to make an editorial change regarding an acronym in the bases of Section 2.1.1. In a letter dated December 2, 2008, the applicant acknowledged the need for the change and included a mark-up of the applicable section in the AP1000 DCD, Revision 17. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant adhered to the SL information as provided in the Westinghouse STS. In addition, AP1000 GTS Section 2 and its Bases do not include any "bracketed information" or "Reviewer's Notes." Therefore, the staff finds that Section 2.0 of the AP1000 GTS and Section B 2.0 of the AP1000 Bases are acceptable.

16.4.3 Limiting Condition for Operation and Surveillance Requirement Applicability

Section 3.0 of the AP1000 GTS and Bases includes general provisions regarding determination of equipment operability and performance of SRs in specific TS Section 3-series (i.e., TS Sections 3.1 through 3.9). There is no proposed change to AP1000 GTS Section 3.0.

16.4.3.1 Reactivity Control Systems

Section 3.1 of the AP1000 GTS and Bases includes requirements for the reactivity control systems, which are designed to reliably control reactivity changes and ensure that the capability to cool the core is maintained under postulated accident conditions.

The specifications provided in Section 3.1 consists of: Sections 3.1.1, “Shutdown Margin”; 3.1.2, “Core Reactivity”; 3.1.3, “Moderator Temperature Coefficient”; 3.1.4, “Rod Group Alignment Limits”; 3.1.5, “Shutdown Bank Insertion Limits”; 3.1.6, “Control Bank Insertion Limits”; 3.1.7, “Rod Position Indication”; 3.1.8, “Physics Tests Exceptions – Mode 2”; and 3.1.9, “Chemical and Volume Control System Demineralized Water Isolation Valves and Makeup Line Isolation Valves,” are consistent with the STS and are found acceptable by the staff. Changes to AP1000 GTS Section 3.1 are as follows:

- In RAI-SRP16-CTSB-34, the staff asked the applicant to clarify the mode of applicability for an SR in the bases of Section 3.1.1. In a letter dated December 2, 2008, the applicant acknowledged the need for the change and included a mark-up of the applicable section in the AP1000 DCD, Revision 17. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16-CTSB-67, the staff asked the applicant to make a minor editorial change regarding the title of an LCO in the Bases portions of Sections 3.1.4 and 3.1.8. In a letter dated December 2, 2008, the applicant acknowledged the need for the change and included a mark-up of the applicable sections in the AP1000 DCD, Revision 17. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16-CTSB-05, the staff asked the applicant to clarify certain notes and their corresponding applicability modes in the specification and Bases portions of Sections 3.1.4, 3.1.5, and 3.1.6. In a letter dated November 19, 2008, the applicant acknowledged the need for the change and included a mark-up of the applicable sections in the AP1000 DCD, Revision 17. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16CTSB-60, the staff asked the applicant to make an editorial change regarding required actions stated in the Bases of Section 3.1.7. In a letter dated December 2, 2008, the applicant acknowledged the need for the change and included a mark-up of the applicable sections in the AP1000 DCD, Revision 17. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16-CTSB-43, the staff asked the applicant to make an editorial change regarding the required reactor power level stated in the specification and Bases portions of Section 3.1.8. In a letter dated December 2, 2008, the applicant acknowledged the need for the change and included a mark-up of the applicable sections in the AP1000 DCD, Revision 17. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16-CTSB-20, the staff asked the applicant to make an editorial change regarding the correct revision year for a reference used in the Bases portion of Section 3.1.8. In a letter dated December 9, 2008, the applicant acknowledged the need for the change and included a mark-up of the applicable sections in the AP1000 DCD, Revision 17. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant adhered to the reactivity control systems information as provided in the Westinghouse STS. In addition, AP1000 GTS Section 3.1 and its Bases do not include any “bracketed information” or “Reviewer’s Notes.” Therefore, the staff finds that Section 3.1 of the AP1000 GTS and Section B 3.1 of the AP1000 Bases are acceptable.

16.4.3.2 Power Distribution Limits

Section 3.2 of the AP1000 GTS and Bases includes requirements for the reactor core power distribution limits, which are designed to reliably control core thermal limits and core power distribution consistent with the design safety analysis. Changes to AP1000 GTS Section 3.2 are described as follows:

- The specifications provided in Section 3.2, which consists of Sections 3.2.1, “Heat Flux Hot Channel Factor”; 3.2.2, “Nuclear Enthalpy Rise Hot Channel Factor”; 3.2.3, “Axial Flux Difference”; 3.2.4, “Quadrant Power Tilt Ratio”; and 3.2.5, “OPDMS-Monitored Parameters,” are consistent with the STS and are found acceptable by the staff.

- In RAI-SRP16-CTSB-68, the staff asked the applicant to make an editorial change regarding the documentation of the use of a reference in the Bases portion of Section 3.2.3. In a letter dated December 2, 2008, the applicant acknowledged the need for the change and included a mark-up of the applicable sections in the AP1000 DCD, Revision 17. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16-CTSB-23, the staff asked the applicant to clarify the mode of applicability stated in the specification and Bases portions of Section 3.2.5. In a letter dated December 2, 2008, the applicant acknowledged the need for the change and included a mark-up of the applicable sections in the AP1000 DCD, Revision 17. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant adhered to the power distribution limits information as provided in the Westinghouse STS. In addition, AP1000 GTS Section 3.2 and its Bases do not include any “bracketed information” or “Reviewer’s Notes.” Therefore, the staff finds that Section 3.2 of the AP1000 GTS and Section B 3.2 of the AP1000 Bases are acceptable.

16.4.3.3 Instrumentation

Section 3.3 of the AP1000 GTS and Bases include requirements for the instrumentation systems that display information required to protect against violating the core fuel design limits and RCS, and to mitigate accidents. Changes to AP1000 GTS Section 3.3 are described as follows:

- Section 3.3, “Instrumentation,” of the AP1000 DCD, Revision 15, was approved by the staff in the certified design. In the AP1000 DCD, Revision 16, and TR-134, Revisions 0 through 5, the applicant made minor editorial changes and updated technical information. The applicant justified other editorial changes in TR-74C, Revision 0. RAI-SRP16-CTSB-69 was submitted to correct editorial errors in these changes. In the AP1000 DCD, Revision 17, the applicant corrected the editorial and typographical errors.

- The applicant removed the brackets [ ] around the completion times in Sections 3.3.1 and 3.3.2., and restored the 92-day frequency to SR 3.3.1.6 and SR 3.3.2.5. The applicant documented the basis for these changes in TR-74, APP-GW-GLR-064, Revision 1, April 13, 2007, “AP1000 Generic Technical Specifications Completion Update on Open Items,” and APP-GW-GSC-020, Revision 0, March 17, 2008, “AP1000 Protection and Safety Monitoring System Technical Specification Completion Time and Surveillance Frequency Justification.” The applicant has incorporated these changes in the AP1000 DCD, Revision 17. The applicant revised the SR completion times to be consistent with APP-GW-GSC-020.

- The applicant stated that ALL values specified for Trip Setpoints and Allowable Values, in Tables 3.3.1-1 and 3.3.2-1, must be confirmed following the completion of the plant-specific setpoint study. After selection of specific instrumentation, the Trip Setpoints can be calculated using the setpoint methodology described in Westinghouse Commercial Atomic Power (WCAP)-16361, APP-PMS-JEP-001, Revision 0, May 2006, “Westinghouse Setpoint Methodology for Protection Systems – AP1000.” In the AP1000 DCD, Revision 17, the applicant has removed all bracketed items for Trip Setpoints and Allowable Values in the tables, but includes a Reviewer’s Note to direct the COL applicant to use the approved methodology to calculate these values. A discussion of the acceptability of the AP1000 Setpoint Control Program (SCP), used to calculate setpoint values with this methodology, is included in Section 16.4.5 of this report.

- In TS 3.3.1, Table 3.3.1-1, equations for overtemperature ΔT (Note 1) and overpower ΔT (Note 2) are provided. The staff previously requested, in RAI-SRP16-CTSB-42, that the applicant provide the technical bases and derivation of the revised overtemperature ΔT and overpower ΔT reactor trip setpoint equations presented in Revision 16, and provide a reference to a document approved by the staff for the basis of the revised equations, or submit the basis for the revised equations to the staff for further review. The response provided for RAI-SRP16-CTSB-42 did not fully address the staff’s request. WCAP-8745-P-A, previously reviewed and approved by the staff, provided the bases for the overtemperature ΔT and overpower ΔT setpoint equations presented in Revision 15 of the DCD. The revised equations presented in the DCD Revision 16 for these reactor trip functions differ from those previously submitted in Revision 15 of DCD Section 7.2.1.1.3 and TS Table 3.3.1-1, Note 1.

  Based on this, the staff believed that the applicant should document the bases for the revised equations; the bases for development of the tables of allowable core thermal power as a function of core inlet temperature at various pressures for the overtemperature ΔT trip equation, the bases for the determination of the preset bias K4 in the overpower ΔT trip equation, and the bases for the constants and bracketed values that appear in the revised equations presented in Revision 16. The staff reviewed TR APP-GW-GLR-137, Revision 0, “Bases of Digital Overpower and Overtemperature

Delta-T (OPΔT/OTΔT) Reactor Trips," submitted by the applicant, in WCAP-8745-P-A, "Design Bases for the Thermal Overpower ΔT and Thermal Over Temperature ΔT Trip Functions," September 1986 (Agencywide Documents Access and Management System (ADAMS) Accession Number ML073521507). The content of this review is found in Chapter 7, Appendix 7.A of this report. The applicant described and clarified these items in more detail, as well as provided commitments to update references in the report and add this additional information. The staff finds these acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16-CTSB-44, the staff requested clarification/consistency of Function 6 (overtemperature ΔT) and Function 7 (overpower ΔT) "required channel" column in Table 3.3-1, "Reactor Trip System Instrumentation." The applicant added "4 (2/loop)" in the required channel column for clarification. This has been reviewed and accepted by the staff. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16-CTSB-45, the staff requested clarification/consistency of Function 12 (reactor coolant pump [RCP] speed-low) "required channel" column in Table 3.3-1, "Reactor Trip System Instrumentation." The applicant added "4 (1/pump)" in the required channel column for clarification. This has been reviewed and accepted by the staff. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16-CTSB-52, the staff requested resolution of conflicting information for the required minimum number of core exit thermocouples per core quadrant. The conflict was between Note (b) in Table 3.3.3-1, "Post Accident Monitoring," and DCD Table 7.5-1, "Instrumentation and Controls," Sheet 2. The applicant changed the number of instruments required from "2 quadrants" to "2 quadrants per Division" in Table 7.5-1, Sheet 2. This has been reviewed and accepted by the staff. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant adhered to the instrumentation information as provided in the Westinghouse STS. In addition, AP1000 GTS Section 3.3 and its Bases include "bracketed information." The staff reviewed each piece of "bracketed information" to understand its intent and to determine whether each was site-specific and appropriately deferred to applicants for construction permits or COLs that reference the AP1000 GTS. The staff concluded that each such item was indeed plant- or site-specific. Therefore, the staff finds that Section 3.3 of the AP1000 GTS and Section B 3.3 of the AP1000 Bases are acceptable.

16.4.3.4 Reactor Coolant System

Section 3.4 of the AP1000 GTS and Bases include requirements for various RCS parameters (i.e., pressure, temperature, flow, etc.) and subsystems (i.e., RCS loops, pressurizer, low-temperature overpressure protection (LTOP), etc.) to ensure the fuel integrity and the RCPB integrity are preserved during all modes of plant operation. Changes to AP1000 GTS Section 3.4 are described as follows:

- In TS 3.4.1, the applicant proposed to use the preliminary bracketed value of 1.41 × 10^6 Liters per minute (Lpm) (301,670 gallons per minute (gpm)), specified in LCO 3.4.1.c for the minimum RCS total flow rate, as a final value based on latest system design specifications, approved engineering calculation notes, and/or verified analysis input assumptions. The staff finds this final value acceptable since it is consistent with supporting information provided in the TS Bases B 3.4.1 and relevant information described in AP1000 DCD Sections 4.4 (Table 4.4-1) and 15.0 (Table 15.0-3).

- The applicant also proposed to change requirements specified in SR 3.4.1.4 for monitoring RCS flow, to reflect an alternate testing method to the precision heat balance (an NRC-accepted method). In RAI-SRP16-CTSB-25, the staff asked the applicant to provide justification for the change. In its December 2, 2008, response, the applicant provided additional details about the basis for the alternate method and also stated the following:

  > The intent of the proposed Section 3.4.1 is to permit either method, whichever is demonstrated to provide less measurement uncertainty....The total uncertainty in measuring flow will depend upon analysis of the baseline flow measurements and the accuracy of the devices used to periodically measure dP caused by RCS flow. If the total uncertainty is not shown to be less than for the precision heat balance plus Delta-T method, then the alternate method would not be used.

  The applicant also indicated that no change to the AP1000 DCD or the TS 3.4.1 and associated bases is required.

  In reviewing this response, the staff noted that the alternate testing method using elbow tabs had been approved for use at the South Texas Project Electric Generating Station. A review of the current South Texas Project TS found the following descriptions for the affected SRs:

  > SR 4.2.5.2 The RCS flow rate indicators shall be subjected to a channel calibration at least once per 18 months.
  >
  > SR 4.2.5.3 The RCS total flow rate shall be determined by precision heat balance or elbow tab dP measurements at least once per 18 months.

  Based on the above, the staff believed a revision to the SR 3.4.1.4 and TS Bases 3.4.1 was needed to incorporate additional details regarding the choice of a testing method that produces better uncertainty analysis results, including a new SR for a channel calibration of the RCS flow rate indicators. In its response, dated August 20, 2009, the applicant proposed to: (1) add a new SR for a channel calibration for RCS flow indicators at the main control room board; and (2) revise SR 3.4.1.4 and TS Bases B 3.4.1 to incorporate a discussion of uncertainty analyses related to the use of elbow tabs as an alternate method for RCS flow verification. The staff finds this response acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In TS 3.4.2, the applicant proposed to use the preliminary bracketed value of 288 °Celsius (C) (551 °Fahrenheit (F)), for the minimum RCS cold-leg temperature for criticality, as a final value based on historical relationships between the no-load operating temperature (292 °C (557 °F)), the minimum temperature for criticality (288 °C (551 °F)), and the limit for Mode 2 physics testing (283 °C (541 °F)). The staff finds this final value acceptable since it is consistent with supporting information provided in the TS Bases B 3.4.2 and relevant information described in AP1000 DCD, Sections 5.4 and 15.0.3.

- In TS 3.4.4, the applicant proposed to replace the preliminary bracketed values of 135 °C (275 °F) with a new final value of 93 °C (200 °F) and to use the preliminary bracketed value of 10 °C (50 °F) as a final value, regarding temperature requirements for the primary coolant and the secondary-side water as listed in Note 2 of LCO 3.4.4. In addition, the applicant proposed to add an extra precautionary note regarding restrictive plant conditions before starting an RCP for the reactor vessel LTOP. In RAI-SRP16-CTSB-55, the applicant was asked to provide clarification of the selected value of 93 °C (200 °F). This value 93 °C (200 °F) is not consistent with the one listed in the Westinghouse STS 135 °C (275 °F). In the March 23, 2009, response letter, the applicant proposed a further change from 93.3 °C ("200 degree F") to 177 °C ("350 degree F") based on an updated LTOP analysis, which now credits a technical design difference for AP1000 related to the variable-speed RCP start-up design limitations (e.g., RCPs are required to be started at a relatively slow pump speed and they are unable to start at full speed) not recognized in the Westinghouse STS (NUREG-1431). The staff finds the changes and justification as provided in this latest response acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- Although no change was proposed to TS 3.4.6 as part of the AP1000 DC amendment application, the staff noted inconsistencies between SR 3.4.6.1 requirements and supporting information in Bases B 3.4.6, regarding lift setpoints for pressurizer safety valves. In RAI-SRP16-CTSB-08, the staff asked the applicant to address these inconsistencies. In its response dated December 17, 2008, the applicant proposed to revise the Bases for SR 3.4.6.1 to indicate +/- 1 percent OPERABLE range for the valve lift settings, to be consistent with SR 3.4.6.1 and with the tolerance established in WCAP-16779, "AP1000 Overpressure Protection Report," April 2007. The staff finds this change acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In TS 3.4.7, the applicant proposed to delete LCO 3.4.7.d for the total primary-to-secondary leakage through both steam generators (SGs) because it is redundant to LCO 3.4.7.e for primary to secondary leakage through any one SG. In addition, changes were proposed to SR 3.4.7.2 to reflect the implementation of a new SG program to maintain the SG tube integrity. The staff agreed with the applicant's position on deleting LCO 3.4.7.d and finds the proposed changes to SR 3.4.7.2 acceptable since they are consistent with other requirements in the AP1000 GTS (GTS 3.4.18, GTS 5.5.4, and GTS 5.6.8).

- In TS 3.4.8, the applicant proposed to add a missing clarifier to the applicability statement that allows stopping all RCPs without having to enter an action statement. The staff finds this change acceptable since the added special plant condition is consistent with remaining TS 3.4.8 requirements.

- The applicant also proposed to replace the preliminary bracketed value of 37,785 Lpm (10,000 gpm) for the minimum RCS flow with a final value of 11,356 Lpm (3,000 gpm). Conforming changes were proposed in SR 3.4.8.1 and related information in the TS Bases to match the new minimum flow value (e.g., the minimum pump speed setting of 25 percent was replaced with a new value of 10 percent). The applicant cited the NRC-accepted response to RAI 440.106 during the Revision 14 AP1000 DC review as justification for the proposed flow reduction. In RAI-SRP16-CTSB-62, the staff asked the applicant to provide additional details to support these changes. In its response dated December 17, 2008, the applicant reiterated information that was provided in the response to RAI 440.106 but also stated the following:

  > AP1000 RCS flow calculations show that the expected RCS flow with a single reactor coolant pump (RCP) operating at its lowest allowable operating speed is approximately 64,352 Lpm (17,000 gpm). The associated reactor vessel flow is approximately 41,640 Lpm (11,000 gpm). This is well above the 11,356 Lpm (3,000 gpm) flow mixing requirement from the LOFT testing, and also above the preliminary bracketed value of 37,854 Lpm (10,000 gpm).

  The staff noted that the new proposed value of 10 percent for the pump minimum speed setting in SR 3.4.8.1, corresponding approximately to a calculated flow of 29,810 Lpm (7,875 gpm), appears to be inconsistent with the lowest allowable operating speed stated above. In its response, dated July 15, 2009, the applicant stated that the mentioned lowest allowable operating speed is for equipment protection while the minimum speed specified in TS 3.4.8 is to reflect the assumed RCS flow through the core in shutdown event analyses. The TS limit will be satisfied if the operating limit is maintained in accordance with plant equipment operating procedures. The staff finds this response acceptable and RAI-SRP16-CTSB-62 is closed.

- Although no change was proposed to TS 3.4.11/12 as part of the AP1000 DC amendment application, the staff noted that the scope of Condition A was not clearly defined. In RAI-SRP16-CTSB-07, the staff asked the applicant to explain the difference in scope of inoperable equipment involved between TS 3.4.11/3.4.12 Condition A, which states “One required flow path inoperable,” and Condition B, which states, “One required stage 1 ADS flow path inoperable AND Either one required stage 2 or stage 3 ADS flow path inoperable.”

  In its October 27, 2008, response letter, the applicant stated the following:

  > As described in the 3.4.11 and 3.4.12 Bases, Conditions A and B cover two different combinations of ADS flow path inoperabilities.. Separate Conditions are specified, since both Conditions A and B may be entered at the same time. The inoperabilities covered by the two Conditions are permissible at the same time, since the safety function can be accomplished by the remaining seven ADS flow paths without a single failure. The loss of capacity while in Conditions A and B is equivalent to a single failure of the power to the valves in one division, as considered in the accident analyses.

  The applicant further stated “the LCO 3.4.11 and LCO 3.4.12 and associated Bases are technically correct, as-is. However, to clarify the system status while in both

Conditions A and B the following statement is added in each of the Bases at the beginning of the Actions sections:

> The loss of automatic depressurization system (ADS) capacity, if both Conditions A and B are entered at the same time, is equivalent to a single failure of the power to the valves in one division, as considered in the accident analyses."

Based on this response and considering the four-stage ADS design, the staff believed that additional changes were required for Condition A to explicitly list Stage 4 ADS flow path in its scope and to clearly indicate the difference between Conditions A and B. In its July 15, 2009, response, the applicant proposed to revise all Action statements in TS 3.4.11 and TS 3.4.12, and the associated TS bases to clearly define the scope of inoperable ADS valves for each LCO condition and to assign a completion time consistent with guidance in the STS for cases with the same remaining operable ADS valves. The staff finds this response acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In TS 3.4.14, the applicant proposed to replace the preliminary bracketed value of 152.4 square centimeters (cm^2) (9.3 square inches (in^2)) for the minimum RCS vent area with a final value of 68 cm^2 (4.15 in^2). In RAI-SRP16-CTSB-35, the staff asked the applicant to provide a justification for the change. In its response dated December 12, 2008, the applicant stated that the change is a result of the final design of the normal residual heat removal system (RNS) suction relief valve with its inlet changed from 10.16 centimeters (cm) (4 inches(in)) to 7.62 cm (3 in). The staff finds the stated justification acceptable since either the RNS suction relief valve or a depressurized RCS with a vent area is considered an acceptable means for providing LTOP. The staff considers RAI-SRP16-CTSB-35 closed.

- In addition, in RAI-SRP16-CTSB-54, the staff asked the applicant to address inconsistencies in the TS bases B 3.4.14 regarding discussion on restarting of one RCP as a heat input event. In its March 23, 2009, response, the applicant proposed to revise LCO 3.4.14 and its associated TS bases to make the descriptions of LCO 3.4.14, Notes 1 and 2 consistent with those specified in LCO 3.4.4 and LCO 3.4.8 for the same situation. The staff finds this response acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In TS 3.4.15, the applicant proposed to use the preliminary bracketed value of 15,272 kilopascal (kPa) (2,215 pounds per square inch gauge (psig)) and 15,549 kPa (2,255 psig), for the range of RCS pressure during performance of SR 3.4.15.1 to verify leakage through each RCS pressure isolation valve, as final values based on the nominal RCS pressure design of AP1000 and the requirements for test pressures identified in American Society of Mechanical Engineers (ASME) Operation and Maintenance (OM) Code ISTC-3630(b). The staff finds the stated reason for the final selected values acceptable.

- At the end of TS Section 3.4, the applicant proposed to add a new TS 3.4.18, "Steam Generator Tube Integrity," to reflect implementation of the NRC-approved TSTF-449, "Steam Generator Tube Integrity," Revision 3. The staff finds the proposed addition of TS 3.4.18 acceptable since implementing TSTF-449 is one acceptable option for addressing the safety issues identified in GL 06-001.

The applicant adhered to the RCS information as provided in the Westinghouse STS, with differences to reflect AP1000 unique design features. With respect to AP1000 unique design features, the GTS are sufficient to assure operation of these features within the bounds of the safety analysis. In addition, AP1000 GTS Section 3.4 and its Bases do not include any "bracketed information" or "Reviewer's Notes." Therefore, the staff finds that Section 3.4 of the AP1000 GTS and Section B 3.4 of the AP1000 Bases are acceptable.

16.4.3.5 Emergency Core Cooling Systems

Section 3.5 of the PTS and Bases includes requirements for the safety-related passive core cooling system (PXS), which is designed to perform emergency core decay heat removal, RCS emergency makeup and boration, and safety injection. Changes to AP1000 GTS Section 3.5 are described as follows:

- In TS Section 3.5.2, the applicant proposed to use the preliminary bracketed value of 0.0057 cubic meters (m^3) (0.2 cubic feet (ft^3)), for the maximum allowable volume of noncondensable gases in each of the core makeup tanks' inlet piping, as a final value based on latest system design specifications, approved engineering calculation notes, and/or verified analysis input assumptions. The staff finds this final value acceptable since it is consistent with related information described in AP1000 DCD Section 6.3.

- In TS Section 3.5.4, the applicant proposed to replace the preliminary bracketed value of 0.011 m^3 (0.4 ft^3), for the maximum allowable volume of noncondensable gases in the passive residual heat removal heat exchanger inlet piping, with a new final value of 0.025 m^3 (0.9 ft^3). In RAI-SRP16-CTSB-36, the staff asked the applicant to provide justification for the change. In its response dated December 12, 2008, the applicant stated that the value of 0.025 m^3 (0.9 ft^3) reflects the correct design value based on the final location for the alarm limit switch installed in the high-point pipe stub section. The staff finds this final value acceptable based on verification that a physical change was made in AP1000 DCD Section 6.3, regarding an increase in pipe size at the level switch location from 0.305 meters (m) to 0.355 m (12 in to 14 in). Therefore, the staff considers RAI-SRP16-CTSB-36 closed.

- In TS Sections 3.5.6 and 3.5.8, the applicant proposed to replace the preliminary bracketed value of 2091 m^3 (73,900 ft^3), for the minimum volume of borated water in the in-containment refueling water storage tank (IRWST), with a new final value of 2069 m^3 (73,100 ft^3). In RAI-SRP16-CTSB-37, the staff asked the applicant to provide justification for the change. In its response dated December 12, 2008, the applicant stated the following:

    > The bracketed volume of 2091 m^3 (73,900 ft^3) represented a preliminary estimate of the minimum design basis IRWST water volume.
    >
    > The un-bracketed value of 2069 m^3 (73,100 ft^3) was updated based on evolving IRWST design details, is consistent with the updated IRWST volume provided in DCD Table 6.3-2 (Sheet 2), and reflects a more

> conservative water volume that was appropriately used in safety analyses."

The staff finds the stated reason acceptable and considers RAI-SRP16-CTSB-37 closed.

The applicant adhered to the ECCS information as provided in the Westinghouse STS. In addition, the AP1000 GTS, Section 3.5, and its Bases do not include "bracketed information" or "Reviewer's Notes." Therefore, the staff finds that Section 3.5 of the AP1000 GTS and Section B 3.5 of the AP1000 Bases are acceptable.

16.4.3.6 Containment Systems

Section 3.6 of the AP1000 DCD GTS and its Bases address requirements for the containment systems, which are designed to contain fission products that may exist in the containment atmosphere following accident conditions.

The specifications provided in Section 3.6 consist of: Sections 3.6.1, "Containment"; 3.6.2, "Containment Air Locks"; 3.6.3, "Containment Isolation Valves"; 3.6.4, "Containment Pressure"; 3.6.5, "Containment Air Temperature"; 3.6.6, "Passive Containment Cooling System (PCS) – Operating"; 3.6.7, "PCS Shutdown"; 3.6.8, "Containment Penetrations"; and 3.6.9, "pH Adjustment," are consistent with the STS and are found acceptable by the staff. Changes to AP1000 GTS Section 3.6 are as follows:

- In RAI-SRP16-CTSB-15, the staff asked the applicant to correct Bases B 3.6.6 to accurately reflect the action statements in TS 3.6.6. In a letter dated October 17, 2008, the applicant acknowledged the need for the change and included a markup of the applicable sections in AP1000 DCD, Revision 17. The staff finds this change acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16-CTSB-16, the staff asked the applicant to correct Bases B 3.6.7 to accurately reflect the action statements in TS 3.6.7. In a letter dated October 17, 2008, the applicant acknowledged the need for the change and included a markup of the applicable sections in AP1000 DCD, Revision 17. The staff finds this change acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16-CTSB-13, the staff asked the applicant to clarify Bases B 3.6.4 regarding maximum peak containment pressure. In a letter dated December 2, 2008, the applicant acknowledged the need for clarification and included a markup of the changes that will be incorporated. The staff finds this change acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In RAI-SRP16.1.1-SEB1-01, the staff asked the applicant to provide details on the equipment hatch and bolt design to ensure that the equipment hatch can be safely installed with four bolts to meet the containment closure requirements during Modes 5 and 6 (TS 3.6.8). In its response dated August 15, 2008, the applicant stated that design specification document APP-MV50-Z0-002, "Equipment Hatch Design

Certification Document," would provide final design information for the equipment hatch installation.

In an audit on November 30, 2009, the staff confirmed that design specification document APP-MV50-Z0-002, Revision 1, provides design criteria for equipment hatch bolts, such that its weight can be supported with only four bolts installed. A typical vendor report prepared for the AP1000 China Sanmen Unit 1 lower equipment hatch by IHI Corporation in Japan was also provided for the staff's review during this audit. The staff noted that this vendor report adequately addresses the applicable design criteria specified in APP-MV50-Z0-002. Although this vendor report was not prepared specifically for a new AP1000 plant to be built in the United States, the staff finds the applicant's approach to address this issue acceptable. The equipment hatch is listed as an ASME Code Section III component in AP1000 DCD Tier 1, Table 2.2.1-1, and as such, ITAAC Item 2.a in Table 2.2.1-3 is applicable to it. This ITAAC item calls for the existence of a design report for the as-built component received from the equipment supplier. The design document APP-MV50-Z0-002, together with the cited ITAAC item, will ensure equipment hatch components will be constructed and installed in accordance with design requirements. Therefore, the staff finds the response acceptable and RAI-SRP16.1.1-SEB1-01 is closed.

- In RAI-SRP16-CTSB-61, the staff asked the applicant to specify the sections of DCD Chapter 15 that support the specific accident discussed in the "Applicable Safety Analyses" section of TS Bases B 3.6.1, B 3.6.2, and B 3.6.3. In its November 19, 2008, response, the applicant stated that:

  > the level of detail provided by the B 3.6.1, B 3.6.2, and B 3.6.3 Bases references to Chapter 15 is consistent with that provided in the STS

  The applicant made no further change to the Bases. The staff found this reason unacceptable. The staff's concern was that DCD Chapter 15 is voluminous as it includes more than 600 pages. Without references to specific sections, validation of the information discussed in the affected TS bases would require significant effort and time from the plant operators who implement TS requirements and often refer to the TS bases for clarifications needed quickly. In its July 15, 2009, response, the applicant provided sufficient details to support its position that reference to specific sections of Chapter 15 is not helpful in these cases for the containment boundary as a physical barrier. The containment integrity and leak tightness are applicable to a wide range of accident scenarios described in Chapter 15. The staff finds this response acceptable and RAI-SRP16-CTSB-61 is closed.

- In RAI-SRP16-CTSB-33, the staff asked the applicant to provide the value of the minimum tri-sodium phosphate (TSP) manufactured density that is used to convert the required TSP amount from a mass number to a volume number. In its December 12, 2008, response, the applicant did not provide the requested information so that the staff could verify the accuracy and completeness of supporting information provided in TS Bases B 3.6.9. In its August 20, 2009, response, and the subsequent October 29, 2009, conference call, the applicant provided the requested information and agreed to revise TS Bases B 3.6.9 to include the new details. The staff finds this response acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant adhered to the containment information as provided in the Westinghouse STS, with differences to reflect AP1000 unique design features. With respect to AP1000 unique design features, the GTS are sufficient to assure operation of these features within the bounds of the safety analysis. In addition, AP1000 GTS Section 3.6 and its Bases include "bracketed information" and "Reviewer's Notes." The staff reviewed each piece of "bracketed information" to understand its intent and to determine whether each was site-specific and appropriately deferred to applicants for construction permits or COLs that reference the AP1000 GTS. The staff concluded that each such item was indeed plant- or site-specific. Therefore, the staff finds that Section 3.6 of the AP1000 GTS and Section B 3.6 of the AP1000 Bases are acceptable.

16.4.3.7 Plant Systems

Section 3.7 of the PTS and Bases include requirements for various systems in the secondary side of the SGs (i.e., the main steam safety valves (MSSVs), the main steam isolation valves (MSIVs), the main feedwater isolation valves (MFIVs), etc.), the spent fuel pool water level and makeup systems, and the main control room habitability system. Changes to AP1000 GTS Section 3.7 are described as follows:

- In TS Section 3.7.1, "Main Steam Safety Valves (MSSVs)," the applicant proposed a slight increase in the relief capacity and the resulting relief setpoint for all but the first-to-open MSSV based on a minor change to the valve inlet piping to conform to ASME Code requirements. Also, the applicant replaced the bracketed values for the restriction on maximum allowable thermal power with inoperable MSSVs in Table 3.7.1-1 with new final values. The staff finds the final data in Table 3.7.1-1 acceptable since they were derived using methodology referenced in the Westinghouse STS, Revision 3.

- In addition, the applicant proposed to change the tolerance for the as-found relief setting for MSSVs in Table 3.7.1-2 from 1 percent to 3 percent. In RAI-SRP16-CTSB-11, the staff asked the applicant to provide justification for the change in Table 3.7.1-2. In its response dated December 17, 2008, the applicant proposed to change this tolerance back to the original value of 1 percent. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In TS Section 3.7.6, "Main Control Room Habitability System," the applicant proposed to use the preliminary bracketed value of 23,443 kPa (3,400 psig) for the required minimum pressure specified in SR 3.7.6.2, as a final value based on latest system design specifications, approved engineering calculation notes, and/or verified analysis input assumptions. The staff found the proposed final value acceptable since it is consistent with relevant information described in AP1000 DCD Section 6.4.2.

- In addition, the staff noted that the AP1000 GTS did not incorporate the NRC-approved TSTF-448, "Control Room Habitability," which was issued to address safety issues identified in GL 2003-001. In RAI-SRP16-CTSB-32, the staff asked the applicant to address these issues. In its response dated November 11, 2008, the applicant stated that it had added a new DCD Section 6.4.5.4, "Main Control Room Envelope Habitability," under Revision 16 to address GL 2003-001. This DCD section describes the periodic testing of the main control room envelope habitability during main control room emergency habitability system operation (pressurization mode) to measure the air inleakage in accordance with the American Society for Testing and Materials (ASTM) E741, "Testing of Palo Verde Units 1-3 Control Room Envelopes." The applicant concluded that this periodic testing commitment in DCD Section 6.4.5.4, combined with the existing LCO 3.7.6 requirements, adequately addresses the GL 2003-01 issues and provides requirements equivalent to those approved in TSTF-448. The applicant proposed no further changes to the AP1000 DCD or the AP1000 GTS. The staff disagreed with this conclusion. In the May 4, 2009, response letter to RAI-SRP6.4-SPCV-01, the applicant proposed to revise TS 3.7.6 and its associated bases to fully incorporate all TSTF-448 requirements. The staff finds this latest response acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue. Also in response to RAI-SRP6.4-SPCV-06, the applicant proposed additional design changes to the control room habitability system. As a result, further changes are proposed to TS 3.7.6 and a new administrative control TS 5.5.13 is added to the AP1000 GTS for testing of the new passive filtration unit. Additional open items to TS 3.7.6 and TS 5.5.13 were identified and documented as part of the staff's evaluation of these design changes in SER Section 6.4. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In TS Section 3.7.9, “Fuel Storage Pool Makeup Water Source,” the applicant provided additional information to the precautionary Note 1 in LCO 3.7.9 for clarification. The staff finds the added text acceptable since it is consistent with relevant information described in AP1000 DCD Section 9.1.3.

- At the end of TS Section 3.7, the applicant proposed to add TS 3.7.11, “Fuel Storage Pool Boron Concentration,” and TS 3.7.12, “Spent Fuel Pool Storage,” to reflect the final design of the spent fuel storage racks. The staff finds the added TS requirements and associated information in the TS bases acceptable since they were formulated in accordance with guidance provided in the Westinghouse STS 3.7.16 and 3.7.17, respectively, and are consistent with relevant information in the AP1000 DCD, Section 9.1. Section 9.1 of this report presents a separate evaluation of the final design of the spent fuel storage racks.

The applicant adhered to the plant systems information as provided in the Westinghouse STS, with differences to reflect AP1000 unique design features. With respect to AP1000 unique design features, the GTS are sufficient to assure operation of these features within the bounds of the safety analysis. In addition, AP1000 GTS Section 3.7 and its Bases do not include “bracketed information” or “Reviewer’s Notes.” Therefore, the staff finds that Section 3.7 of the AP1000 GTS and Section B 3.7 of the AP1000 Bases are acceptable.

16.4.3.8 Electrical Power Systems

Section 3.8 of the AP1000 GTS and Bases include requirements for the plant electrical systems that provide redundant, diverse and dependable power sources for all plant operating conditions. In the event of a total loss of offsite power, onsite diesel generators and batteries are provided to supply electrical power equipment necessary for the safe shutdown of the plant. Changes to AP1000 GTS Section 3.8 are as follows:

- Section 3.8, “Electrical Power Systems,” of the AP1000 DCD, Revision 15, was approved by the staff in the certified design. In the AP1000 DCD, Revision 16, and TR-134, Revisions 0 through 5, the applicant made minor editorial changes and updated technical information. The staff finds these editorial changes acceptable.

- In the AP1000 DCD, Revision 17, the applicant replaced all preliminary information in the brackets with the final information. The applicant documented the basis for these changes in TR-74, Revision 1. The staff finds these changes acceptable due to the justifications found in the reference report.

- The applicant initially proposed retaining brackets [ ] around all preliminary AP1000 DCD values associated with the battery float current. COL applicants referencing the AP1000 DCD would replace preliminary information, provided in brackets [ ], with final plant specific values. In the AP1000 DCD, Revision 17, the applicant replaced all preliminary information in the brackets with the final information. The staff finds this acceptable since it is consistent with the guidance provided in the Institute of Electrical and Electronic Engineers (IEEE) references.

- The applicant inadvertently omitted the “7 days” completion time in TS Section 3.8.1 B.3 and has added it into AP1000 DCD, Revision 17, and Revision 4 of TR-134. The staff finds this editorial change acceptable.

The applicant adhered to the electrical power systems information as provided in the Westinghouse STS. In addition, AP1000 GTS Section 3.8 and its Bases do not include “bracketed information” or “Reviewer’s Notes.” Therefore, the staff finds that Section 3.8 of the AP1000 GTS and Section B 3.8 of the AP1000 Bases are acceptable.

16.4.3.9 Refueling Operations

Section 3.9 of the AP1000 GTS and Bases includes requirement for boron concentration, unborated water sources, nuclear instrumentation, containment penetrations, and water inventory in the refueling pool during Mode 6. Changes to AP1000 GTS Section 3.9 include the following:

- In TS Section 3.9.5, “Containment Penetrations,” the applicant proposed to use the preliminary bracketed information as a final value for the required number of bolts (four) to keep the equipment hatch in place to meet the containment closure requirements during movement of irradiated fuel assemblies within the containment, based on the latest system design specifications, approved engineering calculation notes, and/or verified analysis input assumptions. In RAI-SRP16.1.1-SEB1-01, the staff asked the applicant to provide additional details on the bolt design to ensure the safe installation of the equipment hatch with only four bolts. In its response dated August 15, 2008, the applicant stated that design specification document APP-MV50-Z0-002 would provide final design information for the equipment hatch installation. The discussion and closure of RAI-SRP16.1.1-SEB1-01 is found above in Section 16.4.3.6.

- Also, in TS Sections 3.9.5, “Containment Penetrations”; and 3.9.6, “Containment Air Filtration System (VFS),” the applicant proposed to use the preliminary bracketed value of -0.0311 kPa (-0.125 inches water gauge) relative to outside atmospheric pressure for VFS subsystem testing in SR 3.9.5.3 and SR 3.9.6.3. The applicant proposed using the preliminary value as a final value based on the latest system design specifications, approved engineering calculation notes, and/or verified analysis input assumptions. In RAI-SRP16-CTSB-59, the staff asked the applicant to explain the basis for the selected value. In its response dated August 15, 2008, the applicant stated the following:

> This pressure was chosen based on ASHRAE Applications, which recommends at least 0.0124 kPa to 0.0149 kPa (0.05 to 0.06 inches of water) across boundaries when exfiltration or infiltration is minimized. Conservatively, Westinghouse chose a higher pressure difference of 0.0311 kPa (0.125 inches of water).

The staff finds the stated reason acceptable since the selected value is more conservative than the value used in normal industry practices. Therefore, the staff considers RAI-SRP16-CTSB-59 closed.

- In TS Section 3.9.7, "Decay Time," the applicant proposed to change the minimum decay time of 100 hours to 48 hours to make it consistent with the analysis of the fuel handling accident as described in AP1000 DCD Section 15.7.4. The staff finds this change acceptable for the stated reason.

The applicant adhered to the refueling operations information as provided in the Westinghouse STS. In addition, AP1000 GTS Section 3.9 and its Bases do not include "bracketed information" or "Reviewer's Notes." Therefore, the staff finds that Section 3.9 of the AP1000 GTS and Section B 3.9 of the AP1000 Bases are acceptable.

16.4.4 Design Features

Section 4.0 of the AP1000 GTS includes other design features not covered in TS Section 3-series, such as the site location, the site maps, and other information related to core design and fuel storage design. Changes to AP1000 GTS Section 4.0 are as follows:

- In TS Section 4.3, "Fuel Storage," the applicant proposed various changes to the description of the fuel storage area to reflect the final design for new and spent fuel storage racks and an increase of the maximum capacity of the spent fuel storage racks from 616 to 889 fuel assemblies. Evaluation of the final design modification is provided separately in Section 9.1 of this report. Furthermore, in RAI-SRP16-CTSB-38 and RAI-SRP16-CTSB-39, the applicant was asked to address inconsistencies between the information provided in TS Section 4.3 and DCD Section 9.1. In its response dated December 2, 2008, the applicant proposed revisions to TS Section 4.3 and DCD Section 9.1 to revolve these inconsistencies. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant adhered to the design features information as provided in the Westinghouse STS, with differences to reflect AP1000 unique design features. With respect to AP1000 unique design features, the GTS are sufficient to assure operation of these features within the bounds of the safety analysis. In addition, AP1000 GTS Section 4.0 includes "bracketed information" and "Reviewer's Notes." The staff reviewed each piece of "bracketed information" to understand its intent and to determine whether each was site-specific and appropriately deferred to applicants for construction permits or COLs that reference the AP1000 GTS. The staff concluded that each such item was indeed plant- or site-specific. Therefore, the staff finds that Section 4.0 of the AP1000 GTS is acceptable.

16.4.5 Administrative Controls

Section 5.0 of the AP1000 GTS includes provisions, which address various administrative controls related to plant key personnel responsibilities, plant procedures, special programs and reports, etc., to ensure the plant is safely operated. Changes to AP1000 GTS Section 5.0 are described as follows:

- In TS Section 5.4, "Procedures," the applicant proposed to adopt GL 1982-33, "Supplement 1 to NUREG-0737—Emergency Response Capabilities," dated December 17, 1982, as guidance to be used in the development of the plant emergency operating procedures. This is consistent with the STS and acceptable to the staff.

- In TS 5.5, "Programs and Manuals," and in TS 5.6, "Reporting Requirements," the applicant proposed changes to TS 5.5.4, "Steam Generator Program," and to TS 5.6.8, "Steam Generator Tube Inspection Report," to reflect the implementation of the NRC-approved TSTF-449, Revision 4. The staff finds these changes acceptable since implementing TSTF-449 is one acceptable option for addressing safety issues identified in GL 2006-001. However, since TSTF-449 was prepared to address issues involving SG replacements at current operating plants, in RAI-SRP16-CTSB-76, the staff asked the applicant to make one minor adjustment to its proposed changes in TS 5.5.4 to also accommodate SG initial installations at new nuclear power plants regarding the 100-percent tube inspection during the first refueling outage. In its response dated December 2, 2008, the applicant agreed to make the suggested adjustment in a future DCD revision. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- In TS 5.5.8, the applicant proposed to use the preliminary bracketed numerical values as final values for acceptance criteria used in various tests on the containment air locks. The staff finds these final selected values acceptable since they are consistent with recommendations provided in the Westinghouse STS.

- In connection to TS 3.7.6 regarding implementation of TSTF-448, Revision 3, to address safety issues identified in GL 2003-01, in RAI-SRP16-CTSB-32, the staff asked the applicant to include the description of the Control Room Habitability Program into AP1000 GTS Section 5.5. Discussions and closure of RAI-SRP16-CTSB-32 are addressed in Section 16.4.3.7 above.

- Also, in TS 5.5.11, "Battery Monitoring and Maintenance Program," the applicant proposed to adopt the preliminary bracketed texts that are applicable to "vented lead-acid" batteries, as the final texts based on latest system design specifications. The staff finds this acceptable since it is consistent with recommendations provided in the Westinghouse STS.

- As stated in Section 16.4.3.3 above, in response to RAI-SRP16.3-CTSB-SCP-1, the applicant stated that all values specified for trip setpoints and allowable values in Tables 3.3.1-1 and 3.3.2-1 will be determined via a SCP specified in Section 5.5.21, "Administrative Controls." This is in accordance with DC/COL-ISG-8, "Technical Specification Information that Combined License Applicants Must Provide in Combined License Application," in determining instrumentation trip setpoints and allowable values in TS. After selection of specific instrumentation, the trip setpoints can be calculated using the setpoint methodology specified in the SCP; in WCAP-16361, Revision 0. The staff finds the applicant's response to RAI-SRP16.3-CTSB-SCP-1 acceptable. The staff received the applicant's proposed SCP in an RAI response dated February 19, 2010. Initially, the staff found the proposed SCP unacceptable, and communicated their concerns to the applicant. On May 6, 2010, a revised program was submitted to the staff for review. The staff reviewed the revised SCP and found it to be consistent with the recommendations provided in DC/COL-ISG-8. Based on the comprehensive nature of the SCP, the staff believes a COL applicant can calculate all values necessary to complete information found in Section 3.3 of the TS. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant adhered to the administrative controls information as provided in the Westinghouse STS, except as noted above. In addition, AP1000 GTS Section 5.0 includes "bracketed information" and "Reviewer's Notes." The staff reviewed each piece of "bracketed information" to understand its intent and to determine whether each was site-specific and appropriately deferred to applicants for construction permits or COLs that reference the AP1000 GTS. The staff concluded that each such item was indeed plant- or site-specific. Therefore, the staff finds that Section 5.0 of the AP1000 GTS is acceptable.

16.5 Conclusion

The staff concludes that the changes to the AP1000 GTS and Bases include design-specific parameters and additional TS requirements considered appropriate by the staff. In addition, the staff has compared the additional TS requirements to the relevant NRC regulations, acceptance criteria defined in NUREG-0800, Section 16.0, and other guidance and concludes that the application is in compliance with NRC regulations.

For the reasons set forth above, the staff finds the changes to AP1000 DCD Chapter 16, GTS and Bases, are acceptable and satisfy the requirements of 10 CFR 50.36, 10 CFR 50.36a, and 10 CFR 52.47(a)(11).

17. QUALITY ASSURANCE

17.3 Quality Assurance During the Design Phase

17.3.1 Introduction

Revision 17 of the AP1000 design control document (DCD) proposes to implement the Westinghouse Quality Management System (QMS), Revision 5, for the AP1000 project. The Nuclear Regulatory Commission (NRC) approved Revision 5 to the Westinghouse QMS in a letter dated September 13, 2002. Revision 0 of technical report (TR)-109, APP-GW-GLR-109, "DCD Revision to Incorporate ASME NQA-1-1994 for AP1000," presents the technical justification for implementing the QMS for the AP1000 project. TR-109 justifies standard changes to the AP1000 DCD Sections 3.8, 5.2, 5.4, 17.3, and Appendix 1A. TR-109 also incorporates the American Society of Mechanical Engineers (ASME) Nuclear Quality Assurance (NQA) Standard NQA-1–1994, "Quality Assurance Requirements for Nuclear Facility Applications," into the DCD for AP1000.

17.3.2 Evaluation

NRC regulatory guide (RG) 1.28, Revision 3, "Quality Assurance Program Requirements (Design and Construction)," issued August 1985, endorsed NQA-1-1983 as an acceptable method for complying with the provisions of Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants," to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 50, "Domestic licensing of production and utilization facilities," with regard to the requisite quality assurance (QA) program for the design and construction phases of nuclear power plants.

In Revision 15 of the AP1000 DCD, the applicant committed to the guidance of ASME NQA-1b-1991. As stated in TR-109, the proposed change would revise the version of NQA-1 referenced and committed to in the AP1000 DCD from NQA-1b-1991 to NQA-1-1994. The NRC staff compared the two versions of NQA-1 and found that the 1994 Edition differed from the 1991 Edition primarily in format. NQA-1-1994 consolidates NQA-1 and NQA-2 into a single multipart document and restructures its format to facilitate use of various parts of the standard. The basic requirements of the 1991 Edition were substantially unchanged. Additionally, the applicant evaluated the changes from NQA-1b-1991 to NQA-1-1994. As documented in TR-109, these changes include: (1) reordering of definitions; (2) addition of functions for which personnel need to be qualified; (3) addition of "siting" to the list of activities affecting quality and the list of quality functions to be audited; (4) addition of a paragraph for inspection requirements; and (5) removal of the allowance related to obsolete drawings. The applicant determined that these changes did not represent a reduction in commitment and did not impact the AP1000 design.

In a letter dated June 6, 2008, the applicant responded to the NRC's request for additional information (RAI)-SRP17.3-CQVP-01 regarding missing changes to Revision 16 of the AP1000 DCD associated with TR-109. Specifically, the NRC staff noted that DCD Sections 3.8.3.6, 5.2.3.4.1, and 5.2.4.6 were not modified as described in TR-109, nor did Revision 4 of TR-134, APP-GW-GLR-134, "AP1000 DCD Impacts to Support COLA Standardization," capture the changes. In its response, the applicant stated that Revision 5 of TR-134 would capture the supportive changes described in TR-109. The NRC staff confirmed that TR-134, Revision 5, captures the proposed changes. In addition, the NRC staff confirmed that the changes described in TR-109 and Revision 5 of TR-134 are included in Revision 17 of the AP1000 DCD.

As stated above, the applicant currently implements QMS, Revision 5, which commits to NQA-1-1994. In October 2008, the NRC conducted a QA implementation inspection to verify that design activities conducted for the AP1000 project comply with Revision 5 to the QMS and with the requirements of Appendix B to 10 CFR Part 50 and 10 CFR Part 21, "Reporting of defects and noncompliance." The inspectors verified that Revision 5 of the QMS is adequately implemented and identified three nonconformances to the requirements of Appendix B to 10 CFR Part 50. The applicant has responded to the nonconformances and addressed the actions to correct and prevent recurrence of these nonconformances in a letter dated February 3, 2009. The NRC determined that the actions to correct and prevent recurrence of these nonconformances were adequately addressed by the applicant, as described in a letter dated February 20, 2009, describing the NRC's review of the corrective actions.

The NRC staff identified Open Item OI-SRP 17.3-CQVP-01 for additional inspections of the applicant's implementation of the QMS as it relates to the AP1000 project, if necessary. The NRC has determined that additional inspections are not required to support the licensing decision of the AP1000 DCD Revision 17. Open Item OI-SRP 17.3-CQVP-01 is, therefore, closed.

As required by 10 CFR 52.63, "Finality of standard design certifications," the applicant provided justification for TR-109 in its letter dated May 26, 2007. The applicant stated that DCD Revision 16 includes changes to the certified design information that have resulted from inputs provided by the combined license (COL) applicants that will reference the AP1000 DCD. The applicant stated that the consensus group of AP1000 COL applicants has confirmed all of these changes, and the changes will result in an increased standardization of the certification information that all AP1000 COL applicants will adopt. Based on the NRC staff review of QMS, Revision 5, the NRC staff concludes that the adoption of NQA-1-1994 will result in increased standardization of the design certification (DC) information.

17.3.3 Conclusion

Based on the NRC staff's previous approval and subsequent inspection of the implementation of Revision 5 of the QMS, the NRC staff concludes that the applicant's adoption of NQA-1-1994 is acceptable for Revision 17 of the AP1000 DCD. Based on its review, the NRC staff finds that the QMS, as described in the AP1000 DCD Revision 17, meets the criteria of 10 CFR 52.63(a)(1)(vii) and Appendix B to 10 CFR Part 50 and is, therefore, acceptable.

17.4 Reliability Assurance Program During the Design Phase

17.4.1 Introduction

In the amendment to the AP1000 DCD, the applicant proposed changes to the description of the AP1000 reliability assurance program (RAP). The program has two parts. The first, accomplished during the design phase, is called the design reliability assurance program (D-RAP). The second, formerly called the operational reliability assurance program (O-RAP), is no longer required. References to the O-RAP were removed and operational phase reliability assurance activities (OPRAAs) that accomplish the objectives of the RAP after initial fuel load are now described.

The DCD amendment also clarified the association between the maintenance rule template and Nuclear Energy Institute (NEI) document NEI 07-02A, “Generic FSAR Template Guidance for Maintenance Rule Program Description for Plants Licensed Under 10 CFR Part 52.” The DCA added certain structures, systems, and components (SSCs) to the D-RAP and updated the basis for the SSCs inclusion in the D-RAP as a result of updates to the risk analysis and decisions of the applicant’s expert panel.

Finally, the DCD amendment proposed a change to the inspection, test, analysis and acceptance criteria (ITAAC). The staff documented its evaluation of this change in Section 17.6, “Tier 1 Information.”

In addition to reviewing the amended DCD, the staff reviewed AP1000 combined license standard technical reports TR-117, APP-GW-GLR-117, Revision 1, “Incorporation of the Maintenance Rule,” and TR-132, APP-GW-GLN-132, “Changes to D-RAP Component List.” The staff also reviewed applicable sections of TR-134. These sections identify changes to Chapter 17 of the AP1000 DCD. Related changes also appear in Chapter 14 and Chapter 16 of DCD Tier 2, as well as in Section 3.7 of DCD Tier 1. This information is generic to the design and is expected to apply to all COL applications that reference the AP1000 DC.

17.4.2 Evaluation

The RAP has two stages. The first is referred to as the D-RAP. The second stage applies to reliability assurance activities for an operating plant; the objective during this stage is to ensure that the reliability of SSCs within the scope of the RAP is maintained during plant operations. Programs that are required by other regulations accomplish these reliability assurance activities. A separate, duplicative program would not be beneficial. Accordingly, Item E of the staff requirements memorandum (SRM) dated June 28, 1995, associated with SECY-95-132, “Policy and Technical Issues Associated with the Regulatory Treatment of Non-Safety Systems (RTNSS) in Passive Plant Designs (SECY-94-084),” dated May 22, 1995, states that no separate O-RAP is required for licensees under 10 CFR Part 52, “Licenses, certifications, and approvals for nuclear power plants.”

Instead, the applicants are to incorporate the activities of the RAP after the design phase into existing plant programs. The following are examples of programs that include OPRAAs:

- maintenance rule
- QA
- inservice testing
- inservice inspection
- technical specifications surveillance requirements
- AP1000 investment protection short-term availability controls
- site maintenance

The OPRAA assignment (of activities formerly identified as within the O-RAP) is consistent with the guidance given in SECY-95-132 and with Section 17.4 of NUREG-0800, “Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants.” For this reason, the staff finds the OPRAA assignments to be acceptable. This change also meets the requirement of 10 CFR 52.63(a)(1)(vii) in that it “[c]ontributes to increased standardization of the certification information.”

The applicant has deleted from the DCD Section 17.4.7.2, “D-RAP, Phase II”; Section 17.4.7.2.1, “Information Available to Combined License Applicant”; and Section 17.4.7.3, “D-RAP, Phase III.” The applicant justified these deletions by the incorporation of the generic final safety analysis report (FSAR) template in NEI 07-02A. The staff has endorsed NEI 07-02A and determined that it provides an acceptable method for complying with the requirement in 10 CFR 52.79(a)(15), “Contents of applications; technical information in final safety analysis report.” Specifically, FSARs must describe the program for monitoring the effectiveness of maintenance to meet the requirements of 10 CFR 50.65, “Requirements for monitoring the effectiveness of maintenance at nuclear power plants” (also known as the Maintenance Rule), as well as how the program is to be implemented. This will satisfy the acceptance criteria of NUREG-0800 Section 17.6, “Maintenance Rule,” and is, therefore, acceptable to the staff. This change also meets the requirement of 10 CFR 52.63(a)(1)(vii) in that it “[c]ontributes to increased standardization of the certification information.”

The applicant has deleted four sections of the AP1000 DCD that addressed COL Information Items 17.5.3, 17.5.5, 17.5.6, and 17.5.7.

COL Information Item 17.5.3 states that “The COL applicant or holder will establish [probabilistic risk assessment] PRA importance measures, the expert panel process, and other deterministic methods to determine the site-specific list of SSCs under the scope of the RAP.” NEI 07-02A, Section 17.X.1.1, “Maintenance rule scoping per 10 CFR 50.65(b),” addresses this information item. Section 17.X.1.1 provides guidance on PRA insights for the SSCs, the establishment of the expert panel, the process for updating and maintaining the Maintenance Rule scope and SSC classifications, and the use of other deterministic methods for scoping SSCs.

The AP1000 DCD, COL Information Item 17.5.5 states the following:

> The following activities are represented in Figure 17.4-1 as “Plant Maintenance Program.” The Combined License applicant is responsible for performing the tasks necessary to maintain the reliability of risk-significant SSCs. Reference 8 [NUREG/CR-5695, “A Process for Risk-Focused Maintenance,"] contains examples of cost-effective maintenance enhancements, such as condition monitoring and shifting time-directed maintenance to condition-directed maintenance.

NEI 07-02A, Section 17.X.3, “Maintenance Rule Program Relationship with Reliability Assurance Activities,” addresses this information. Section 17.X.3 provides guidance on the implementation of operational programs for reliability assurance. These programs include QA, Maintenance Rule, maintenance, surveillance testing, inservice inspection, and inservice testing.

COL Information Item 17.5.6 states, “The Maintenance Rule (10 CFR 50.65) is relevant to the Combined License applicant’s maintenance activities in that it prescribes SSC performance-related goals during plant operation.”

NEI 07-02A addresses performance-related goals throughout the document. Specifically, Section 17.X.1.1 provides guidance on how SSCs in the Maintenance Rule program are evaluated against performance criteria to determine if goals must be established. In Section 17.X.1.2, the guidance states that goals are established for SSCs classified as (a)(1) status. Section 17.X.1.4 specifies a periodic evaluation of the performance, condition monitoring, goals, and preventive maintenance activities for SSCs in the Maintenance Rule program.

The AP1000 DCD, COL information item 17.5.7 states the following:

> In addition to performing the specific tasks necessary to maintain SSC reliability at its required level, the O-RAP activities include:
>
> - Reliability data base—Historical data available on equipment performance. The compilation and reduction of this data provides the plant with source of component reliability information.
> - Surveillance and testing—In addition to maintaining the performance of the components necessary for plant operation, surveillance and testing provides a high degree of reliability for the safety-related SSCs.
> - Maintenance plan—This plan describes the nature and frequency of maintenance activities to be performed on plant equipment. The plan includes the selected SSCs identified in the D-RAP.

These bulleted items are covered under NEI 07-02A, Section 17.X.3. The first bulleted item is also captured in Section 17.X.4, "Maintenance Rule Program Relationship with Industry Operating Experience Activities."

The staff considers NEI 07-02A to be an acceptable way to address these COL information items. These information items are considered to have been addressed for COL holders that implement programs consistent with this guidance. This change also meets the requirement of 10 CFR 52.63(a)(1)(vii) in that it "[c]ontributes to increased standardization of the certification information."

Most components included in the D-RAP (listed in Table 17.4-1, "Risk-significant SSCs within the Scope of D-RAP" and in Tier 1, Table 3.7-1, "Risk-Significant Components") are listed on the basis of a computed measure of risk importance. Specifically, a basic event with a risk achievement worth (RAW) greater than 2.0 or a risk reduction worth (RRW) greater than 0.005 is considered important to risk, as are the associated SSCs. SSCs may be assigned to the D-RAP for other reasons (for example, an appropriately constituted expert panel judges that they are important). The D-RAP list identifies only the expert panel as the basis for the inclusion of certain components, which implies that these components do not meet the quantitative risk importance criteria. The staff requested additional information to justify this conclusion in four cases:

(1) Reactor coolant pump switchgear circuit breakers:

ECS ES 31	ECS ES 41	ECS ES 51	ECS ES 61
ECS ES 32	ECS ES 42	ECS ES 52	ECS ES 62

In a letter dated September 5, 2008, the applicant provided additional information to justify the classification of the reactor coolant pump (RCP) without reference to the

RAW. The failures of the RCP switchgear circuit breakers are captured in the following events.

RC1CB051GO	PUMP A FAILS TO TRIP—BREAKER FAILS TO OPEN
RC1CB052GO	PUMP A FAILS TO TRIP—BREAKER FAILS TO OPEN
RC1CB053GO	PUMP A FAILS TO TRIP—BREAKER FAILS TO OPEN
RC1CB054GO	PUMP A FAILS TO TRIP—BREAKER FAILS TO OPEN
RC1CB061GO	PUMP B FAILS TO TRIP—BREAKER FAILS TO OPEN
RC1CB062GO	PUMP B FAILS TO TRIP—BREAKER FAILS TO OPEN
RC1CB063GO	PUMP B FAILS TO TRIP—BREAKER FAILS TO OPEN
RC1CB064GO	PUMP B FAILS TO TRIP—BREAKER FAILS TO OPEN

In addition, the applicant stated the following:

> Fault tree logic requires all four pumps to shutdown; however, there are two breakers for each pump with only one of two breakers necessary to shutdown one pump. Consequently, CCF of the RCP switchgear circuit breakers is not modeled and, therefore, the RCP circuit breakers are in the D-RAP (Table 17.4-1) only due to the recommendation of the expert panel (EP).

The DCD for the certified design reported that following an event such as a loss-of-coolant accident (LOCA), steam generator tube rupture, or a stuck-open valve in the main steam line, RCPs must trip, or operator action will be required to achieve safe shutdown. Failure to trip RCPs can prevent operation of the core makeup tanks. Consequently, the staff expects a common-cause failure (CCF) to trip all RCPs to be significant, even if it does not lead to core damage in large LOCAs and some medium LOCAs.

This was confirmed in APP-GW-GL-022, “AP1000 Probabilistic Risk Assessment,” Revision 8 (the PRA report), which reported the CCF of RCP circuit breakers to open, represented by event RPX-CB-GO (see Table 29-2, “Common-Cause Failure Calculations,” page 29-22). Item 36 in Table 50-23 of the same report, “Risk Importances Sorted by Risk Increase,” shows RPX-CB-GO to be a member of more than 400 cutsets with a RAW greater than 50. It appears in reactor coolant loop, RCN, and RCT fault trees. The NRC staff identified this as Open Item OI-SRP17.4-SPLA-01.

In a letter dated May 13, 2009, the applicant proposed a revision to Table 17.4-1, indicating that these breakers are identified as risk-significant because of high RAW for CCF. The staff finds this to be acceptable and considers the open item to be resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

(2) 125-volt direct current 24-hour batteries, inverters, and chargers

The batteries provide power for the protection and safety monitoring system and safety-related valves. In a letter dated September 5, 2008, the applicant reported that the risk-significance criteria are not met by the basic events for these components without considering common cause. The risk-significance criteria for including the inverters, batteries, and battery chargers based on the PRA modeling of common cause for these components support inclusion in the D-RAP. The rationale for inclusion is changed to RAW/CCF for 125-volt dc 24-hour batteries, inverters, and chargers.

A subsequent design modification changed the voltage of the 1E direct current (dc) system to 250 volts direct current (Vdc). The staff's evaluation of this modification is documented in Section 8.3.2 of this safety evaluation. This had no impact on the way the system is modeled in the PRA and so PRA insights and results were not affected. In a letter dated April 20, 2010, the applicant proposed to revise Table 17.4-1 in Tier 2, reflecting the changes to the design and adding the associated 1E 250 Vdc buses to the explicit scope. This makes the table consistent with the amended design and it is, therefore, acceptable to the staff. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

(3) In-containment refueling water storage tank vents

These vents (PXS-MT-03) provide a pathway to vent steam from the in-containment refueling water storage tank (IRWST) into the containment. In a letter dated September 5, 2008, the applicant reported that the method of modeling documented in APP-GW-GL-022 had been revised in the change discussed in TR-102, APP-GW-GLR-102, "AP1000 Probabilistic Risk Assessment Update Report."

The risk significance of IRWST vents based on the new PRA modeling for large-release frequency (LRF) supports inclusion in the D-RAP. The rationale for inclusion now reflects RAW for the IRWST vents. This is acceptable to the staff.

(4) Motor-operated valves in automatic depressurization system stages 1, 2, and 3

In the AP1000 DC PRA, the applicant reported a RAW value of greater than 40 for the event that represents failure-to-open for 32 combinations of three motor-operated valves (MOVs) in automatic depressurization system (ADS) stages 2 and 3.

In a letter dated September 5, 2008, the applicant reported that the criteria for including MOVs in ADS stages 1, 2, and 3 based on the PRA modeling (risk significance) of basic events before consideration of common cause for these components does not support inclusion of these MOVs in the D-RAP.

However, two common-cause groupings model CCFs of the ADS MOVs. One models the CCF to operate the MOVs of the ADS first, second, and third stages. The criteria for including MOVs in ADS stages 1, 2, and 3 based on LRF risk significance of this CCF supports their inclusion in the D-RAP. The other grouping models the CCFs of 32 combinations of three MOVs in stages 2 and 3 to fail to operate. The criteria for including MOVs in ADS stage 2 and 3 based on CDF and LRF risk significance supports inclusion of stage 2 and stage 3 MOVs in the D-RAP.

The rationale for including these MOVs in D-RAP now reflects RAW/CCF for MOVs in ADS stages 1, 2, and 3. This is acceptable to the staff.

Several additions to the D-RAP have been identified on the basis of risk significance in the internal events Level 1 PRA:

- chemical and volume control (CVS) letdown discharge isolation valve inside reactor containment (CVS-PL-V045)
- CVS control letdown discharge isolation valve outside reactor containment (CVS-PL-V047)
- a new diverse actuation system cabinet outside the main control room
- 6,900-volt alternating current buses ECS-ES-1 and ECS-ES-2, which are power buses fed by the onsite diesel generators and offsite power
- normal residual heat removal system (RNS) stop check valves (RNS-PL-V007A/B and RNS-PL-V015A/B) on the discharge of the RNS pumps, which prevent backflow from the reactor coolant system (RCS)

In addition, two components have been added on the basis of the Level 2 PRA:

- RNS check valve (RNS-PL-V013), which provides a flow path from the RNS pumps to the RCS
- RNS check valve (RNS-PL-V056), which provides a flow path from the cask loading pit to the RNS pump inlet

These additions are consistent with DCD Section 17.4.7.1.5, “SSCs to be Included in D-RAP,” and thus they are acceptable to the staff.

17.4.3 Conclusion

The applicant proposes changes to the RAP, described in the AP1000 DCA request. Both the removal of references to the O-RAP and the description of OPRAAs that complement the D-RAP to accomplish RAP objectives are consistent with NUREG-0800 Section 17.4. For this reason, they are acceptable to the staff.

The staff has endorsed adoption of NEI 07-02A, which allows closure of certain COL information items. The staff considers COL Information Items 17.5.3, 17.5.5, 17.5.6, and 17.5.7 to be closed for COL holders that implement programs consistent with this guidance.

The applicant added certain SSCs to the D-RAP and updated the basis for SSC inclusion in the D-RAP to include updates to the risk analysis and decisions of the applicant’s expert panel. These changes result from proposed design changes and updated risk analysis. They are consistent with the methodology previously approved and, therefore, acceptable to the staff.

These changes meet the requirement of 10 CFR 52.63(a)(1)(vii) in that each one “[c]ontributes to increased standardization of the certification information.”

17.6 Tier 1 Information

17.6.1 Information

Certain SSCs were added to the AP1000 D-RAP. The basis for SSC inclusion in the D-RAP was revised in some cases as a result of updates to the risk analysis and decisions of the applicant's expert panel.

In addition, the applicant proposed a change to the ITAAC for D-RAP.

In addition to reviewing the amended DCD, the staff reviewed TR-132. The staff also reviewed applicable sections of TR-134 and APP-GW-GLE-007, "ITAAC Changes" (Impact Document 07). In these, changes to Section 3.7 of Tier 1 of the AP1000 DCD are identified. Related changes also appear in Chapters 14, 16, and 17 of DCD Tier 2. This information is generic to the design and is expected to apply to all COL applications that reference the AP1000 DC.

17.6.2 Evaluation

Several additions to the D-RAP have been identified on the basis of risk significance in the internal events Level 1 PRA:

- CVS letdown discharge isolation valve inside reactor containment (CVS-PL-V045)
- CVS letdown discharge isolation valve outside reactor containment (CVS-PL-V047)
- Normal RNS stop check valves (RNS-PL-V007A/B and RNS-PL-V015A/B) on the discharge of the RNS pumps, which prevent backflow from the RCS

In addition, two components have been added on the basis of the Level 2 PRA:

- RNS check valve (RNS-PL-V013), which provides a flow path from the RNS pumps to the RCS.
- RNS check valve (RNS-PL-V056), which provides a flow path from the cask loading pit to the RNS pump inlet.

The nominal voltage of the 24-hour batteries was changed from 125 Vdc to 250 Vdc. (The staff's review of this modification is documented in Section 8.3.2 of this safety evaluation.)

Finally, the applicant revised the method by which certain SSCs were identified to clarify the rationale for their inclusion.

Subject to confirmation, the additions and changes will be consistent with DCD Section 17.4.7.1.5, "SSCs to be Included in D-RAP." They will be reflected in DCD Tier 1, Section 3.7, "Design Reliability Assurance Program," Table 3.7-1, "Risk-Significant Components," and Table 2.2.1-1 (untitled). The staff finds the proposed changes to Tier 1 will make Tier 1 and Tier 2 consistent and, therefore, they are acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

In APP-GW-GLE-007, "ITAAC Changes," (Impact Document 07), the applicant proposed an alternative to the existing D-RAP ITAAC. In Table 3.7-3, “Inspections, Tests, Analyses and Acceptance Criteria,” the approved existing acceptance criterion is as follows:

> A report exists and concludes that the estimated reliability of each as-built component identified in Table 3.7-1 is at least equal to the assumed reliability and that industry experience including operations, maintenance, and monitoring activities were assessed in estimating the reliability of these SSCs.

To this, the applicant proposed to add:

> For an as-built component with reliability less than the assumed reliability an evaluation shall show that the net effect of as-built component reliabilities does not reduce the overall reliability. Or, an evaluation shall show that there is not a significant adverse effect on the core melt frequency or the large release frequency in the PRA applicable to the plant.

The staff could not conclude that the proposed alternative would satisfy the expectations documented in the SRM dated June 28, 1995, for SECY-95-132.

D-RAP ITAAC should provide assurance that the reliability and availability of risk-significant SSCs are consistent with the certified design (subject to deviations and plant-specifics approved in the COL and reflected in the FSAR). In RAI-SRP17.4-SPLA-04, the staff requested that the applicant propose an alternative D-RAP ITAAC that provides reasonable assurance that the plant is designed and will be constructed in a manner that is consistent with the key assumptions and risk insights for risk-significant SSCs within the scope of D-RAP. The NRC staff identified this as Open Item OI-SRP17.4-SPLA-04.

In a letter dated March 30, 2010, the applicant proposed a revised D-RAP ITAAC. The applicant proposed new language in Table 3.7-3, “Inspections, Tests, Analyses and Acceptance Criteria.” The proposed design commitment now reads as follows: “The D-RAP ensures that the design of SSCs within the scope of the reliability assurance program (Table 3.7-1) is consistent with the risk insights and key assumptions (e.g., SSC design, reliability, and availability).” The ITAAC is to be completed by an analysis: “An analysis will confirm that the design of RAP SSCs identified in Table 3.7-1 has been completed in accordance with applicable D-RAP activities. The following acceptance criteria are provided:

> An analysis report documents that safety-related SSCs identified in Table 3.7-1 have been designed in accordance with a 10 CFR 50 Appendix B quality program.
>
> An analysis report documents that nonsafety-related SSCs identified in Table 3.7-1 have been designed in accordance with a program which satisfies quality assurance requirements for SSCs important to investment protection.

The staff finds that satisfying this commitment will provide adequate assurance that the design products used to procure, manufacture, transport, store, install, inspect, and test risk-significant SSCs are traceable to the licensed design. It is consistent with SRM for SECY-95-132. This component of ITAAC complements the others in providing confidence that the as-built plant is, at the time of initial fuel loading, consistent with the certified design. For this reason, it is acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

17.6.3 Conclusion

Revisions to DCD Tier 1 Table 3.7-1, "Risk-Significant Components," and Table 2.2.1-1 (untitled) have been proposed. With these changes, the Tier 1 information corresponds to the Tier 2 information in Table 17.4-1, "Risk-Significant SSCs within the Scope of D-RAP," as it has been clarified and updated to reflect the amended design. These additions and changes are consistent with the previously approved methodology and, therefore, they are acceptable to the staff.

The staff reviewed the applicant's proposed change to D-RAP ITAAC. The staff finds that the proposed D-RAP ITAAC will provide assurance that the reliability and availability of risk-significant SSCs are consistent with the certified design (subject to deviations and plant specifics approved in the COL and reflected in the FSAR). It is consistent with the SRM for SECY-95-132 and is, therefore, acceptable to the staff.

These changes meet the requirement of 10 CFR 52.63(a)(1)(vii) in that each one "[c]ontributes to increased standardization of the certification information."

18. HUMAN FACTORS ENGINEERING

Westinghouse has submitted information in support of its design certification (DC) amendment application that Westinghouse considers "proprietary" within the meaning of the definition provided in Title 10 of the *Code of Federal Regulations* (10 CFR) 2.390(b)(5). Westinghouse has requested that this information be withheld from public disclosure and the Nuclear Regulatory Commission (NRC) staff agrees that the submitted information sought to be withheld includes proprietary commercial information and should be withheld from public disclosure. This chapter of the NRC staff's evaluation includes proprietary information that has been redacted in order to make the evaluation available to the public. The redacted information appears within "square brackets" as follows:

[ ]

The complete text of this chapter, containing proprietary information can be found at Agencywide Documents Access and Management System (ADAMS) Accession Number ML112091879 and can be accessed by those who have specific authorization to access Westinghouse proprietary information.

18.2 Element 1: Human Factors Engineering Program Management

18.2.5 AP1000 Human Factors Engineering Program Plan (no comparable NUREG-1793 section)

18.2.5.1 Summary of Technical Information

The applicant added APP-OCS-GBH-001, Revision 0, "AP1000 Human Factors Engineering Program Plan," issued January 2008 (hereafter referred to as the AP1000 Human Factors Engineering (HFE) Program Plan, as a reference in Section 18.2.6.1 of the design control document (DCD) to establish completion of combined license (COL) Information Item 2-1. In technical report (TR)-90 (APP-GW-GLR-090, Revision 0, "Strategy for the Closure of the AP1000 Design Control Document, Chapter 18, 'Human Factors Engineering (HFE) COL Information Items,'" issued February 2007), the applicant stated that the AP1000 HFE Program Plan captures the technical content discussed in DCD Section 18.2, and describes implementation methods for incorporating HFE into the AP1000 design process. It is designed to serve as an implementation manual for the engineering staff.

18.2.5.2 Staff Evaluation

The staff determined that this additional reference is consistent with Revision 15 of the AP1000 DCD. It describes the scope of the HFE program in terms of each of the elements identified in NUREG-0711, "Human Factors Engineering Program Review Model," issued February 2004. The reference also describes the processes used to incorporate HFE into the AP1000 design process.

18.2.5.3 Conclusion

The staff concludes that this change does not affect the conclusion in Section 18.2.4 of NUREG-1793, “Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design,” issued September 2004).

The AP1000 HFE Program Plan continues to implement NUREG-0711 guidelines.

18.2.6 Evaluation of COL Information Item 18.2-1 (no comparable NUREG-1793 section)

18.2.6.1 Summary of Technical Information

COL Information Item 18.2-1 states the following:

> The COL applicant referencing the AP1000 certified design is responsible for the execution of a U.S. Nuclear Regulatory Commission (NRC)-approved HFE Program.

In DCD Revision 17, the applicant stated:

> [The] AP1000 Human Factors Engineering Program Plan fully captures the information certified in Section 18.2 and provides execution guidance for the NRC-approved HFE Program. The ongoing confirmation that the AP1000 HFE Program Plan is being executed as required is demonstrated by fulfillment of the other COL Information Items in Chapter 18. The final confirmation that the HFE Program Plan has been executed will be demonstrated by completion of the ITAAC [Inspections, Tests, Analyses and Acceptance Criteria] (Tier 1 Material, Table 3.2-1, Items 1 to 13).

18.2.6.2 Evaluation

From a program overview perspective, the applicant used Revision 17 to document changes in the status of a number of COL information items and inspection, test, analyses, and acceptance criteria (ITAAC). TRs provided for staff review include the supporting documentation. When the TRs indicate that partial progress has been made and additional work to address information items is ongoing, the staff evaluated redundancy between the COL information item and the ITAAC. If the staff identified redundancy, then the COL action item was closed. In all cases, the review ensured that final design product completion was appropriately tracked. The staff identified all documents used to conclude that the NUREG-0711 criteria were satisfactorily implemented, and Westinghouse docketed the documents.

With respect to COL Information Item 18.2-1, the staff determined that the information item is closed based on the following:

(1) The AP1000 HFE Program Plan is consistent with AP1000 DCD, Revision 15. It describes the scope of the HFE program in terms of each of the NUREG-0711 elements. It provides additional information on where and how the overall design process should use HFE guidance and, thus, provides reasonable assurance that the applicant will implement and undertake the required HFE activities for the AP1000 design at the most appropriate time in the project schedule. This program element requires no additional product development.

(2) COL information items in other sections and the ITAAC listed in Table 3.2-1 address specific HFE design products that require completion. Retaining this generic information item is redundant with the remaining open information items and ITAAC.

(3) The applicant must implement the HFE verification and validation (V&V) program in accordance with ITAAC Table 3.2-1, Item 1 (DCD Revision 17). This includes five specific tasks that validate and verify HFE program implementation and concludes with an as-built inspection of the human-system interfaces (HSIs) as constructed at the time of plant startup. The combination of these actions provides better verification of field implementation than would be accomplished under this COL information item.

18.2.6.3 Conclusion

The staff concludes that COL Information Item 18.2-1 is redundant to existing ITAAC included in Tier 1, Table 3.2-1. Consequently this COL information item is closed. ITAAC Item 1 (DCD Revision 17) will verify the execution of the NRC-approved HFE program.

18.2.7 Evaluation of COL Information Item 18.2-2 (no comparable NUREG-1793 section)

18.2.7.1 Summary of Technical Information

COL Information Item 18.2-2 states the following:

> Specific information regarding the location of the emergency operations facility and emergency operations facility communications will be provided by the Combined Operating License applicant to address the Combined License information requested in this subsection.

18.2.7.2 Evaluation

The applicant stated in TR-134 (APP-GW-GLR-134, Revision 4, “AP1000 Standard COLA Technical Report,” issued March 2008) that TR-136 (APP-GW-GLR-136, Revision 1, “AP1000 Human Factors Program Implementation for the Emergency Operations Facility and Technical Support Center,” issued October 2007) partially addresses the information requested by this information item. In TR-136, the applicant described the method used to apply the AP1000 HFE Program Plan to technical support centers (TSCs) and emergency operations facilities (EOFs) used to support AP1000 plants and stated that the COL applicant has overall responsibility for the human factors adequacy of the TSC and EOF. In APP-OCS-GGR-110-P, Revision 1, “AP1000 Technical Support Center and Emergency Operations Facility Workshop,” issued February 2008, the applicant described in detail how it developed the information in TR-136.

In TR-136 and subsequently in AP1000 DCD Revision 17, the applicant made changes to this COL information item that deleted HFE design responsibilities that were included in the previously approved COL information item in the DCD, Revision 15. In response to request for additional information (RAI)-SRP18-COLP-21, dated July 31, 2009, the applicant removed EOF and TSC location requirements and added responsibilities for EOF and TSC human factors attributes.

Deletion of location requirements is acceptable because the HFE design is not dependent on location. The location of the EOF and TSC is subject to regulatory guidance. This is addressed in Section 13.3, “Emergency Planning,” of this report.

The addition of COL responsibility for defining EOF and TSC human factors attributes is consistent with the intent of the original, approved COL information item and ensures that the HFE design outside the scope of the AP1000 DCD is addressed. In a subsequent revision to the AP1000 DCD, the applicant incorporated the RAI response into the DCD text, which resolves this issue.

From the program description provided in TR-136 and APP-OCS-GGR-110-P, the NRC staff noted a well-structured and disciplined assessment of the HFE requirements applicable to the TSC and EOF. The following examples demonstrate how the applicant used the AP1000 HFE Program Plan and appropriate regulations to identify the HFE design requirements of the TSC/EOF:

- Westinghouse and utility personnel worked together to identify the functional requirements for the TSC/EOF. The diverse experience in this group supported a thorough evaluation.

- Westinghouse extracted specific requirements from the AP1000 DCD; the AP1000 HFE Program Plan; NUREG -0711, Revision 2; NUREG-0696, “Functional Criteria for Emergency Response Facilities,” issued February 1981; and NUREG-0654/FEMA-REP-1, Revision 1, “Criteria for Preparation and Evaluation of Radiological Emergency Response Plans and Preparedness in Support of Nuclear Power Plants,” issued March 2002. These documents serve as the basis for identifying the TSC/EOF functional requirements. Identification of functional requirements is one of the basic steps required in the AP1000 HFE Program Plan and NUREG-0711. APP-OCS-GGR-110-P provides complete documentation of how Westinghouse identified applicable functions.

- Westinghouse and utility representatives conducted an operating experience review (OER). Application of lessons learned from operating experience is one of the basic steps required in the AP1000 HFE Program Plan and NUREG-0711.

- Westinghouse completed a task analysis incorporating OER results, observations from emergency plan drills at V.C. Summer and Harris nuclear sites, input from emergency procedures from four different utilities, and review comments from both Westinghouse and utility personnel. In TR-136, the applicant stated that it will capture the requirement for this task analysis in the Operational Sequence Analysis-2 (OSA-2) Implementation Plan. A task analysis is one of the basic steps required in the AP1000 HFE Program Plan, NUREG-0711, and OSA-2 incorporates accepted methods for performing task analyses.

- In accordance with TR-136, Section 2.4.4, Westinghouse has identified applicable HSI design guidelines from the AP1000 HSI design guidelines (APP-OCS-J1-002, Revision 0, “AP1000 Human System Interface Design Guidelines”) to promote the human factors design adequacy of the TSC/EOF design. This ensures that standard HSI design requirements will be applied to the appropriate elements of HSI design.

- EOF/TSC HFE design elements outside the AP1000 scope are addressed via a COL information item. This provides reasonable assurance that a complete HFE design will be achieved for these emergency facilities.

Based on the activities outlined above, the applicant's use of a tailored approach in applying the AP1000 HFE program to the TSC and EOF is solidly based on NUREG-0711. The applicant has documented the TSC and EOF task analysis results in APP-OCS-JOA-001, "HFE Analysis to Support TSC and EOF Design." Open Item OI-SRP18-COLP-18 tracked completion of the task analysis and documentation of the results. This open item has been addressed by issuance of the report, which satisfactorily summarizes task analysis results associated with the EOF and TSC and is closed.

18.2.7.3 Conclusion

The applicant has developed a sufficient basis for applying a tailored HFE program to the TSC and EOF and has documented the TSC and EOF task analysis results in the APP-OCS-JOA-001 report. The revised COL Information Item 18.2-2 accurately communicates the COL applicant's responsibility for HFE design of the EOF and TSC. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which incorporates the revised COL information.

18.2.8 Evaluation of Tier 1 Information—Design Commitment 3, ITAAC Table 3.2-1 (DCD Revision 15)

18.2.8.1 Summary of Technical Information

ITAAC Design Commitment 3 (DCD Revision 15) reads as follows:

> Design Commitment: The HSI design is performed for the operation and control system in accordance with the HSI design implementation plan.
>
> Inspection, Tests, and Analyses: An evaluation of the implementation of the HSI design.
>
> Acceptance Criteria: A report exists and concludes that the HSI design for the operation and control system was conducted in conformance with the implementation plan and includes the following documents:
>
> – Operation and Control Centers System Specification Document
>
> – Functional requirements and design basis documents for the alarm system, plant information system, wall panel information system, controls (soft and dedicated), and the qualified data processing subsystems
>
> – Design guideline documents (based on accepted HFE guidelines, standards, and principles) for the alarm system, displays, controls, and Anthropometrics
>
> – Design specifications for the alarm system, plant information system, wall panel information system, controls (soft and dedicated), and the qualified data processing subsystems

- Engineering test report document summarizing outcomes of each man-in-the-loop engineering test iteration performed to support HSI design

In DCD Revision 17, the applicant deleted this ITAAC based on completion of the work it described.

18.2.8.2 Evaluation

The staff did not find a one-to-one correlation between the list of completed documents in TR-82 (APP-GW-GLR-082, Revision 0, “Execution and Documentation of the Human System Interface Design Implementation Plan,” issued May 2007) and the AP1000 DCD, Tier 1, ITAAC Table 3.2, Design Commitment 3 (DCD Revision 15), acceptance criteria. Design documents were not identified for the following areas:

- functional requirements and design-basis documents for the plant information system
- functional requirements and design-basis documents for controls (soft and dedicated)
- functional requirements and design-basis documents for the qualified data processing subsystems

RAI-SRP18-COLP-05 requested clarification of the discrepancy. The applicant’s response, dated May 28, 2008, indicated that terminology changes resulted in the inclusion of the areas listed above in the “Distributed Control and Information System” (APP-OCS-J1-010, “AP1000 Display System Functional Requirements”). The staff found that this document includes the functional requirements and design-basis information for the systems listed above. The staff concluded that this change was limited to renaming and reorganizing information to improve clarity and did not affect the intent of the ITAAC.

Open Item OI-SRP18-COLP-01A, identified that the applicant had not completed all the design specifications listed in the ITAAC. These design specifications were subsequently completed along with specifications for systems not listed.

The staff reviewed the completed documents referenced in TR-82, along with the information provided in the RAI, and concluded that these documents appropriately implement the HSI design implementation plan, as described in AP1000 DCD, Revision 17. This included the documents referenced in the ITAAC. Clarity was consistently good across the procedural hierarchy, and the specificity of design requirements had increased in the transition from the functional design level to design specifications. These procedures provide reasonable assurance that the design process will effectively implement standardized HFE design requirements. Based on these results, OI-SRP18-COLP-01A has been satisfactorily addressed and is closed. The staff evaluates the translation of these design documents to a physical design as part of ITAAC Table 3.2-1 Design Commitment 1b (DCD Revision 17).

18.2.8.3 Conclusion

The staff concludes that the proposed change to delete Design Commitment 3 of the ITAAC is supported by the quality of the design documents that have been produced. The design documents provide the level of detail needed to provide reasonable assurance that the HFE design will be effectively implemented within the control room, remote shutdown station, and local control stations. Design Commitment 3 in ITAAC Table 3.2-1 (DCD Revision 15) is closed.

The DCD changes provide detailed human factors design information that would otherwise have to be addressed through verification of the ITAAC. Therefore, the changes to the DCD eliminate the need for design acceptance criteria in accordance with the finality criteria in 10 CFR Part 52.63(a)(1)(iv).

18.5 Element 4: Task Analysis

18.5.5 Evaluation of Operational Sequence Analysis-2 Implementation Plan and Results Summary

18.5.5.1 Summary of Technical information

In AP1000 DCD, Revision 17, the discussion of OSA-2 deleted the description of a specific theoretical model for evaluating operator workload measures, but still committed to conducting an evaluation of the effect of the HSI design and the task demands on operator workload. In TR-81 (APP-GW-GLR-081, Revision 1, "Closure of COL Information Item 18.5-1, Task Analysis," issued May 2007) and in the RAI-TR81-COLP-01 response dated January 29, 2008, the applicant indicated that APP-OCS-J1R-210, Revision 1 "AP1000 Operational Sequence Analysis (OSA-2) Implementation Plan," would identify the most appropriate task analysis methods to use.

18.5.5.2 Evaluation

The staff reviewed the OSA-2 Implementation Plan, which describes the applicant's methods for analyzing the collected task sequence information needed to satisfy the four issues addressed in the DCD: (1) completeness of available information; (2) time to perform tasks; (3) operator workload analysis; and (4) operational crew staffing. The staff concludes that it is acceptable to remove the prescriptive language from the DCD because the applicant provided a robust implementation plan containing detailed information describing how to conduct an OSA analysis, the tasks that should be part of the analysis, and the expected results from the analysis.

The staff also reviewed APP-OCS-J1R-220, Revision B, "AP1000 Operational Sequence Analysis (OSA-2) Summary Report," which describes the results of conducting the activities described in the implementation plan.

18.5.5.3 Conclusion

Based on its review of the implementation plan and the summary report, the staff has determined that sufficient information exists to address the NUREG-0711 review criteria as described in the COL closure section below.

18.5.6 Evaluation of COL Information Item 18.5-1 (NUREG-1793 Item 18.5.3-3)

18.5.6.1 Summary of Technical Information

COL Information Item 18.5-1 states the following:

> Combined License applicants referencing the AP1000 certified design will address the execution and documentation of the task analysis implementation plan presented in Section 18.5.

Appendix F of NUREG-1793 broke this COL information item into two pieces and reworded the information item so that it reads:

> FSER Item 18.5.3-3: The staff reviewed the applicant's task analysis at an implementation plan level of detail; finished products to complete the element were not available for review, but the methodology for conducting a complete task analysis was evaluated. The COL applicant will use this methodology to conduct a complete HFE task analysis after design certification.
>
> FSER item 18.5.3-2: The COL applicant will utilize the information from the AP1000-specific task analysis in the development of its procedures and training programs.

This section addresses execution of the task analysis implementation plan, which Westinghouse completed. TR-81 was submitted to document the task analysis results. The report recommends a revision to Tier 1 of the DCD ITAAC to reflect completion of the AP1000 function-based task analysis and provides a basis for closure of COL Information Item 18.5-1. The applicant also provided the OSA-2 Implementation Plan, which describes the methodology used to conduct the second round of OSA.

18.5.6.2 Evaluation

The staff evaluated the information provided by the applicant in the OSA-2 Implementation Plan and the OSA-2 Summary Report against acceptance criteria from NUREG-0711, Revision 2.

NUREG-0711, Section 5.4(1), states Criterion 1 as the following:

> The scope of the task analysis should include the following:
>
> - selected representative and important tasks from the areas of operations, maintenance, test, inspection, and surveillance
> - a full range of plant operating modes, including startup, normal operations, abnormal and emergency operations, transient conditions, and low power and shutdown conditions
> - Human Actions (HAs) that have been found to affect plant risk by means of PRA importance and sensitivity analyses should also be considered risk-important

- where critical functions are automated, all human tasks, including monitoring of the automated system and execution of backup actions if the system fails

Evaluation of Criterion 1

The staff reviewed OSA-2 Summary Report, which provides the results of the OSA-2 for the AP1000 design in accordance with the OSA-2 Implementation Plan. The OSA-2 Implementation Plan summarizes [ ] components and the corresponding [ ] maintenance, test, inspection, and surveillance (MTIS) tasks used for the task analysis. The inclusion of representative and important tasks from the areas of operations, MTIS during OSA-2 implementation satisfies the requirements in the first bullet of NUREG-0711 Criterion 1.

The OSA-2 Implementation Plan identified [ ] risk-important tasks, including tasks during normal operations, emergency and abnormal operations, and shutdown conditions. The inclusion of these tasks within the scope of the task analysis implementation plan satisfies the requirements of the second bullet of NUREG-0711 Criterion 1.

As described in the AP1000 DCD, the applicant performed OSA-2 for a representative subset of tasks including risk-important human actions, risk-important tasks, and tasks that have human performance concerns. The applicant used human reliability analysis (HRA) to identify [ ] scenarios and associated tasks described in the implementation plan as risk-important tasks. This is an acceptable method for identifying risk-important tasks. The applicant used probabilistic risk assessment (PRA) to identify estimated timeframes for completing the tasks, as well as the beginning and ending steps. For example, the plan discusses tasks associated with [ ] an [ ], and a [ ]. These events are considered to be within the design basis, and risk-important tasks are associated with them. The identification and inclusion of these risk-important tasks within the scope of the OSA-2 Implementation Plan satisfies the third bullet of NUREG-0711 Criterion 1.

The OSA-2 Implementation Plan discusses [ ] tasks identified during OSA-1 as having human performance concerns. These [ ]. The selection of tasks that have associated human factors concerns demonstrates that the applicant has chosen to analyze critical automated functions. The implementation plan describes the backup actions to be taken in case of a failure. Analysis of automated system failures and backup actions during OSA-2 satisfies the fourth bullet of NUREG-0711 Criterion 1.

The staff has determined that the scope of the task analysis is consistent with NUREG-0711 Criterion 1.

NUREG-0711, Section 5.4 (2), states Criterion 2 as the following:

> Tasks should be linked using a technique such as operational sequence diagrams. Task analyses should begin on a gross level and involve the development of detailed narrative descriptions of what personnel have to do. The analyses should define the nature of the input, process, and output needed by and of personnel.

Evaluation of Criterion 2

Consistent with the NUREG-0711 criterion, the applicant used the [ ] methodology to conduct two rounds of analysis. The first analysis, OSA-1, identified risk-important tasks, [ ] for safe operation and safe shutdown for the AP1000 design. OSA-2 used the tasks identified from OSA-1 to estimate [ ].

The staff reviewed the OSA-1 report titled "AP1000 Operational Sequence Analysis (OSA) Summary Report," Revision 0, (APP-OCS-J1R-120) and the implementation plans for OSA-1 (APP-OCS-J1R-110) and OSA-2, (APP-OCS-J1R-210). These reports describe the applicant's methods for analyzing the collected sequence information needed to satisfy the four issues identified in the DCD:

(1) Completeness of information: Establish the necessary information for successful task performance. The results of this analysis feed into the interface design process to ensure necessary information is available to the operator performing the task activities.

(2) Time to perform tasks: Establish that the operators will be able to complete tasks within the time available. This information is based on assumptions about the time required to access displays, select and actuate controls, etc. The OSA-2 Summary Report discusses that the generally acceptable range of "good" or appropriate operator workload is between 50 and 80 percent. A workload greater than 80 percent indicates a potential overload, while a workload less than 50 percent indicates a potential underload.

(3) Operator Workload: Establish the impact of task requirements and the HSI design on operator workload.

(4) Operational crew staffing: Establish staffing requirements. The results of the operator workload assessment and the identification of time constraints are used to review the adequacy of staffing assumptions, HSI design, task allocation and work organization.

Since the OSA-1 analysis was more general than the OSA-2 analysis, and the information from OSA-1 was used as input into OSA-2, the applicant's task analysis is consistent with NUREG-0711 Criterion 2 that the analysis should begin on a gross level (OSA-1) and become more detailed as the analysis proceeds.

Because of the overlap between Criteria 2 and 3, the staff presents its evaluation of the applicant's task analysis with regard to development of detailed narrative descriptions under Criterion 3 below and addresses the input, process, and output needed by and from personnel.

Based on its evaluation, the staff concludes that the applicant has satisfactorily met NUREG-0711 Criterion 2.

NUREG-0711, Section 5.4(3), states Criterion 3 as the following:

> The task analysis should be iterative and become progressively more detailed over the design cycle. It should be detailed enough to identify information and control requirements to enable specification of detailed requirements for alarms, displays, data processing, and controls for human task accomplishment.

Evaluation of Criterion 3

Westinghouse conducted OSA-1 and OSA-2 and described these analyses in APP-OCS-J1R-120, Revision 0, and APP-OCS-J1R-220, Revision B, respectively. The staff evaluated these documents and found that OSA-1 focused on specifying the operational requirements for a set of selected tasks. OSA-1 also identified risk-important tasks and thoroughly described the [ ]. An [ ] was developed to show information such as [ ]. The staff determined that OSA-1 lays the foundation for and describes the tasks that were analyzed during OSA-2. These analyses meet the NUREG-0711 criterion that the task analysis should be iterative and become progressively more detailed over the design cycle, because the task analysis was repeated and OSA-2 is more detailed than OSA-1.

The staff reviewed the task analysis documents to determine whether the task analyses conducted were detailed enough to identify information and control requirements to enable specification of detailed requirements for alarms, displays, data processing, and controls for human task accomplishment. The staff's evaluation addressed the input, process, and output needed by and from personnel (part of Criterion 2 above). OSA-2 Implementation Plan, Section 2.2.1 indicates that once the sequences for analysis have been identified, information related to the tasks in each sequence must be selected, including the following:

- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]

- [ ]
- [ ]
- [ ]

To illustrate this aspect of the task analysis data collection process, the applicant provided an example task analysis for [ ] in the OSA-2 Summary Report. For one risk-important task, "[ ]" the applicant identified (1) [ ].

Based on its review of the process discussed in the applicant's OSA-2 Implementation Plan and the example provided, the staff concludes that the task analyses conducted were detailed enough to identify information and control requirements to enable specification of detailed requirements for alarms, displays, data processing, and controls for human task accomplishment.

Based on its evaluation, the staff concludes that the applicant has satisfactorily met NUREG-0711 Criterion 3.

NUREG-0711, Section 5.4(4), states Criterion 4 as the following:

> The task analysis should address issues such as:
>
> - the number of crew members
> - crew member skills
> - allocation of monitoring and control tasks to the (a) formation of a meaningful job, and (b) management of crew member's physical and cognitive workload.

Evaluation of Criterion 4

Section 2.3.3 of the task analysis implementation plan describes operator workload analysis as an evaluation of the effect of the HSI design and the demands on operator workload. The methodology used for assessing [ ].

Section 2.3.4 of the task analysis implementation plan discusses the analysis of operational crew staffing. When the OSA indicates [ ]. The applicant uses the results from the OSA to [ ]. The applicant provided an example of the [

].

The staff has concluded that Westinghouse has conducted a thorough task analysis using both OSA-1 and OSA-2 and has described in detail the results from its analysis. The OSA-2 analysis was conducted in accordance with the implementation plan, which addresses issues such as the number of crew members, crew member skills, and allocation of monitoring and control tasks.

NUREG-0711, Section 5.4 (5), states Criterion 5 as the following:

> The task analysis results should be used to define a minimum inventory of alarms, displays, and controls necessary to perform crew tasks based on both task and instrumentation and control requirements.

Evaluation of Criterion 5

The OSA-2 Implementation Plan, Section 2.3.1, states that the [ ]. The HSI design process uses the [ ] of OSA-2. This approach is consistent with the information described in Revisions 15 through 17 of the DCD and satisfies NUREG-0711 Criterion 5.

NUREG-0711, Section 5.4 (6), states the following as Criterion 6:

> The task analysis should provide input to the design of HSIs, procedures, and personnel training programs.

Evaluation of Criterion 6

The OSA-1 analysis identified inputs to the HSI design including display requirements, display design constraints, performance time constraints, inventory (alarms, controls, parameters), and display organization and navigation constraints. OSA-2 is performed as part of the design development process to understand the estimated operator workload, performance time estimates, staffing issues, and error potential associated with each task. The staff concludes that, as with OSA-1, the results of OSA-2 provide input to the design of HSIs by providing a set of requirements and constraints on operator task performance.

In NUREG-1793, Section 18.5.3, the staff identified COL Information Item 18.5-1 (NUREG-1793 Item 18.5.3-2), which states, “The COL applicant will use the information from the AP1000-specific task analysis in the development of its procedures and training programs.” In response to RAI-SRP18.5-COLP-01, dated May 28, 2008, the applicant referred to Sections 5.6 and 5.7 of the AP1000 HFE Program Plan (APP-OCS-GBH-001), which describes two documents: APP-OCS-GER-031, “The Incorporation of Human Factors Engineering into the Development of the AP1000 Plant Procedures,” and APP-OCS-GER-041, “The Incorporation of Human Factors Engineering into the Development of the AP1000 Plant Training Program.” According to the applicant’s response to the RAI, the purpose of these documents is to capture the operator training and procedure information identified in the task analyses. These reports ensure that information related to training and procedures is identified, recorded, and communicated to those responsible for the development of the training programs. Open Item OI-SRP18-COLP-17 tracked completion of these documents. The staff has reviewed the completed documents and determined that information from OSA-1 and OSA-2 analyses useful to procedures and training program development has been identified, extracted, and compiled such that it can be used as direct input by procedure and training developers. Accordingly, the staff finds that Criterion 6 has been satisfactorily addressed and the open item is closed.

NUREG-0711, Section 5.4 (7), states Criterion 7 as the following:

> Considerations should be addressed for plant modifications that are likely to affect HAs previously identified as risk-important, cause existing HAs to become risk-important, or create new actions that are risk-important.

Evaluation of Criterion 7

The applicant is not required to address the impact of plant modifications on risk-important HAs because Revision 17 of the AP1000 DCD applies to new plant construction.

18.5.6.3 Conclusion

In its evaluation of Revision 15 of the AP1000 DCD, the staff reviewed the function-based task analysis and OSA-1 results and concluded that the applicant had developed an acceptable task analysis implementation plan to satisfy the NUREG-0711 criteria for task analyses. The COL applicant was expected to use this methodology to conduct a complete task analysis after DC (Reference COL Action Item 18.5.3-3). To close this action item, Revision 17 of the AP1000 DCD referenced additional task analysis documents, which describe an implementation plan for conducting a second operational sequence analysis (OSA-2) and provide a summary report of the OSA-2 results. The OSA-2 Implementation Plan and OSA-2 Summary Report focus on risk-important human actions, tasks with high human performance concerns, and on MTIS activities. Based on its evaluation of Revision 17 of the DCD and the referenced reports, the staff concludes that the applicant's task analysis conforms to all applicable criteria from NUREG-0711, Section 18.5.

18.5.7 Evaluation of COL Information Item 18.5-1 (NUREG-1793 Item 18.5.3-2)

18.5.7.1 Summary of Technical Information

COL Information Item 18.5-1 from the DCD does not correlate well with its counterpart, NUREG-1793 Item 18.5.3-2 which states:

> The COL applicant will utilize the information from the AP1000-specific task analysis in the development of its procedures and training programs.

The DCD Information Item 18.5-1 (see previous section) focuses on documentation of task analysis results and the staff identified information item addresses application of that information.

18.5.7.2 Evaluation

In response to RAI-SRP18.5-COLP-01, the applicant referred to Sections 5.6 and 5.7 of the AP1000 HFE Program Plan, which describes two documents (APP-OCS-GER-031 and APP-OCS-GER-041). These documents capture the operator training and procedure information identified in the task analyses. They provide an acceptable vehicle for communicating this information to those responsible for the development of the procedure and training programs. This directly addresses the DCD related action to document the task analysis results.

Using task analysis results to support procedure program development is satisfactorily addressed in the writer's guides, which are discussed in Section 18.9.5.2 of this report.

Using task results to support training program development is not directly addressed in the DCD. When the DCD Revision 15 safety evaluation report (SER) was prepared, no action was taken to include an additional COL information item to reflect the conclusions in the SER. Addition of the action to DCD Revision 18 is considered unnecessary. The bases material has been made readily available. COL applicants can use this information as appropriate as they develop systems approach to training (SAT) based training programs in accordance with industry and regulatory guidance.

18.5.7.3 Conclusion

This COL information item is closed because APP-OCS-GER-031 and APP-OCS-GER-041 adequately communicate the task analysis results applicable to procedure and training program development. As mentioned earlier, this work was being tracked by Open Item OI-SRP18-COLP-17, which has been closed.

18.5.8 Evaluation of COL Information Item 18.5-2 (NUREG-1793 Item 18.5.3-1)

18.5.8.1 Summary of Technical Information

COL Information Item 18.5-2 (NUREG-1793 Item 18.5.3-1) states the following:

> [A] COL applicant referencing the AP1000 certified design will document the scope and responsibilities of each Main Control Room position, considering the assumptions and results of the task analysis.

The applicant submitted TR-52 (APP-GW-GLR-010, Revision 2, "AP1000 Main Control Room Staff Roles and Responsibilities," issued June 2007) as a basis for closing COL Information Item 18.5-2 (NUREG-1793 Item 18.5.3-1).

18.5.8.2 Evaluation

TR-52 states that the applicant has fully addressed the COL information item. Revision 18 of the DCD incorporates the applicable changes. As described in Section 4.5 of TR-52, the role of the shift technical advisor (STA) for the AP1000 design, including the role of assessing possible significant plant abnormalities observed during normal operations, is consistent with the typical responsibilities of the STA as listed in NUREG-0737, "Clarification of TMI Action Plan Requirements," issued November 1980.

The staff issued RAI-TR52-COLP-12 asking the applicant to further clarify the duties and responsibilities in some key areas, including the reactor operator (RO) and STA roles in communication and coordination. In its response, dated November 16, 2007, the applicant clarified the roles and responsibilities of the RO and STA, describing the responsibilities for all main control room (MCR) ROs to communicate with the MCR supervisor and local equipment operators (EOs) to ensure coordination of local unit evolutions with plant operations. The RAI response also described the responsibilities of the MCR supervisor to maintain awareness of directions given to the EOs and to evaluate any abnormal conditions or operating concerns reported by either the ROs or the EOs. The OSA-2 Implementation Plan and the OSA-2 Summary Report also address MCR responsibilities. These responsibilities conform to the requirements in 10 CFR 50.54, "Conditions of licenses."

18.5.8.3 Conclusion

The staff finds that TR-52 adequately describes the MCR staff roles. The applicant's response to RAI-TR52-COLP-12 addresses each section of the RAI not addressed in TR-52; including specifying how each STA responsibility matches with the list of 12 responsibilities in Appendix C to NUREG-0737. These documents in combination provide sufficient information to close COL Information Item 18.5-2 (NUREG-1793 Item 18.5.3-1).

18.5.9 Evaluation of Tier 1 Information—Design Commitment 2, ITAAC Table 3.2-1 (DCD Revision 15)

18.5.9.1 Summary of Technical Information

ITAAC Design Commitment 2 reads as follows:

> Design Commitment: The applicant performs a task analysis in accordance with the task analysis implementation plan.
>
> Inspection, Tests, and Analyses: An evaluation of the implementation of the task analysis will be performed.
>
> Acceptance Criteria: A report exists and concludes that function-based task analyses were conducted in conformance with the task analysis implementation plan and include the following functions:
>
> – Control reactivity
> – Control reactor coolant system (RCS) boron concentration
> – Control fuel and cladding temperature
> – Control RCS coolant temperature, pressure, and inventory
> – Provide RCS flow
> – Control main steam pressure
> – Control steam generator inventory
> – Control containment pressure and temperature
> – Provide control of main turbine
>
> A report exists and concludes that operational sequence analyses (OSAs) were conducted in conformance with the task analysis implementation plan. OSAs performed include the following:
>
> – Plant heatup and startup from post-refueling to 100 percent power
>
> – Reactor trip, turbine trip, and safety injection
>
> – Natural circulation cooldown (startup feedwater with steam generator)
>
> – Loss of reactor or secondary coolant

– Post-loss-of-coolant accident (LOCA) cooldown and depressurization

– Loss of RCS inventory during shutdown

– Loss of the normal residual heat removal system (RNS) during shutdown

– Manual automatic depressurization system (ADS) actuation

– Manual reactor trip via the protection and monitoring system (PMS), via diverse actuation system (DAS)

– ADS valve testing during mode 1

In DCD Revision 17, the applicant deleted this ITAAC because it had completed the work described.

18.5.9.2 Evaluation

The task analysis consists of a function-based task analysis and two OSA analyses (OSA-1 and OSA-2). As documented in its safety evaluation of the AP1000 DCD Revision 15, the staff reviewed the function-based task analysis and OSA-1 results and concluded that these task analyses are complete. As part of the DCD Revision 17 review, the staff reviewed the OSA-2 Implementation Plan and OSA-2 Summary Report. The reports describe the detailed methodology the applicant used to conduct OSA-2, as well as the results and impact on the four issues described in the OSA-2 Implementation Plan: 1) completeness of available information; 2) time to perform tasks; 3) operator workload analysis; and 4) operational crew staffing. As described, the task analysis was used in establishing the basis for the HFE design.

The staff reviewed the OSA-2 Summary Report (APP-OCS-J1R-220), Revision A, which provides the results of OSA-2 for the AP1000 design in accordance with the implementation plan. The implementation plan summarizes [ ] components and the corresponding [ ] MTIS tasks for analysis. The results summary report also describes [ ] scenarios and [ ] associated tasks that were described in the implementation plan and analyzed during OSA-2 implementation. Open Item OI-SRP18-COLP-02A documented that the task analysis had not been completed for all of the MTIS tasks. This work was subsequently completed and submitted for staff review in OSA-2 Summary Report (APP-OCS-J1R-220), Revision B. Revision B of the results summary report includes the following information:

(1) The report summarizes the analysis of the [ ] risk-important MTIS tasks.

Westinghouse includes a description of the [ ] and the task analysis results for the MTIS in its results summary report. [ ] similar to OSA, which provides a [ ]. This analysis uses "[ ]" logic, which enables the evaluator to determine [ ] for the MTIS tasks. This is consistent with the specification in Criterion 2 (in Section 5.4 of NUREG-0711) that the applicant uses a process like OSA. Appendix C to the summary report presents the results of the MTIS analyses.

Section 2.1 of the summary report discusses the [ ] scenarios developed as a basis for the total of [ ] tasks to be analyzed using the OSA-2 methodology. (The [ ] tasks equate to [ ] scenarios because [ ].) For each scenario, the description in Appendix A to the summary report includes the [ ]. Appendix B to the summary report discusses the results of the analyses.

The summary report briefly describes the OSA-2 analyses of these [ ] scenarios and [ ] tasks. The analyses identified [ ] risk-important tasks and the following [ ].

The OSA-2 Summary Report contains tables giving detailed [ ], as well as the [ ]. The descriptions include the [ ]. For example, each scenario and its related tasks are labeled as “[ ]. In the case of an [ ], the first basic event is [ ]. The beginning step or cue in this case is the [ ]. The second cue is that at [ ]. Westinghouse continues to describe the next few events including the [ ]. This analysis continues until the [ ]. Westinghouse’s OSA-2 for this particular task includes [ ]. In this case, each task associated with the basic event [ ].

The staff has concluded that the task analysis for Revision 17 of the AP1000 DCD is complete and has sufficient depth to support control room inventory identification and workload analysis. Open Item OI-SRP18-COLP-02A is closed and Design Commitment 2 in ITAAC Table 3.2-1 (DCD Revision 15) is complete and closed.

18.5.9.3 Conclusion

The staff has reviewed the OSA-2 Implementation Plan, Revision 1, and the OSA-2 Summary Report, Revision B, and has determined that the applicant has adequately addressed the criteria found in Section 5 of NUREG-0711. In addition, the staff’s review has determined that there is sufficient information to close COL Information Item 18.5-2 (NUREG-1793 Item 18.5.3-1), COL Information Item 18.5-1 (NUREG-1793 Item 18.5.3-2) and COL Information Item 18.5-1 (NUREG-1793 Item 18.5.3-3). Design Commitment 2 in ITAAC Table 3.2-1 (DCD Revision 15) is complete and closed. The task analysis that was completed under this ITAAC provides reasonable assurance that a complete Control Room Inventory has been identified. The task analysis also demonstrates that the HFE design ensures an acceptable workload for the operators.

The DCD changes provide detailed human factors design information that would otherwise have to be addressed through verification of the ITAAC. Therefore, the changes to the DCD eliminate the need for design acceptance criteria in accordance with the finality criteria in 10 CFR Part 52.63(a)(1)(iv).

18.7 Element 6: Human Reliability Analysis

The applicant made no substantive changes to this section. However, Westinghouse submitted TR-59 (APP-GW-GLR-011, Revision 0, “AP1000 Standard Combined License Technical Report, Execution and Documentation of the Human Reliability Analysis/Human Factors Engineering Integration”) to close COL Information Item 18.7-1.

18.7.5 Evaluation of COL Information Item 18.7-1

18.7.5.1 Summary of Technical Information

COL Information Item 18.7-1 states the following:

> Combined license applicants referencing the AP1000 certified design will address the execution and documentation of the human reliability analysis/human factors engineering integration implementation plan that is presented in Section 18.7.

Westinghouse submitted TR-59 to close COL Information Item 18.7-1. TR-59 summarizes the applicant's method for conducting the HRA/HFE evaluation for the AP1000 and unites the relevant HRA/HFE evaluation implementation plan with the results documentation.

The staff reviewed and approved Westinghouse Commercial Atomic Power (WCAP)-14651, Revision 2, "Integration of Human Reliability Analysis with Human Factors Engineering Design Implementation Plan," as a supporting document for DCD Revision 15. Sections 2 through 5 of WCAP-14651 describe the major aspects of the plan:

- Section 2 discusses the PRA/HRA identification of critical HAs and risk-important tasks.
- Section 3 describes the task analyses for critical HAs and risk-important tasks.
- Section 4 discusses the reexamination of critical HAs and risk-important tasks.
- Section 5 provides information on the validation of HRA performance assumptions.

The staff used this implementation plan (in addition to NUREG-0800, "Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants," Chapter 18, "Human Factors Engineering," Revision 2, issued March 2007, and NUREG-0711, Revision 2) to review WCAP-16555, Revision 1, "AP1000 Identification of Critical Human Actions and Risk Important Tasks." In addition to TR-59, Westinghouse provided WCAP-16555 to the NRC to close COL Information Item 18.7-1. In WCAP-16555, the applicant provided the results of the evaluation of the AP1000 PRA/HRA that identifies the critical HAs and risk-important tasks for plant operation.

18.7.5.2 Evaluation

The staff determined that WCAP-16555 addresses Section 2 of the WCAP-14651 implementation plan. The applicant addressed Sections 3 through 5 of the implementation plan in Parts 1 and 2 of the OSA.

Section 2 of WCAP-14651 relates to Criterion 1 in Section 7.4 of NUREG-0711, which states the following:

> Risk-important human actions should be identified from the PRA/HRA and used as input to the HFE design effort.
>
> - These actions should be developed from the Level 1 (core damage) PRA and Level 2 (release from containment) PRA including both internal and external events. They should be developed using selected (more than one) importance measures and HRA sensitivity analyses to provide

reasonable assurance that an important action is not overlooked because of the selection of the measure or the use of a particular assumption in the analysis.

Section 2 of WCAP-14651 discusses the PRA/HFE identification of critical HAs and risk-important tasks. Sections 2.1 and 2.2, respectively, describe the process used to identify critical HAs and risk-important tasks. Section 2.2 is divided into three sections describing the process to identify the risk-important quantitative, qualitative, and qualitative MTIS criteria.

Evaluation Criterion 1—Critical Human Actions: Section 2.1 of WCAP-14651 states that the applicant will determine critical HAs using both deterministic and PRA criteria. In Section 3.1 of WCAP-16555, the applicant presented the results of the analyses, which determined that there were no critical actions for the AP1000. For the deterministic criterion, there were no Type A (as defined in Sections 7.5.2.1 and 7.5.3.1 of the DCD) post-accident instruments and no HAs were required to mitigate any design-basis accident. For the PRA criteria, the analysis showed that no HA, when failed in the PRA, results in a core damage frequency (CDF) of 1×10^{-4} core damage events per reactor-year or greater. Further, no HA, when failed in the PRA, results in a large release frequency of 1×10^{-5} events per reactor-year. Thus, there are no critical actions for the AP1000 plant. This is in accordance with the design objectives of the AP1000.

Evaluation Criterion 2—Quantitative and Qualitative Risk-Importance Criteria: Section 2.2 of WCAP-14651 states that the applicant will use both quantitative and qualitative criteria to identify the risk-important tasks of the AP1000 design. The quantitative criteria are a risk achievement worth (RAW) of 3.0 and a risk reduction worth (RRW) of 1.1. The RAW is a value that examines the increase in risk that would result if a single HA were to fail. The RRW value examines the decrease in risk that would result if an HA were made perfectly reliable for a given process or parameter. The focused PRA reduced these values to an RAW of 2.0 and an RRW of 1.05.

Section 3.2 of WCAP-16555 and related tables provide the results of the evaluation using the RAW and RRW measures. The applicant performed evaluations for both the CDF and the large early release frequency and considered the internal events, flooding, fire, and shutdown PRAs. The applicant identified about 20 risk-important tasks, summarized in Table 3.2-2. The staff also compared the HAs in the dominant sequences with the top operator actions determined by the risk-importance measures. The dominant sequences and the operator actions were consistent. The staff finds that the applicant's use of quantitative risk-importance criteria meets the objective of the implementation plan.

Section 2.2 of WCAP-14651 includes five qualitative criteria for identifying additional risk-important tasks in conjunction with an expert panel. The applicant used the criteria listed in WCAP-16555, Section 2.2.1, to identify the qualitative risk-important HAs. These criteria are consistent with those in the implementation plan. The applicant also provided the results of this evaluation in Sections 2.2.1 and 3.2.1 of WCAP-16555. The expert panel identified three HAs that were added to the list of risk-important tasks. This approach to identifying the qualitative risk-important HAs is consistent with that given in the implementation plan. The staff finds this to be acceptable.

Evaluation Criterion 3—MTIS Risk-Importance Qualitative Criteria: Section 2.2 of WCAP-14651 provides qualitative criteria for identifying risk-important MTISs.

In Section 3.3 of WCAP-16555, the applicant gives the methodology used to identify the MTIS activities for the risk-important structures, systems, and components (SSCs). A group of engineers representing various disciplines and backgrounds, including HFE, HRA, and PRA, reviewed the results produced by this methodology. The applicant also provided Tables 3.3-1 and 3.3-2, which present the results of the MTIS evaluation. Table 3.3-1 includes the initial list of SSCs considered for MTIS activities, along with any other components that may be risk-important and have interfaces with the control room but may not have been included in the initial list. Lastly, Table 3.3-2 lists the representative MTIS activities that will receive the HFE review. In cases where the same MTIS activity was repeated for different SSCs, one of those MTIS activities from that list was chosen to represent (or selected as a “representative” of) that group.

The staff requested clarification in RAI TR-59-11 about the activities outside of the control room and whether they were included in the set of MTIS tasks identified through the expert panel. The staff noted that the Davis-Besse reactor vessel incident is an example of the need for proper MTIS task identification. The reactor vessel is a risk important SSC, and inspection of the vessel exterior would be an MTIS activity that seems worthy of appropriate planning at the design stage to address human factors issues associated with this activity. Thus, by including activities outside of the control room, accessibility can be assured and procedures and training provided to avoid the kinds of problems that occurred with reactor vessel leakage and corrosion. In its response dated July 27, 2007, the applicant provided information clarifying that operator actions outside of the control room were considered and noted that two of the actions considered were outside of the control room. Further, the passive nature of the plant design limits the use of manual control valves, and the manual control valves that are risk-important have main control room position indication.

The staff finds that the applicant has acceptably implemented the process specified in WCAP-14651 to identify the MTIS risk-important tasks.

Criterion 2 in Section 7.4 of NUREG-0711 states the following:

> Risk-important HAs and their associated tasks and scenarios should be specifically addressed during function allocation analyses, task analyses, HSI design, procedure development, and training. This will help verify that these tasks are well supported by the design and within acceptable human performance capabilities (e.g., within time and workload requirements).

Criterion 2 Evaluation

WCAP-14651, Section 3, describes the process for including the HRA risk-important activities in the task analysis. Westinghouse’s OSA documents (for OSA-1 and OSA-2) summarize how the applicant input the HRA risk-important tasks into the task analysis. The OSA-1 Summary Report, Table 3-1, specifically addresses the risk-important tasks. The OSA also detailed task sequences and performance requirements. The applicant gave details of its methodology for task identification with regard to emergency operating procedures (EOPs), system operating procedures, and general operating procedures (GOPs). Section 4.2.4 of the OSA-1 Summary Report presents recommendations for the risk-important actions. Finally, in Section 1 of the OSA-1 Summary Report, Westinghouse stated that the results of the OSA are a set of requirements and constraints on operator task performance and that these are fed into the HSI design. The staff finds that the applicant has acceptably implemented the process described in the implementation plan.

Criterion 3 in Section 7.4 of NUREG-0711 states the following:

> The use of PRA/HRA results by the HFE design team should be specifically addressed; that is, how are risk-important HAs addressed (through HSI design, procedural development, and training) under the HFE program to minimize the likelihood of operator error and provide for error detection and recovery capability.

The applicant submitted the implementation methodology for OSA-2 to address part of Sections 3 and 4 in WCAP-14651. The applicant also provided the OSA-2 Summary Report for review. These documents meet the objectives of Sections 3 and 4 of WCAP-14651, by assigning focus areas for operators, by including MTIS activities in OSA-2, and by using operating procedures during the process. The staff finds that the applicant acceptably implemented the process described in the implementation plan.

Criterion 4 in Section 7.4 of NUREG-0711 states the following:

> HRA assumptions such as decision making and diagnosis strategies for dominant sequences should be validated by walkthrough analyses with personnel with operational experience using a plant-specific control room mockup or simulator. Reviews should be conducted before the final quantification stage of the PRA.

WCAP-14651 describes the process for the validation of the HRA performance assumptions. The applicant is implementing this process as part of its integrated system validation for the AP1000. Section 10.0 of this report details the review of the process used to integrate the HRA risk-important HAs.

18.7.5.3 Conclusion

The staff concludes that TR-59 (APP-GW-GLR-011), WCAP-16555, and the related RAI response (RAI-TR59-11) describe an acceptable approach to implementing WCAP-14651 and to meeting the criteria in Section A.6 of NUREG-0800 and Section 7.4 of NUREG-0711. Based on this material COL Information Item 18.7-1 is closed.

18.7.6 Evaluation of Tier 1 Information—Design Commitment 1, ITAAC Table 3.2-1, Tier 1, Section 3.2 (DCD Revision 15)

18.7.6.1 Summary of Technical Information

ITAAC Design Commitment 1 reads as follows:

> Design Commitment: The integration of HRA with HFE design is performed in accordance with the implementation plan.
>
> Inspection, Tests, and Analyses: The applicant will perform an evaluation of the implementation for the integration of HRA with HFE design.

Acceptance Criteria: A report exists and concludes that critical human actions (if any) and risk important tasks were identified and examined by task analysis, and used as input to the HSI design, procedure development, staffing, and training.

In DCD Revision 17, the applicant deleted this ITAAC based on completion of the work it described.

18.7.6.2 Evaluation

This ITAAC was deleted in Revision 16 of the AP1000 DCD (but the number was kept as a place holder), then subsequently removed entirely from Revision 17. For Revision 17 to the DCD, the applicant has provided the methodology and summary reports that show the risk-important tasks were examined and would have input into the other HFE elements listed in the acceptance criteria. Also, the work products provided by the applicant demonstrate the following:

- There are no “critical human actions” because of the AP1000 passive design.
- “Risk-important actions” as well as “significant” actions are identified and included in the HFE design process in accordance with NUREG-0711 guidance.
- The OSA-1 analysis included all identified actions from the HRA. OSA-2 is a reiterative analysis (see Section 18.5 of this report) that also includes input from the HRA.

18.7.6.3 Conclusion

The staff concludes that Design Commitment 1 in ITAAC Table 3.2-1 (DCD Revision 15) is complete and closed and the COL Information Item 18.7-1 is complete and closed because risk-important HAs have been identified in accordance with the implementation plan and these HAs have been appropriately implemented in the HFE design via the task analysis in OSA-2.

The DCD changes provide detailed human factors design information that would otherwise have to be addressed through verification of the ITAAC. Therefore, the changes to the DCD eliminate the need for design acceptance criteria in accordance with the finality criteria in 10 CFR Part 52.63(a)(1)(iv).

18.8 Element 7: Human-System Interface Design

18.8.3 General Human System Interface Design Feature Selection

18.8.3.1 Summary of Technical Information

In DCD Section 18.8.1.8, the applicant deleted reference to the use of computer-based models of cognitive response to control room events as an analytic method supporting workload analysis. The applicant substituted the term “task analysis”: the sentence now reads, “Analytic methods include the use of task analysis.”

18.8.3.2 Evaluation

NUREG-1793 Section 18.8.1.3 discusses task analysis only from a generic perspective as one of the NUREG-0711 elements. NUREG-1793 Section 18.8 does not include specific methods for evaluating workload. In both cases, the change described above does not affect the evaluation or conclusions from this section of the safety evaluation. Section 18.5, "Task Analysis," provides an evaluation of the impact of the change on task analysis.

18.8.3.3 Conclusion

The staff concludes that this change does not affect the evaluation or results documented in NUREG-1793 Section 18.8.1.3.

18.8.4 Evaluation of COL Information Item 18.8-1

18.8.4.1 Summary of Technical Information

COL Information Item 18.8-1 states the following:

> The COL applicant referencing the AP1000 certified design is responsible for the execution and documentation of the HSI design implementation plan.

The applicant issued TR-82 to address this COL information item. In this document, the applicant stated that the COL item has been fully addressed and no additional work is required by the COL applicant.

18.8.4.2 Evaluation

The applicant has satisfactorily completed documentation of the HSI design implementation plan. The staff reviewed the completed documents referenced in TR-82 and concluded that they appropriately execute the HSI design implementation plan, as described in the AP1000 DCD, Revision 15. The specificity of design requirements clearly increased in the transition from the functional design level to design specifications. The documents were consistently clear across this procedural hierarchy. The scope of and specificity in the design documents provide reasonable assurance that the design process will effectively produce the design document needed to support procurement, construction and inspection activities.

This COL information item is redundant to Design Commitment 3 from ITAAC Table 3.2-1 (DCD Revision 16), which states that the HSI design is performed for the operation and control system in accordance with the HSI design implementation plan. Based on this redundancy, the COL information item is closed.

18.8.4.3 Conclusion

The applicant is completing design documents in accordance with the HSI design implementation plan. While the applicant has not completed execution of the HSI design implementation plan, the COL information item is being closed because it is redundant to an existing ITAAC.

18.8.5 Review of Human Factors Evaluation Style Guide (APP-OCS-J1-002) against NUREG-0711 Criteria

18.8.5.1 Summary of Technical Information

The applicant submitted AP1000 HSI Design Guidelines (APP-OCS-J1-002, Revision 0). This document implements several NUREG-0711 criteria that have not been previously reviewed at the implementation plan level. The evaluation below verifies that the AP1000 HSI Design Guidelines effectively address applicable NUREG-0711 criteria.

18.8.5.2 Evaluation

Criterion 1—Style Guide

NUREG-0711, Section 8.4.5, “HSI Detailed Design and Integration Criteria,” Criterion 1 states the following:

> Design-specific HFE design guidance (style guide) should be developed. The design of the HSI features, layout, and environment should incorporate HFE guidelines.

In APP-OCS-J1-002, the applicant provided a detailed set of HFE requirements for all HSIs similar to the level of detail in NUREG-0700, Revision 2, “Human-System Interface Design Review Guidelines,” issued May 2002. The goal of the document is to ensure that the AP1000 designs comply with applicable HFE design principles.

The staff concludes that this document meets this criterion for design-specific HFE guidance.

Subcriterion—Style Guide Content

NUREG-0711, Section 8.4.5, Criterion 1, states the following:

> The content of the style guide should be derived from (1) the application of generic HFE guidance to the specific application, and (2) the development of the applicant’s own guidelines based upon design-related analyses and experience. The applicant may justify guidelines that are not derived from generic HFE guidelines based on an analysis of recent literature, analysis of current industry practices and operational experience, tradeoff studies and analyses, and the results of design engineering experiments and evaluations. The guidance should reflect the applicant’s design decisions that address the specific goals and needs of the HSI design.

In APP-OCS-J1-002, the applicant included a list of technical references used to develop specific HFE guidance for the AP1000 design. The applicant used NUREG-0700 as a major source. The following references also support the AP1000 HFE design guidance:

- [ ]
- [ ]
- [ ]

- [ ]
- [ ]
- [ ]
- [ ]

The staff concludes that these technical references represent a diverse and thorough set of inputs for the AP1000 guidance. The AP1000 design guidance includes design principles and specific design criteria for all of the AP1000 HSIs.

Subcriterion—Scope and Level of Detail

NUREG-0711, Section 8.4.5, Criterion 1, states the following:

> The topics in the style guide should address the scope of HSIs included in the design and address the form, function, and operation of the HSIs, as well as environmental characteristics relevant to human performance.

In APP-OCS-J1-002, Section 3, the applicant described the scope of the design guidelines. This includes the MCR, remote shutdown station, and TSC. Specific HSI interfaces include the plant information system, alarm system, computerized procedures, safety systems, soft controls, dedicated controls, DAS, and large screen displays. The scope addresses all areas described by the previously reviewed program-level documents. APP-OCS-J1-002, Section 26, includes environment-related criteria.

The staff concludes that the design guideline addresses the HSI scope satisfactorily. The level of detail is consistent with that found in NUREG-0700, an accepted program for HFE design criteria.

Subcriterion—Guideline Specificity

NUREG-0711, Section 8.4.5, Criterion 1, states the following:

> The individual guidelines should be expressed in concrete, easily observable terms. In general, generic HFE guidelines should not be used in their abstract form. Such generic guidance should be translated into more specific design guidelines that can, as much as possible, provide unambiguous guidance to designers and evaluators. They should be detailed enough to permit their use by design personnel to achieve a consistent and verifiable design that meets the applicant’s guideline.

The level of detail provided in individual guidelines is consistent with the specificity in NUREG-0700. In general, the guidelines provide quantifiable direction. For many of the guidelines, and particularly for those cases in which more general direction is given, the basis for the guideline is included. This reference provides direction on guideline implementation. The guidance is divided into required and optional categories, which provides additional support to the designers and evaluators.

The staff concludes that the direction provided in the design guidance document is of sufficient detail that design personnel will be able to achieve a consistent and verifiable design.

Subcriterion—Style Guide Ease of Use

NUREG-0711, Section 8.4.5, Criterion 1, states the following:

> The style guide should provide procedures for determining where and how HFE guidance is to be used in the overall design process. The style guide should be written so that designers can readily understand it. The style guide should support the interpretation and comprehension of design guidance by supplementing text with graphical examples, figures, and tables.

APP-OCS-J1-002 provides generic direction stating that the design guidance will be used during the design process and to facilitate design verification. Implementation plans for both of these activities refer to the use of the [ ]. The plans cross-reference between [ ] and the applicable sections of APP-OCS-J1-002, which will likely facilitate the use of the [ ], as indicated in the criterion, [ ], and the [ ] is provided to answer questions that might arise as to the applicability of the design guidance.

The staff concludes that the design guidance in APP-OCS-J1-002 is presented in a manner likely to facilitate its use by designers and evaluators. The applicant has provided sufficient cross-referencing in procedures to ensure their appropriate use.

Subcriterion—Usability

NUREG-0711, Section 8.4.5, Criterion 1, states the following:

> The guidance should be maintained in a form that is readily accessible and usable by designers and that facilitates modification when the contents require updating as the design matures. Each guideline included in the guidance documentation should include a reference to the source upon which it is based.

The applicant maintains APP-OCS-J1-002 on its electronic document tracking system as a controlled document. This ensures document accessibility and facilitates usability by virtue of word search capability. The document itself is [ ]. The applicant has demonstrated the ability to keep the document updated by incorporating more detail on [ ]. Each guideline includes a reference to source material; this should also aid the designer in determining how best to implement the requirements and to facilitate the evaluation of tradeoffs.

18.8.5.3 Conclusion

The staff concludes that APP-OCS-J1-002 provides specific HFE design guidance that satisfactorily implements NUREG-0711 criteria. The document provides sufficient detail to ensure that the process is consistently followed and provides reasonable assurance that design requirements are properly factored into the HSIs.

18.9 Element 8: Procedure Development

The applicant made no substantive changes to this section. However, Westinghouse submitted TR-70 (APP-GW-GLR-040, Revision 1, "Plant Operations, Surveillance, and Maintenance Procedures") to close COL Information Item 18.9-1.

18.9.5 Evaluation of COL Information Item 18.9-1

18.9.5.1 Summary of Technical Information

COL Information Item 18.9-1 was identified in NUREG-1793 and does not have a counterpart in the DCD. This COL action item is divided into two parts. The COL action item states the following:

> With regard to procedure development, the COL applicant will (1) address the procedure development considerations in NUREG-0711, and (2) identify the minimum documentation that the COL applicant will provide to the staff to complete its review.

Westinghouse submitted TR-70 for staff review. This report documents the methodology, criteria, and schedules for procedure development. The document addresses the information needed to close COL Information Item 18.9-1. The applicant made the TR-70 supporting documents available to the staff for the purpose of closing COL Information Item 18.9-1. Two of these documents were the writer's guides for normal operating procedures and two-column operating procedures (APP-GW-GJP-100, Revision G, "AP1000 Normal Operating Procedures (NOPs) Writer's Guideline," and APP-GW-GJP-200, Revision D, "Writer's Guideline for Two Column Procedures," respectively). The writer's guidelines explain the programmatic process that controls the preparation of the normal operating procedures and two column procedures.

The goal of the staff's review was to address each part of the action item. Consequently, the evaluation is described in two parts. Part 1 details how the applicant addressed the procedure development considerations in NUREG-0711. Part 2 describes the documents that were submitted to the staff for review.

18.9.5.2 Part 1—Evaluation

The staff reviewed TR-70 in combination with the writer's guides. The staff verified that the applicant had implemented the guidelines specified in WCAP-14690, "Designer's Input to Procedure Development for the AP600." WCAP-14690 is the staff-approved document that describes the methodology the COL applicant should use to develop procedures. In NUREG-1793, the staff approved the use of this document as a guide for procedures development and an acceptable guideline for creation of an implementation plan for the AP1000. In its review, the staff found that the writer's guides meet the criteria in NUREG-0711, Section 9.4, for the basis, development, and content of the AP1000 two column and normal operating procedures. The staff found that the information in TR-70 is consistent with the guidelines in WCAP-14690. Section 2.0 of WCAP-14690 details the general criteria that an applicant should implement to develop procedures. TR-70 addresses all of the guidance criteria in Section 2.0 of WCAP-14690. Section 4.0 of WCAP-14690 provides guidance on the process that should be used to write the plant-specific EOPs. Sections 3.0 and 5.0 of the WCAP describe the guidance for creation of the implementation plan with regard to computer-based procedures (CBPs). The following section documents the CBP evaluation as a subpart to addressing Part 1 of COL Information Item 18.9-1.

Human Factors Engineering Aspects of Computer-Based Procedures

The applicant did not address the impact of computerized procedures and accessibility in the original DC application. In the staff's evaluation of the AP1000 DCD, NUREG-1793 states the following:

> Evaluation of the applicant's computerized procedure system was not included in the design certification for the AP1000. WCAP-14690, Revision 1, provides information on the computer-based procedure system which will serve as the interface to the plant procedures.

NUREG-0700, Section 8; Interim Staff Guidance (ISG)-05 ("Task Working Group #5: Highly-Integrated Control Room—Human Factors Issues"); and NUREG-0711, Section 9.4, Criteria 7 and 9, are used to evaluate the methodology used to design the CBP system and the interaction between the operator and that system. ISG-05 is used as complementary review guidance for Criterion 9.

Criterion 7 states the following:

> An analysis should be conducted to determine the impact of providing CBPs and to specify where such an approach would improve procedure utilization and reduce operating crew errors related to procedure use. The justifiable use of CBPs over paper procedures should be documented. An analysis of alternatives in the event of loss of CBPs should be performed and documented.

In TR-70 or in the supporting referenced documentation, the applicant addressed the impact and utilization of CBPs not addressed in the original DC application. In Section 2.7 of TR-70, Revision 1, the applicant stated that comments from operations personnel involved in the human factors testing of the AP1000 control room design, and specifically the computerized procedure system, have been generally favorable. The applicant also documented the results of the analysis of the impact of providing CBPs in the referenced report WCAP-14645-NP, Revision 3, "Human Factors Engineering Operating Experience Review Report for the AP1000 Nuclear Power Plant." The staff reviewed WCAP-14645-NP, Revision 3. The applicant identified multiple human performance issues with the CBPs and then noted the solution, or proposed solution, for each issue.

The staff issued RAI-SRP18-COLP-14 to the applicant requesting the analysis of alternatives to CBPs, in the event that a loss of CBPs occurs. In the RAI-SRP18-COLP-14 response dated August 4, 2008, the applicant stated that it would conduct this analysis as part of the second OSA, described in Section 2.1 of APP-OCS-J1R-210.

Subsequent to this RAI, the staff reviewed APP-OCS-J1R-220, Revision B, OSA-2 Summary Report. The OSA-2 Summary Report identifies the [ ]. This task, [ ], has [ ] that are described in Scenario 16. Also, in this section of the summary report, Westinghouse described how the [ ]. Appendix B, Section B.22, to the report gives details of the [ ] steps described in Scenario 16.

Open Item OI-SRP-COLP-19 was established to track an RAI clarifying how a loss of CBPs is managed. In the RAI-SRP18-COLP-19 response, dated September 1, 2009, the applicant provided the staff with this clarification:

- [ ].
- [ ].
- [ ].

Based on this information the open item was closed.

The staff conducted an audit of the CBP interface at the Westinghouse Energy Center in Monroeville, Pennsylvania in September 2009. During the audit the staff reviewed the AP1000 Computerized Procedure System (CPS) design process, including supporting documentation, as well as the characteristics and functions of the current system as implemented in the AP1000 engineering test simulator. The CPS characteristics and functions included [ ].

Based on the audit the staff concluded that the Westinghouse AP1000 CPS system was designed in accordance with the NRC certified HSI Design Implementation Plan and that all supporting documentation was acceptable and consistent with the NRC design review guidance including the guidance specific to CBP systems. The design as currently implemented is consistent with Westinghouse's design procedures and documentation.

Criterion 9 states the following:

> The physical means by which operators access and use procedures, especially during operational events, should be evaluated as part of the HFE design process. This criterion generally applies to both hard-copy and computer-based procedures, although the nature of the issues differs somewhat depending on the implementation.

The staff used ISG-05 as the complementing review guidance for NUREG-0711, Section 9.4, Criterion 9. ISG-05 provides review criteria for how the user will interface with the CBP system. The applicant provided the documentation to satisfy the ISG-05 criteria in APP-OCS-J1-020, Revision A, "Computerized Procedures System Functional Requirements." APP-OCS-J1-020 documents how the operator physically interfaces with the computer procedure system. The technical information in APP-OCS-J1-020 is consistent in addressing the criteria in ISG-05. CBPs are designed to be the primary procedure interface and access is gained via the video display units. Audit observations confirmed that the CBP system is easily accessed from visual display unit (VDU) menus. Navigation to a specific procedure is via a procedure menu. Navigation between procedures is typically driven by embedded links but the operator can also return to the main menu to select the desired procedure. Navigation was found to be simple and straightforward. Use of the hardcopy procedures, which are available in the control room as a backup to the CBPs, followed conventional practices. The staff submitted RAI-SRP18-COLP-11 requesting clarification of the CBP automation and whether the AP1000 computer procedure system would be computer-paced or user-paced. In its

RAI-SRP18-COLP-11 response, dated August 4, 2008, the applicant stated that this issue would not be of any consequence because the computer-paced function would be removed. The staff found this response acceptable.

18.9.5.3 Part 1—Conclusion

The staff determined that TR-70 and the writer's guides for normal and two column procedures together constitute an acceptable implementation plan for procedure development. This is because: (1) the documents address the criteria in the staff-approved WCAP-14690, which explains the process the procedure writer should take to develop an implementation plan; and (2) the documents also address the applicable criterion in the procedures development chapter in NUREG-0711.

The staff concludes that Westinghouse has designed a system that ensures the usability and usefulness of CBPs. Specifically, loss of the CBP HSI is appropriately addressed in procedures and training. Support provided for the transition to paper based procedures provides reasonable assurance that such a failure would not significantly impact the operator's ability to implement the appropriate accident response procedures. Further, the staff concluded that Westinghouse's approach for implementing a new technology into the control room and operating practices was acceptably conservative and should provide for a smooth transition to computerized operation of important procedures, such as EOPs. This approach will minimize any safety concerns associated with the loss of the CPS.

Based on the preceding information, the staff concludes that COL Information Item 18.9-1, Part 1 is complete and closed.

18.9.5.4 Part 2—Evaluation

To address the second part of COL Information Item 18.9-1, in addition to submitting TR-70, the applicant stated in Revision 17 of the AP1000 DCD that the COL applicant will be responsible for addressing the operational and programmatic issues and training to complete the AP1000 COL licensing process. Westinghouse would be responsible for managing the development, review, and approval of the AP1000 normal operating, abnormal operating, emergency operating, refueling and outage planning, alarm response, administrative, and MTIS procedures, as well as the procedures that address the operation of post-72-hour equipment.

18.9.5.5 Part 2—Conclusion

In DCD Tier 2, Revision 17, responsibility for completing this COL action was assumed by Westinghouse. As described above, sufficient documentation has been submitted to satisfy the criteria in NUREG-0711, Section 9.4. COL applicants have continuing responsibilities related to training and procedures but these are evaluated as part of operating program inspections. This Westinghouse response satisfies Part 2 of COL Information Item 18.9-1 (NUREG-1793 Item 18.9.3-1).

The staff concludes that the applicant's procedure development program provides reasonable assurance that procedures will support and guide human interaction with plant systems, as well as control plant-related events and activities. Human engineering principles and criteria are applied, along with all of the other design requirements, to develop procedures that are technically accurate, comprehensive, explicit, easy to use, validated, and in conformance with 10 CFR 50.34(f)(2)(ii). In addition, this closes OI-SRP18-COLP-19.

The staff concludes that COL Information Item 18.9-1, Part 2 is complete and closed. COL Information Item 13.5-1 covers the remainder of the procedures development.

18.11 Element 10: Human Factors Verification and Validation

Westinghouse submitted the following implementation plans to address COL Information Item 18.11-1 and ITAAC Design Commitment 4, Tier 1, Table 3.2-1 (DCD Revision 15):

- APP-OCS-GEH-120, "AP1000 Human Factors Engineering Design Verification Plan," Revision B
- APP-OCS-GEH-220, "AP1000 Human Factors Engineering Task Support Verification Plan," Revision B
- APP-OCS-GEH-320, "AP1000 Human Factors Engineering Integrated System Validation Plan," Revision D (Integrated System Validation (ISV) Plan)
- APP-OCS-GEH-321, "AP1000 Human Factors Engineering Integrated System Validation Scenario Information," Revision B (ISV Scenario Plan)
- APP-OCS-GEH-420, "Human Factors Engineering Discrepancy Resolution Process," Revision B
- APP-OCS-GEH-520, "AP1000 Human Factors Engineering Design Verification at Plant Startup," Revision B

NUREG-0711 states the following:

> An implementation plan gives the applicant's proposed methodology for meeting the acceptance criteria of the element. An implementation plan review gives the applicant the opportunity to obtain staff review of and concurrence in the applicant's approach before conducting the activities associated with the element. Such a review is desirable from the staff's perspective because it provides the opportunity to resolve methodological issues and provide input early in the analysis or design process when staff concerns can more easily be addressed than when the effort is completed.

The staff will verify the final results of the design analyses to ensure that the design is completed in accordance with the process specified in the implementation plans in accordance with the design acceptance criteria (DAC) approach. This may occur via a DC amendment, the COL application review, or through the ITAAC closure process.

When conducting an implementation plan review, the staff needs to:

- understand how the detailed methodology will be implemented
- determine that the methodology can be reliably conducted by design personnel
- be confident that the methodology will provide results that will be acceptable as evaluated by the relevant NUREG-0711 review criteria

18.11.5 Evaluation of COL Information Item 18.11-1

18.11.5.1 Summary of Technical Information

COL Information Item 18.11-1 states the following:

> Combined License applicants referencing the AP1000 certified design will address the development, execution and documentation of an implementation plan for the verification and validation of the AP1000 Human Factors Engineering Program. The programmatic level description of the AP1000 verification and validation program presented and referenced by Section 18.11 will be used by the Combined License applicant to develop the implementation plan.

18.11.5.2 Evaluation

COL Information Item 18.11-1 includes two distinct activities related to the AP1000 HFE program V&V. The first activity addresses development of an implementation plan. Design Commitment 4, Tier 1, Chapter 3, ITAAC Table 3.2-1, of the AP1000 DCD, Revision 15, also addresses this commitment. The second activity is to execute and document the execution of the implementation plan. Design Commitment 5, Tier 1, Chapter 3, ITAAC Table 3.2-1, of the AP1000 DCD, Revision 15, addresses this commitment.

18.11.5.3 Conclusion

The NRC staff notes that COL Information Item 18.11-1 is similar to existing Design Commitments 4 and 5, ITAAC Table 3.2-1 (DCD Revision 15). The development of the implementation plans has been completed and these implementation plans are evaluated below under Evaluation of Tier 1 Information Design Commitment 4 below. The execution and documentation of the implementation plans will be addressed in Design Commitment 5, ITAAC Table 3.2-1. Thus, COL Information Item 18.11-1 is no longer needed since the work has either been completed by Westinghouse or will be completed under the DCD ITAAC 5.

18.11.6 Evaluation of Tier 1 Information—Design Commitment 4, ITAAC Table 3.2-1, Tier 1, Section 3.2 (DCD Revision 15), Part 1 of 5, HSI Task Support Verification

18.11.6.1 Summary of Technical Information

ITAAC Design Commitment 4 reads as follows:

> Design Commitment: An HFE program verification and validation implementation plan is develop[ed] in accordance with the programmatic level description of the AP1000 human factors verification and validation plan.
>
> Inspection, Test, and Analysis: An inspection of the HFE verification and validation implementation plan will be performed.
>
> Acceptance criteria (part 1): A report exists and concludes that the HFE verification and validation implementation plan was developed in accordance with the programmatic level description of the AP1000 human factors verification and validation plan and includes the …HSI task support verification activity.

In DCD Revision 17, the applicant deleted this ITAAC based on completion of the work it described.

18.11.6.2 Evaluation

NUREG-0711, Section 11.4.2.2, Criterion 1, states the following:

> The criteria for task support verification come from task analyses of HSI requirements for performance of personnel tasks.

Evaluation of Criterion 1

In APP-OCS-GEH-220, the applicant provided a specific verification plan for each of the task analysis inputs as outlined below:

- Section 2.2 is the verification plan for the function based task analysis. APP-OCS-J1A-030, Revision A, "FBTA Summary Report," provides [ ]. The [ ]. If the final design does not implement the recommendations, [ ].

- Section 2.3 is the verification plan for OSA-1. These tasks are derived from [ ]. A database is used to maintain the tasks identified by this analysis. Before final task verification, the plan requires the database to be [ ]. The independent verifier ensures that for each unique operator action, [ ].

- Section 2.4 is the verification plan for OSA-2 [ ]. If a new task is identified, then the OCS product manager ensures that disposition of the task is addressed. For each task identified in OSA-2, a list of [ ]. The independent verifier then confirms that the HSI resource is available, the HSI display information is appropriate, the communication facility is available and located appropriately, and the labeling is correct.

- Section 2.5 is the verification plan for the OSA-2 tasks specific to [ ]. Verification follows the same process as that used for OSA-1.

- Section 2.6 is the verification plan for the OSA-2 tasks specific to [ ]. Verification follows the same process as that used for OSA-1.

The staff concludes that APP-OCS-GEH-220 provides clear, specific direction on how the results of each specific task analysis are verified. Acceptance criteria are stated within the procedure and, when combined with the use of an independent verifier, provide reasonable assurance that the HSI requirements properly incorporate the task analysis results.

NUREG-0711, Section 11.4.2.2, Criterion 2, "General Methodology," states the following:

> The HSIs and their characteristics (as defined in the HSI inventory and characterization) should be compared to the personnel task requirements identified in the task analysis.

Evaluation of Criterion 2

The implementation plan for task support verification, as outlined above, provides clear direction that the final HFE design is to be compared to personnel task requirements. Direction is provided to document and justify or resolve all deviations. The direction is structured so that each task is specifically addressed. This supports a clear communication of source documents and acceptance criteria to be used in the verification.

The staff concludes that APP-OCS-GEH-220 provides sufficient details to satisfactorily demonstrate implementation of this NUREG criterion for the general methodology of task verification.

NUREG-0711, Section 11.4.2.2, Criterion 3, states the following:

> Human engineering discrepancies (HEDs) should be identified when an HSI needed for task performance is not available or when HSI characteristics do not match personnel task requirements.

Evaluation of Criterion 3

In APP-OCS-GEH-220, the applicant stated that any time an HSI resource or an appropriate display is not available; a discrepancy worksheet is filled out. The procedure specifically states the following verification points:

- [ ].
- [ ].
- [ ].
- [ ].
- [ ].

When the V&V evaluation is complete, the OCS product manager assesses each work discrepancy worksheet. Discrepancies that are directly justified as exceptions are not considered HEDs. The applicant documents justified discrepancies as part of future report APP-OCS-GER-120, “AP1000 HFE Task Support Verification Report,” along with a list of HEDs identified by discrepancy reports. APP-OCS-GEH-420 provides an implementation plan for resolving the discrepancy worksheets that are not justified by the product manager.

The staff concludes that APP-OCS-GEH-220 provides sufficient details of the implementation plan to satisfactorily demonstrate implementation of this NUREG criterion for identifying task requirement deficiencies during task verification.

NUREG-0711, Section 11.4.2.2, Criterion 4, states the following:

> An HED should be identified for HSIs that are available in the HSI, but are not needed for any task.…

Evaluation of Criterion 4

In APP-OCS-GEH-220, Sections 2.3.2 (OSA-1) and 2.4.2 (OSA-2), the applicant stated that the independent verifier will check each display for information and/or controls that are not associated with task requirements. Deviations must be documented on a discrepancy worksheet.

The staff concludes that APP-OCS-GEH-220 provides sufficient details to satisfactorily demonstrate implementation of this NUREG criterion for identifying unnecessary HSI components during task verification.

18.11.6.3 Conclusion

The staff concludes that APP-OCS-GEH-220 provides an implementation plan that satisfactorily implements the guidance in NUREG-0711 relative to task support verification. The level of detail provided and the use of an independent verifier provides reasonable assurance that the HSI requirements properly incorporate the results from all task analyses performed. This element of ITAAC Design Commitment 4 (DCD Revision 15), as described above, is complete and closed.

The DCD changes provide detailed human factors design information that would otherwise have to be addressed through verification of the ITAAC. Therefore, the changes to the DCD eliminate the need for design acceptance criteria in accordance with the finality criteria in 10 CFR Part 52.63(a)(1)(iv).

18.11.7 Evaluation of Tier 1 Information—Design Commitment 4, ITAAC Table 3.2-1, Tier 1, Section 3.2 (DCD Revision 15), Part 2 of 5, HFE Design Verification

18.11.7.1 Summary of Technical Information

ITAAC Design Commitment 4 reads as follows:

> Design Commitment: An HFE program verification and validation implementation plan is develop[ed] in accordance with the programmatic level description of the AP1000 human factors verification and validation plan.
>
> Inspection, Test, and Analysis: An inspection of the HFE verification and validation implementation plan will be performed.
>
> Acceptance criteria (Part 2): A report exists and concludes that the HFE verification and validation implementation plan was developed in accordance with the programmatic level description of the AP1000 human factors verification and validation plan and includes the …HFE Design Verification activity.

In DCD Revision 17, the applicant deleted this ITAAC based on completion of the work it described.

18.11.7.2 Evaluation

NUREG-0711, Section 11.4.2.3, Criterion 1, states the following:

> The HFE guidelines serve as review criteria. Selection of specific guidelines depends on the characteristics of the HSI components included in the scope of review and whether the applicant has developed a design-specific guideline document. NUREG-0700 may be used for HFE design verification.

Evaluation of Criterion 1

In APP-OCS-GEH-120, the applicant stated that HSI resources and operation and control centers are verified against APP-OCS-J1-002. APP-OCS-J1-002 satisfactorily implements NUREG-0711, Section 8.4.5(1), as described in Section 18.8. It includes guidance from NUREG-0700, Revision 2, and Commission Electrotechnique Internationale/International Electrotechnical Commission (CEI/IEC) 964, "Design for Control Rooms of Nuclear Power Plants," which program-level documents specifically cite. The report also includes results from operating experience review, function-based task analysis, and other industry guidance.

The staff concludes that APP-OCS-GEH-120 provides sufficient direction to ensure that the HFE guidelines serve as review criteria and have an appropriate level of detail. The report is also consistent with the program description.

NUREG-0711, Section 11.4.2.3, Criterion 2, states the following:

> The applicant should compare the characteristics of the HSI components with the HFE guidelines to determine whether the HSI is acceptable or discrepant (i.e., an HED).
>
> The applicant should evaluate discrepancies as potential indicators of additional issues.

Evaluation of Criterion 2

In APP-OCS-GEH-120 the applicant provided a complete list of [ ] (Section 1.2.2). The general process description in Section 2.1 specifies that each [ ] APP-OCS-J1-002. Appendices B and C provide [ ]. APP-OCS-J1-002 provides pass/fail criteria. A discrepancy worksheet documents all discrepancies. Disposition of discrepancies can be handled immediately by the OCS product manager or submitted to the AP1000 HFE engineering discrepancy resolution process described in APP-OCS-GEH-420. A future report, APP-OCS-GER-120, will describe all discrepancies and their justification or resolution.

The staff concludes that the implementation plan provides a disciplined process for verifying that the HSI design effectively implements design acceptance criteria. Discrepancies are documented and subjected to a corrective action process that evaluates the potential for additional issues. The staff concludes that APP-OCS-GEH-120 provides sufficient detail to satisfactorily demonstrate implementation of this NUREG criterion for design verification methodology.

NUREG-0711, Section 11.4.2.3, Criterion 3, states the following:

> The applicant should document HEDs in terms of the HSI component involved and explain how the characteristics depart from a particular guideline.

The evaluation of this criterion is contained in the evaluation of Criterion 2, directly above.

18.11.7.3 Conclusion

The staff concludes that APP-OCS-GEH-120 provides an implementation plan that satisfactorily implements the NUREG-0711 criteria associated with design verification. The document provides reasonable assurance that the HSI designs reflect the design requirements. This element of ITAAC Design Commitment 4 (DCD Revision 15), as described above, is complete and closed.

18.11.8 Evaluation of Tier 1 Information—Design Commitment 4, ITAAC Table 3.2-1, Tier 1, Section 3.2 (DCD Revision 15), Part 3 of 5, Integrated System Validation

18.11.8.1 Summary of Technical Information

At the time of the Westinghouse AP1000 DC, based on Revision 15 of the DCD, HFE V&V was reviewed and found acceptable at a programmatic level. The Westinghouse V&V program was described in WCAP-15860, "Programmatic Level Description of the AP1000 Human Factors Verification and Validation Plan," Revision 2, dated October 2003. Pursuant to Section 18.11.1 of the AP1000 DCD, a COL applicant referencing the AP1000 is committed to developing an implementation plan for V&V consistent with the NRC approved programmatic description in WCAP-15860. ITAAC Design Commitment 4 (Tier 1 Section 3.2, Human Factors Engineering, Table 3.2-1) states:

> Design Commitment: An HFE program verification and validation implementation plan is develop[ed] in accordance with the programmatic level description of the AP1000 human factors verification and validation plan.
>
> Inspection, Test, and Analysis: An inspection of the HFE verification and validation implementation plan will be performed.
>
> Acceptance criteria (part 3): A report exists and concludes that the HFE verification and validation implementation plan was developed in accordance with the programmatic level description of the AP1000 human factors verification and validation plan and includes the …Integrated System Validation activity.

To fulfill this commitment, Westinghouse has submitted WCAP-16769-P, "AP1000 Human Factors Engineering Verification and Validation," and two implementation plans:

- APP-OCS-GEH-320 (ISV Plan)
- APP-OCS-GEH-321 (ISV Scenario Plan)

Open Item OI-SRP18-COLP-03A was created by the staff to track the review of these documents.

18.11.8.2 Evaluation

The purpose of this review is to determine whether the applicant's ISV Plan and its companion document, the ISV Scenario Plan, provide an acceptable implementation plan in accordance with NUREG-0711. These documents are evaluated using WCAP-15860 and the NUREG-0711 review criteria for operational condition sampling and ISV.

18.11.8.2.1 Applicable Review Criteria

When the staff has an NRC-certified, programmatic-level description of an HFE activity, the review criteria used to evaluate an implementation plan come from two sources: the certified, programmatic description and NUREG-0711. The programmatic description, WCAP-15860, identifies the general ISV approaches and constraints. The staff's review of the ISV Plan's compliance with WCAP-15860 is discussed in Section 18.11.8.2.2 below.

NUREG-0711 criteria were used to evaluate the detailed methodology (taking into account the approved approach described in the WCAP). The ISV review criteria used were from the following sections of NUREG-0711:

- Section 11.4.1 - Operation Condition Sampling
  - Sampling Dimensions (3 review criteria)
  - Identification of Scenarios (2 review criteria)

- Section 11.4.3 - Integrated System Validation
  - Test Objectives (1 review criteria)
  - Validation Test Beds (9 review criteria)
  - Plant Personnel (4 review criteria)
  - Scenario Definition (3 review criteria)
  - Performance Measurement (5 review criteria)
  - Test Design (9 review criteria)
  - Data Analysis and Interpretation (5 review criteria)
  - Validation Conclusions (2 review criteria)

In this document, the NUREG-0711 criteria are used to assess the completeness of the ISV Plan and its acceptability as an implementation plan. The results of the staff's evaluation of the ISV Plan with respect to the NUREG-0711 criteria are provided in Sections 3 and 4 for operational condition sampling and ISV methodology, respectively.

18.11.8.2.2 Compliance with the WCAP-15860

The staff evaluated whether the ISV Plan was developed in accordance with the commitments made in WCAP-15860 and whether the ISV Plan satisfies the NRC review criteria of NUREG-0711, Section 11. In general, the ISV Plan follows the commitments made in WCAP-15860. Inconsistencies noted in earlier revisions of the ISV Plan were documented in RAI-22 and the specific details have now been acceptably addressed in Revision D of the ISV Plan.

Additionally, Section 1.5 of the ISV Plan now states that the ISV Plan conforms to the commitments, scope, purpose, and issues as stated in WCAP-15860, with the exception of two areas where exceptions have been taken. The staff has reviewed these two exceptions and found them acceptable for the reasons stated below.

Exception 1: WCAP-15860 states that ISV will utilize currently qualified operating crews as the participants. However, as AP1000 is a new plant design, the ISV participants will not be fully qualified and experienced AP1000 operators. The ISV subjects will not have the same task performance proficiency as that of fully qualified AP1000 operators.

Evaluation: The staff finds this exception acceptable because the ISV Plan continues to include operating experience specifications that are sufficient to ensure valid testing. The ISV will be relatively more demanding and thus a more conservative test of the HFE design. Section 18.11.8.2.4.3, "Plant Personnel," of this report provides additional detail.

Exception 2: WCAP-15860 states that ISV will address all of the EOPs. However, the ISV Plan states that the ISV scenarios will include a representative subset of the EOPs. The ISV scenarios will ensure that all functional operator knowledge, skills, and abilities addressed in the EOPs are assessed.

Evaluation: The staff finds this exception acceptable because:

- The applicable NUREG-0711 review criteria do not call for 100 percent coverage of procedures during ISV. Section 18.11.8.2.3, "Compliance with NUREG-0711 - Operational Conditions Sampling (OCS)," of this report provides additional detail.

- Westinghouse verified the following:

> The ISV scenarios will ensure that all functional operator knowledge, skills and abilities addressed in the AP1000 EOPs are examined and validated in ISV. While the ISV scenarios may not explicitly cause the operators to enter each of functional recovery procedures, the demand to perform similar EOP steps will be represented [ ]

Additionally, prior to the ISV, [ ]. It also ensures a thorough ISV process. Thus, this exception is acceptable.

18.11.8.2.3 Compliance with NUREG-0711 - Operational Conditions Sampling (OCS)

NUREG-0711, Section 11.4.1, states, "The sampling methodology will identify a range of operational conditions to guide V&V activities. The review of operational conditions sampling considers the dimensions to be used to identify and select conditions and their integration into scenarios."

The objective of reviewing operational condition sampling is to verify that the applicant has identified a sample of operational conditions that: (1) includes conditions that are representative of the range of events that could be encountered during operation of the plant; (2) reflects the characteristics that are expected to contribute to system performance variation; and (3) considers the safety significance of HSI components. These sample characteristics are best identified through the use of a multidimensional sampling strategy to provide reasonable assurance that variation along important dimensions is included in the V&V evaluations.

The staff reviewed the defined scenarios in the ISV Plan and the ISV Scenario Plan to determine whether the OCS dimensions were addressed. The aspects of the specified OCS, both from WCAP-15860 and from NUREG-0711 have been addressed by the ISV Plan and the ISV Scenario Plan.

18.11.8.2.3.1 Sampling Dimensions

The sampling dimensions addressed in NUREG-0711, Section 11.4.1.2, include plant conditions, personnel tasks, and situational factors known to challenge personnel performance.

(1) The following plant conditions should be included:

- normal operational events including plant startup, plant shutdown or refueling, and significant changes in operating power

- failure events, e.g.,
  - instrument failures [e.g., safety-related system logic and control unit, fault tolerant controller, local “field unit” for multiplexer (MUX) system, MUX controller, and break in MUX line] including instrumentation and control (I&C) failures that exceed the design basis, such as a common mode I&C failure during an accident

  - HSI failures (e.g., loss of processing and/or display capabilities for alarms, displays, controls, and computer-based procedures)

- transients and accidents, e.g.,
  - transients (e.g., turbine trip, loss of off-site power, station blackout, loss of all feedwater, loss of service water, loss of power to selected buses or MCR power supplies, and safety and relief valve transients)

  - accidents (e.g., main steam line break, positive reactivity addition, control rod insertion at power, anticipated transient without scram, and various-sized LOCAs)

  - reactor shutdown and cool down using the remote shutdown system

- reasonable, risk-significant, beyond-design-basis events, which should be determined from the plant-specific PRA

- consideration of the role of the equipment in achieving plant safety functions [as described in the plant safety analysis report (SAR)] and the degree of interconnection with other plant systems. A system that is interconnected with other systems could cause the failure of other systems because the initial failure could propagate over the connections. This consideration is especially important when assessing non-Class 1E electrical systems.

Evaluation of Criterion (1)

WCAP-15860, Section 4.6 includes an extensive and multi-dimensional set of criteria that address this particular criterion. The ISV Plan was developed based on this criterion and includes [ ] separate scenarios, which are detailed in the ISV Scenario Plan. ISV Plan, Section 5.1.1, “Events,” lists the various [ ] scenarios. Also, the ISV Scenario Plan has an Appendix A titled, “Scenario Specifications” that provides the [ ] scenarios. The scenarios themselves follow in the rest of Appendix A. Additionally, the ISV Scenario Plan, Appendix E, “Tasks of Special Interest,” lists each [ ] and in which scenario(s) it is addressed. Appendix E also provides a cross reference between scenarios and the [ ]. This scenario information was compared with the commitments of WCAP-15860 and with the NUREG-0711 criteria. The ISV Plan and ISV Scenario Plan together were found to satisfy both the programmatic plan and NUREG-0711 and meet the criterion on plant conditions.

(2) The following types of personnel tasks should be included:

- Risk-significant HAs, systems, and accident sequences - All risk-important HAs should be included in the sample. These include [those] identified in the PRA and those identified as risk-important in the SAR and NRC's SER. Situations where human monitoring of an automatic system is risk-important should be considered. Additional factors should be sampled that contribute highly to risk, as defined by the PRA, including:
  - dominant human actions (selected via sensitivity analyses)
  - dominant accident sequences
  - dominant systems (selected via PRA importance measures such as RAW or RRW)

- OER-identified difficult tasks—The sample should include all personnel tasks identified as problematic during the applicant's review of operating experience.

- Range of procedure guided tasks—These are tasks that are well defined by normal, abnormal, emergency, alarm response, and test procedures. The operator should be able to, as part of rule-based decision-making, understand and execute the specified steps. Regulatory guide (RG) 1.33, "Quality Assurance Program Requirements (Operation)," Revision 2, Appendix A, includes several categories of "typical safety-related activities that should be covered by written procedures." The sample should include appropriate procedures in each relevant category:

  - administrative procedures

  - general plant operating procedures

  - procedures for startup, operation, and shutdown of safety-related systems

  - procedures for abnormal, off normal, and alarm conditions

  - procedures for combating emergencies and other significant events

  - procedures for control of radioactivity

  - procedures for control of measuring and test equipment and for surveillance tests, procedures, and calibration

  - procedures for performing maintenance

  - chemistry and radiochemical control procedures

- Range of knowledge-based tasks—these are tasks that are not as well defined by detailed procedures. Knowledge-based decision-making involves greater reasoning about safety and operating goals and the various means of achieving them. A situation may call for knowledge-based decision-making if the rules do not fully address the problem, or the selection of an appropriate rule is not clear. An example in a pressurized water reactor plant may be the difficulty in diagnosing a steam generator tube rupture (SGTR) with a failure of radiation monitors on the secondary side of the plant because: (1) there is no main indication of the rupture (the presence of radiation in secondary side); and (2) the other effects of the rupture (i.e., slight changes in pressures and levels on the primary and secondary sides) may be attributed to other causes. While the operators may use procedures to treat the symptoms of the event, the determination that the cause is an SGTR may warrant situation assessment based on an understanding of the plant's design and the possible combinations of failures that could result in the observed symptoms. Errors in rule-based decision-making result from selecting the wrong rule or incorrectly applying a rule. Errors in knowledge-based decision-making result from mistakes in higher-level cognitive functions such as judgment, planning, and analysis. The latter are more likely to occur in complex failure events where the symptoms do not resemble the typical case, and thus, are not amenable to pre-established rules.

- Range of human cognitive activities—The sample should include the range of cognitive activities performed by personnel, including:

  - detection and monitoring (e.g., of critical safety-function threats)

  - situation assessment (e.g., interpretation of alarms and displays for diagnosis of faults in plant processes and automated control and safety systems)

  - response planning (e.g., evaluating alternatives for recovery from plant failures)

  - response implementation (e.g., in-the-loop control of plant systems, assuming manual control from automatic control systems, and carrying out complicated control actions)

  - obtaining feedback (e.g., of the success of actions taken)

- Range of human interactions—the sample should reflect the range of interactions among plant personnel, including tasks that are performed independently by individual crew members and tasks that are performed by crew members acting as a team. These interactions among plant personnel should include interactions between:

  - MCR operators (e.g., operations, shift turnover walkdowns)

  - MCR operators and auxiliary operators

  - MCR operators and support centers (e.g., the TSC and the emergency offsite facility)

  - MCR operators with plant management, NRC, and other outside organizations

- Tasks that are performed with high frequency.

Evaluation of Criterion (2)

As stated in the evaluation of Criterion (1) above, ISV Plan, Section 5.1.1, and ISV Scenario Plan, Appendix E, list the various evolutions (both high frequency and less common tasks), transients, accidents, and risk-important HAs that are included in the [ ] scenarios. The ISV Scenario Plan, Appendix A, provides the [ ] actual scenarios. This scenario information was compared with the commitments of WCAP-15860 and with the NUREG-0711 criteria. The ISV documents satisfy both documents.

The risk-important HAs and tasks are identified in TR-59/WCAP-16555. WCAP-16555, Section 3.2, identifies [ ] post-accident risk-important HAs in Table 3.2-2. The ISV Plan draft included essentially all of these [ ] risk-important HAs in scenarios. However, the risk-important HA to [ ] was excluded in the ISV scenario Plan. An RAI-SRP18-COLP-53 was written. In the ISV Scenario Plan, this risk-important HA is now included as part of Scenario 18, "Loss of RNS during Mid-Loop Operation." Thus, all risk-important HAs are now addressed in at least one ISV scenario (a few are included in two scenarios). This risk-important HA also has local aspects that cannot be adequately simulated as part of ISV. Thus, the actual verification of acceptability of planned local actions associated with the [ ] will need to be deferred until the plant is built. Therefore, the RAI response proposes adding this to the HFE Design Verification at Plant Startup, APP-OCS-GEH-520. The staff reviewed APP-OCS-GEH-520, Revision B, submitted in a letter dated August 2, 2010, and found that verification of local control action has been added to the document.

The ISV Scenario Plan, Appendix F, previously listed the PRA risk-dominant systems for AP1000. This appendix was deleted from Revision B but is still available in the AP1000 PRA. These systems were verified to all be addressed in the scenarios. [ ].

The following important tasks identified from OSA analyses were included in the ISV, as shown in the ISV Scenario Plan, Appendix E, Table E-1: "Loss of DDS"; [ ]. The following OER important tasks were also identified and included in the ISV Table E-1 and the ISV scenarios: [ ].

The scenarios presented in WCAP-15860 and the ISV Scenario Plan were also found to adequately address a broad range of: procedure–guided tasks, human cognitive activities, and human interactions. Thus, the ISV scenarios were found to adequately address the types of personnel tasks specified in the NUREG-0711 Criterion 2 pending confirmation of RAI-SRP18-COLP-53.

(3) The sample should reflect a range of situational factors that are known to challenge human performance, such as:

- Operationally difficult tasks—The sample should address tasks that have been found to be problematic in the operation of nuclear power plants (e.g., procedure versus situation assessment conflicts). The specific tasks selected should reflect the operating history of the type of plant being validated (or the plant's predecessor).

- Error-forcing contexts—Situations specifically designed to create human errors should be included to assess the error tolerance of the system and the capability of operators to recover from errors should they occur.

- High-workload conditions—The sample should include situations where human performance variation due to high workload and multitasking situations can be assessed.

- Varying-workload situations—The sample should include situations where human performance variation due to workload transitions can be assessed. These include conditions that exhibit: (1) a sudden increase in the number of signals that must be detected and processed following a period in which signals were infrequent; and (2) a rapid reduction in signal detection and processing demands following a period of sustained high task demand.

- Fatigue and circadian factors—The sample should include situations where human performance variation due to personnel fatigue and circadian factors can be assessed.

- Environmental factors—The sample should include situations where human performance variation due to environmental conditions such as poor lighting, extreme temperatures, high noise, and simulated radiological contamination can be assessed.

Evaluation of Criterion (3)

The ISV Plan and ISV Scenario Plan address operationally difficult tasks as identified via the OSA analyses and through the OER. These are summarized in the ISV Scenario Plan, Appendix F, and are discussed in the review of Criterion (2) above. The scenarios have [ ]. This is described in the ISV Plan, Section 5.1.3, "Complications." These complications also are added to the transient or accident scenarios to [ ].

The applicant took exception to addressing fatigue and circadian factors, relying on APP-OCS-GEH-320, Section 5.1.3, which states that the ISV does not address fatigue and circadian factors since it is considered to be impractical to attempt to mimic the conditions that are typical on the operating site. The staff agrees with this position and notes that 10 CFR Part 26, "Fitness for duty programs," Subpart I addresses managing fatigue.

[ ]. For example, [ ]. Other environmental factors are addressed as part of APP-OCS-GEH-520.

Thus, the ISV plans acceptably address Criterion 3.

18.11.8.2.3.2 Identification of Scenarios

The results of the sampling should be combined to identify a set of scenarios to guide subsequent analyses. A given scenario may combine many of the characteristics identified by the operational event sampling.

Evaluation of Criterion (1)

The [ ] scenarios have been developed for use in ISV. The scenarios are quite varied and they do combine the various characteristics outlined in the operational event sampling. Detailed scenario descriptions are provided in the ISV Scenario Plan. The documents reviewed satisfy this criterion.

The scenarios should not be biased in the direction of over representation of the following:

- scenarios for which only positive outcomes can be expected
- scenarios that for integrated system validation are relatively easy to conduct administratively (scenarios that place high demands, data collection or analysis are avoided)
- scenarios that for integrated system validation are familiar and well structured (e.g., which address familiar systems and failure modes that are highly compatible with plant procedures such as “textbook” design-basis accidents)

Evaluation of Criterion (2)

As noted above under Criterion 1, a robust set of [ ] scenarios has been developed and they are described in the ISV Scenario Plan. These scenarios have many failure events both as the key item of the scenario and as peripheral issues. They are not limited to familiar, typical, or easy-to-conduct scenarios or those with only positive outcomes. The documents reviewed satisfy this criterion.

18.11.8.2.4 Integrated System Validation

The objective of reviewing integrated system validation methodology is to verify that the applicant’s methodology will validate the integrated system design (i.e., hardware, software, and personnel elements) using performance-based tests that will determine whether it acceptably supports safe operation of the plant.

18.11.8.2.4.1 Test Objectives

(1) Detailed objectives should be developed to provide evidence that the integrated system adequately supports plant personnel in the safe operation of the plant. The test objectives and scenarios should be developed to address aspects of performance that are affected by the modification [of the] design, including personnel functions and tasks affected by the modification. The objectives should be to:

    - Validate the role of plant personnel.

- Validate that the shift staffing, assignment of tasks to crew members, and crew coordination (both within the control room as well as between the control room and local control stations and support centers) is acceptable. This should include validation of the nominal shift levels, minimal shift levels, and shift turnover.

- Validate that for each human function, the design provides adequate alerting, information, control, and feedback capability for human functions to be performed under normal plant evolutions, transients, design-basis accidents, and selected, risk-significant events that are beyond-design basis.

- Validate that specific personnel tasks can be accomplished within time and performance criteria, with a high degree of operating crew situation awareness, and with acceptable workload levels that provide a balance between a minimum level of vigilance and operator burden. Validate that the operator interfaces minimize operator error and provide for error detection and recovery capability when errors occur.

- Validate that the crew can make effective transitions between the HSIs and procedures in the accomplishment of their tasks and that interface management tasks such as display configuration and navigation are not a distraction or undue burden.

- Validate that the integrated system performance is tolerant of failures of individual HSI features.

- Identify aspects of the integrated system that may negatively affect integrated system performance.

Evaluation of Criterion (1)

The objectives of the AP1000 ISV are identified in Section 4.2 of WCAP-15860, which has been approved by NRC as part of the original AP1000 DC. They included:

1. Establish the adequacy of the integrated HSI for achieving HFE program goals
2. Confirm allocation of function and the structure of tasks assigned to personnel
3. Validate the EOPs and associated HSI
4. Confirm the dynamic aspects of the HSI for task accomplishment
5. Evaluate and demonstrate error tolerance to human and system failures
6. Establish the adequacy of staffing and of the HSI to support staff to accomplish their tasks

These objectives have been included in Section 1.2 of the ISV Plan. This approach acceptably meets the staff's review criterion.

18.11.8.2.4.2 Validation Testbeds

(1) Interface Completeness—The testbed should completely represent the integrated system. This should include HSIs and procedures not specifically required in the test scenarios. For example, adjacent controls and displays may affect the ways in which personnel use those that are addressed by a particular validation scenario.

Evaluation of Criterion (1)

(2) ISV Plan, Section 2, indicates that the ISV will be performed at a dedicated, purpose-built facility. The facility will employ a high fidelity, near full-scope simulator to represent the AP1000 systems and the MCR. This simulator will satisfy the general requirements of Sections 3 and 4 of American National Standards Institute/American National Standard (ANSI/ANS)-3.5-1998, “Nuclear Power Plant Simulators for Use in Operator Training and Examination.”

NUREG-0711 indicates the use of ANSI/ANS-3.5-1998 is an acceptable testbed. This satisfies Criterion 1.

(2) Interface Physical Fidelity—A high degree of physical fidelity in the HSIs and procedures should be represented, including presentation of alarms, displays, controls, job aids, procedures, communications, interface management tools, layout and spatial relationships.

Evaluation of Criterion (2)

The AP1000 testbed will acceptably meet this criterion (see the evaluation of Criterion 1). In addition, in the ISV Plan, Section 5.1.2, “Procedures,” the applicant states that the following types of procedures for AP1000 are incorporated into ISV Scenario Plan, and will be used:

- Optimal Recovery
- Functional Recovery
- Shutdown Procedures
- Normal Operating Procedures (NOPs)
- Abnormal Operating Procedures (AOPs)
- Refueling and Outage Procedures
- Alarm Response Procedures (ARPs)
- Maintenance and Surveillance Guidelines
- [ ]
- [ ]
- [ ]

This approach acceptably meets the staff’s review criterion.

(3) Interface Functional Fidelity—A high degree of functional fidelity in the HSIs and procedures should be represented. All HSI functions should be available. High functional fidelity includes HSI component modes of operation, i.e., the changes in functionality that can be invoked on the basis of personnel selection and/or plant states.

Evaluation of Criterion (3)

The AP1000 testbed will acceptably meet this criterion (see the evaluation of Criterion 1).

(4) Environment Fidelity—A high degree of environment fidelity should be represented. The lighting, noise, temperature, and humidity characteristics should reasonably reflect that

expected. Thus, noise contributed by equipment, such as air handling units and computers should be represented in validation tests.

Evaluation of Criterion (4)

Due to the constraints of the building, the simulator does not include the passive cooling fins; instead, there is a conventional office building tiled ceiling. This results in the lighting system being somewhat different, although it is still representative of the final lighting system design. In addition, the heating and ventilation is provided by a conventional office building system and is, therefore, not representative of the final as-built MCR. Also, the acoustic properties cannot be completely replicated, although they will be similar (i.e., painted walls, hard ceiling tiles). The simulator will be as representative as possible of the final MCR design, so that the design can be assessed. The applicant believes the differences will have minimal or no impact on ISV crew performance. [ ]. Also, the applicant noted in its response to RAI-SRP18-COLP-49, dated February 2, 2010, that the environmental conditions will be fully assessed in APP-OCS-GEH-520. This approach provides sufficient environmental fidelity for ISV and acceptably meets Criterion 4.

(5) Data Completeness Fidelity—Information and data provided to personnel should completely represent the plant systems monitored and controlled from that facility.

Evaluation of Criterion (5)

The AP1000 testbed will acceptably meet this criterion (see the evaluation of Criterion 1).

(6) Data Content Fidelity—A high degree of data content fidelity should be represented. The information and controls presented should be based on an underlying model that accurately reflects the reference plant. The model should provide input to the HSI in a manner such that information accurately matches that which will actually be presented.

Evaluation of Criterion (6)

The AP1000 testbed will acceptably meet this criterion (see the evaluation of Criterion 1).

(7) Data Dynamics Fidelity—A high degree of data dynamics fidelity should be represented. The process model should be capable of providing input to the HSI in a manner such that information flow and control responses occur accurately and in a correct response time; e.g., information should be provided to personnel with the same delays as would occur in the plant.

Evaluation of Criterion (7)

The AP1000 testbed will acceptably meet this criterion (see the evaluation of Criterion 1).

(8) For important actions at complex HSIs remote from the MCR, where timely and precise HAs are required, the use of a simulation or mockup should be considered to verify that human performance requirements can be achieved. (For less risk-important HAs or where the HSIs are not complex, human performance may be assessed based on analysis such as task analysis rather than simulation.)

Evaluation of Criterion (8)

The use of local control stations (LCSs) and the Remote Shutdown Workstation (RSW) are included in the ISV scenarios. Scenario 7 for [ ] is included in the ISV Scenario Plan. The RSW will be validated using [ ]. Operators will be able to [ ]. ISV Plan, Section 2.1, "Physical Scope and Fidelity", describes the details of the simulated RSW panel. Other LCSs are also included in the ISV Scenario Plan. The one local action that is risk important relates to [ ]. The actual verification of acceptability of planned local actions [ ] will need to be deferred until the plant is built. The staff reviewed APP-OCS-GEH-520 against the response to RAI-SRP18-COLP-53 R1 received in a letter dated May 21, 2010. The staff confirmed the document conforms to the RAI response.

(9) The testbeds should be verified for conformance to the testbed characteristics identified above before validations are conducted.

Evaluation of Criterion (9)

Section 2.3 of the ISV Plan describes the simulator testing to be performed prior to ISV evaluations. The ISV Plan references the ISV Scenario Plan for detail concerning how the testing will be performed. That information is provided in ISV Scenario Plan, Appendix C, "Simulator Testing." The objective of this simulator testing in preparation for ISV is to demonstrate that the simulator responds in a manner similar to the reference unit while utilizing the operating procedures and that it meets ANSI/ANS 3.5-1998. The testing will be carried out [ ]. This includes an estimated [ ] of testing. In addition, the ISV Plan, Section 3.3 describes pilot testing of each ISV scenario to ensure simulator readiness, and to confirm effective functioning of test protocols and data collection. This will be done by personnel different from the test subjects.

This provides an acceptable and comprehensive approach to testbed verification. This approach acceptably meets the staff's review criterion.

18.11.8.2.4.3 Plant Personnel

(1) Participants in the validation tests should be representative of actual plant personnel who will interact with the HSI, e.g., licensed operators rather than training or engineering personnel.

Evaluation of Criterion (1)

Section 4.9 of the ISV Plan indicates that validation crews will consist of currently qualified operating crews. The applicant takes partial exception to this item from the program plan, as described in the ISV Plan, Section 1.5, Item 1. Since the AP1000 is a new plant design, the ISV participants will not be fully qualified and experienced AP1000 operators. The ISV subjects will not have the same task performance proficiency as that of fully qualified AP1000 operators. This is reasonable for ISV, and it does make the ISV somewhat more demanding. In accordance with Section 4.1, "Subjects," of the ISV Plan, the ISV subjects will be comprised of the following:

1. A group that has completed the [ ].

2. A group that has partially completed the [ ]. These subjects will have undertaken [ ] training program. Subjects will comprise [ ]. They will have completed [ ] of AP1000 systems training and [ ] of procedure/simulator based training.

3. A limited group of [ ].

Thus, The ISV crews are samples taken from the crews of the AP1000 customer utilities, as described above. This approach acceptably meets the staff's review criterion.

(2) To properly account for human variability, a sample of participants should be used. The sample should reflect the characteristics of the population from which the sample is drawn. Those characteristics that are expected to contribute to system performance variation should be specifically identified and the sampling process should provide reasonable assurance that variation along that dimension is included in the validation. Several factors that should be considered in determining representativeness include: license and qualifications, skill/experience, age, and general demographics.

Evaluation of Criterion (2)

Section 4.1.1 of the ISV Plan discussed participant selection. Two utilities will be providing [ ] crews each. A set of criteria will be provided to the utilities to guide selection of crew members. The criteria include successful completion of training, age range, skills and abilities range, qualifications variation, and prior experience variation. In addition, no operators participating in previous AP1000 tests will be used. This approach acceptably meets the staff's review criterion.

(3) In selection of personnel, consideration should be given to the assembly of minimum and normal crew configurations, including shift supervisors, reactor operators, shift technical advisors, etc., that will participate in the tests.

Evaluation of Criterion (3)

In Section 4.1.2, "Crew Size and Number," of the ISV Plan, the applicant states that the typical crew size for ISV will be [ ]. The crew size will also be varied as a complication in specific scenarios. The maximum control room staff is also specified in Section 4.1.2 and consists of [ ] personnel. The maximum staffing level will be addressed by [ ]. The actual staffing level is specified for each scenario in the ISV Scenario Plan, Section A.n.3, "Scenario Participants" (for n = 1 to [ ]). Scenario participants vary from [ ] to [ ]. This reasonably addresses minimum, normal and maximum staffing levels, plus other values in between, and is acceptable.

In its RAI-SRP18-COLP-26 response of July 12, 2010, the applicant committed to delete TR-52 from the DCD and replace it with APP-OCS-GJR-003, Revision 2, "AP1000 Main Control Room Staff Roles and Responsibilities" to document new staffing values. This is acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

(4) To prevent bias in the sample, the following participant characteristics and selection practices should be avoided:

- participants who are [ ]
- participants in [ ]
- participants who are selected for some specific characteristic, such as using crews that are identified as good or experienced.

Evaluation of Criterion (4)

As described in ISV Plan, Section 4.1, “Subjects”; Section 4.1.1, “Selection”; and Section 4.1.2, “Crew Size and Number”, the applicant will use COL utility personnel as test participants and not design personnel. Section 4.1 states that care will be taken to ensure that the test participants do not obtain any prior knowledge of the scenarios to be used in ISV. The participants will not include subjects that participated in the HFE Tests. Section 4.1.1 states that participating utilities will be requested to assign typical crews for ISV testing based on availability. Crews will not be selected for ISV based on individual characteristics. This approach acceptably meets the staff’s review criterion.

18.11.8.2.4.4 Scenario Definition

(1) The operational conditions selected for inclusion in the validation tests should be developed in detail so they can be performed on a simulator. The following information should be defined to provide reasonable assurance that important performance dimensions are addressed and to allow scenarios to be accurately and consistently presented for repeated trials:

- description of the scenario and any pertinent "prior history" necessary for personnel to understand the state of the plant upon scenario start-up

- specific initial conditions (precise definition provided for plant functions, processes, systems, component conditions and performance parameters, e.g., similar to plant shift turnover)

- events (e.g., failures) to occur and their initiating conditions, e.g., time, parameter values, or events

- precise definition of workplace factors, such as environmental conditions

- task support needs (e.g., procedures and technical specifications)

- staffing objectives

- communication requirements with remote personnel (e.g., load dispatcher via telephone)

- the precise specification of what, when and how data are to be collected and stored (including videotaping requirements, questionnaire and rating scale administrations)

- specific criteria for terminating the scenario.

Evaluation of Criterion (1)

The ISV Scenario Plan provides scenario descriptions for each of the [ ] scenarios to be part of ISV. Each scenario in the document includes the following:

- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]

Each scenario provides the above information in acceptable detail. At this time, only three scenarios have complete observer guides. These three provide an acceptable example of how the remaining observer guides will be completed. This approach acceptably meets the staff's review criterion.

(2) Scenarios should have appropriate task fidelity so that realistic task performance will be observed in the tests and so that test results can be generalized to actual operation of the real plant.

Evaluation of Criterion (2)

This criterion is addressed through the use of a simulation facility for ISV that satisfies the general requirements of Sections 3 and 4 of ANSI/ANS-3.5-1988; use of COL plant operating personnel in training for operations; and use of realistic but challenging scenarios. This approach conforms to NUREG-0711 Criterion 2.

(3) When evaluating performance associated with operations remote from the MCR, the effects on crew performance due to potentially harsh environments (i.e., high radiation) should be realistically simulated (i.e., additional time to don protective clothing and access radiologically controlled areas).

Evaluation of Criterion (3)

The ISV Plan notes that the use of LCSs is included in the ISV scenarios and they will use simulated interactions with local operations that extend beyond the MCR. Scripted responses will be provided for the operations support staff to perform specified roles as plant personnel in applicable scenarios (e.g., local operators). This is acceptable.

There is one local control action that is a risk-important HA. This is [ ] and is included in an ISV scenario. The actual verification of acceptability of planned local actions associated with the hatches will need to be deferred until the plant is built. This is an acceptable approach. Therefore, the RAI response proposes adding this to APP-OCS-GEH-520. The staff reviewed APP-OCS-GEH-520, Revision B, submitted in a letter dated August 2, 2010, and found that verification of local control action has been added to the document.

18.11.8.2.4.5 Performance Measurement

The review of performance measurement covers measurement characteristics, performance measure selection, and performance criteria.

18.11.8.2.4.5.1 Measurement Characteristics

(1) Performance Measurement Characteristics—Performance measures should acceptably exhibit the following measurement characteristics to provide reasonable assurance that the measures are of good quality (it should be noted that some of the characteristics identified below may not apply to every performance measure):

- Construct Validity—A measure should accurately represent the aspect of performance to be measured.

- Diagnosticity—A measure should provide information that can be used to identify the cause of acceptable or unacceptable performance.

- Impartiality—A measure should be equally capable of reflecting good as well as bad performance.

- Objectivity—A measure should be based on phenomena that are easily observed.

- Reliability—A measure should be repeatable; i.e., if the same behavior is measured in exactly the same way under identical circumstances, the same measurement result should be obtained.

- Resolution—A measure should reflect the performance at an appropriate level of resolution, i.e., with sufficient detail to permit a meaningful analysis.

- Sensitivity—A measure's range (scale) and the frequency of measurement (how often data are collected) should be appropriate to the aspect of performance being assessed.

- Simplicity—A measure should be simple both from the standpoint of executing the tests and from the standpoint of communicating and comprehending the meaning of the measures.

- Unintrusiveness—A measure should not significantly alter the psychological or physical processes that are being investigated.

Evaluation of Criterion (1)

Section 6 of the ISV Plan describes the performance measures to be used to evaluate integrated system performance. The characteristics of the measures are addressed in Section 6.2. Several of the measures are well-known, commonly used measures with established, acceptable measurement characteristics, such as the [ ]. For others developed by Westinghouse, the basis of the measures is identified. For example, a measure of team performance will be used that is based on a [ ]. This approach acceptably meets the staff's review criterion.

18.11.8.2.4.5.2 Performance Measure Selection

(1) A hierarchal set of performance measures should be used, which includes measures of the performance of the plant and personnel (i.e., personnel tasks, situation awareness, cognitive workload, and anthropometric/physiological factors). Some of these measures could be used as "pass/fail" criteria for validation and the others to better understand personnel performance and to facilitate the analysis of performance errors. The applicant should identify which are in each category.

Evaluation of Criterion (1)

Section 6.1 of the ISV Plan describes the measures to be used. The measures are hierarchal including [ ]. Thus, an acceptable hierarchal set of performance measures will be used to assess integrated system performance.

Section 6.3.1 of the ISV Plan identifies the measures to be used as pass/fail (P/F) criteria. P/F measures are measures reflecting [ ]. This provides a reasonable set of measures to serve as P/F criteria.

Performance measures to be used as diagnostic measures are discussed in ISV Plan, Section 6.3.2. The measures are listed in Table 6.3-2 and include all measures collected during ISV trials with the exception of the P/F measures.

This approach acceptably meets the staff's review criterion.

(2) Plant Performance Measurement—Plant performance measures representing functions, systems, components, and HSI use should be obtained.

Evaluation of Criterion (2)

Section 6 of the ISV Plan discusses ISV performance measurement. P/F plant-level measures involve applicable technical [ ]. Plant-level diagnostic measures are also defined for each scenario so that [ ]. For example, for the [ ]. This approach acceptably meets the staff's review criterion.

(3) Personnel Task Measurement—For each specific scenario, the tasks that personnel are [needed] to perform should be identified and assessed. Two types of personnel tasks should be measured: primary (e.g., start a pump), and secondary (e.g., access the pump status display). Primary tasks are those involved in performing the functional role of the operator to supervise the plant; i.e., monitoring, detection, situation assessment,

response planning, and response implementation. Secondary tasks are those personnel [need to] perform when interfacing with the plant, but which are not directed to the primary task, such as navigation and HSI configuration. This analysis should be used for the identification of potential errors of omission.

- Primary tasks should be assessed at a level of detail appropriate to the task demands. For example, for some simple scenarios, measuring the time to complete a task may be sufficient. For more complicated tasks, especially those that may be described as knowledge-based, it may be appropriate to perform a more fine-grained analysis such as identifying task components: seeking specific data, making decisions, taking actions, and obtaining feedback. Tasks that are important to successful integrated system performance and are knowledge-based should be measured in a more fine-grained approach.

- The measurement of secondary tasks should reflect the demands of the detailed HSI implementation, e.g., time to configure a workstation, navigate between displays, and manipulate displays (e.g., changing display type and setting scale).

- The tasks that are actually performed by personnel during simulated scenarios should be identified and quantified. (Note that the actual tasks may be somewhat different from those that should be performed). Analysis of tasks performed should be used for the identification of errors of commission.

- The measures used to quantify tasks should be chosen to reflect the important aspects of the task with respect to system performance, such as:

    - time
    - accuracy
    - frequency
    - errors (omission and commission)
    - amount achieved or accomplished
    - consumption or quantity used
    - subjective reports of participants
    - behavior categorization by observers

Evaluation of Criterion (3)

Section 6 of the ISV Plan discusses ISV performance measurement. Measurement of operator tasks involves both P/F and diagnostic variables. Successful performance of risk-important HAs is a P/F variable. For example, for the [ ] as tasks to assess using P/F measures. For diagnostic purposes, the performance of key tasks is measured. These actions are listed in the observer guides for each scenario. This approach acceptably meets the staff's review criterion.

(4) Situation Awareness—Personnel situation awareness should be assessed. The approach to situation awareness measurement should reflect the current state-of-the-art.

Evaluation of Criterion (4)

Section 6 of the ISV Plan discusses ISV performance measurement. Situation awareness is measured using the [ ]. SART is a widely used and acceptable measure of situation awareness. This approach acceptably meets the staff's review criterion.

(5) Cognitive Workload—Personnel workload should be assessed. The approach to workload measurement should reflect the current state-of-the-art.

Evaluation of Criterion (5)

Section 6 of the ISV Plan discusses ISV performance measurement. Cognitive workload is measured using the [ ]. This approach acceptably meets the staff's review criterion.

(6) Anthropometric and Physiological Factors— Anthropometric and physiological factors include such concerns as visibility of indications, accessibility of control devices, and ease of control device manipulation that should be measured where appropriate. Attention should be focused on those aspects of the design that can only be addressed during testing of the integrated system, e.g., the ability of personnel to effectively use the various controls, displays, workstations, or consoles in an integrated manner.

Evaluation of Criterion (6)

Section 6 of the ISV Plan discusses ISV performance measurement. Information on general aspects of anthropometrics, including control room layout and workstation configuration, have been included in the [ ]. An assessment of anthropometric and physiological factors will also be made during HFE Design Verification. This approach acceptably meets the staff's review criterion.

18.11.8.2.4.5.3 Performance Criteria

(1) Criteria should be established for the performance measures used in the evaluations. The specific criteria that are used for decisions as to whether the design is validated or not should be specified and distinguished from those being used to better understand the results.

Evaluation of Criterion (1)

Section 6.3, "Criteria," of the ISV Plan discusses the criteria to be used in evaluating performance measures. P/F performance measures are used to validate the design as was discussed in Section 4.5.2, "Performance Measure Selection, of this report. The general acceptance criteria are (1) [ ].

For diagnostic measures, criteria are identified in ISV Plan, Table 6.3-2. The table provides criteria for all diagnostic measures. For example, the criteria for evaluating workload include: (1) average rating of workload across subjects from questionnaire is < 85 (range 0 to 100); (2) subjects demonstrate behavior, as specified in the scenario description for each scenario, that their workload is within a reasonable range and there are no indications of stress caused by excessive workload; and (3) No workload issues are identified through questionnaire comments, debriefing, video and audio recording review. Failure to meet the criteria is evaluated by the HED resolution process (APP-OCS-GEH-420) to determine its priority.

This approach acceptably meets the staff's review criterion.

(2) The basis for criteria should be defined, e.g., requirement-referenced, benchmark referenced, normative referenced, and expert-judgment referenced.

Evaluation of Criterion (2)

Section 6.3, "Criteria," of the ISV Plan discusses the criteria to be used in evaluating performance measures. The basis for criteria for P/F measures is [ ]. The criteria established for diagnostic measures are based [ ]. This approach acceptably meets the staff's review criterion.

18.11.8.2.4.6 Test Design

18.11.8.2.4.6.1 Coupling Crews and Scenarios

(1) Scenario Assignment—Important characteristics of scenarios should be balanced across crews. Random assignment of scenarios to crews is not recommended. The value of using random assignment to control bias is only effective when the number of crews is quite large. Instead, the validation team should attempt to provide each crew with a similar and representative range of scenarios.

Evaluation of Criterion (1)

Section 3.2 of the ISV Plan discussed assignment of participants to trials. A final run order will be identified after pilot testing so aspects such as scenario duration can be determined. However, an example is provided in Table 3.3-1 of a counter balanced presentation of scenarios to crews. In the example, [ ]. Assignments are made [ ]. The constraints and considerations are clearly identified in the ISV plan. This approach acceptably meets the staff's review criterion.

(2) Scenario Sequencing—The order of presentation of scenario types to crews should be carefully balanced to provide reasonable assurance that the same types of scenarios are not always being presented in the same linear position, e.g., the easy scenarios are not always presented first.

Evaluation of Criterion (2)

Section 3.2 of the ISV Plan discussed assignment of participants to trials. As noted in the evaluation of Criterion (1), the final trial orders will be determined following pilot testing. One of the principles to be followed in that determining the final run order is to balance the order to accommodate the types of concerns raised in the review criterion. For example, the Plan states that "[ ]." Such considerations should minimize the possibility of linear position effects. This approach acceptably meets the staff's review criterion.

18.11.8.2.4.6.2 Test Procedures

(1) Detailed, clear, and objective procedures should be available to govern the conduct of the tests. These procedures should include:

- The identification of which crews receive which scenarios and the order that the scenarios should be presented.

- Detailed and standardized instructions for briefing the participants. The type of instructions given to participants can affect their performance on a task. This source of bias can be minimized by developing standard instructions.

- Specific criteria for the conduct of specific scenarios, such as when to start and stop scenarios, when events such as faults are introduced, and other information discussed in Section 11.4.3.2.4, "Scenario Definition."

- Scripted responses for test personnel who will be acting as plant personnel during test scenarios. To the greatest extent possible, responses to communications from operator participants to test personnel (serving as surrogate for personnel outside the control room personnel) should be prepared. There are limits to the ability to preplan communications since personnel may ask questions or make requests that were not anticipated. However, efforts should be made to detail what information personnel outside the control room can provide, and script the responses to likely questions.

- Guidance on when and how to interact with participants when simulator or testing difficulties occur. Even when a high-fidelity simulator is used, the participants may encounter artifacts of the test environment that detract from the performance for tasks that are the focus of the evaluation. Guidance should be available to the test conductors to help resolve such conditions.

- Instructions regarding when and how to collect and store data. These instructions should identify which data are to be recorded by:

  - simulation computers

  - special purpose data collection devices (such as situation awareness data collection, workload measurement, or physiological measures)

  - video recorders (locations and views)

  - test personnel (such as observation checklists)

  - subjective rating scales and questionnaires.

- Procedures for documentation, i.e., identifying and maintaining test record files including crew and scenario details, data collected, and test conductor logs. These instructions should detail the types of information that should be logged (e.g., when tests were performed, deviations from test procedures, and any unusual events that may be of importance to understanding how a test was run or interpreting test results) and when it should be recorded.

Evaluation of Criterion (1)

The evaluation below is numbered to correspond to the bulleted criteria above.

1. Section 3.2 of the ISV Plan addresses crew assignment to scenarios. See the discussion of crew assignments in Section 4.6.1, "Coupling Crews and Scenario," Criterion 1 of this report above. This acceptably meets the subcriterion.

2. Section 5.2 of the ISV Plan addresses the requirements for crew briefing in general. The briefing will [ ]. Detailed information on crew briefings is included in the scenario descriptions for Scenarios 1, 2 and 12 in the ISV Scenario Plan. The information provided in these three detailed scenarios is complete and consistent with the high-level guidance in the ISV Plan. For example, the briefing for Scenario 2 is:

   [ ].

   This acceptably meets the subcriterion.

3. [ ]:

   - [ ]
   - [ ]
   - [ ]

   This acceptably meets the subcriterion.

4. Section 5.2.2, "Communications with ISV Personnel," of the ISV Plan describes the general approach for communicating with ISV crews. The Plan indicates that scripted responses will be used when test personnel act as plant personnel, such as a local operator. The Plan further states that "[ ]." These scripted responses are included in the ISV Scenario Plan. For example, for Scenario 1, the following instruction is provided:

   [ ].

   This acceptably meets the subcriterion.

5. Section 5.2.3, "Unforeseen Events," of the ISV Plan provides guidance on interacting with participants when unexpected difficulties arise. The guidance addresses events unrelated to the testing, such as fire drills, as well as related events, such as simulator anomalies. The plan outlines responsibilities for interacting with crews and guidance on resuming versus restarting trials. This acceptably meets the subcriterion.

6. Section 5.2.1, "General Procedures and Documentation," and Section 5.2.4, "Storage of Data," of the ISV Plan define the responsibilities and procedures for management of ISV

data. For example, the Plan identifies the ISV coordinator as the individual responsible for data management. With regard to simulator recorded data, the Plan indicates that "The discrete event data and plant parameter data from the simulator will be stored on a server and burnt onto discs. The file names for this data will identify the scenario number, the crew, and will be dated and time-stamped."

Further, the ISV Plan indicates that "At the end of each scenario, the ISV Coordinator will distribute and collect the completed post-trial questionnaires for the subjects, and at the end of the crews and observers participation in ISV, the ISV Coordinator will distribute and collect the final questionnaires for the subjects and observers. All of this information is hardcopy, and will be clearly marked and stored in a secure location."

This acceptably meets the subcriterion.

7. Section 5.2, "ISV Procedures," of the ISV Plan provides procedures for documenting all data collected during the ISV. The guidance in the ISV Plan addresses all forms of data, e.g., simulator logs and questionnaires. The procedures are sufficiently explicit to ensure data is not mishandled or lost (see examples in the evaluations above). This acceptably meets the subcriterion.

In summary, the ISV Plan provides detailed, clear, and objective procedures to govern the conduct of the ISV tests. This approach acceptably meets the staff's review criterion.

(2) Where possible, test procedures should minimize the opportunity of tester expectancy bias or participant response bias.

Evaluation of Criterion (2)

The ISV Plan indicates that observers will be independent of the project and that their assignment to trials will be systematically varied. The use of standardized and scripted responses should also help to minimize bias. This approach acceptably meets the staff's review criterion.

18.11.8.2.4.6.3 Test Personnel Training

(1) Test administration personnel should receive training on:

- the use and importance of test procedures
- experimenter bias and the types of errors that may be introduced into test data through the failure of test conductors to accurately follow test procedures or interact properly with participants
- the importance of accurately documenting problems that arise in the course of testing, even if due to test conductor oversight or error.

Evaluation of Criterion (1)

Section 4.3 of the ISV Plan addresses training of test personnel. It states that the training for the ISV staff will be sufficient to ensure effective execution of the test scenarios and data collection. This training will occur during the pilot testing of the simulator and ISV scenarios.

The training will be specific for the tasks to be performed during ISV. Test conductor roles will be rehearsed prior to ISV. The training will include how and when to communicate with the participants. Scripted responses will be provided for the operations support staff to perform specified roles as plant personnel in applicable scenarios (e.g., local operators). In addition, training will be given on the importance of the ISV procedures and the possible impact of not following the ISV procedures. This will help ensure consistency of the ISV staff performance and behavior across the scenarios. This approach acceptably meets the staff's review criterion.

18.11.8.2.4.6.4 Participant Training

(1) Participant training should be of high fidelity; i.e., highly similar to that which plant personnel will receive in an actual plant. The participants should be trained to provide reasonable assurance that their knowledge of plant design, plant operations, and use of the HSIs and procedures is representative of experienced plant personnel. Participants should not be trained specifically to perform the validation scenarios.

Evaluation of Criterion (1)

Sections 4.1 and 4.1.3 of the ISV Plan discuss participant training. Operations personnel from the customer utilities participating in the AP1000 training program will be used for ISV. Training will include both classroom and hands-on simulator components. The training will be developed and delivered by the Westinghouse Training Group.

The training program will provide personnel with detailed AP1000 systems and plant knowledge. The program will be presented using a combination of classroom instruction, self-study, procedure walk through, and exercises. Training will include [ ] of AP1000 systems training and [ ] of procedure/simulator based training. This will include EOPs, AOPs, and GOPs.

This approach acceptably meets the staff's review criterion.

(2) Participants should be trained to near asymptotic performance (i.e., stable, not significantly changing from trial to trial) and tested prior to conducting actual validation trials. Performance criteria should be similar to that which will be applied to actual plant personnel.

Evaluation of Criterion (2)

Sections 4.1 and 4.1.3 of the ISV Plan describe the training program for ISV participants. As discussed under Criterion (1), the program provides sufficient training such that the skill and knowledge levels of participants should not be significantly changing between trials. This approach acceptably meets the staff's review criterion.

18.11.8.2.4.6.5 Pilot Testing

(1) A pilot study should be conducted prior to conducting the integrated validation tests to provide an opportunity to assess the adequacy of the test design, performance measures, and data collection methods.

Evaluation of Criterion (1)

Section 3.3 of the ISV Plan indicates pilot testing will be performed to address these aspects of the test. The objectives of simulator pilot testing are to demonstrate that the simulator responds in a manner similar to the reference unit while utilizing the plant operating procedures, to ensure simulator readiness, and to minimize the likelihood of test failures or delays. The pilot testing will be carried out in [ ], as described in the ISV Scenario Plan, Appendix C. In addition to the testing of the simulator model, thorough pilot testing of all scenarios will be carried out. This approach acceptably meets the staff's review criterion.

(2) If possible, participants who will operate the integrated system in the validation tests should not be used in the pilot study. If the pilot study must be conducted using the validation test participants, then:

- the scenarios used for the pilot study should be different from those used in the validation tests; and

- care should be given to provide reasonable assurance that the participants do not become so familiar with the data collection process that it may result in response bias.

Evaluation of Criterion (2)

Section 3.3 of the ISV Plan states that the participants for ISV will not be involved in pilot testing. Rather, the pilot testing will be performed by the Westinghouse simulator development staff, with support as needed from other Westinghouse personnel. This acceptably addresses Criterion (2). This approach acceptably meets the staff's review criterion.

18.11.8.2.4.7 Data Analysis and Interpretation

(1) Validation test data should be analyzed through a combination of quantitative and qualitative methods. The relationship between observed performance data and the established performance criteria should be clearly established and justified based upon the analyses performed.

Evaluation of Criterion (1)

Section 7, "Processing of Results," of the ISV Plan [ ]. This approach acceptably meets the staff's review criterion.

(2) For performance measures used as pass/fail indicators, failed indicators must be resolved before the design can be validated. Where performance does not meet criteria for the other performance measures, the results should be evaluated using the HED evaluation process.

Evaluation of Criterion (2)

Section 7.3 of the ISV Plan indicates that each scenario is run [ ] times with [ ] different crews. If a scenario fails a P/F criterion an HED is defined and resolved. The scenario is then rerun a minimum of [ ] times with [ ]. With respect to diagnostic measures, observation of a small number of HEDs will result in a [ ] trial being run using a [ ]. This approach will help confirm whether an HED exists or not. The applicant indicated that, if the results of the [ ] trial confirm an issue, an HED will be identified and resolved. The scenario then will be re-run [ ] times using [ ]. This approach acceptably meets the staff's review criterion.

(3) The degree of convergent validity should be evaluated, i.e., the convergence or consistency of the measures of performance.

Evaluation of Criterion (3)

Section 7.2 of the ISV Plan indicates that the degree of convergence of measures will be assessed in the interpretation of the results. The Plan states:

> The degree to which convergent (i.e., consistent) results are observed from different measurement techniques will be [ ] and the results will presented in the ISV results report. The analysis will determine if the different measurement techniques indicate the same problems. If so, it strengthens the conclusion that a problem exists and it needs to be addressed. Likewise, if none of the measurement techniques indicates that there is a problem (i.e., different measurement techniques record successful performance), then it increases the degree of certainty that a problem does not exist.

This approach acceptably meets the staff's review criterion.

(4) The data analyses should be independently verified for correctness of analysis.

Evaluation of Criterion (4)

Section 7.2 of the ISV Plan indicates that independent verification of results will be performed using applicable Westinghouse quality assurance procedures provided in APP-GW-GAP-100, "Inter-Business Unit Edition Policies & Procedures." This approach acceptably meets the staff's review criterion.

(5) The inference from observed performance to estimated real-world performance should allow for margin of error; i.e., some allowance should be made to reflect the fact that actual performance may be slightly more variable than observed validation test performance.

Evaluation of Criterion (5)

Section 6.3.1, "Pass/Fail Criteria," of the ISV Plan indicates that for P/F criteria, each scenario specifies that [ ]. In order to ensure margin, there are also typically acceptance criteria relating to not exceeding the [ ].

Regarding the risk-important HAs, [ ]. Section 6.3.1 of the ISV Plan states that "In a number of cases in the PRA, the [ ]. Therefore, the [ ] to perform the risk-important human actions will be closely monitored. If a case occurs where the [ ] is potentially insufficient to ensure reliable operator performance, this will be identified as [ ]." The method of identifying and documenting the [ ] for performing the risk-important HAs is described in the ISV Scenario Plan, in the Scenario Specifications and in the Observer Guides for the scenarios.

RAI-SRP18-COLP46 requested more information on the mechanism for specifying and documenting the [ ] needed to accomplish the risk-important HAs in the ISV Scenarios. In its response, dated August 2, 2010, the applicant stated that the “[ ]. The HFE analyst will use [ ] in Section 6.2, “Methods,” of the ISV Plan to complete this calculation. This approach limits the potential of results being influenced by the observer’s judgment or the observer missing a task step, event or operator action. The [ ] provide an objective confirmation of the observation results.

This approach acceptably meets the staff’s review criterion.

18.11.8.2.4.8 Validation Conclusions

(1) The statistical and logical bases for determining that performance of the integrated system is and will be acceptable should be clearly documented.

Evaluation of Criterion (1)

Section 7.4 of the ISV Plan provides the commitment to document the basis for validation conclusions. The ISV Plan states “The basis for concluding that the AP1000 MCR, HSI resources, procedures, and operator training are adequate (or not) will be described (i.e., that the integrated system performed acceptably during testing and can be expected to support safe operation in actual use).” This approach acceptably meets the staff’s review criterion.

(2) Validation limitations should be considered in terms of identifying their possible effects on validation conclusions and impact on design implementation. These include:

- aspects of the tests that were not well controlled
- potential differences between the test situation and actual operations, such as absence of productivity-safety conflicts
- potential differences between the validated design and plant as built (if validation is directed to an actual plant under construction where such information is available or a new design using validation results of a predecessor).

Evaluation of Criterion (2)

Section 7.4 of the ISV Plan provides the commitment to document test limitations. This approach acceptably meets the staff’s review criterion.

18.11.8.3 Conclusion

The staff concludes that APP-OCS-GEH-320 and APP-OCS-GEH-321 provide implementation plans that conform to the NUREG-0711 criteria associated with ISV. The staff’s review of the AP1000 ISV Plan and the ISV Scenario Plan concludes that the plans are comprehensive and thorough and provide reasonable assurance that the ISV will effectively identify any operator challenges associated with the HSI design. Open Item OI-SRP18-COLP-03A was created to track the completion of these documents. Based on the preceding information, the staff concludes that this open item and the corresponding element of ITAAC Design Commitment 4 (DCD, Revision 15) are complete and closed.

The DCD changes provide detailed human factors design information that would otherwise have to be addressed through verification of the ITAAC. Therefore, the changes to the DCD eliminate the need for design acceptance criteria in accordance with the finality criteria in 10 CFR Part 52.63(a)(1)(iv).

18.11.9 Evaluation of Tier 1 Information—Design Commitment 4, ITAAC Table 3.2-1, Tier 1, Section 3.2 (DCD Revision 15), Part 4 of 5, Issue Resolution Verification

18.11.9.1 Summary of Technical Information

ITAAC Design Commitment 4 reads as follows:

> Design Commitment: An HFE program verification and validation implementation plan is develop[ed] in accordance with the programmatic level description of the AP1000 human factors verification and validation plan.
>
> Inspection, Test, and Analysis: An inspection of the HFE verification and validation implementation plan will be performed.
>
> Acceptance criteria (part 4): A report exists and concludes that the HFE verification and validation implementation plan was developed in accordance with the programmatic level description of the AP1000 human factors verification and validation plan and includes the …Issue Resolution Verification activity.

In DCD Revision 17, the applicant deleted this ITAAC based on completion of the work it described.

18.11.9.2 Evaluation

NUREG-0711, Section 11.4.4.2, Criterion 1, states the following:

> Discrepancies could be acceptable within the context of the fully integrated design. If sufficient justification exists, a deviation from the guidelines may not constitute an HED. The technical basis for such a determination could include an analysis of recent literature or current practices, tradeoff studies, or design engineering evaluations and data. The applicant should identify unjustified discrepancies as HEDs to be addressed by the HED resolution.

Evaluation of Criterion 1

Each of the three V&V implementation plans previously referenced (APP-OCS-GEH-120, APP-OCS-GEH-220, and APP-OCS-GEH-320) include sections directing that all discrepancies be documented on a discrepancy worksheet. The Operation and Control System product manager screens the worksheet. If the discrepancy can be directly justified, it is not considered an HED. Unjustified discrepancies are identified as HEDs, and the applicant must address them using the formal resolution process in APP-OCS-GEH-420. The staff concludes that procedures referenced in this section provide sufficient details to satisfactorily demonstrate implementation of this NUREG criterion for HED justification.

NUREG-0711, Section 11.4.4.2, Criterion 2, states the following:

The HED analysis should include the following:

- Plant system—The potential effects of all HEDs relevant to a single-plant system should be evaluated. The potential effects of these HEDs on plant safety and personnel performance should be determined, in part, by the safety significance of the plant system, their effect on the accident analyses summarized in the SAR, and their relationship to risk-significant sequences in the plant PRA.

- HED scope—The scope of the HED should consider the following:

  - Global features HEDs—These HEDs relate to configurational and environmental aspects of the design, such as lighting, ventilation, and traffic flow. They relate to general human performance issues.

  - Standardized features HEDs—These HEDs relate to design features that are governed by the applicant's design guidelines used across various controls and displays of the HSI (e.g., display screen organization and conventions for format, coding, and labeling). Because a single guideline may be used across many aspects of the design, a single HED could be applicable to many personnel tasks and plant systems.

  - Detailed features HEDs—These HEDs relate to design features that are not standardized, thus their generality has to be assessed.

  - Other—This subcategory specifically pertains to HEDs identified from integrated system validation that cannot be easily assigned to any of the three preceding categories.

- Individual HSI or procedure—HEDs should be analyzed with respect to individual HSIs and procedures. The potential effects of these HEDs on plant safety and personnel performance are determined, in part, by the safety significance of the plant system that is related to the particular component.

- Personnel function—HEDs should be analyzed with respect to individual personnel functions. The potential effects of these HEDs is determined, in part, by the importance of the personnel function to plant safety (e.g., consequences of failure) and the cumulative effect on personnel performance (e.g., degree of impairment and types of potential errors).

  The applicant should also analyze HEDs with respect to the cumulative effects of multiple HEDs on plant safety and personnel performance.

  In addition to addressing the specific HEDs, the analysis should treat the HEDs as indications of potentially broader problems.

Evaluation of Criterion 2

In APP-OCS-GEH-420, Section 2.2, the applicant stated that the [ ], which the OCS product manager approves. The assessment [ ]. This prioritization addresses the first bullet from the NUREG-0711 criterion above:

- Priority 1: [ ]
  - [ ].
  - [ ].
- Priority 2: [ ]:
  - [ ]
  - [ ]
  - [ ]
- Priority 3: All others

APP-OCS-GEH-420, Section 2.3, addresses the HED scope. In this section, the applicant stated that the cumulative effects of Priority 1 and 2 HEDs are analyzed by organizing HEDs into the following categories:

- [ ]
- [ ]
- [ ]
- [ ]
- [ ]
- [ ]

This last category identifies [ ], and others using the same definitions as the NUREG criterion. By separating the [ ]. This addresses the remaining parts of the NUREG-0711 criterion above.

APP-OCS-GEH-420, Section 2.5, states that an [ ]; an evaluation is performed to [ ]. The categorization described above is used to identify these generic implications.

The staff concludes that APP-OCS-GEH-420 provides sufficient details to satisfactorily demonstrate implementation of this NUREG criterion for HED analysis.

NUREG-0711, Section 11.4.4.2, Criterion 3, states the following:

> The applicant should use a systematic evaluation to identify HEDs for correction. Priority 1 HEDs are those with direct, indirect, or potential safety consequences. Priority 2 HEDs are those that do not have significant safety consequences, but do have potential consequences to plant performance/operability, nonsafety-related personnel performance/efficiency, or other factors affecting overall plant operability. The remaining HEDs are those that do not satisfy the criteria associated with the first and second priorities. Resolution of these HEDs

> is not an NRC safety concern but may be resolved at the discretion of the applicant.

Evaluation of Criterion 3

This criterion is addressed in the previous section.

NUREG-0711, Section 11.4.4.2, Criterion 4, states the following:

> The applicant should fully document each HED, including assessment category (priority for correction), associated plant system, associated personnel function, and associated HSI or procedure. The documentation should clearly show whether the HED was dismissed or identified as needing design modification, and the basis for this determination in terms of consequence to plant safety or operation should be clearly described.

Evaluation of Criterion 4

Section 2 of APP-OCS-GEH-420 includes documentation requirements. In summary, when the HFE engineer justifies an HED, he or she [ ]. When an HED is resolved by a design solution, a [ ] is used in conjunction with a [ ] to identify the best solution. Solutions will be consistent with the system requirements used to design the system. Design solutions follow the design process which documents the impact on safety.

The staff concludes that APP-OCS-GEH-420 provides sufficient details to satisfactorily demonstrate implementation of this NUREG criterion for HED evaluation documentation.

NUREG-0711, Section 11.4.4.2, Criterion 5, states the following:

> The applicant should identify design solutions to correct HEDs. The design solutions should be consistent with system and personnel requirements identified in the preparatory analysis (i.e., operating experience review, function and task analysis, and HSI characterization).

Evaluation of Criterion 5

APP-OCS-GEH-420, Section 2.6, states that the design solution will be consistent with the system requirements used to design the system. By comparing proposed changes to the HFE design to the original system requirements, the applicant will ensure the original design basis is maintained or adjusted as necessary.

The staff concludes that APP-OCS-GEH-420 provides sufficient details to satisfactorily demonstrate implementation of this NUREG criterion for development of HED design solutions.

NUREG-0711, Section 11.4.4.2, Criterion 6, states the following:

> The applicant should evaluate designs by repeating the appropriate V&V analyses. When the problems identified by an HED cannot be fully corrected, the applicant should provide appropriate justification.

Evaluation of Criterion 6

In APP-OCS-GEH-420, Section 2.8, the applicant stated that, for design solutions associated with the HFE design verification plan or HFE task support verification plan, independent verifiers will evaluate the HSI design changes using the same standards, guidance, and methodology as described in the applicable verification plan. For design solutions associated with the integrated system validation plan, the human factors team will determine the appropriate evaluation process, using a graded approach, based on the complexity and impact of the design changes. Independent verifiers will then perform the evaluation process.

The staff concludes that APP-OCS-GEH-420 provides sufficient details to satisfactorily demonstrate implementation of this NUREG criterion for design solution evaluation.

18.11.9.3 Conclusion

The staff concludes that APP-OCS-GEH-420 provides an implementation plan that satisfactorily addresses the NUREG-0711 criteria associated with tracking and resolving HEDs. This implementation plan provides reasonable assurance that issues will be identified during all stages of the design process and that these issues will be prioritized and resolved in an efficient manner. This element of ITAAC Design Commitment 4 (DCD Revision 15) as described above is complete and closed.

The DCD changes provide detailed human factors design information that would otherwise have to be addressed through verification of the ITAAC. Therefore, the changes to the DCD eliminate the need for design acceptance criteria in accordance with the finality criteria in 10 CFR Part 52.63(a)(1)(iv).

18.11.10 Evaluation of Tier 1 Information—Design Commitment 4, ITAAC Table 3.2-1, Tier 1, Section 3.2 (DCD Revision 15), Part 5 of 5, Plant HFE/HSI (as Designed at the Time of Plant Startup) Verification

18.11.10.1 Summary of Technical Information

ITAAC Design Commitment 4 reads as follows:

> Design Commitment: An HFE program verification and validation implementation plan is develop[ed] in accordance with the programmatic level description of the AP1000 human factors verification and validation plan.
>
> Inspection, Test, and Analysis: An inspection of the HFE verification and validation implementation plan will be performed.
>
> Acceptance criteria (part 5): A report exists and concludes that the HFE verification and validation implementation plan was developed in accordance with the programmatic level description of the AP1000 human factors verification and validation plan and includes the…. Plant HFE/HSI (as designed at the time of plant startup) Verification activity.

In DCD Revision 17, the applicant deleted this ITAAC based on completion of the work it described.

18.11.10.2 Evaluation

The applicant submitted APP-OCS-GEH-520 to address this part of ITAAC 4. Open Item OI-SRP18-COLP-4A was created to track completion of the staff's review of this document. The acceptance criteria for this implementation plan are found in NUREG-0711 Section 12, "Design Implementation." The staff evaluation of this plan is being provided in this section of the SER so that material applicable to ITAAC 4 closure is kept together.

NUREG-0711, Section 12.4.6, Criterion 1, states the following:

> Aspects of the design that were not addressed in V&V should be evaluated using an appropriate V&V method. Aspects of the design addressed by this criterion may include design characteristics such as new or modified displays for plant-specific design features and features that cannot be evaluated in a simulator such as Control Room lighting and noise.

Evaluation of Criterion 1

In APP-OCS-GEH-520, Section 1, the applicant states that specific aspects of the OCS. HSI design that cannot be evaluated in a simulator will be evaluated via a walk down of the applicable plant area after construction. This plan applies to all control areas included in the HFE scope including the MCR, the remote shutdown room, TSC, radioactive waste control, and LCSs. APP-OCS-GER 120 and APP-OCS-GER-220 document the results of the design and task analysis verification and are used as the basis for identifying design verifications that have not been completed. The procedure specifically identifies lighting, noise, ambient temperature and humidity, the closed circuit TV system, communication facilities, and maintainability as areas that will be evaluated. The applicant indicates that where appropriate physical measurements will be taken for key environmental features including lighting, thermal conditions, and acoustics.

The staff concludes that APP-OCS-GEH-520 provides sufficient details to satisfactorily demonstrate implementation of this NUREG criterion.

NUREG-0711, Section 12.4.6, Criterion 2, states the following:

> The final (as-built in the plant) HSIs, procedures, and training should be compared with the detailed design description to verify that they conform to the design that resulted from the HFE design process and V&V activities. Any identified discrepancies should be corrected or justified.

Evaluation of Criterion 2

In APP-OCS-GEH-520, the applicant states that the as-built HSIs will be verified to the same as those that resulted from the HFE program. A team is used to complete the verification. The team uses the expected design configuration and control information, including the style guide, detailed design descriptions, and guidance on evaluating maintainability, to compare the as-built design against. The adequacy of procedures and training are addressed as part of the staff's operating program inspections.

The staff concludes that APP-OCS-GEH-520 provides sufficient details to satisfactorily demonstrate implementation of this NUREG criterion.

NUREG-0711, Section 12.4.6, Criterion 3, states the following:

> All HFE-related issues documented in the issue tracking system should be verified as adequately addressed.

Evaluation of Criterion 3

In APP-OCS-GEH-520, the applicant states that all HEDs will be verified as being adequately addressed.

The staff concludes that APP-OCS-GEH-520 provides sufficient details to satisfactorily demonstrate implementation of this NUREG criterion.

18.11.10.3 Conclusion

The staff concludes that APP-OCS-GEH-520 provides an implementation plan that satisfactorily addresses the NUREG-0711 criteria associated with the as-built design verification. The scope and methods described provide reasonable assurance that the as-built HFE design configuration will mirror the design described in the DC. This element of ITAAC Design Commitment 4 (DCD Revision 15) as described above is complete and closed; therefore, Open Item OI-SRP18-COLP-04A is closed.

The DCD changes provide detailed human factors design information that would otherwise have to be addressed through verification of the ITAAC. Therefore, the changes to the DCD eliminate the need for design acceptance criteria in accordance with the finality criteria in 10 CFR Part 52.63(a)(1)(iv).

18.16 Tier 2* Information

The staff has determined that the following information referenced in DCD Tier 2, Chapter 18, Revision 17, must be designated as Tier 2* information in the AP1000 DCD. This information is in addition to the information identified as Tier 2* for Revision 15 of the DCD as documented in Section 18.16 of NUREG-1793.

1. APP-OCS-GEH-120, Revision B, “AP1000 Human Factors Engineering Design Verification Plan.” (This report explains the applicant’s method for design verification.)

2. APP-OCS-GEH-220, Revision B, “AP1000 Human Factors Engineering Task Support Verification Plan.” (This report explains the applicant’s method for task support verification.)

3. APP-OCS-GEH-320, Revision D, “AP1000 Human Factors Engineering Integrated System Validation Plan.” (This report explains the applicant’s method for performing the ISV.)

4. APP-OCS-GEH-420, Revision B, “Human Factors Engineering Discrepancy Resolution Process.” (This report explains the applicant’s method for resolving HEDs.)

5. APP-OCS-GEH-520, Revision B, “AP1000 Plant Startup HFE Design Verification Plan.” (This report explains the applicant’s method for verifying the as-built design.)

Based on guidance provided in the NUREG-0800 Section 14.3 and Branch Technical Position HICB-16 (Guidance on the level of detail required for design certification application under 10 CFR Part 52, "License, certifications, and approvals for nuclear power plants") the staff has concluded that all Tier 2* material associated with Chapter 18 will revert to Tier 2 after the plant first achieves full-power operation. This includes Tier 2* information identified in NUREG-1793. This is a change from how HFE-related Tier 2* material was addressed for the previously approved DCD Revision 15 where there was no expiration date. 10 CFR Part 52, Appendix D, "Design Certification Rule for the AP1000 Design," Sections VIII.B.6.b and VIII.B.6.c describe regulatory requirements associated with Tier 2* material and will be amended to reflect this change.

The additional documents were identified as Tier 2* because they describe the specific process the applicant will use to accomplish the final HFE design. The staff has verified that this process conforms to the regulatory guidance in NUREG-0737, which in turn supports the staff's conclusions that the HFE design provides reasonable assurance the Control Room staff can safely control plant operations via the HSIs. These documents also include acceptance criteria that will be used when inspecting the final HFE design conforms to Table 3.2-1 ITAAC.

The applicant responded to RAI-SRP18-COLP-23 R3, dated August 2, 2010, revising Tier 1 and Tier 2 of the DCD to reflect these additional Tier 2* references. In addition, the introduction of the DCD addresses Tier 2* references and specifies when the * designation expires in Table 1-1. The applicant responded to RAI-SRP18-COLP-54, dated August 18, 2010, revising the table to include the additional references listed above and to note all HFE Tier 2* references will expire when the COL holder first achieves 100 percent power operation. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

19. SEVERE ACCIDENTS

19.0 Background

In December 2005, the U.S. Nuclear Regulatory Commission (NRC) issued Supplement 1 to NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design." NUREG-1793 and its supplement documented the basis for certifying the AP1000 design. Subsequently, the agency has issued new or revised requirements and guidance for addressing severe accidents in the following documents:

Title 10 of the Code of Federal Regulations (10 CFR) Part 52

The Commission issued 10 CFR Part 52, ""Licenses, certifications, and approvals for nuclear power plants," on April 18, 1989. This rule provides for issuing early site permits, standard design certifications (DCs), and combined licenses (COLs) with conditions for nuclear power reactors. It details the review procedures and licensing requirements for applications for these new permits, certifications, and licenses. It is intended to achieve the early resolution of licensing issues, as well as to enhance the safety and reliability of nuclear power plants.

The NRC revised the rule on August 28, 2007. Specifically, 10 CFR 52.47, "Contents of applications; technical information," now requires an application for a DC to describe the design-specific probabilistic risk assessment (PRA) and its results. 10 CFR 52.79, "Contents of applications; technical information in final safety analysis report," now requires each COL applicant to describe the plant-specific PRA and its results.

Regulatory Guide 1.200

Regulatory guide (RG) 1.200, "An Approach for Determining the Technical Adequacy of Probabilistic Risk Assessment Results for Risk-Informed Activities,", was issued in February 2004, then revised in January 2007 and March 2009. It describes one acceptable approach for determining whether the quality of PRA provides sufficient confidence in the results to support regulatory decision making for light-water reactors. RG 1.200 endorses, with certain restrictions, a standard published by the American Society of Mechanical Engineers (ASME); ASME RA-S-2002, "Standard for Probabilistic Risk Assessment for Nuclear Power Plant Applications," including Addenda A and B. It also endorses Nuclear Energy Institute (NEI) 00-02, "Probabilistic Risk Assessment Peer Review Process Guidance."

Interim Staff Guidance

DC/COL-ISG-1, "Interim Staff Guidance on Seismic Issues of High Frequency Ground Motion in Design Certification and Combined License Applications," which clarified the implementation of a performance-based approach for determining site-specific ground motion and methodology for evaluating the effects of high frequency ground motion.

DC/COL-ISG-3, "Probabilistic Risk Assessment Information to Support Design Certification and Combined License Applications," clarifies the expectations of the staff with respect to the level of detail to be described and results to be reported in applications.

DC/COL-ISG-20, “Interim Staff Guidance on Implementation of a Seismic Margin Analysis for New Reactors Based on Probabilistic Risk Assessment,” provides more detail on the seismic margin analysis and identifies what to document at the time of application for a COL, and prior to operation.

19.1 Probabilistic Risk Assessment

19.1.1 Introduction

Westinghouse Electric Company, LLC (Westinghouse or the applicant) filed an application for an amendment to the AP1000 DC rule (10 CFR Part 52, Appendix D, “Design Certification Rule for the AP1000 Design”) and provided a revised design control document (DCD). Westinghouse had submitted a design-specific PRA of the AP1000 design as part of the AP1000 design documentation for the certified design. Westinghouse did not submit a revised PRA report with the amendment request; however, Westinghouse did describe, in a number of technical reports (TRs), the changes to the PRA that would result from the design modifications proposed in the amendment. The proposed changes to the DCD reflect these modifications.

The NRC’s regulations at 10 CFR Part 52 no longer require submittal of the PRA report. Instead, applicants are to provide, in the DCD, a description of the PRA and a summary of its results. The design-specific PRA is available for the staff’s review and still forms the basis for the site-specific, plant-specific PRAs that COL applicants must describe and COL licensees must upgrade and update before loading fuel.

Since certification of the AP1000 design, Westinghouse upgraded the PRA as part of a conversion from proprietary software to a widely used program, the Computer-Aided Fault-Tree Analysis System (CAFTA). The PRA was also updated to reflect proposed design changes. As part of the AP1000 DC amendment application, it reported all resulting changes to the insights, assumptions, and results of the analysis.

In addition to the revised DCD, the staff reviewed the following AP1000 COL standard TRs:

- Westinghouse Commercial Atomic Power (WCAP)-16555, APP-GW-GL-011, “AP1000 Identification of Critical Human Actions and Risk Important Tasks,” March 2006

- TR-6, APP-GW-GLR-021, “AP1000 As-built COL Information Items,” June 2006

- TR-34, APP-GW-GLN-016, “AP1000 Licensing Design Change Document for Generic Reactor Coolant Pump,” November 2006

- TR-36, APP-GW-GLR-016, “AP1000 Pressurizer Design,” May 2006

- TR-66, APP-GW-GLR-070, “Development of Severe Accident Management Guidance,” January 2007

- TR-88, APP-GW-GLR-065, “AP1000 Instrumentation & Control (I&C) Data Communication and Manual Control of Safety Systems and Components,” Revision 1, May 2009

- TR-97, APP-GW-GLN-022, Revision 1, “DAS [diverse actuation system] Platform Technology and Remote Indication Change,” May 2007

- TR-101, APP-GW-GLR-101, “AP1000 Probabilistic Risk Assessment Site-Specific Considerations,” Revision 1, October 2007

- TR-102, APP-GW-GLR-102, “AP1000 PRA Update Report,” Revision 1, November 2009

- TR-105, APP-GW-GLN-105, Revision 2, “Building and Structure Configuration, Layout and General Arrangement Design Updates,” October 2007

- TR-106, APP-GW-GLN-106, Revision 1, “Mechanical System and Component Design Update,” September 2007

- TR-130, APP-GW-GLR-130, “Editorial Format Changes Related to Combined License Applicant and Combined License Information Items,” June 2007

- TR-134, APP-GW-GLR-134, Revision 5, “AP1000 DCD Impacts to Support COLA Standardization,” June 2008

- TR-135, APP-PRA-GER-001, “AP1000 Design Change Proposal Review for PRA and Severe Accident Impact,” Revision 1, December 1, 2009

- TR-147, APP-GW-GLN-147, Revision 1, “AP1000 CR and IRWST Screen Design,” March 2008

This information is generic to the design and applies to all COL applications that reference the AP1000 DC.

19.1.1.1 Background and NRC Review Objectives

The general objectives of the NRC’s review of the most recent AP1000 DCD revision include the following:

- identification of new risk-informed safety insights based on systematic evaluations of risk associated with the amended design

- confirmation that regulatory treatment of nonsafety systems (RTNSS) remains appropriate

- confirmation that the DC requirements, such as inspection, tests, analyses, and acceptance criteria (ITAAC), design reliability assurance program (D-RAP), and technical specifications, as well as COL and interface requirements, are amended as appropriate

- confirmation that the conclusions reached in the previous certification remain valid

During the construction stage, the COL applicant will ensure that detailed design documents are consistent with the certified design so that the key assumptions and risk insights from the PRA remain valid. (These assumptions and insights are documented in DCD Table 19.59-18. The D-RAP ITAAC confirm this by ensuring that appropriate quality controls have been applied in the development of detailed design for procurement and construction.) The COL applicant will ensure, through other ITAAC and preoperational programs, that the configuration of the plant, as built, is consistent with the detailed design. The Commission believes that updated PRA insights, if properly evaluated and used, could strengthen programs and activities in areas such as training, development of emergency operating procedures (EOPs), reliability assurance, maintenance, and evaluations performed pursuant to 10 CFR 50.59, "Changes, tests and experiments." The design-specific PRA, developed as part of the DC process, should be revised to account for site-specific information, as-built (plant-specific) information refinements in the level of design detail, technical specifications, plant-specific EOPs, and design changes. The COL licensee is responsible for these updates. This is part of COL Information Item 19.59.10-2.

The NRC requires the COL applicant to develop a plant-specific PRA based on the design-specific PRA. At the time of application, the plant-specific PRA of internal events (both at power and shutdown) must address, at a minimum, proposed deviations from the certified design. The plant-specific PRA of external events must evaluate external events applicable to the proposed site and confirm that they are bounded by the PRA. This is also part of COL Information Item 19.59.10-2. The staff expects that the COL applicant and licensee will use the plant-specific PRA and revised failure rates (when available) to update, as appropriate, its reliability assurance programs (including the quality assurance program and the maintenance rule program).

19.1.1.2 Evaluation of Probabilistic Risk Assessment Quality and Closure of Open Issues

The NRC staff evaluated the information submitted by the applicant in accordance with NUREG-0800, "Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants." For Chapter 19, the staff used Section 19.0, "Probabilistic Risk Assessment and Severe Accident Evaluation for New Reactors," and Section 19.1, "Determining the Technical Adequacy of Probabilistic Risk Assessment Results for Risk-Informed Activities."

In TR-102, the applicant described conversion of the PRA modeling software package from its proprietary program, WesSAGE, to the more widely used program, CAFTA. The applicant also updated the AP1000 PRA to include the most recent instrumentation and controls (I&C) design information. The applicant documented the basis for its determination that structures, systems, and components (SSCs) modeled in the PRA were not affected by other design changes in a manner that affected the PRA.

In its original review of the AP1000 PRA, the staff relied on the similarity between the AP600 and AP1000 certified designs to reduce the review effort. This similarity (e.g., in system design and overall plant layout) allowed the use of the AP600 PRA as the starting point in the development of the AP1000 PRA. Similarly, the PRA associated with the currently certified AP1000 design was the starting point for upgrading and updating the AP1000 PRA in support of the DC amendment. In addition to reviewing the description of changes to the PRA, the staff reviewed the description of the new I&C design, specifically the plant control system (PLS) and the protection and safety monitoring system (PMS).

The staff used reported PRA results, as well as the results of sensitivity, uncertainty, and importance analyses, to focus its review. The staff also used applicable insights from previous PRA studies regarding key parameters and design features.

The review of the quality and completeness of the AP1000 PRA included the issuance of several requests for additional information (RAIs) to the applicant related to TR-102. Following its review of the responses to the RAIs, in August 2007, the staff conducted an audit at the applicant's offices, focusing on three principal areas:

1. assessment of the applicant's process to upgrade the PRA model, including the process by which they assessed the design and operational changes for potential impact on the PRA

2. review of the changes to the model since the applicant submitted the previous PRA report, especially those resulting from proposed changes to the certified design

3. inspection of the model itself to confirm that the model accurately reflected modifications to the design and that the model is a suitable basis for PRAs required of COL applicants that reference the AP1000 DC

In the process, the staff reviewed the qualifications of personnel involved in PRA-related activities and found them to be acceptable. The staff also examined the procedures the applicant used to review modifications for their potential impact on the PRA, to identify and correct problems in the model, to implement changes to the model, and to assess the results of analysis. During this review, the staff developed further requests for additional information based on NUREG-0800 Chapter 19, discussed below.

Section 19.1.10 of this report provides a summary and the resolution of open items. These are issues resulting from the review of Chapter 19 that had not been resolved when the draft of this report was prepared for review by the Advisory Committee on Reactor Safeguards.

19.1.2 Special Advanced Design Features

19.1.2.1 Special Advanced Design Features for Preventing Core Damage

The applicant proposed changes to the certified AP1000 design that have the potential to affect the PRA. The following sections discuss these changes.

19.1.2.1.2 Defense-In-Depth Active Nonsafety-Related Systems

The AP1000 design incorporates several active systems that are capable of performing some of the same functions as those performed by the safety-related passive systems. The availability of such redundant systems minimizes the challenge to the safety-related passive systems by providing core cooling during normal plant shutdowns and serving as a first line of defense during accidents.

The diverse actuation system (DAS) provides an alternate means for initiating automatic and manual reactor trip and actuation of selected engineered safety features that is diverse from the safety-related PMS. An additional DAS squib valve control cabinet, spatially separated from the DAS cabinet in the control room, provides additional confidence that operators can take manual actions to depressurize the reactor coolant system (RCS) and initiate key functions, such as in-containment refueling water storage tank (IRWST) injection, containment recirculation, and IRWST drain to containment. In DCD Table 19.59-18, the applicant clarified the degree of diversity between the PMS and the DAS. Section 7.7 of this report includes the staff evaluation of this modification. In RAI-SRP19.0-SPLA-06, the staff requested information on the potential of this modification to affect the timing of steps taken to mitigate an anticipated transient without scram (ATWS) event (positively or negatively) and to reduce risk by providing a spatially diverse actuation station.

In a letter dated August 21, 2008, the applicant responded that the addition of the remote DAS cabinet would not result in a significant change to the risk importance of any SSC or human action. The probability of using this remote cabinet is very low, as it would require several very unlikely events to occur. An example of such a situation would be the need to use manual controls coupled with the need to evacuate the control room and the failure or unavailability of the remote PMS panels. It is very likely that a fire or event that would make the control room and the remote PMS panel unavailable for manual operation would also result in a successful automatic shutdown of the AP1000. In addition, human reliability analyses (HRAs) for the DAS use values that represent low probability of success, high-stress situations. This supports the conclusion that the modification would not result in a significant change to the risk importance of any SSC or human action. For that reason, the AP1000 PRA does not model the use of this remote panel separately from use of the one in the control room.

The staff noted that the PRA models manual action as a single basic event irrespective of the location from which that action is taken. Furthermore, the proposed modification reduces uncertainty in the performance of the action. Because the need to use the remote DAS cabinet requires multiple, simultaneous, and highly unlikely events, the risk importance of SSCs or human actions would not be significantly altered by additional detail in the model. For these reasons, the staff concludes that the applicant's decision not to alter the modeling of this system is conservative and acceptable. The staff considers RAI-SRP19.0-SPLA-06 resolved.

19.1.2.1.7 Redundant Long-Term Recirculation Systems

RCS recirculation is required for long-term core cooling during loss-of-coolant accidents (LOCAs) and whenever the feed-and-bleed method is used to cool the core during an accident. In the AP1000, recirculation can be achieved either by gravity (through the safety-related IRWST injection lines) or pumping (through the nonsafety-related normal residual heat removal system (RNS)) with suction from the containment sump. Two redundant recirculation lines exist (one for each of the two redundant IRWST injection lines). Furthermore, each recirculation line has two paths that are redundant, with the exception of the recirculation screens. Though there are two separate screens, the applicant does not characterize them as redundant and explicitly models their common-cause failures (CCFs). Section 6.2.1.8 of this report documents the staff's evaluation of the screen design.

In RAI-SRP19.0-SPLA-04, the staff asked the applicant to discuss the impact of changes to the design of the recirculation system on the results and insights of the shutdown risk assessment.

In a letter dated July 22, 2008, the applicant stated that the structural integrity of the new recirculation screen configuration exceeds that of the screen-like material typically used in current pressurized-water reactor (PWR) sump screens, precluding the need for trash racks. Screen testing demonstrated that the new screens will not experience a significant head loss while operating within design-basis flow/debris conditions. A qualitative assessment concluded that the enhancement will reduce failure probability, while the increased flow area will improve accident response.

The staff finds it reasonable to expect that the proposed modification will improve performance of the recirculation screens as compared to the certified design. Although the large, interconnected screens are not independent, the staff finds that the applicant adequately addressed CCF of the screens. For these reasons, the staff concludes that the applicant's decision not to alter the modeling of this system is conservative and acceptable. The staff considers RAI-SRP19.0-SPLA-04 resolved.

19.1.2.1.9 Canned Reactor Coolant Pumps

The AP1000 design originally specified canned reactor coolant pumps (RCPs). In TR-34, the applicant specified sealless RCPs, which may be canned-motor or wet-winding pumps. For both canned-motor and wet-winding pumps, the motor and all rotating components are inside a pressure vessel. The pressure vessel consists of the pump casing, thermal barrier, stator shell, and stator cap, all of which are designed for full RCS pressure. Because the rotor and shaft connecting it to the impeller are contained within the pressure boundary, a seal is not required to restrict leakage out of the pump into containment. In addition, the heat exchanger that cools the RCP has been modified; it is now external to the pump. The applicant asserts that these changes do not alter the PRA model.

Section 5.4 of this report discusses the staff's evaluation of changes to the RCP design. The pump design is important because the use of sealless RCPs in the AP1000 design eliminates the RCP seal LOCA (an important contributor to risk for most operating commercial PWRs). In addition, water is used to lubricate and remove heat from pump bearings, eliminating the need for RCP lubricating oil systems and the attendant fire hazard. Because the proposed design alternative of a wet-winding rotor changes neither the failure modes of the RCP and its heat exchanger nor the estimated reliability of these components, the staff concludes that no change to the internal events PRA model is required. However, this change had an impact on the seismic margin analysis. The staff's evaluation of this issue is addressed in Section 19.1.5.1, "Probabilistic-Risk-Assessment–Based Seismic Margin Analysis."

19.1.2.1.10 Improved Control Room Design and Digital Instrumentation and Control Systems

The AP1000 control room is an advanced design that is expected to provide information that is presented to the operator in a way that is more easily used than the displays in currently operating reactor designs. Similarly, control is expected to be easy and consistent, and nearly all actions can be performed from a single station. Section 7.1.4 of this report documents the staff's review of the AP1000 control room design.

The PRA took no credit for the impact of the advanced control room on normal operations and emergency response (e.g., initiating event frequency or HRA). Because the impact of an advanced control room is still the subject of research and control room design verification and validation cannot be performed until a control room is simulated, the staff concludes that this approach is conservative and acceptable for the DC.

During the August 2007 audit of the applicant's PRA, the staff identified a discrepancy in the CCF probability of PMS component interface modules for the recirculation squib valve (V-118). The applicant immediately initiated corrective action. In RAI-SRP19.0-SPLA-07, the staff requested correction of the discrepancy and an updated report of PRA results. Specifics requested included: (1) the results of re-solving and re-quantifying the baseline and RTNSS full-power PRA, the shutdown PRA, and the external events PRA; (2) new risk insights identified during requantification of the previously mentioned PRAs; and (3) the results of the revised importance analysis.

In a letter dated August 21, 2008, the applicant reported that, in addition to correcting the discrepancy, analysts identified measures to improve the realism of the PRA for I&C systems. Specifically, the analyses found the values selected for PMS and PLS component common-cause beta factors to be overly conservative. The applicant has revised the model to reflect component-specific common-cause beta factors for PMS and PLS system components modeled in the PRA.

In the same letter, the applicant committed to revising TR-102 to reflect: (1) the results of re-solving and re-quantifying the baseline and RTNSS full-power PRA, the shutdown PRA, and the external events PRA; (2) any new risk insights identified during requantification of the previously mentioned PRAs; and (3) the results of the revised importance analyses. The applicant also reported that “requantification of the at-power PRA indicate[s] that the core damage frequency (CDF) and large release frequency (LRF) values and top cutsets closely compare with these items documented in the [previously submitted Level 1 internal events] PRA….”

In a letter dated November 6, 2008, the applicant reported some results of model correction and requantification. (The software used for this process automatically re-solves the model each time the model is requantified.) The letter reported only those results of the PRA that were point estimates of CDF and LRF (total, at power, shutdown, and sensitivity to nonsafety SSCs). The applicant reported no other changes in risk insights or importance analysis. The staff noted several changes that met the criteria of DC/COL-ISG-3 during the October 2009 onsite audit of the PRA. For example, the applicant had not reported a shutdown PRA sequence of significance. In another case, design improvements had eliminated a risk-significant component. Because these and similar changes were not reflected, the staff did not find this letter to be fully responsive. The staff identified the absence of some corrected results in the DCD as Open Item OI-SRP19.0-SPLA-07.

In a letter dated December 17, 2009, the applicant proposed revisions to the DCD. The staff’s evaluation of these proposed revisions and resolution of the open item is documented in Section 19.1.4.1, “Level 1 Shutdown Internal Events Probabilistic Risk Assessment.”

19.1.2.1.11 Large Pressurizer and Low-Power Density

The AP1000 pressurizer is large in comparison to the pressurizer of currently operating plants. This reduces the frequency of reactor scrams by increasing transient operation margins. This feature also moderates the pressure rise during certain transient events, such as loss of main feedwater, thus reducing the likelihood of a challenge to the primary safety valves. A larger pressurizer volume, as compared to currently operating plants, also helps lower the peak pressure that can be reached after a postulated ATWS event.

The applicant found it necessary to alter the design of the pressurizer. TR-36 details this change. Section 5.4.5 of this report documents the staff’s evaluation of this design change. The applicant did not propose a change to the PRA because of this modification.

Because the applicant analyzed the proposed design changes to the pressurizer and found that they do not alter system-level thermal-hydraulic response or success criteria, the staff concludes that no change to the internal events PRA model is necessary. However, this change had an impact on the seismic margin analysis. The staff's evaluation of this issue is addressed in Section 19.1.5.1, "Probabilistic-Risk-Assessment–Based Seismic Margin Analysis."

19.1.2.2 Special Advanced Design Features for Core Damage Consequence Mitigation

The following design features improve the ability of the containment to accommodate the challenges associated with severe core damage accidents. The AP1000 PRA and supporting deterministic analyses model the impact of these features on severe accident mitigation and containment performance.

19.1.2.2.4 External Reactor Vessel Cooling

To accommodate the higher decay heat level in the AP1000, Westinghouse needed to refine the AP600 reactor vessel insulation system (RVIS). The design was modified to increase the critical heat flux (CHF) at the surface of the reactor pressure vessel (RPV), enhancing the heat transfer through the RPV to the surrounding water. TR-24, APP-GW-GLR-060, "Reactor Vessel Insulation System - Verification of In-Vessel Retention Design Bases," February 2007, addresses COL Information Item 5.3-5 by verifying that reactor vessel insulation is consistent with the design bases established for in-vessel retention of a damaged core. COL Information Item 5.3-4 requires a structural analysis of the AP1000 reactor vessel insulation and support structure. TR-24 reports relevant results of that analysis.

The effectiveness of external reactor vessel cooling in the AP1000 design depends, in part, on a RVIS that provides an engineered pathway for supplying water cooling to the vessel exterior and venting steam from the reactor cavity during severe accidents. It is designed to limit thermal losses during normal operations. Section 5.3 of this report documents this design, which is discussed in Section 19.1.8.24 and evaluated in Section 19.2.3.3.1.3.2.

In RAI-TR24-SPLA-06, the staff noted that some paints and coatings used to protect the reactor vessel during shipping could have detrimental effects on CHF performance. In TR-106, the applicant stated that the external surface of the reactor vessel is bare metal. AP1000 DCD Section 5.3.4.5 now reflects the fact that a temporary protective coating applied before shipment will protect carbon steel surfaces. In DCD Section 19.34.2.1, the applicant stated that the vessel will have no coatings on the outside surface of the reactor vessel. This ensures that wetability of the surface will not be inhibited and CHF performance will not be degraded; the staff finds this acceptable. The COL licensee must remove these temporary coatings. The staff requested additional basis for confidence that this will be accomplished.

In a letter dated April 14, 2009, the applicant clarified the nature of the protective covering, which is to be an industrial form of shrink wrap that will be removed in the receiving process. The staff agrees that no additional controls are required; the statement in DCD Section 19.34.2.1 is sufficient and RAI-TR24-SPLA-06 is resolved.

19.1.2.3 Residual Risk from Changes Not Explicitly Modeled

The applicant reviewed all design changes for their potential to affect risk. TR-135 documented the process used for this review as well as the results of that process. The staff noted that, if a design change proposal (DCP) dealt with an SSC modeled in the PRA, the applicant evaluated its potential to affect the PRA results. However, the applicant did not necessarily evaluate other changes that may have an impact (e.g., changes to assumptions or PRA insights, as well as changes to model logic or changes that may alter probabilistic parameter estimates).

For example, a new or revised operating procedure might alter, for some modes, the alignment of an SSC in a manner that is inconsistent with documented insights or assumptions. The equipment would then require realignment to prevent or mitigate the consequences of an event applicable to the mode in question. It may be appropriate to model a different basic event (and supporting SSCs) in the PRA model for that mode. Alternatively, additional constraints or conditions to control risk may be appropriate before initiating the proposed procedure. The staff expects the applicant to perform such assessments, even if it will usually result in a determination that no explicit model change or procedural constraint is necessary.

In RAI-SRP19.0-SPLA-05, the staff identified the specific example of vacuum fill operation and asked the following:

> Please identify and briefly describe each DCP incorporated in the amended design and assess its potential to have such an impact on the PRA. For each DCP that may have an impact upon the PRA or other risk studies (e.g., seismic and internal fire) please evaluate and report its potential significance.

In a letter dated September 5, 2008, the applicant provided the results of its evaluation of the vacuum fill operation. In addition, the applicant reported that it made a change in the process used for future DCPs. The applicant reviewed each one for its impact on the PRA, with no initial screening for PRA-modeled SSCs. This effort included a documented review of the PRA assumptions and PRA insights affected, potential changes to model logic and probability data, the effect of operational changes on component modeling, and the impact on other risk studies (e.g., seismic and internal fire). The documentation of the review identifies and briefly describes every DCP and provides the rationale used to determine its impact on the plant risk and changes to the PRA or other risk studies (e.g., seismic and internal fire).

The staff concludes that the applicant performed an appropriate evaluation of the risk implications of vacuum fill operations and that the design change process will provide adequate assurance that the risk implications of all changes after Revision 17 of the DCD will be assessed. In a letter dated April 23, 2009, the applicant provided a schedule for re-evaluation (using the revised criteria) of all DCPs processed to date: changes reflected in Revision 17 of the DCD will be re-evaluated first and re-evaluation of all earlier changes will be documented prior to initial fuel loading. The results will be reflected in the plant-specific PRA as upgraded and updated prior to initial fuel load. The COL licensee is responsible for these updates as part of COL Information Item 19.59.10-2. The staff finds that this provides adequate assurance that the risk implications of all changes will be appropriately assessed and, if necessary, analyzed. This is an acceptable method for controlling residual risk from changes that are not explicitly modeled in the internal events PRA. The staff considers RAI-SRP19.0-SPLA-05 resolved.

19.1.3 Safety Insights from the Internal Events Risk Analysis (Operation at Power)

Safety insights from the internal events Level 1 PRA include the following:

- dominant accident sequences contributing to CDF

- areas in which certain AP1000 design passive and defense-in-depth features were the most effective in reducing risk as compared to currently operating reactor designs
- major contributors to the estimated CDF from internal events, such as hardware failures, system unavailabilities, and human errors
- major contributors to maintaining the built-in plant safety (to ensure that risk does not increase unacceptably)
- major contributors to the uncertainty associated with the estimated CDF
- sensitivity of the estimated CDF from internal events to: (1) potential biases in numerical values; (2) assumptions made; (3) lack of modeling details in certain areas; and (4) previously raised safety issues

Safety insights from the internal events Level 2 PRA include the following:

- core damage sequences and accident classes contributing to containment failure
- frequency and conditional probability of containment failure
- leading contributors to containment failure and risk

19.1.3.1 Level 1 Internal Events Probabilistic Risk Assessment

In TR-102, the applicant described the results of the PRA that it had upgraded and updated to conform to the amended design.

The staff conducted an audit of the PRA model upgrade and update. The staff reviewed the qualification of the PRA staff, procedures used for conversion, and processes for updating the PRA. In addition, the staff examined the PRA model itself with emphasis on new fault trees developed for I&C systems. Chapter 7 of this report documents the staff's review of I&C system design changes. The staff also reviewed the electrical system model changes for consistency with Revision 1 of TR-79. Chapter 8 of this report documents the staff's review of electrical system design changes.

The staff found that the development of the I&C model was consistent with the amended I&C design, as described in TR-39, APP-GW-GLN-004, "Instrumentation and Control Design Change," May 2006; WCAP-16675-NP, APP-GW-GLR-071, "AP1000 Protection and Safety Monitoring System Architecture Technical Report," Revision 2, May 2009; APP-GW-GLR-018, "Failure Modes and Effects Analysis and Software Hazards Analysis for AP1000 Protection System," June 2006; and TR-97, Revision 1. TR-80, APP-GW-GLR-080, "Mark-up of AP1000 Design Control Document Chapter 7," October 2007, documents the impact of these design changes on the DCD. Chapter 7 of this report documents the staff's review of the I&C design changes. (Many of the design changes had no impact on the PRA and, therefore, no impact on the severe accident analysis, as documented in TR-102 and TR-135.)

In a letter dated November 6, 2008, the applicant reported some results of the PRA model requantification. The applicant estimated the mean CDF for the AP1000 design from internal events during operation at power to be about 2.41×10^{-7} per year, unchanged from what the previous PRA reported. The applicant characterized this as equivalent, given appropriate treatment of uncertainties.

Although the applicant did not modify the initiating event frequencies in the model, the contribution of each initiating event to CDF changed slightly. The applicant reported that these changes were associated with the I&C model revision and updated electrical power dependencies. The applicant's assessment suggested that the changes were not of sufficient magnitude to alter the risk insights derived from the PRA results. For example, the top ten cutsets were identical, and the CDF attributable to failure of the most risk-significant system (the PMS) changed by only a small factor (i.e., it became about half as significant). Various LOCA initiating events continue to dominate the CDF profile (about 85 percent), followed by reactor vessel rupture (about 4 percent) and transient events (about 4 percent). Contributions from steam generator tube rupture (SGTR) events are slightly higher (about 4 percent), while ATWS sequences and loss of offsite power/station blackout events contribute even less than before (less than 1 percent).

Based on these results and the audit that provided confidence in the model upgrade and update process, the staff finds that the amended Level 1 internal events PRA at power did not change significantly. The staff finds that a plant-specific PRA report that is identical to the PRA for the certified design continues to provide an acceptable basis for risk insights and assumptions related to internal events.

However, changes to the design have altered some of the insights derived from the PRA (e.g., improving the design by eliminating a risk-significant SSC). As discussed in Section 19.1.2.1.10, in RAI-SRP19.0-SPLA-07, the staff requested the results of re-solving and requantifying the baseline and RTNSS full-power PRA, shutdown PRA, and external events PRA, as well as the results of the revised importance analyses. In a letter dated August 21, 2008, the applicant committed to re-solve and requantify the model after making some corrections. In a revised response dated November 6, 2008, the applicant altered this commitment, as discussed in Section 19.1.2.1.10, above, where it is identified as Open Item OI-SRP19.0-SPLA-07. Resolution of the open item is documented in Section 19.1.4.1 of this report.

19.1.3.2.3.3 Human Actions

In WCAP-16555, the applicant reviewed human actions with respect to risk achievement worth (RAW) and risk reduction worth (RRW). In addition, the applicant reviewed human actions required for maintenance, test, inspection, and surveillance (MTIS) support. The applicant stated that, on a deterministic basis, no human actions were required to mitigate any design-basis accident (DBA) or to prevent core damage following a DBA.

The applicant also identified 19 human actions as most significant from a probabilistic standpoint, though none of them came within an order of magnitude of the criteria previously accepted for a "critical" human action. The applicant added the following three human actions because an expert panel considered them to be significant:

1. Failure to recognize the need for and failure to isolate the RNS system, given rupture of the RNS piping when the plant is at hot/cold conditions (RHN-MAN04): The applicant added this action because of the short time available for the operator to act and the conflicting goals (maintaining core cooling by the RNS versus isolating a leak or break in the RNS piping).

2. Failure to recognize the need for and failure to actuate the hydrogen control system, given core damage following a LOCA (VLN-MAN01): The applicant added this action because its limiting RAW is relatively close to the criteria, and it is a function within the scope of RTNSS.

3. Failure to close equipment hatch and personnel airlocks following core damage during a shutdown event: The applicant added this action because human action importance could not be calculated for shutdown, internal events, or LRF. The expert panel considered that, under these conditions, the largest risk of large release would come from failure to close the containment. Closing the containment under these conditions involves closing the equipment hatch, personnel hatches, and temporary penetrations.

As noted by the staff, DCD Table 19.59-18 documents that it is important to maintain the ability to close containment hatches and penetrations during MODE 5 and MODE 6 before steam is released into the containment. There is a commitment for procedures and training to ensure that this action will be taken when required.

The staff found that the results were consistent with the methodology prescribed for the certified design and that the applicant conservatively identified risk-important human actions. For these reasons, the staff finds the results to be consistent with NUREG-0800 and, therefore, acceptable.

19.1.3.3.3 Important Insights from Level 3 PRA and Supporting Sensitivity Analyses

The applicant deleted the discussion of Level 3 PRA from Tier 2. The Level 3 PRA is now described only in the environmental assessment.

19.1.4 Safety Insights from the Internal Events Risk Analysis for Shutdown Operation

19.1.4.1 Level 1 Shutdown Internal Events Probabilistic Risk Assessment

The staff compared the results of the shutdown PRA, as seen in the current model, with the results reported in Revision 16 of the DCD (unchanged in Revision 17). Many of the results significantly differ from those reported in DCD Section 19.59.5.1, “Summary of Shutdown Level 1 Results.” For example, Section 19.59.5.1 discusses the dominant sequences and key contributors to risk. The staff compared this documentation to the top 15 cutsets and the top 20 component basic events ranked by RAW from the CAFTA results. Loss of component cooling (supplied by the service water system [SWS]) or service water (supplied by the circulating water system [CWS]) during drained conditions contributes at least 73 percent to the CDF, as seen in the CAFTA results, versus 64 percent as reported in the DCD. Loss of the RNS initiating event during drained conditions contributes at least 10 percent to the CDF as compared to 6 percent reported in the DCD. Inadvertent draining through valve V024 (IEV-LOCA24ND) contributes more to the CDF than the risk of RCS overdraining, as seen in the CAFTA results. However, the DCD does not report this event. Some of these changes appear to meet the importance criteria of DC/COL-ISG-3 and, therefore, should be documented.

In RAI-SRP19.0-SPLA-13, the staff asked the applicant to update DCD Table 19.59-15, "Summary of AP1000 Results," and to provide the following information:

1. a list of cutsets for the AP1000 shutdown PRA that contribute to 95 percent of total shutdown CDF and any that contribute as much as 1 percent of total shutdown CDF

2. a list of all SSCs in the shutdown PRA with their RAWs (if RAW greater than 2)

3. a list of all human actions modeled in the shutdown PRA with their RAW

4. a list of all CCFs in the shutdown PRA with their RAW (if RAW greater than 2) (or confirmation that all are described in WCAP-16555)

In a letter dated August 21, 2008, the applicant stated that the next revision of TR-102 would include the PRA model changes discussed in response to RAI-SRP19.0-SPLA-13. In a subsequent letter dated November 6, 2008, the applicant stated that it would revise TR-102 but proposed no changes to the DCD. The NRC staff identified this as the first part of Open Item OI-SRP19.0-SPLA-13.

The staff conducted an audit of the corrected and amended PRA model at the applicant's offices on October 13–15, 2009, as documented in an audit report dated November 22, 2009. The staff determined that identified deficiencies in the PRA model had been corrected. In a letter dated December 17, 2009, the applicant proposed revisions to the DCD to amend the description of shutdown PRA results. The staff finds that the proposed changes to the DCD are consistent with DC/COL-ISG-3 and, therefore, acceptable. Therefore, Open Item OI-SRP19.0-SPLA-07 (addressed in Section 19.1.2.1.10) and Open Item OI-SRP19.0-SPLA-13 are considered resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

19.1.4.2 Dominant Accident Sequences Leading to Core Damage

In RAI-SRP19.0-SPLA-13, the staff also asked the applicant to confirm that the list of major contributors to risk for each sequence that contributes more than 1 percent to the shutdown CDF remains consistent with the cutset results and to revise the DCD as necessary to describe all such sequences.

In the August 21, 2008 letter, the applicant stated that the next revision of TR-102 would include the PRA model changes discussed in this RAI-SRP19.0-SPLA-13 response. In a subsequent letter dated November 6, 2008, the applicant stated that it would revise TR-102 but proposed no changes to the DCD. The staff identified this as the second part of Open Item OI-SRP19.0-SPLA-13.

In a letter dated December 17, 2009, the applicant proposed revisions to the DCD. The staff's evaluation of these proposed revisions and resolution of Open Item OI-SRP19.0-SPLA-13 is documented in Section 19.1.4.1, above.

19.1.4.3 Risk-Important Design Features

The applicant now describes actuation of IRWST injection as the result of a fourth-stage automatic depressurization system (ADS) signal rather than a low hot-leg level signal. In the first part of RAI-SRP19.0-SPLA-04, the staff asked the applicant to clarify the impact of this modification on the shutdown risk assessment.

The applicant responded in a letter dated July 22, 2008, that it had modified the logic description in the DCD to represent more clearly how the system is intended to function during shutdown conditions.

Appendix 19E to DCD Revision 15 described the logic in the AP1000 as follows:

- actuation of IRWST injection on low (empty) hot-leg level on a two-out-of-two basis (RCS hot-leg level channel basis)

- actuation of fourth-stage ADS valves on low (empty) hot-leg level on a two-out-of-two basis (RCS hot-leg level channel basis)

The DCD provides the following revised description:

- actuation of fourth-stage ADS valves on low (empty) hot-leg level on a two-out-of-two basis (RCS hot-leg level channel basis)

- actuation of fourth-stage ADS causes actuation of IRWST injection

This logic configuration forms the basis for the PRA model and shutdown risk assessment. The change in wording for the logic for actuation of IRWST injection has no impact on the results and insights of the shutdown risk assessment.

The staff agrees that the clarification did not alter the functional response of the system and confirmed that the change in description did not affect shutdown PRA insights. The staff considers the first part of RAI-SRP19.0-SPLA-04 resolved.

COL Information Item 18.7-1 includes the following statement:

> Since inadvertent opening of RNS valve V024 results in a draindown of RCS inventory to the IRWST and requires gravity injection from the IRWST, the COL applicant will have administrative controls to ensure that inadvertent opening of this valve is unlikely. The control room design will take into account this error.

In RAI-SRP19.0-SPLA-09, the staff requested information on the features of the control room design that will ensure that inadvertent opening of valve V024 is unlikely.

In a letter dated August 21, 2008, the applicant responded that, during shutdown, electrical power to valve V024 is blocked (breakers open and manually locked out) when RNS is in operation. This prevents inadvertent operation when the RCS would be depressurized. (ADS valves are open during shutdown conditions in accordance with Technical Specification 3.4.13.)

A permissive signal (valves V001A/B and V002A/B are fully closed and valve V023 is open) is required to permit manual opening of this valve V024. DCD Figure 7.2-1 shows a corresponding interlock to open the RNS hot-leg suction isolation valves, which is prevented if the IRWST cross-connects to the RNS (valves V023 and V024) are not fully closed.

The staff finds this to be an acceptable method of ensuring that inadvertent opening of a valve V024 is unlikely. The staff considers this portion of COL Information Item 18.7-1 to be closed and RAI-SRP19.0-SPLA-09 resolved.

19.1.4.3.2 Loss-of-Coolant Accidents during Safe Shutdown or Cold Shutdown or Both with the Reactor Coolant System Intact

The applicant modified the containment recirculation design to provide large, interconnected screens without separate trash racks or coarse and fine screens. Section 6.2.1.8 of this report documents the staff's assessment of this change. In the second part of RAI-SRP19.0-SPLA-04, the staff asked the applicant to clarify the impact of this modification on the shutdown risk assessment.

The applicant, in a response dated July 22, 2008, stated that the DCD reflects the use of large, interconnected recirculation screens for recirculation flow. The passive core cooling system (PXS) has two banks of interconnected screens that filter recirculation flow. The staff evaluated these screens using the guidance in RG 1.82, Revision 3, "Water Sources for Long-Term Recirculation Cooling Following a Loss-of-Coolant Accident," November 2003. The screens are constructed of perforated stainless steel plate that is used to form pockets. Actions taken to close Generic Safety Issue 191, "Experimental Studies of Loss-of-Coolant-Accident-Generated Debris Accumulation and Head Loss with Emphasis on the Effects of Calcium Silicate Insulation," May 2005, and to respond to generic letter (GL) 2004-02, "Potential Impact of Debris Blockage on Emergency Recirculation during Design Basis Accidents at Pressurized-Water Reactors," dated September 13, 2004, resulted in more robust sump screen designs. As is the case with current operating plants, the structural integrity of the AP1000 screens precludes the need for trash racks. TR-147 also discusses the design of the AP1000 screens. Section 6.2.1.8 of this report documents the staff's evaluation of the screens.

The applicant judged the changes in the screen design to have no negative impact upon the PRA results; thus, the DCD PRA was not changed to reflect modifications to the screens. The applicant judged these changes to have a positive impact upon the PRA, with a lower failure probability of the screens resulting from the enhanced design and increased flow area. The DCD PRA did not credit this change in failure probability.

The staff confirmed that the PRA appropriately modeled the CCF of the screens, using a conservatively large beta factor. For the DC amendment, the modeling is conservative and, therefore, acceptable to the staff. The staff considers the second part of RAI-SRP19.0-SPLA-04 resolved.

19.1.4.3.6 Loss of the Normal Residual Heat Removal System (due to Loss-of-Coolant Accidents) or Loss of the Normal Residual Heat Removal System or Its Support Systems during Reactor Coolant System Open Conditions

When the RCS is open, the importance of the RNS is higher than at other times because safety-related heat removal paths may not be available. An external event (high winds) can have an impact on alternating current power sources required for RNS function because those sources (and their fuel) are not protected by safety-related structures. In addition, if the RNS becomes unavailable, the containment must be closed before boiling begins in the RCS.

In RAI-SRP19.0-SPLA-18, the staff asked the applicant to evaluate high winds while in MODE 5 and MODE 6 or to provide an acceptable basis for screening such events from consideration.

The associated risks should be quantified and possibly controlled. The NRC staff identified this as OI-SRP19.0-SPLA-18.

In a letter dated March 26, 2009, the applicant addressed high wind events occurring in MODE 5 and MODE 6. The applicant stated that emergency response requirements or emergency action levels will require that the RCS be taken out of mid-loop operation and prohibit entry when a potentially severe high wind event is anticipated. In addition, the response describes how core cooling is accomplished if diesel generators are not available.

The staff finds that the proposed measures are appropriate and sufficient to justify screening high wind events during MODE 5 and MODE 6 from further analysis. Controls on the implementation of emergency response requirements are an acceptable way to ensure that these measures will be implemented. The staff considers Open Item OI-SRP19.0-SPLA-18 to be closed.

19.1.5 Safety Insights from the External Events Risk Analysis

Three sections of the AP1000 DCD address PRA of external events consistent with DCD Section 1.9.5.2.14:

1. A risk-based seismic margin analysis (SMA), documented in DCD Section 19.55 and Appendix 19A, both titled “Seismic Margin Analysis,” addresses seismic events. Sections 19.1.5.1 of this report document the staff’s evaluation of the SMA.

2. APP-GW-GL-022, “AP1000 Probabilistic Risk Assessment,” of July 2004, Revision 8, Chapter 57, “Fire Risk Assessment,” documents analysis of the risk associated with internal fires. (The analysis is not discussed in this report because it has not changed since initial certification of the AP1000 design.)

3. DCD Section 19.58, “Winds, Floods, and Other External Events,” addresses remaining external events. Sections 19.1.5.4 through 19.1.5.7 of this report document the staff’s evaluation.

The objectives of the external events risk analysis provided in Section 19.58 of the AP1000 DCD are threefold:

1. Determine screening criteria and identify potential external events that may affect the AP1000 risk on a site-specific basis.

2. Provide generic risk analyses, based on bounding assumptions regarding site-specific parameters (e.g., frequency of each category of hurricanes) for relevant external events.

3. Provide guidance to COL applicants regarding the verification of the applicability of these generic analyses to a specific site.

The AP1000 DCD addresses those external initiating events or external hazards whose causes are external to the plant, other than seismic events. Based on the modified individual plant examinations of external events (IPEEE) guidelines, DCD Section 19.58 discusses the following external events or external hazards:

- high winds (including tornadoes)

- external floods
- external fires
- transportation and nearby facility accidents

The scope of this analysis does not include sabotage, which is consistent with the SRP and therefore acceptable to the staff. The information provided in DCD Section 19.58 is based primarily on the following:

- NRC guidance for the preparation and submittal of IPEEE for operating nuclear power plants

- the AP1000 DC PRA

- site-specific information related to external events for several proposed sites to build a nuclear plant referencing the AP1000 design

On June 28, 1991, the NRC issued Supplement 4 to GL 88-20, "Individual Plant Examination of External Events (IPEEE) for Severe Accident Vulnerabilities," requesting that each licensee conduct an IPEEE. NUREG-1407, "Procedural and Submittal Guidance for the Individual Plant Examination of External Events for Severe Accident Vulnerabilities," documents NRC guidelines for conducting IPEEE and on the structure and content of the IPEEE submittal. The staff examined these guidelines to verify their applicability to new reactor licensing and to investigate their completeness. The staff concludes that the IPEEE guidelines are applicable to the process of COL application after they are properly modified as follows:

- The IPEEE, performed by operating reactor licensees, takes into account plant-specific licensing information regarding external hazards that is not necessarily available to a COL applicant. For example, NUREG-1407 states, "[the] effects of external fires, other than loss of offsite power (LOSP), have been evaluated during the operating license (OL) review against sufficiently conservative criteria." Thus, the assumptions made in NUREG-1407 (e.g., in deriving the list of external events to be included in the IPEEE submittal) must be examined to determine whether a COL applicant must address events that were not included in the DCD.

- The baseline risks of the AP1000 design, as assessed in the DC PRA, are lower than the corresponding risks of an average operating plant. At operating reactors, the combined CDF for external events may be of the same magnitude as CDF for internal events. For this reason, the criteria for screening external events from the quantitative evaluation must be properly adjusted to maintain the conclusion reached in the DC—that the AP1000 design represents a reduction in risk compared to existing plants.

The applicant gathered site-specific external events information from utilities interested in the AP1000 design and performed a generic analysis for each external event, based on the most limiting parameters from any site. In TR-101, the applicant identified potential external events that may affect the AP1000 risk.

The staff finds that these external hazards are most likely a complete list of external events associated with candidate sites for an AP1000 plant as of the date of this report. The staff evaluated the analysis of the AP1000 response to external events according to the SRP, which states that the applicant's analyses should be "comprehensive in scope and address all applicable...external events and all plant operating modes." The staff requested additional information in RAI-TR101-SPLA-01 through RAI-TR101-SPLA-08 to clarify the report. In a letter dated October 19, 2007, the applicant responded. The staff requested additional clarification on RAI-TR101-SPLA-03 (external fires) and RAI-TR101-SPLA-06 (external flooding), which was provided in a letter dated February 8, 2008.

The applicant added consideration of external fires to the external events PRA and provided additional information on flooding caused by storm surge.

The methods used by the applicant to analyze external hazards, as documented in TR-101 and described in the DCD, are consistent with RG 1.200. Therefore, the external events analysis is acceptable to the staff given the input parameters used. There are two exceptions: the release of hazardous materials from nearby facilities and the treatment of high winds.

The analysis neither included an explicit discussion of the release of hazardous materials from nearby facilities (other than pipelines) nor identified this issue as a COL information item. The staff is concerned that some toxic materials are immediately dangerous to life and health at concentrations lower than the materials evaluated for pipelines, and some may not be readily detected. In RAI-SRP19.0-SPLA-17, the staff requested an assessment of risk from the release of toxic materials and a basis for a COL applicant to confirm that the assessment bounds the risk at the proposed site.

In a letter dated March 9, 2009, the applicant addressed the release of hazardous materials from nearby facilities and provided justification for screening of toxic releases from further analysis. The applicant stated that no operator action was credited, obviating the need to evaluate specific toxic release events with respect to type and amount of material released. The result of the analysis was a conditional core damage probability of 6.26×10^{-8}. From this, a limiting event frequency was provided for COL applicants to use to confirm that the generic analysis is applicable to their proposed sites. The applicant identified several conservatisms in this analysis. In addition to the assumption that operators were immediately and completely unable to perform any protective or mitigating actions, design features that assure control room habitability for 72 hours, under nearly all circumstances, were not credited.

In the same response, the applicant clarified the basis for using an initiating event frequency of 1×10^{-6} for the analysis of marine explosions. The applicant confirmed that screening of the event was based on a negligible contribution to core damage frequency so long as the criteria of RG 1.91, "Evaluations of Explosions Postulated To Occur on Transportation Routes Near Nuclear Power Plants," Revision 1 are met.

The staff agrees that there is considerable conservatism in the analysis of toxic gas release events that was described, and finds that it provides an acceptable basis for screening such events from further risk assessment. The limiting event frequency for toxic releases in the DCD provides an appropriate basis for COL applicants to confirm that this analysis bounds conditions where they propose to build a plant that references the AP1000 certified design. The staff considers the description of external events from transportation and nearby facility accidents to be complete and RAI-SRP19.0-SPLA-17 is resolved.

The applicant did not address the case of high winds while in MODE 5 and MODE 6. This scenario should be screened from consideration or the associated risks quantified and possibly controlled. The applicant addressed this concern in the March 26, 2009 response to RAI-SRP19.0-SPLA-18. The staff's evaluation is provided in Section 19.1.4.3.6 of this report.

The COL applicant must verify that the generic analysis for each external event bounds conditions at the proposed site. In a letter dated August 23, 2010, the applicant provided a COL information item to ensure that this action is taken by COL applicants.

DCD Section 2.2 requires a COL applicant to identify design changes in its safety analysis report if the occurrence of an external event that leads to severe consequences is 1×10^{-6} per year or greater. Accordingly, the COL applicant should assess the risk associated with any safety hazard that does not meet this criterion for being screened from further evaluation. In addition, the licensee must reevaluate the external event risk when a site-specific, plant-specific PRA is available.

The criteria for screening out external events from the quantitative evaluation are adjusted to maintain (for a plant referencing the AP1000 design) the conclusion reached in the DC—that the AP1000 design represents a reduction in risk compared to existing plants. The AP1000 DCD uses the following criteria with respect to risk evaluation of external events or hazards:

- An event or hazard with frequency less than 1×10^{-7} per year is screened from further evaluation.

- An event or hazard with frequency of 1×10^{-7} per year or higher is screened from further evaluation if a qualitative or bounding analysis shows that the associated CDF is less than 1×10^{-8} per year.

- An event or hazard with frequency of 1×10^{-7} per year or higher that cannot be shown to contribute less than 1×10^{-8} per year to CDF must be addressed in the risk analysis.

Each COL applicant must confirm that the high winds, floods, and other external events analysis documented in the DCD are applicable to the site for which the COL application is submitted (i.e., the spectrum of events at the site is bounded by the events analyzed in the DCD). Chapter 19 of the COL final safety analysis report (FSAR) should document this applicability evaluation. Further evaluation will be required if any unbounded, site-specific susceptibilities are found.

The NRC requires, where applicable to the site, that the COL applicant perform a site-specific, PRA-based analysis of external flooding, hurricanes, or other external events pertinent to the site to reveal any site-specific vulnerabilities. It is sufficient for the COL applicant to provide the basis for a conclusion that, for the proposed site, a particular external event is no more frequent and no more severe than that same event as modeled for the certified design. The COL licensee must develop plant-specific and site-specific risk information before loading fuel. This is part of COL Information Item 19.59.10-2.

In addition, the PRA used to support the AP1000 DC will be updated, as necessary, when site-specific and plant-specific (as-built) data become available. The COL applicant will review differences between the as-built plant and the design used as the basis for the AP1000 PRA to determine whether the PRA results are significantly impacted. Special emphasis should be placed on areas of the design that either were not part of the certified design or were not detailed in the certification. This is part of COL Information Item 19.59.10-2.

In RAI-SRP19.0-SPLA-02, the staff asked the applicant to clarify how SSCs are designed to withstand the effects of flooding. In its July 22, 2008, response letter, the applicant responded that the AP1000 is protected against floods up to the 30.5 meter (m) (100-foot (ft)) level. The 30.5 m (100-ft) level corresponds to the plant ground level. From this point, the ground is graded so that water will naturally flow away from the structures. Additionally, all seismic Category I SSCs below grade (below ground level) are designed to withstand hydrostatic pressures, and they are protected against flooding by a water barrier consisting of waterstops and a waterproofing system.

The staff finds that the design of safety-related SSCs below the 30.5 m (100-ft) level provides adequate protection from the effects of external flooding. Section 3.4 of this report discusses the staff's evaluation of internal flooding.

The COL applicant referencing the AP1000 certified design is responsible for: (1) confirming in the COL application that the information provided in Section 19.58 of the DCD is applicable to the selected site; and (2) addressing all site-specific action items discussed in Section 19.58 of the DCD.

The staff concluded that the methods used in the AP1000 PRA to evaluate external events provide the insights necessary to determine whether any design or procedural vulnerabilities exist for these external events. These methods provide insights needed for DC requirements, such as ITAAC. The staff finds that, for the events specified in the DCD, the reported results are acceptable. However, the case of high winds while in a shutdown mode had not been addressed. The staff identified this as Open Item OI-SRP19.0-SPLA-18. Subsequently, additional information was provided by the applicant; the staff's evaluation is documented in Section 19.1.4.3.2 of this report.

19.1.5.1 Probabilistic-Risk-Assessment–Based Seismic Margin Analysis

All seismic Category I SSCs are designed to remain functional when subjected to an earthquake, defined in 10 CFR Part 50, "Domestic licensing of production and utilization facilities," Appendix S, "Earthquake Engineering Criteria for Nuclear Power Plants" as the safe shutdown earthquake (SSE). 10 CFR 100.23, "Geologic and seismic siting criteria," also applies to site-specific seismic hazard. The seismic analysis and design of the AP1000 plant is based on the certified seismic design response spectra (CSDRS) shown in DCD Tier 1, Figures 1.0-1 and 1.0-2. The CSDRS are based on RG 1.60, "Design Response Spectra for Seismic Design of Nuclear Power Plants," with an enhanced spectral acceleration in the 25-hertz (Hz) region. Its peak ground acceleration (PGA) is 0.3 g, while its dominant energy content is in the frequency range of 2 to 10 Hz.

In the DC amendment, the applicant presented another set of seismic response spectra in DCD Tier 1, Figures 1.0-3 and 1.0-4. The results of the applicant's analyses for the new set of seismic response spectra are shown in TR-115, APP-GW-GLR-115, "Effect of High-Frequency Seismic Content on SSCs," Revision 1, October 2008. This is a seismic analysis of the AP1000 nuclear island using hard-rock, high-frequency (HRHF) spectra that bound three different site conditions in the central and eastern United States. In addition to the results of these linear-elastic analyses for the design basis load determination, the applicant conducted detailed foundation structure interaction analyses using an approved coherency function to account for the scattering effect of seismic input. The effect of incoherency in seismic input at different points on a large foundation slab tends to reduce response for SSCs with natural frequencies from 25 to 50 Hz. TR-115 also provides supplemental criteria for selection and testing of equipment whose function might be sensitive to high-frequency acceleration. Section 3.7 of this report discusses the staff's evaluation of the seismic design.

In SECY 93-087, “Policy, Technical, and Licensing Issues Pertaining to Evolutionary and Advanced Light-Water Reactor (ALWR) Designs,” Section II.N, “Site Specific Probabilistic Risk Assessments and Analysis of External Events,” the staff recommended a PRA-based seismic margin approach. At the plant level, high confidence in low probability of failure (HCLPF) should be established by ensuring that the seismic capacity of SSCs needed for safe shutdown is much larger than required for the design-basis earthquake. In a staff requirements memorandum dated July 21, 1993, the Commission modified that recommendation:

> PRA insights will be used to support a margins type assessment of seismic events. A PRA based seismic margins analysis will consider sequence level HCLPF [value]s and fragilities for all sequences leading to core damage or containment failures up to approximately one and two thirds the ground motion acceleration of the design-basis safe shutdown earthquake (SSE).

The applicant established a review-level earthquake (RLE) to demonstrate a one and two-thirds margin over the SSE, corresponding to the seismic design response spectra specified in DCD Tier 1, Figures 1.0-1, 1.0-2, 1.0-3 and 1.0-4.

For specific sites, the ground motion response spectra (GMRS) are obtained from site-specific, probabilistic seismic hazard–based analysis. Many of the GMRS of the central and eastern U.S. rock sites show response amplitudes that exceed the CSDRS for some frequency ranges. For this reason, an HRHF spectrum has been developed that bounds three hard-rock sites where AP1000 plants are proposed. DCD Figures 3I.1-1 and 3I.1-2 compare the HRHF at foundation level against the AP1000 CSDRS for both the horizontal and vertical directions for 5-percent damping. The HRHF spectrum exceeds the CSDRS for a range of frequencies above about 15 Hz. At high frequencies of vibratory excitation, the relative displacement is small and produces insignificant increase in stress. As an example, at 25 Hz and a spectral acceleration of 1.0g, the relative displacement is 0.016 inch. This is too small to cause damage.

In TR-115, the applicant evaluated representative SSCs that have been identified as “potentially sensitive to high-frequency input” in locations where the GMRS demonstrated an exceedance (magnitude greater than the CSDRS) in the high-frequency region.

In TR-144, APP-GW-GLN-144, “AP1000 Design Control Document High Frequency Seismic Tier 1 Changes,” Revision B, December 2007, the applicant stated that additional equipment dynamic qualification effort beyond the seismic design bases for operating nuclear power plants to address high-frequency response effects is not warranted. However, the applicant noted that the effect of high-frequency input on potentially sensitive active components requires additional consideration in accordance with interim staff guidance DC/COL-ISG-1.

In TR-144, the applicant concluded that, for structures, the HRHF loads would not govern the design. For the primary component supports and reactor coolant loop nozzles, seismic loads from the CSDRS bound those from the high-frequency input. Consequently, the staff considered these items to be acceptable seismic design for the HRHF input. For piping systems, the applicant concluded that the results of the HRHF seismic analysis are bounded by the stress results of the AP1000 CSDRS seismic analysis.

For safety-related electrical equipment, the applicant concluded that the qualification methodology (analytical evaluations and testing procedures) currently employed generally leads to a more conservative design than that resulting from the HRHF spectra. Supplemental seismic testing of high-frequency-sensitive safety-related equipment or implementation of one of the high-frequency screening techniques, approved in DC/COL-ISG-1, may be required to demonstrate acceptability under HRHF seismic demand conditions. Based on the acceptability of the seismic design and supplemental criteria for potentially susceptible equipment, the applicant stated that the conclusions of the PRA-based SMA are unchanged. In a recent update to seismic PRA based systems analysis, the applicant conducted a PRA sensitivity study ignoring the functions of all safety related electrical equipment; this study shows that the plant-level HCLPF value remains unchanged. This is primarily because of the passive design where key active components are designed to perform their safety functions when nonsafety-related support systems fail. This point is discussed further below.

Section 3.7 of this report discusses the staff evaluation of the seismic design. Subsequent to the application, the staff issued Interim Staff Guidance, DC/COL-ISG-20. This clarifies the staff's expectations for information to be included with an application for DC and the application for a license. It also identifies actions that the COL licensee must take to verify that the plant was built as designed.

For structures, primary component supports, and reactor coolant loop nozzles, as well as piping systems, the staff concludes that the applicant has demonstrated that, for the range of frequencies relevant to these SSCs, seismic loads are enveloped by CSDRS. This provides a sufficient basis for the staff to conclude that the seismic margins for these SSCs are acceptable.

In addition to the new parameters for the AP1000 generic site, the application for amendment to the certified design proposed a number of design changes that may affect the seismic capacity of equipment required to bring the plant to a safe, stable condition and to maintain containment integrity. Some proposed changes added seismic Category I SSCs to the design; others were deleted. These changes have the potential to affect the AP1000 SMA. Because of the changes, the staff requested an updated description of the results and insights of the AP1000 SMA.

Moreover, for safety-related equipment that is potentially sensitive to high-frequency excitation, the staff could not conclude that the applicant demonstrated adequate seismic margin, given the higher amplitude of high-frequency components of the GMRS. Although safety-related equipment that exhibits natural frequencies within the HRHF exceedance range will be subject to supplemental high-frequency seismic evaluation to confirm an acceptable seismic design, the applicant must clarify the basis for confirming that seismic margin is adequate.

The SMA for the certified design identifies HCLPF at the sequence level using a minimum-maximum[6] approach. Each COL applicant referencing the design should describe relevant site features and provide the basis for concluding that an acceptable seismic margin is maintained using this method or an alternative that is adequately justified. The staff identified these issues as Open Item OI-SRP19.0-SPLA-12.

In a letter dated August 23, 2010, the applicant provided a proposed revision to Section 19.55 of the DCD, "Seismic Margin Analysis," reporting the results of an updated, PRA-based SMA that

---

[6] In the minimum-maximum or "min/max" approach, in a sequence where the failure of any individual SSC would cause core damage, the lowest individual SSC HCLPF value is used to characterize the entire sequence. If there is a sequence where the failure of multiple SSCs must occur to result in core damage, the highest HCLPF value for any of those SSCs is used.

reflects the current site parameters for the standard design. In Section 19.59.10.5, "Combined License Information," new and revised COL information items were proposed. The staff finds that the proposed changes to the DCD are consistent with DC/COL-ISG-3 and DC/COL-ISG-20; therefore, Open Item OI-SRP19.0-SPLA-12 is resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

19.1.5.1.1 Dominant Accident Sequences for Seismic Events

The applicant's risk-informed SMA identified accident sequences for seismic events. For the SMA, the dominant sequences and associated cutsets are those that limit HCLPF values for the plant, irrespective of their likelihood. The margins approach does not support the determination that these are important contributors to seismic risk in a probabilistic sense, but allows identification of the plant features that are important to the plant level HCLPF value. The redundancy and diversity available in achieving that HCLPF value can also be confirmed.

The PRA-based SMA shows that the AP1000 design meets or exceeds the 0.5g HCLPF value. The applicant also performed a bounding analysis, using simplified and conservative assumptions, to identify paths by which the containment could be bypassed, fail to isolate, or fail. This analysis assumed that the reactor vessel fails because of failure of the fuel (HCLPF value 0.5g) and that the containment fails if the reactor vessel fails. Thus, the plant HCLPF for large release is the same as for core damage. This is an artifact of the applicant's conservative approach to SMA. For the AP1000, the conditional containment failure probability is nearly a full order of magnitude less than 1.0; LRF is much less than CDF. Because of design features to ensure in-vessel retention of the core, these are very conservative assumptions. Nevertheless, the AP1000 satisfies the expectation of the Commission as expressed in SECY-93-087 that the plant HCLPF value will be at least one and two-thirds times the SSE. Therefore, the staff concludes that seismic risk for the AP1000 design is acceptable.

COL applicants will confirm that site-specific features do not reduce the HCLPF value of a proposed plant. The capacity of as-built SSCs will be confirmed by a seismic walkdown to be performed after construction; the plant HCLPF value must remain at least as high as the value for the certified design.

The updated SMA was performed in a manner that was essentially identical to the SMA for the certified design. The capacity of those components required to bring the plant to a safe, stable condition was assessed. In some cases, for a particular SSC, a different method of calculating the seismic capacity of an SSC was selected from among several options that are acceptable to the staff.

In the risk-based SMA, no credit is taken for nonsafety-related systems. Because such systems are not seismic Category I, it is assumed that they become unavailable as a consequence of the seismic initiating event. The HCLPF value associated with transmission line ceramic insulators is low (0.09g), so all seismic events are assumed to entail loss of off-site power. Since the diesel generators are nonsafety-related and, therefore, assumed not to be available, all seismic accident sequences involve station blackout (loss of all alternating current (ac) power). The analysis investigated and accounted for the potential for adverse interactions between nonsafety-related SSCs (assumed to be damaged) and safety-related systems. The event and fault trees developed for the internal events PRA were modified to accommodate seismic events. In this way, the random failures and human errors modeled in the internal events portion of the PRA are captured in the seismic analysis.

The modified event and fault trees were merged and cutsets for all sequences that lead to core damage were generated. Most of the HCLPF values for components and structures were obtained through computing a conservative deterministic failure margin (CDFM), performing a probabilistic fragility analysis, or using deterministic methods. The HCLPF values for electrical equipment, where test results are documented, were obtained by comparing required response spectra to test response spectra for similar types of equipment.

19.1.5.1.2 Risk-important Features and Operator Actions for Seismic Events

The limiting SSCs for which seismically induced failure would lead directly to core damage include the pressurizer and the fuel in the reactor vessel (a HCLPF value of 0.5 g). This HCLPF value was also assumed for a large number of SSCs that may be sensitive to high frequency excitation. By design, even if these frequency-sensitive components are determined to have a lower seismic capacity, the plant HCLPF value would remain the same (0.5 g).

Updated HCLPF values for most structures indicate higher seismic capacity. An exception is the polar crane: due to a change in the design loading of the crane, it has become the limiting SSC for gross structural failure (0.55 g). Although parts of nonsafety-related structures have been upgraded to seismic Category II, the SMA did not take credit for these changes. The staff finds this to be conservative and therefore acceptable.

Operator actions are not credited in the SMA model for events that control the plant HCLPF value. The staff concludes that this is conservative, as the inclusion of operator actions in the models would only have the potential to increase the plant HCLPF.

19.1.5.1.3 Insights from Uncertainty, Importance, and Sensitivity Analyses for Seismic Events

Uncertainty analysis for seismic events is performed to quantify the range of values within which the results of an analysis could reasonably be expected to fall. Hazard curves, the result of a seismic hazards analysis, have a large uncertainty due to variability in source term and attenuation relationships. The large uncertainties in the hazard curves will dominate the resulting core damage frequency analysis, but uncertainties in equipment and structure fragilities are subject to much lower variability, since more and better information exist for them. This makes sensitivity analysis for SSCs less meaningful. Consequently, staff finds that performing a convolution of seismic hazard and fragility is not necessary for a generic plant design; consequently, a sensitivity analysis of plant HCLPF to SSC fragility is not meaningful. No additional uncertainty analysis was performed because uncertainty is directly addressed in the margins method. HCLPF values represent the seismic capacity (peak acceleration expressed in terms of the acceleration of gravity) at which there is 95 percent confidence that equipment needed for safe shutdown will fail less than 5 percent of the time. This provides margin to bound uncertainty while avoiding the extremes of the probability distributions.

Because the margins method does not quantify risk, importance analyses were not performed. The applicant did, however, perform an additional sensitivity analysis on the effects of changes in certain assumptions used in the SMA. The applicant chose to vary the HCLPF values for equipment that is to be seismically qualified by testing. When these values are varied from 0.5 g to 0.3 g, the HCLPF value is not changed for any sequence or event. Consequently, the plant HCLPF value was also unchanged.

The AP1000 SMA has shown that the plant HCLPF value is at least one and two-thirds the ground motion acceleration of the design-basis SSE. Because it limits the plant HCLPF value (0.50 g), the nuclear fuel is included within the scope of the reliability assurance program (RAP). The pressurizer, although its upper support weld was assigned the same HCLPF value in the SMA, was not included in the RAP because an alternative method of analysis shows it to have a significantly higher HCLPF value (0.56 g, based on the upper support strut). Because the SMA takes no credit for nonsafety-related systems to mitigate seismic events, the results of the SMA do not affect the probabilistic criteria used to select nonsafety-related SSCs for inclusion in the RAP. The staff concludes that the result of PRA-based SMA, as amended to include hard-rock and soil sites, meets the Commission expectation for adequate margin expressed in its staff requirements memorandum (SRM) to SECY-93-087.

19.1.5.4 High Winds Evaluation

High winds can affect plant structures in two ways: (1) structures can collapse or overturn from the excessive loading when wind forces exceed the load capacity of the structure; and (2) lifting and thrusting can cause materials to act as missiles against plant structures that house safety-related equipment. In addition, the applicant investigated the potential for debris generated by high winds to clog the passive containment cooling system (PCS) drains and directly or indirectly to block the PCS air baffle.

The AP1000 structures protecting safety-related features are designed to withstand winds of up to 483 kilometers per hour (km/h) per hour (300 miles per hour (mph)), as well as missiles generated by these winds (see design-basis wind speed discussed in Chapter 2 of the DCD). Also, the AP1000 operating basis wind speed is 233 km/h (145 mph), as discussed in Chapter 2 of the DCD. In general, there is some margin above the design and operating bases that the risk evaluation of high winds neither assesses nor credits. The applicant made the following assumptions in evaluating the risk from high winds:

- Safety-related structures, which house safety-related equipment, are not impacted by high winds of any kind (tornados and hurricanes, including extra-tropical cyclones) if the wind speed does not exceed 483 km/h (300 mph).
- Nonsafety-related structures, which are designed and built according to uniform building code and house nonsafety-related defense-in-depth or investment protection equipment, are not impacted by high winds of any kind (tornados and hurricanes, including extra-tropical cyclones) if the wind speed does not exceed 233 km/h (145 mph).
- High-wind events exceeding 483 km/h (300 mph) are extremely rare events with a frequency of less than $1{\times}10^{-7}$ per year; therefore, they are screened out from the risk analysis based on the screening criteria discussed in Section 19.1.5, above. The COL applicant referencing the AP1000 design must verify this assumption.

The applicant states in DCD Section 19.58.2.1 that no tornados or hurricanes are expected to reach 483 km/h (300 mph) winds per the enhanced Fujita scale for tornados and the Saffir-Simpson scale for hurricanes. Though the staff does not assign an upper wind speed limit to these scales, the conclusion is consistent with the staff's position documented in RG 1.76, "Design-Basis Tornado and Tornado Missiles for Nuclear Power Plants," Revision 1. For the continental United States, the staff considers the highest tornado wind speed with a frequency of $1{\times}10^{-7}$ to be 370 km/h (230 mph). AP1000 safety-related structures are designed to withstand winds of 483 km/h (300 mph). Clearly, the expected frequency of 483 km/h

(300 mph) tornadoes is significantly lower. For plants that are to be sited in the continental U.S., such events may be screened from further analysis.

Based on these assumptions, the applicant performed generic risk evaluations using initiating event frequencies that it described as "bounding." Six tornado event categories (defined in Table 19.58-1 of the DCD, which describes the enhanced Fujita scale for tornados) and five hurricane event categories (defined in Table 19.58-2 of the DCD, which describes the Saffir-Simpson scale for hurricanes) were evaluated. In addition, the applicant considered extra-tropical cyclones as a single category of high winds. Extra-tropical cyclones are normal storms and thunderstorms with winds expected to fall below the operating basis of 233 km/h (145 mph). The analysis assumed a bounding frequency of extra-tropical cyclones equal to 3×10^{-2} per year. COL applicants referencing the AP1000 design must verify that the frequency of each of the 12 high wind categories at the proposed site is bounded by the frequency assumed in Section 19.58 of the AP1000 DCD.

High winds cannot be screened out from the evaluation using the initiating event frequency criterion because the assumed frequency of high winds is greater than 1×10^{-7} per year. However, bounding risk assessments have shown that the CDF associated with high winds is less than the criterion of 1×10^{-8} per year. Therefore, the applicant did not perform detailed risk assessments for high winds. The applicant did perform risk assessments for three cases—a baseline case and two sensitivity cases:

- The baseline case assumes two kinds of failures: (1) an unrecoverable LOSP event for all 12 high wind categories since the site switchyard is unprotected; and (2) failure of all nonsafety-related structures for three categories of tornados (designated as EF3, EF4, and EF5 in Table 19.58-1 of the DCD) and three categories of hurricanes (designated as Category 3, 4, and 5 in Table 19.58-2 of the DCD), which exceed the operating basis of 233-km/h (145-mph) winds that could impact nonsafety-related structures. The applicant assumed that the failure of the nonsafety-related structures leads to the failure of all nonsafety-related systems credited in the AP1000 PRA with the exception of the manual DAS. The DAS manual actuation cables are located within the nuclear island and are, therefore, protected against high winds.

- The first sensitivity case assumes an unrecoverable LOSP event for all 12 high wind categories but no other failures. This sensitivity case removes the conservative assumption that all nonsafety-related structures fail when the operating basis of 233 km/h (145 mph) for high winds is exceeded, even though all structures are designed with some margin to withstand winds above the operating basis.

- The second sensitivity case assumes that all 12 high wind categories cause both an unrecoverable LOSP event and the failure of all nonsafety-related structures. This sensitivity case is a very conservative upper case since it assumes that all nonsafety-related structures fail even for categories of high winds that do not exceed the operating basis of 233 km/h (145 mph).

Table 19.58-3 of the AP1000 DCD summarizes the three risk assessment cases. The estimated CDF for the baseline case is about 5×10^{-9} per year, which is less than the criterion of 1×10^{-8} per year. Therefore, no detailed risk assessment of high winds is necessary. The CDF for the first and second sensitivity cases are about 2.3×10^{-9} and 1.4×10^{-8}, respectively. The first sensitivity case indicates that the estimated risk is not significantly sensitive to assumptions about the impact on nonsafety-related structures of high winds exceeding the operating basis.

The second sensitivity case indicates that the screening criterion of CDF less than 1×10^{-8} per year is almost met even under very conservative assumptions about the failure of nonsafety-related structures. The staff finds that the bounding risk assessments documented in Section 19.58 of the AP1000 DCD show that, under the stated assumptions for external events (which must be verified by the COL applicant), the risk from high winds (tornados and hurricanes) is so small that no detailed risk assessments for high winds are needed. In RAI-SRP19.0-SPLA-03, the staff requested the addition of COL information items to enumerate the assumptions to be verified. In a letter dated August 21, 2008, the applicant proposed to amend the DCD to state, "A site specific review of the generic PRA should be conducted to verify that the assumptions in the PRA bound the site specific conditions for the applicant's site." In a letter dated August 23, 2010, the applicant proposed a revision to Section 19.59.10.5, "Combined License Information," with a revised COL information item to make this explicit. The staff finds that the proposed change is consistent with RG 1.200 and acceptable; therefore, RAI-SRP19.0-SPLA-03 is resolved.

In addition to structural failures, the applicant investigated the potential for blockage or plugging of the PCS airflow path by debris generated by high winds. The applicant found that blockage or plugging of the PCS airflow path could occur by blockage of the screens, failure of the louvers, or blockage of the chimney outlet. However, because of the presence of certain design features and operational requirements, these failure mechanisms are highly unlikely (i.e., their frequency is smaller than 1×10^{-7} per year). For this reason, the PRA does not model them:

- Large openings are distributed around the circumference of the shield building, just underneath the roof. Screens and fixed, always-open louvers designed to prevent foreign objects or debris from entering the air flowpath cover these openings, providing an area through which air can flow into an enclosed plenum.

- Ducts made of pipe slant upward from this plenum through the shield wall. They supply air to a common plenum above the outer flow annulus inside the shield building.

- A walkway provides access for inspection of the flowpaths and removal of debris.

- There is a surveillance requirement to verify that the airflow path is unobstructed.

- The chimney outlet is designed to produce the necessary airflow in the event of an accident. The outlet contains heavy grates to guard against missiles. Screens prevent the entry of foreign objects into the annulus around containment. During normal operation, a positive airflow prevents ice and snow from entering the chimney.

In RAI-SRP19.0-SPLA-01, the staff requested that insights related to high winds and containment cooling be added to the DCD (RAI-SRP19.0-SPLA-01 also discussed external flooding as addressed in Section 19.1.5.5). In a letter dated July 22, 2008, the applicant proposed a revision to DCD Table 19.59-18, identifying these features and requirements among the PRA assumptions and insights. This is consistent with NUREG-0800 and is, therefore, acceptable to the staff.

In a letter dated March 4, 2008, the applicant responded to a request for information from the staff (RAI-TR142-SPCV-02 through RAI-TR142-SPCV-04). The applicant provided the results of an analysis demonstrating that most of the inlet area would have to be blocked before the PCS function is degraded. In addition, the applicant stated the following:

> There is a possibility that these [inlet] screens could become clogged with airborne debris. For this reason, there is access to the louvers and screens by an enclosed walkway between the wall containing the louvers and the shield building wall. Regular inspections of the louvers will be made and the screens will be kept free of debris. The frequency of inspections is expected to be once per month, and may change depending on the degree of blockage observed.

The staff finds that this commitment and the surveillance requirement (SR) provide assurance that significant air blockages will not exist before high winds or ice storms. Because of the very large degree of blockage that would be required to challenge containment cooling, the elevation of the openings, and the design of the airflow path, the staff considers the frequency of such an event to be negligible.

In DCD Revision 17, insights related to the protected location of DAS manual actuation cables and the assurance of adequate containment cooling air flow have been added to Table 19.59-18. The staff considers the portions of RAI-SRP19.0-SPLA-01 related to high winds to be resolved.

19.1.5.5 External Flooding Evaluation

The applicant assessed various scenarios with the potential to raise water levels and concluded that, even in combination, external flooding of safety-related SSCs (and certain risk-significant investment protection equipment) is prevented. For that reason, the effect of external flooding on risk-significant SSCs was not evaluated. Although storms, dam failure, and other external phenomena can cause flooding, the analysis assumed that the generic site was not subject to flooding by flash floods or failure of an upstream dam. COL applicants must show that this is also true for their proposed site. Otherwise, COL applicants must evaluate the other external events that can raise water levels at the site.

The risk evaluation of external floods is based on the following features from the design basis of the plant documented in Section 2 of the AP1000 DCD:

- The AP1000 is protected against floods up to the 30.5 m (100-ft) level, which corresponds to the plant ground level. From this point, the ground is graded so that water naturally flows away from the plant structures.

- The plant is designed such that the 30.5 m (100-ft) level is slightly above grade and the level of anticipated external flooding. Below grade is protected against flooding by a water barrier consisting of waterstops and a waterproofing system. Seismic Category I SSCs below grade are designed to withstand hydrostatic pressures.

- The seismic Category I SSCs below grade (below ground level) are protected against flooding by a water barrier consisting of waterstops and a waterproofing system.

In RAI-SRP19.0-SPLA-01, the staff also requested that these insights related to external flooding be added to the DCD (RAI-SRP19.0-SPLA-01 also discussed high winds cooling, addressed in Section 19.1.5.4).

In a letter dated July 22, 2008, the applicant proposed a revision to DCD Table 19.59-18 identifying these features and requirements among the PRA assumptions and insights. This is consistent with NUREG-0800 and is, therefore, acceptable to the staff. In DCD Revision 17, insights related to external flooding have been added to Table 19.59-18. The staff considers the portions of RAI-SRP19.0-SPLA-01 related to external flooding to be resolved.

The risk evaluation of external floods is highly specific to the proposed plant site. A detailed risk analysis of external floods requires information not only on potential sources of water but also on local configurations such as dikes, surface grading, locations of structures, and location of equipment within the structures. However, bounding assumptions about candidate sites are used to show that external floods can be screened from detailed risk evaluation. Assuming that the ground is graded away from the structures and there is no site susceptibility to dam failure or flash flooding, the remaining source of external flooding is storm surges capable of reaching the plant ground level. Hurricanes can produce the highest storm surges. The applicant performed a screening risk evaluation using as a reference the site most susceptible to external floods from hurricane surge water among potential candidate sites for an AP1000 plant. This site is located at an elevation of 13.7 m (45 ft) above sea level and in an area where the highest storm surges due to hurricanes have occurred. All other proposed sites are located at higher elevations above sea level. Therefore, it would require a 13.7 m (45-ft) hurricane storm surge to reach the plant ground level. Any surge that stops below ground level at the plant has no impact on the plant due to flooding. Based on the Saffir-Simpson hurricane scale (Table 19.58-2 of the AP1000 DCD), only Category 5 hurricanes have the ability to generate storm surges in excess of 5.49 m (18 ft). Historically, the highest observed storm surges occurred during hurricane Katrina in 2005 and hurricane Camille in 1969. The maximum high water mark observation occurred during hurricane Katrina with a surge of 8.47 m (27.8 ft) above normal tide levels at Pass Christian, on the immediate Gulf Coast just east of St. Louis Bay.

Based on the historical information, documented in Section 19.58.2.2 of the DCD, the applicant stated that a hurricane storm surge in excess of 8.53 m (28 ft) can be classified as a rare event and a hurricane storm surge in excess of 13.7 m (45 ft) as an extremely rare event and can be assigned a frequency of 1×10^{-7} per year or less. In addition, a risk assessment that was performed as a sensitivity study, which assumed loss of the switchyard and all nonsafety-related SSCs, indicated that the CDF associated with external floods is insignificant when areas containing safety-related equipment are protected. Therefore, by recognizing the fact that the AP1000 design provides features (e.g., barriers) that provide protection against the propagation of flooding to areas where safety-related equipment is located, external floods that do not closely approach ground level at the plant are screened from detailed risk evaluation in accordance with the criteria discussed in Section 19.1.5.

On the basis of the discussion in DCD Section 19.58 and the large margin between the greatest storm surge observed and the water level required to affect plant safety, the staff finds that the frequency of external flooding caused by storm surge is negligibly small. The screening criteria are met and no further analysis is required. The staff expects a COL applicant to verify the applicability of the screening criteria to the proposed site.

COL applicants must confirm that all possible mechanisms of external flooding at the proposed site have been assessed, including credible combinations of those mechanisms. Otherwise, the COL applicant must screen out these external events by demonstrating that they occur with negligible frequency. COL Information Item 19.59.10-2 requires the COL applicant to re-evaluate the qualitative screening of external events.

Because this approach is consistent with RG 1.200, the staff considers this an acceptable way to address the risk of external flooding.

19.1.5.6 Transportation and Nearby Facilities Accident Evaluation

Section 19.58.2.3 of the AP1000 DCD discusses the risk from external events related to transportation accidents near the nuclear plant and to accidents at nearby industrial and military facilities. DCD Section 19.58 discusses the following types of accidents: (1) aviation, (2) marine, (3) pipeline, and (4) railroad and truck. The staff finds that these accidents form an acceptable set of transportation and nearby facility accidents based on the modified IPEEE guidelines discussed in Section 19.1.5, above. Each COL applicant should verify that these analyses bound all such hazards relevant to the proposed site.

19.1.5.6.1 Aviation Accidents

The risk evaluation for aviation accidents considers two cases: (1) small aircraft impact; and (2) commercial aircraft impact. The applicant screened small aircraft impact accidents from detailed risk evaluation by performing a bounding risk evaluation based on a limiting frequency of 1.2×10^{-6} impact events per year.

For small aircraft impact accidents, the applicant performed a bounding risk evaluation that assumed a limiting initiating event frequency of 1.2×10^{-6} per year, together with an LOSP and loss of nonsafety systems. The likelihood that the impact of a small aircraft would challenge the safety systems (all located within the nuclear island) is considered negligible. Assuming that a small aircraft impact could cause an LOSP and loss of nonsafety systems, the applicant showed that the associated CDF is less than 1×10^{-8} per year.

The applicant screened commercial-size aircraft impact accidents from detailed risk evaluation by assuming a limiting frequency of 1×10^{-7} impact events per year. Each COL applicant will demonstrate the assumed limiting event frequency for the selected site of 1.2×10^{-6} per year for small aircraft and 1×10^{-7} per year for commercial-size aircraft.

19.1.5.6.2 Marine Accidents

Sites close to large waterways with ship and/or barge traffic need to evaluate the risk associated with marine accidents. Marine accidents pose a hazard to a nuclear power plant due to: (1) release of hazardous material towards the plant; and (2) explosion with resulting damage to the plant.

The applicant evaluated the risk associated with the release of hazardous material towards the plant, following a marine accident, using a bounding analysis that assumed a limiting initiating event frequency of 1×10^{-6} per year, and showed that the associated CDF is less than 1×10^{-8} per year. Therefore, based on the screening criteria discussed in Section 19.1.5, the release of hazardous material in a marine accident requires no detailed risk evaluation. The applicant modeled the risk impact of a toxic release by assuming a reactor trip and guaranteed failure of all operator actions credited in the PRA (the toxic release is not expected to lead to any direct failure of safety equipment). This is a conservative analysis because the AP1000 has an additional level of defense against toxic airborne material. Specifically, with warning that a release has occurred, the operators can actuate passive control room habitability. This system isolates the control room from normal heating, ventilation, and air conditioning (HVAC) and actuates a separate system supplied from compressed air containers. The compressed air slightly pressurizes the control room above atmospheric pressure, preventing the entrance of toxic material for at least 72 hours. (This is adequate time for operators to deal with the event.)

The staff review finds that the bounding evaluation, documented in Section 19.58.2.3.2 of the AP1000 DCD, demonstrates that the risk associated with the release of hazardous materials in a marine accident is insignificant, assuming a limiting initiating event frequency of 1×10^{-6} per year. The COL applicant for the selected site will demonstrate the assumed frequency of 1×10^{-6} per year for release of hazardous materials that could pose a hazard to the plant by a marine accident.

The applicant screened out qualitatively the risk associated with an explosion following a marine accident with resulting damage to the plant from a detailed analysis based on the acceptance criteria of event frequency less than 1×10^{-7} per year and CDF less than 1×10^{-8} per year for the following reasons:

- Loss of service water events resulting from a marine explosion is not a nuclear safety concern for AP1000 since the design does not include a service water intake structure.

- RG 1.91 provides the acceptance criterion of an overpressure event in excess of 6.9 kilopascal (kPa) (1 pound per square inch (psi)) at a frequency of less than 1×10^{-6} per year.

- Margin above the RG 1.91 acceptance criterion has been demonstrated. A study for the Waterford site, NUREG/CR-5042, "Evaluation of External Hazards to Nuclear Power Plants in the United States: Other External Events," Supplement 2, indicated that the AP1000 safety-related buildings can withstand overpressures above the RG 1.91 acceptance criterion of 6.9 kPa (1 psi).

The staff review finds that the risk associated with an explosion following a marine accident is insignificant when the RG 1.91 acceptance criterion of an overpressure event in excess of 1 psi at a frequency of less than 1×10^{-6} per year is met. The COL applicant will demonstrate that the RG 1.91 criterion of an overpressure event in excess of 1 psi at a frequency of less than 1×10^{-6} per year is met for the selected site.

19.1.5.6.3 Pipeline Accidents

Sites close to pipelines need to evaluate the risk associated with pipeline accidents. Pipeline accidents pose a hazard to a nuclear power plant because of the potential for: (1) a release of hazardous material towards the plant; and (2) an explosion with resulting damage to the plant. The applicant evaluated the risk associated with the release of hazardous material towards the plant following a pipeline accident using a bounding analysis that assumed a limiting initiating event frequency of 1×10^{-6} per year. This analysis showed that the associated CDF is less than 1×10^{-8} per year. Therefore, based on the screening criteria discussed in Section 19.1.5, the release of hazardous material in a pipeline accident requires no detailed risk evaluation. The applicant modeled the risk impact of a toxic release by assuming a reactor trip and guaranteed failure of all operator actions credited in the PRA (the toxic release is not expected to lead to any direct failure of safety equipment). This is a conservative analysis because the AP1000 has an additional level of defense against toxic airborne material. Specifically, with a warning that a release has occurred, the operators can actuate passive control room habitability. This system isolates the control room from normal HVAC and actuates a separate system supplied from compressed air containers. The compressed air slightly pressurizes the control room above atmospheric pressure, preventing the entrance of toxic material for 72 hours. (This is adequate time for operators to deal with the event.)

The risk associated with an explosion following a pipeline accident with resulting damage to the plant was screened out qualitatively from a detailed analysis, based on the acceptance criteria of event frequency less than 1×10^{-7} per year. Section 19.58.2.3.3 of the AP1000 DCD documents an approach (pipeline accident model) that qualitatively illustrates potential scenarios from gas pipeline accidents. This approach briefly discusses the following considerations for evaluating the frequency of pipeline accidents: (1) gas pipe rupture frequency estimation; (2) gas cloud formation probability estimation; (3) gas cloud transportation and nondispersion probability estimation; and (4) onsite gas cloud ignition probability estimation.

The staff review finds that the risk associated with pipeline accidents is insignificant, assuming that the COL applicant will demonstrate that the frequency criterion of 1×10^{-7} per year is met for the proposed site for pipeline accidents that could pose a hazard to the plant. The frequency of pipeline accidents will be evaluated by the COL applicant using the approach discussed in Section 19.58.2.3.3 of the DCD or another approach acceptable to the staff.

19.1.5.6.4 Railroad and Truck Accidents

Railroad and truck accidents could pose a hazard to an AP1000 plant, and COL applicants need to evaluate the risk associated with such accidents. As for marine and pipeline accidents, railroad and truck accidents could pose a hazard to a nuclear power plant because of the potential for: (1) a release of hazardous material towards the plant; and (2) an explosion with resulting damage to the plant. However, railroad and truck accidents are expected to be less likely to occur (e.g., because of the improved security barriers established at U.S. nuclear power plants) and cause less plant damage than aviation or marine accidents if they should happen. For these reasons, the risk impact from railroad and truck accidents is insignificant if the initiating event frequency criterion of 1×10^{-7} per year is met.

The staff review finds that the risk associated with railroad and truck accidents is insignificant, assuming that the COL applicant can demonstrate that the frequency criterion of 1×10^{-7} per year is met for the proposed site for railroad and truck accidents that could pose a hazard to the plant.

19.1.5.7 External Fires

External fires are those that occur outside the controlled site boundary. Potential effects on the plant could be LOSP, forced isolation of the plant ventilation, and control room evacuation. External fires are not expected to spread on site because of site clearing during the construction phase and control of combustibles during construction and operation. In RAI-TR101SPLA-03, the staff requested that the applicant consider external fires more explicitly.

In a letter dated February 8, 2008, the applicant agreed to address that based on site-specific information, the COL applicant should reevaluate the qualitative screening of external fires. Accordingly, based on the criteria discussed in Section 19.1.5, above, which were used to screen out external hazards in the PRA, a risk evaluation should be performed if the COL applicant cannot demonstrate that the frequency of external fires that could pose a hazard to the plant is less than 1×10^{-7} per year. If the COL applicant identifies any site-specific susceptibilities, the site-specific PRA performed by licensees to address COL Information Item 19.59.10-2 should include external fires.

This is consistent with RG 1.200 and, therefore, acceptable to the staff. The staff considers RAI-TR101SPLA-03 resolved.

19.1.5.8 Conclusions

Information documented in Section 19.58 of the AP1000 DCD addresses the second part of COL Information Item 19.59.10-2 which reads as follows:

> Based on site-specific information, the COL should also re-evaluate the qualitative screening of external events…. If any site-specific susceptibilities are found, the PRA should be updated to include the applicable external event.

The information provided in Section 19.58 of the AP1000 DCD includes the following objectives:

- to show that screening criteria are met and to identify external events that may impact the AP1000 risk on a site-specific basis

- to provide generic risk analyses, based on bounding assumptions regarding site-specific parameters (e.g., frequency of each category of hurricanes) for some external events

- to provide guidance to COL applicants regarding the verification of the applicability of these “generic” analyses to a specific site

Based on modified IPEEE guidelines, DCD Section 19.58 discusses the following external events or external hazards:

- high winds (including tornadoes)
- external floods
- transportation and nearby facility accidents
- external fires

The staff review finds that these external hazards are most likely a complete list of events associated with candidate sites for an AP1000 plant. However, as stated in DCD Section 2.2.1, “Combined License Information for Identification of Site-specific Potential Hazards,” the COL applicant must verify that this list adequately addresses external hazards at the proposed site. The COL applicant should use site-specific information to verify that the assumptions made in the analyses performed during the DC stage are applicable. For example, screening on the basis of event frequency of external flooding due to tsunamis or upstream dam failures may not be possible at all sites.

The staff finds that the generic risk analyses and other information provided in Section 19.58 of the AP1000 DCD are acceptable, including the screening of events from inclusion in the PRA, given the documented assumptions.

However, these analyses are based on assumptions that are expected to envelop site-specific information at sites selected to build a nuclear plant referencing the AP1000 design. The COL applicant referencing the information provided in DCD Section 19.58 must: (1) confirm in the COL application that the information provided in Section 19.58 of the DCD is applicable to the selected site; and (2) ensure that the assumptions made in the generic risk evaluations documented in Section 19.58 of the DCD bound the site-specific conditions for the applicant’s site. This is in agreement with the stipulation made in Section 19.58.3 of the AP1000 DCD, which states that the COL applicant should conduct a site-specific review of the generic PRA to verify that the assumptions in the PRA bound the site-specific conditions for the applicant's site (COL Information Item 19.59.10-2).

19.1.8.24 Reactor Pressure Vessel Thermal Insulation System

The AP1000 design includes a reflective RVIS that provides an engineered flow path to allow water ingress and venting of steam for external reactor vessel cooling (ERVC) in the event of a severe accident involving core relocation to the lower plenum. COL Action Item 19.2.3.3.1.3.2-1 calls for the COL applicants to complete the design for the RPV thermal insulation system. Section 39.10.2 of the AP1000 PRA specifies its functional requirements. In addition to RCS depressurization and reactor cavity flooding, several other conditions are necessary: (1) the reactor vessel thermal insulation system design must be consistent with ULPU Configuration V testing with prototypical insulation (ULPU-2000 is a boiling heat transfer test facility at the University of California at Santa Barbara used to investigate in-vessel retention of a damaged core); (2) the RVIS must maintain its integrity under the hydrodynamic loads associated with ERVC and not be subject to clogging of the coolant flow path by debris; and (3) RPV exterior coatings do not preclude the wetting phenomena identified as the cooling mechanism in the ULPU testing.

The applicant has completed the design of the RVIS. In TR-24, the applicant provided information to demonstrate that the RVIS is designed to provide adequate cooling to ensure in-vessel retention of a damaged and relocated core. On this basis, the applicant proposed to close COL Information Item 5.3-5. The staff's evaluation is in Section 19.2.3.3.1.3.2 of this report.

19.1.9 Conclusions and Findings

The staff has evaluated the AP1000 design PRA quality and its use in the design and certification processes. The NRC concludes that the quality and completeness of the AP1000 PRA are adequate for its intended purposes, which are to support the design and certification processes and satisfy the requirements of 10 CFR 52.47. The approaches used by the applicant for both the core damage and containment analyses are logical and sufficient to achieve the desired goals of describing and quantifying potential core damage scenarios and containment performance during severe accidents.

The use of PRA in the AP1000 design process improved the unique passive features of the design by providing a better understanding of plant response, including potential system interactions, during postulated accidents beyond the design basis. Such features contributed to the reduced CDF and conditional containment failure probability estimates of the AP1000 design when compared to those of operating PWRs. The applicant used the PRA results and insights to identify areas in which it is particularly important to implement the certification and operational requirements assumed during the design and certification processes (e.g., ITAAC, RTNSS requirements, D-RAP, COL information items, and technical specifications).

The staff reviewed the description and results of the PRA provided in the amendment. The staff finds that they are consistent with the requirements of 10 CFR 52.47 and the guidance provided in RG 1.200, NUREG-0800 Sections 19.0 and 19.1, as well as DC/COL-ISG-1, DC/COL-ISG-3 and DC/COL-ISG-20. Therefore, the staff concludes that the amended AP1000 design meets the NRC's safety goals and represents an improvement in safety over current operating PWRs in the United States.

19.1.10 Resolution of Safety Evaluation Report Open Items

Open Item OI-SRP19.0-SPLA-07: The applicant must implement corrective actions after the audit, re-solving and requantifying the corrected model as well as revising TR-102 and making associated changes to the DCD consistent with DC/COL-ISG-3.

As discussed in Section 19.1.2.1.10, "Improved Control Room Design and Digital Instrumentation and Control Systems," this open item has been resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Open Item OI-SRP19.0-SPLA-12: The applicant must confirm that an acceptable seismic margin is maintained for HRHF sites.

As discussed in Section 19.1.5, "Seismic Margin Analysis," this open item has been resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Open Item OI-SRP19.0-SPLA-13: The applicant must provide an updated DCD description of events (HAs, common cause, and basic) and sequences contributing most to risk, both at power and while shutdown.

As discussed in Section 19.1.4, "Safety Insights from the Internal Events Risk Analysis for Shutdown Operation," this open item has been resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Open Item OI-SRP19.0-SPLA-14: The applicant must resolve the discrepancy in the containment inventory of radionuclides used for the survivability evaluation, determining whether the environmental assessment should include mechanical penetrations and hatches (e.g., gasket materials) and providing a licensee COL information item to finalize the list of equipment that must survive.

As discussed in Section 19.2.3.3.7, "Equipment Survivability," this open item has been resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Open Item OI-SRP19F-SPLA-01: In a letter dated March 19, 2010, the applicant submitted the results of an analysis consistent with guidance from the Nuclear Energy Institute. It was prepared using NEI 07-13, "Methodology for Performing Aircraft Impact Assessments for New Plant Designs," which has been endorsed in draft guide (DG)-1176, "Guidance for the Assessment of Beyond-Design-Basis Aircraft Impacts." The staff's evaluation of this aircraft impact assessment (AIA) is in Section 19F of this report.

19.1.11 Combined License Information Items

19.1.11.1 As-Built Seismic Margin Assessment

COL Information Item 19.59.10-1 (COL Action Items 19A.2-1 and 19A.2-2) is associated with an as-built SSC HCLPF comparison to seismic margin evaluation. In TR-6, the applicant noted that a COL applicant cannot complete the review and proposes instead to complete these actions before fuel loading.

However, at the time of COL application, site-specific features with the potential to affect the SMA should be described and assessed to confirm that the SMA documented in the DCD is applicable to a plant located on the proposed site. Alternatively, additional analysis to demonstrate adequate seismic margin is required. COL Information Item 19.5.10-6 is a COL applicant item.

Because the SMA requires a confirmatory walkdown, which cannot be performed until construction of seismic SSCs has been completed, the staff agrees that evaluation of as-built conditions cannot be provided with the COL application. The staff concludes that performance of the as-built SMA before fuel loading is timely and, therefore, acceptable. COL Information Item 19.59.10-1 should be completed by the licensee.

19.1.11.2 Site-Specific, Plant-Specific Probabilistic Risk Assessment

COL Information Item 19.59.10-2 is associated with evaluating an as-built plant versus design in AP1000 PRA and site-specific PRA external events. In TR-6, the applicant noted that a COL applicant cannot complete an as-built review and proposes that the COL applicant referencing the AP1000 certified design will, instead, review differences between the as-built plant and the design used as the basis for the AP1000 PRA and Table 19.59-18. The applicant proposed that, if a screening analysis shows that the effect of the differences could result in a significant increase in CDF or LRF, the PRA would be updated to reflect these differences. In addition, the COL applicant should reevaluate the qualitative screening of external events. If any site-specific susceptibilities are found, the PRA should be updated to include the applicable external event.

The staff agrees that the design-specific PRA is a sufficient and acceptable basis for drawing safety conclusions for a license and should be described in the COL FSAR (with appropriate discussion of plant-specific features and departures from the certified design). The FSAR should also identify key assumptions and insights from this PRA. The staff finds that documentation and qualitative screening of external events, specific to the proposed plant site, is an acceptable way to confirm that site-specific vulnerabilities do not require further risk assessment and need not be included in PRA results and insights reported in the FSAR. This part of COL Information Item 19.5.10-2 is a COL applicant item.

However, the staff finds that each licensee’s PRA should model significant plant-specific and site-specific differences from the design PRA, whether positive or negative, to be consistent with DC/COL-ISG-3. This is necessary to support operational-phase reliability assurance activities, when more realistic assessment of risk is needed to avoid masking activities of risk significance. This part of COL Information Item 19.5.10-2 is to be completed by the COL licensee.

19.2 Severe Accident Performance

19.2.2 Deterministic Assessment of Severe Accident Prevention

19.2.2.1.2 Mid-Loop Operation

During refueling or maintenance activities, the RCS is sometimes reduced to a “mid-loop” level. The applicant summarized the specific AP1000 design features that address mid-loop operations in DCD Tier 2, Section 5.4.7.2.1, “Design Features Addressing Shutdown and Mid-Loop Operations.” In addition, DCD Tier 2, Table 16.3-2, “Investment Protection Short-Term Availability Controls,” ensures that the RNS is available during mid-loop operation.

Section 19.3, “Shutdown Evaluation,” of this report documents the staff’s evaluation of shutdown risk. Because RTNSS has not been amended, it is not discussed in this supplement. DCD Tier 2, Table 16.3-2, documents the availability controls provided for the RNS during normal and reduced inventory. The staff concludes that the AP1000 design conforms to the mid-loop operation guidance specified in SECY-93-087 and is, therefore, acceptable.

19.2.3.3.1.3.2 Reactor Pressure Vessel Thermal Insulation System

Section 5.3.5 describes the design of the RPV thermal insulation system. Section 19.1.2.2.4 discusses considerations related to risk assessment. This section addresses the staff’s evaluation of conformance of the final design of the RVIS to the ULPU Configuration V testing, its integrity under the hydrodynamic loads associated with ERVC, absence of susceptibility to clogging, and absence of coatings that could interfere with wetting phenomena that contribute to effective heat removal.

In RAI-TR24-SPLA-01, the staff noted an apparent stepwise change in the cross-section of the annulus formed between the RVIS and the reactor vessel, formed by the neutron shield. This RAI also requested other information with respect to dimensions that could be important to the adequacy of the flow path. In a letter dated August 21, 2007, the applicant provided additional details about the modeling of the flow path and flow areas. This allowed the staff to confirm that the design was consistent with the ULPU Configuration V testing. The staff considers RAI-TR24-SPLA-01 resolved.

The applicant changed the design of the RVIS inlet closure devices from floating balls to hinged, buoyant doors. In RAI-TR24-SPLA-02, Part 1, the staff requested additional information to confirm that this was consistent with the ULPU Configuration V testing. In RAI-TR24-SPLA-07, the staff requested additional details on the configuration of the doors and the forces acting on them. In the August 21, 2007 letter, the applicant provided additional details about these active components of the system and the effect on flow areas and flow resistance. Because the new design retains the characteristic of actuation by buoyant forces, the cross-sectional area is maintained, and flow resistance is reduced, the staff considers this change to be an acceptable way to conform to the ULPU Configuration V testing.

Similarly, the applicant changed the design of steam vent ducts that provide a flow path for the steam/water within the reactor vessel insulation annular space to flow back to the containment flood-up region. In RAI-TR24-SPLA-02, Part 2, the staff requested that the applicant assess the impact of these design modifications. In the August 21, 2007 letter, the applicant explained that the previous design had multiple miter bends instead of a sudden contraction in the area of the flow path. The modification reduces flow resistance and allows higher mass flow. Because the results of the testing conservatively bound the expected performance of the RVIS, the staff considers this change to be an acceptable way to conform to the ULPU Configuration V testing. The staff considers RAI-TR24-SPLA-02 and RAI-TR24-SPLA-07 resolved.

The staff noted that the RVIS doors and the reactor coolant drain tank room ventilation damper, though described by the applicant as “passive,” are considered by the staff to be active components. In RAI-TR24-SPLA-03, the staff requested information on periodic verification of the performance of moving parts, and in RAI-TR24-SPLA-08, a discussion of as low as is reasonably achievable (ALARA) considerations for testing and maintenance was requested. In the August 21, 2007 letter, the applicant confirmed that RVIS is in the D-RAP. Proper fit and freedom of motion of the doors is confirmed during hot functional testing. Visual inspection and testing for freedom of rotation is to be performed during refueling outages at ten-year intervals, coordinated with other inspections in the same area. Individual doors and frames are designed for removal as a unit, so replacement, if required, would take little time. Because the applicant has applied a level of control and testing consistent with Commission policy on RTNSS and ALARA, the staff considers this to be acceptable and both RAI-TR24-SPLA-03 and RAI-TR24-SPLA-08 are resolved.

Because the design of the RVIS is consistent with the ULPU Configuration V testing, the staff’s evaluation of hydrodynamic loads and previous findings with respect to the potential for clogging of the flow path are unchanged.

In RAI-TR24-SPLA-06, the staff requested resolution of earlier test results (ULPU Configuration III and BETA tests) dealing with the wetability of the reactor pressure vessel surface if it were coated. The applicant revised the DCD to reflect a commitment to ensure that the reactor vessel exterior is bare metal.

On the basis of the additional description, the staff was able to confirm that the new design is consistent with the ULPU Configuration V ntesting and is, therefore, acceptable. The staff concludes that COL Action Item 19.2.3.3.1.3.2-1 is closed for COL applicants referencing the AP1000 DCD. The staff considers RAI-TR24-SPLA-06 resolved.

19.2.3.3.7 Equipment Survivability

Electrical and mechanical equipment must survive to prevent and mitigate the consequences of severe accidents. The applicant addressed equipment survivability in Appendix 19D, “Equipment Survivability Assessment,” to DCD Tier 2, which includes general requirements and equipment classification. Appendix D to the AP1000 PRA supporting document presents the analysis performed to determine the severe accident environmental conditions.

In TR-68, APP-GW-GLR-069, “Equipment Survivability Assessment,” May 2007, the applicant submitted revised analysis in support of the DC amendment. In reviewing TR-68, the staff noted that the severe accident environmental conditions were revised.

In APP-GW-VP-025, “AP1000 Equipment Survivability Assessment,” an attachment to TR-68, the applicant stated that it had revised the fraction of the core inventory released to the containment atmosphere from the original PRA Appendix D and that the values are consistent with the accident source term information presented in NUREG-1465, “Accident Source Terms for Light-Water Nuclear Power Plants—Final Report.”

However, the staff identified certain analytical assumptions documented in APP-GW-VP-025 that did not appear to be consistent with NUREG-1465 and asked the applicant to clarify and confirm the basis for the results documented in TR-68. The NRC staff identified this as the first part of Open Item OI-SRP19.0-SPLA-14.

In a letter dated May 12, 2009, the applicant submitted additional information to resolve the perceived lack of consistency, and supplemented this with a letter dated September 8, 2009. The staff reviewed supporting calculations during an audit at the applicant's offices on October 13-15, 2009, documented in an audit report dated November 22, 2009. The staff is satisfied that the post-accident conditions were determined in a manner consistent with the applicable regulatory guidance, and the first of three parts of Open Item OI-SRP19.0-SPLA-14 is considered to be closed.

During the development of the severe accident management guidance (SAMG) for AP1000, additional requirements were defined for accident management in Time Frame 2 (in-vessel severe accident phase) and Time Frame 3 (ex-vessel severe accident phase). For example, previously unidentified methods of injecting water into the containment were added (e.g., providing makeup to overflow the IRWST by the RNS system). The use of containment spray was identified as a severe accident strategy (e.g., injecting water into containment and containment heat removal). Another method of depressurizing the RCS in Time Frame 2 was identified (i.e., reactor vessel head venting).

Finalizing certain system designs resulted in the need to update lists of associated equipment and instrumentation. For example, the applicant eliminated low-pressure steam generator feed systems (i.e., service water and condensate water) from consideration.

Lastly, the applicant changed the equipment and instrumentation identification to conform to updated naming conventions for AP1000. The new list of equipment and instrumentation reflects the amended AP1000 design.

The applicant has not completed the identification of equipment and instrumentation for prevention of core damage (e.g., Time Frame 0 and Time Frame 1) because the EOPs are still in development. Upon finalization of the EOPs, the applicant can identify and assess the survivability of the equipment and instrumentation used in those procedures. This should be identified as a licensee COL information item. The NRC staff identified this as the second part of Open Item OI-SRP19.0-SPLA-14.

In a letter dated May 12, 2009, the applicant submitted additional information that clarified the method by which this licensee COL information item is addressed. The staff finds that no additional holder item is required and, therefore, the second of three parts of Open Item OI-SRP19.0-SPLA-14 is considered to be closed. In general, the applicant claims that the AP1000 provides reasonable assurance that equipment, both electrical and mechanical, designed for mitigating the consequences of severe accidents will perform its functions as intended.

The staff questioned the completeness of the list of SSCs required for containment isolation. First, if a hydrogen monitor outside containment were required, additional penetrations might need to be included. In addition, it was not clear that the equipment survivability assessment needs to include mechanical penetrations and hatches (e.g., gasket materials) to ensure containment integrity. The NRC staff identified this as the third part of Open Item OI-SRP19.0-SPLA-14.

In a letter dated May 12, 2009, the applicant submitted additional information, and supplemented this with a letter dated September 8, 2009. The staff is satisfied that a hydrogen monitor outside containment was not included in the certified design and finds that there is no regulatory basis for requiring it. The applicant provided appropriate controls to ensure that gasket materials of mechanical penetrations and hatches will be capable of surviving post-accident conditions. In addition, the applicant has proposed an acceptable clarification of the DCD. The third of three parts of Open Item OI-SRP19.0-SPLA-14 is considered resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

19.2.5 Accident Management

Accident management encompasses those actions taken during the course of an accident by the plant operating and technical staff to: (1) prevent core damage; (2) terminate the progress of core damage if it begins and retain the core within the reactor vessel; (3) maintain containment integrity as long as possible; and (4) minimize offsite releases. Severe accident management is the process of extending the EOPs well beyond the plant design basis into severe fuel damage regimes and making full use of existing plant equipment, operator skills, and creativity to terminate severe accidents and limit offsite releases.

The NRC has taken an active role in ensuring that utilities adopt acceptable accident management practices. In January 1989, the staff issued SECY-89-012, “Staff Plans for Accident Management Regulatory and Research Programs,” which discusses essential elements of a utility accident management plan and offers an approach for accident management implementation. Subsequently, the NRC worked with the industry to define the scope and attributes of a utility accident management plan and to develop guidelines for plant-specific implementation. Section 5 of NEI 91-04, Revision 1, “Severe Accident Closure Guidelines,” which lays out the elements of the industry’s severe accident management closure actions that have been accepted by the staff, resulted from these efforts. This program involves the development of: (1) a structured method by which utilities may systematically evaluate and enhance their abilities to deal with potential severe accidents; (2) vendor-specific accident management guidelines for use by individual utilities in establishing plant-specific accident management procedures and guidance; and (3) guidance and material to support utility activities related to training in severe accidents. Using the guidance developed through this program, each operating plant has implemented a plant-specific accident management plan as part of an industry initiative.

Based on its reviews of these efforts, severe accident evaluations in individual plant examinations, and industry PRAs, the staff concluded that improvements to utility accident management capabilities could further reduce the risk associated with severe accidents. Although new reactor designs are to have enhanced capabilities for the prevention and mitigation of severe accidents, accident management remains an important element of defense in depth for these designs. However, the staff expects the increased attention on accident prevention and mitigation in these designs to alter the scope and focus of accident management relative to that for operating reactors. For example, the staff expects increased attention on accident prevention and the development of error-tolerant designs to decrease the need for operator intervention, while increasing the time available for such action if necessary. This permits a greater reliance on support from outside sources. For longer times after an accident (several hours to several days), the need for human intervention and accident management will continue.

For both operating and advanced reactors, the overall responsibility for accident management, including development, implementation, and maintenance of the accident management plan, lies with the nuclear utility, because the utility bears ultimate responsibility for the safety of the plant and for establishing and maintaining an emergency response organization capable of effectively responding to potential accident situations. However, the vendors have played key roles in providing essential SAMG and strategies for implementation. This guidance has served as the basis for severe accident management procedures and for training utility personnel in carrying out the procedures. Computational aids for technical support have been developed, information needed to respond to a spectrum of severe accidents has been provided, decision making responsibilities have been delineated, and utility self-evaluation methodologies have been developed.

A COL applicant referencing the AP1000 design must develop and implement SAMG using the suggested framework provided in WCAP-13914, “Framework for AP600 Severe Accident Management Guidance,” Revision 3. This WCAP outlines a plan based on the Westinghouse Owners Group (WOG) SAMG for currently operating plants. Its scope is to address significant core damage accidents that might be possible in the AP600 and to provide the framework for developing guidance on how to cope with these accidents after the emergency response guidelines are no longer applicable. TR-66 extends this framework to the AP1000 design.

In NUREG-1793, the staff states that it expects the COL applicant to follow the recommendations provided in WCAP-13914 in developing its plant-specific accident management guidance (COL Action Item 19.2.5-1). The applicant has taken steps to facilitate this process by producing TR-66, the AP1000 framework document, and the AP1000 SAMG.

The applicant prepared and submitted TR-66 to close COL Information Item 19.59.10-4 with respect to development of the SAMG. The information item states the following:

> The combined license applicant referencing the AP1000 certified design will develop and implement severe accident management guidance using the suggested framework provided in WCAP-13914, “Framework for AP600 Severe Accident Management Guidance.”

APP-GW-GL-027, “Framework for AP1000 Severe Accident Management Guidance Development,” documents the framework for the AP1000. Based on this framework, the applicant has also developed SAMG for the AP1000 (APP-GW-GJR-400, “AP1000 Severe Accident Management Guidelines,” Revision A of January 2007), which COL licensees will implement at each site using the AP1000 design. TR-66 is a road map for COL licensees using these guidelines.

In RAI-SRP19.0-SPLA-15, the staff requested clarification of the schedule for development and implementation of SAMG. In a letter dated August 21, 2008, the applicant provided the requested information.

The starting point for the technical basis for the AP1000 is Electric Power Research Institute (EPRI) TR-101869, “Severe Accident Management Technical Basis Document” (Volumes 1 and 2). This document details the severe accident phenomenological understanding as it was in the early 1990s, when it formed the basis for the WOG guidelines. For the most part, this understanding is still current, although a number of important technical issues have been resolved and a few new ones identified since then. For example, direct containment heating in large-volume PWRs is no longer considered to be a major threat, but induced SGTRs in high-pressure scenarios have become a major concern. The AP1000 SAMG consists of three volumes:

1. An executive volume describes the methodology and criteria for the development of the AP1000 SAMG. It includes all of the material in the framework document, an overview of the AP1000 SAMG, a writer's guide for writing the SAMG and background documents, and a number of other important items related to the decision making process, interfaces between the AP1000 EOPs and the SAMG, and interfaces between the SAMG and the site emergency plan.

2. A guideline volume includes the SAMG guidelines to be used by the control room staff and the engineering support staff in the technical support center (TSC) in responding to a severe accident.

3. A background volume details the technical basis for the guidance found in the guidelines volume.

Section 5.1 of NEI 91-04 states that accident management consists of those actions taken during the course of an accident by the plant's emergency response organization (ERO), particularly the plant operations, technical support, and plant management staff, to achieve the following:

- prevent the accident from progressing to core damage
- terminate core damage progression once it begins
- maintain the capability of the containment as long as possible
- minimize onsite and offsite releases and their effects

The latter three actions constitute a subset of accident management referred to as severe accident management or, more specifically, severe accident mitigation.

NEI 91-04 also states that the goal of severe accident management is to enhance the capabilities of the ERO to mitigate severe accidents and prevent or minimize any offsite releases. The objective is to establish core cooling and to manage any current or immediate threats to the fission product barriers. Accomplishing this ERO should make full use of existing plant capabilities, including standard and nonstandard uses of plant systems and equipment.

The NRC staff agrees that NEI 91-04 properly defines the scope of severe accident management and believes that the framework for SAMG should be consistent with this scope.

The AP1000 SAMG consists of three parts: control room SAMG, TSC SAMG, and TSC challenge response guidance. The control room SAMG consists of two separate guidelines. The control room staff uses the first of these guidelines until the TSC is functional and its staff is ready to use the TSC SAMG. The staff uses the second guideline after the TSC is functional; this guideline provides the staff with a structured set of activities when the TSC is evaluating the plant conditions and potential responses.

The TSC staff will execute the TSC SAMG, using the diagnostic flow chart (DFC) and the severe challenge status tree to select the appropriate strategies to respond to variations in the key parameters. These strategies are described by the seven severe accident guidelines:

1. inject into containment
2. depressurize the RCS
3. inject into the steam generators
4. inject into the RCS
5. reduce fission product releases
6. control containment conditions
7. reduce containment hydrogen

The guidelines specify a method for a systematic, logical evaluation of the possible strategies and a process of deciding which actions to implement.

Another guideline, SAEG-1, monitors long-term activities after a particular strategy is implemented. Such activities depend on a number of factors, including the equipment put into service to implement the strategies, equipment already in service before implementing the SAMG that relates to the control of a DFC parameter, limitations on equipment usage identified in the guidelines that evaluate the possible strategies, equipment no longer in service if implementation of a strategy is discontinued, and changes in plant conditions following implementation of severe accident management strategies.

A final guideline, SAEG-2 for SAMG termination, comes into play when the plant has been put into a safe, stable state. At this time, selected parameters in the DFC are below their setpoint values and are stable or decreasing, and no new SAMG strategies will be required. However, generic SAMG exit guidance has been developed.

Four computational aids have been developed to assist the TSC staff in diagnosing and formulating appropriate strategies:

1. RCS injection to recover the core
2. injection rate for long-term heat removal
3. hydrogen flammability in containment
4. containment water level and volume

The NRC staff reviewed TR-66, the AP1000 framework document (APP-GW-GL-027), and the executive volume of the AP1000 SAMG. The staff confirmed that the AP1000 SAMG reflects current understanding of severe accident progression. The staff examined the remaining two volumes to ensure that they are an appropriate extension of the EPRI guidance, consistent with the SAMG developed by the WOG for operating reactors, and address all necessary high-level actions. The DCD appropriately references these documents.

Since concerns over hydrogen generation suggest maximizing the flow rate, while concerns about a degraded reactor vessel (overheating and wall thinning at or near the surface of the pool of relocated core material) suggest that flow should be controlled, in RAI-SRP19.0-SPLA-16, the staff asked the applicant to explain how it will provide guidance to resolve potentially conflicting considerations when introducing water to a dry reactor vessel after core relocation (full or partial) to the bottom head.

In a letter dated August 21, 2008, the applicant stated that it will update the AP1000 SAMG for “inject into the RCS” to address the recommended rate of injection into the RCS for situations in which the injection capability is recovered after significant core damage has occurred. The applicant will add a new item in the evaluation of the potential negative impacts of injecting into the RCS to note that high injection flow rates will minimize the potential for significant hydrogen generation while lower, controlled flow rates will minimize the potential for failure of the reactor vessel. The evaluation will explain that hydrogen generation caused by low flow rates will only be a concern if a significant amount of hydrogen is already in the containment indicating a failure of the hydrogen igniters or the recombiners, or both. On the other hand, the concern about reactor vessel integrity due to high injection flow rates will only exist when a prolonged period has elapsed since the onset of high core temperatures and the reactor vessel will be externally cooled by submergence in water.

Attachment B to the guideline and the associated background document will also provide a full discussion of the conditions under which each of the concerns is applicable. The staff considers RAI-SRP19.0-SPLA-16 resolved. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

On the basis of this review, the staff concludes that SAMG for the AP1000 is consistent with NEI 91-04 and is a logical extension of the WOG SAMG. The discussions of the high-level actions, supported by the background documents provided, establish a sound technical basis for AP1000 COL applicants to develop their severe accident management procedures and training.

For this reason, the staff considers AP1000 COL Information Item 19.59.10-4 to be closed for COL applicants referencing the AP1000 DCD.

19.3 Shutdown Evaluation

19.3.7 Outage Planning and Control

In RAI-SRP19.0-SPLA-10, the staff asked the applicant to clarify whether the development of freeze seal guidelines is the responsibility of the COL applicant; is included in the procedure development described in TR-70, APP-GW-GLR-040, “Plant Operations, Surveillance, and Maintenance Procedures,” Revision 1, August 2007; or is controlled in some other way.

The applicant modified DCD Section 13.5 to include the following statement: “If freeze seals are to be used, plant-specific guidelines will be developed to reduce the potential for loss of RCS boundary and inventory when they are in use,” and confirmed that COL Information Item 13.5-1 includes the guidelines for use of freeze seals. It is among the guidelines identified as “Phase 3” procedure activities. The staff considers RAI-SRP19.0-SPLA-10 resolved.

NUREG-1793 described other COL action items related to shutdown procedures that the staff consolidated in COL Information Item 13.5-1. In RAI-SRP19.0-SPLA-11, the staff asked the applicant how it would identify these action items to the COL applicant:

- COL Action Item 19.1.8.1-4: The COL applicant will implement the maintenance guidelines as described in WCAP-14837, “AP600 Shutdown Evaluation Report.”

- COL Action Item 19.1.8.3-1: The COL applicant is responsible for developing procedures…to close containment hatches and penetrations following an accident during MODE 5 and MODE 6 before steam is released into the containment.

- COL Action Item 19.1.8.16-1: The COL applicant will have policies that maximize the availability of normal residual heat removal (valve V-023) and procedures to open this valve during cold shutdown and refueling operations when the RCS is open and the passive residual heat removal system cannot be used for core cooling.

- COL Action Item 19.1.8.16-2: The COL applicant will develop administrative controls to ensure that inadvertent opening of RNS valve V-024 is unlikely since inadvertent opening results in a draindown of the RCS inventory to the IRWST and requires gravity injection from the IRWST.

- COL Action Item 19.1.8.16-4: The COL applicant will maintain procedures to respond to low hot-leg level alarms.

- COL Action Item 19.3.7-1: The COL applicant will develop an outage planning and control program and will appropriately address the factors that improve low-power and shutdown operations consistent with DCD Tier 2, Chapter 19E, “Shutdown Evaluation,” and NUMARC 91-06, “Guidelines for Industry Actions To Assess Shutdown Management.”

- COL Action Item 19.1.8.7-1: The COL applicant will implement procedures and policies to have the nonsafety-related wide-range pressurizer level indication during cold shutdown.

Each of these action items has a corresponding entry in DCD Table 19.58-18. COL licensees referencing the AP1000 design must verify that the insights and assumptions documented in this table are satisfied. The staff finds this to be an acceptable method for ensuring that appropriate administrative controls will be applied. The staff considers RAI-SRP19.0-SPLA-11 resolved.

In TR-70, the applicant suggested that the procedures in Phase 3 need not be developed until after a COL is issued.

The staff agrees that these guidelines do not need to be completed at the time of application and finds that the program described in TR-70 is an acceptable method for providing assurance that appropriate guidance will be developed in a timely manner.

19.3.10 Flood Protection

NUREG-1793 states the following:

> The design provides fire detection and suppression capability. The design also provides flooding control features and sump level indication. The COL applicant is expected to take compensatory measures to maintain adequate detection and suppression capability during maintenance activities. This is part of COL Action Item 19.1.8.1-3.

The staff expects the COL licensees to take compensatory measures to maintain adequate detection capability during maintenance activities. The staff identified two COL information items that address fire detection and suppression but not flooding. In RAI-SRP19.0-SPLA-08, the staff asked the applicant to clarify how it will address concerns about flooding detection, barrier integrity, and control.

The applicant's August 21, 2008, response focused on aspects of the AP1000 design that obviate the need to compensate for a maintenance-related breach of flooding barriers. Specifically, the design does not include any watertight doors; flood barriers are permanent fixtures that are neither opened nor altered by normal activities, including maintenance. Moreover, the CDF contribution from internal flooding is extremely low.

The staff agrees with the applicant's assessment of internal flooding risk. As stated in NUREG-1793, the results of the AP1000 study for internal flooding show that the AP1000 design is adequate because internal floods during shutdown do not represent a significant risk contribution. The staff considers RAI-SRP19.0-SPLA-08 resolved.

19.5 Conclusion

The staff evaluated the information submitted by the applicant in accordance with NUREG-0800 Sections 19.0 and 19.1. In addition to its review of the documents identified above, the staff conducted a regulatory audit on August 9 and 10, 2010.

The applicant has updated the AP1000 PRA to include the most recent I&C design information. Additionally, to facilitate future updates, the applicant converted the PRA software package from the proprietary WesSAGE software package to the CAFTA software package. The applicant also documented the basis for its determination that other design changes did not affect the SSCs modeled in the PRA in a manner that affected the PRA.

In addition to reviewing the description of changes to the PRA, the staff reviewed the description of the new I&C design, specifically the PLS and PMS. The staff reviewed the methods and procedures for conversion of the PRA model from WesSAGE to CAFTA in the applicant's offices. The staff also reviewed the process by which the applicant incorporated the design changes in the PRA.

The staff noted that the applicant has a formal procedure for the review of design packages to ensure that it identifies and addresses any impact on the PRA. Design change packages are evaluated for the potential to alter the PRA model or to affect PRA assumptions or insights.

With the resolution of the open items described in Section 19.1.10 of this report, the staff concludes that the results and insights of the upgraded and updated design-specific PRA for the AP1000 demonstrate that the design meets the Commission's safety goals. These results and insights are an acceptable basis for the risk-informed review of the amended AP1000 DCD.

19F Aircraft Impact

This section describes the staff's evaluation of design features and functional capabilities of the AP1000 that are credited by the applicant to show that the facility can withstand the impact of a large commercial aircraft. These design features and functional capabilities were described in a letter dated March 19, 2010, that proposed changes to AP1000 DCD, Appendix 19F, "Malevolent Aircraft Impact." Upon reviewing the appendix, the staff found that the descriptions of design features and functional capabilities were incomplete. In RAI-SRP19F-AIA-01, the staff identified specific areas in the DCD that required augmentation. In response, the applicant proposed amendments to Appendix 19F and related sections of other DCD chapters.

The impact of a large commercial aircraft is a beyond-design-basis event. 10 CFR 50.150, "Aircraft impact assessment," requires applicants for new nuclear power reactors[7] to perform an assessment of the effects on the designed facility of the impact of a large, commercial aircraft. Applicants for DC are required to submit: (1) a description of the design features and functional capabilities identified as a result of the assessment in their DCD with (2) a description of how the identified design features and functional capabilities meet the acceptance criteria in 10 CFR 50.150(a)(1). Applicants subject to 10 CFR 50.150 must make the complete AIA available for NRC inspection in accordance with 10 CFR 50.70, "Inspections"; 10 CFR 50.71, "Maintenance of records, making of reports"; and Section 161.c of the Atomic Energy Act of 1954, as amended.

Regulatory Criteria

The staff used the following regulations and guidance to perform this review:

Regulations

10 CFR 50.150(a)(1) requires that applicants perform a design-specific assessment of the effects on the facility of the impact of a large, commercial aircraft. Using realistic analyses, the applicant shall identify and incorporate into the design those design features and functional capabilities to show that, with reduced use of operator actions: (i) The reactor core remains cooled, or the containment remains intact; and (ii) spent fuel cooling or spent fuel pool (SFP) integrity is maintained.

10 CFR 50.150(b) requires that the FSAR include a description of: (1) the design features and functional capabilities that the applicant has identified in accordance with 10 CFR 50.150(a)(1); and (2) how those design features and functional capabilities meet the assessment requirements of 10 CFR 50.150(a)(1).

Review Guidance

DG-1176 provides guidance for meeting the requirements in 10 CFR 50.150(a). It documents NRC endorsement of the methodologies described in the guidance prepared by NEI 07-13, Revision 7.

---

[7] "Applicants for new nuclear power reactors" is defined in the Statement of Considerations for the Aircraft Impact Rule [74 FR 28112, June 12, 2009].

Supplementary information for the aircraft impact assessment rule [74 FR 28112], which indicates, among other things, that for the NRC to conclude that the rule has been met, it must find that the applicant has performed an AIA reasonably formulated to identify design features and functional capabilities to show, with reduced use of operator action, that the acceptance criteria in 10 CFR 50.150(a)(1) are met.

The following are NRC staff interim review guidelines:

a. Reasonably Formulated Assessment

   The NRC considers an aircraft impact assessment performed by qualified personnel using a method that conforms to the guidance in NEI 07-13, Revision 7, to be a method which is reasonably formulated. The NRC considers qualified personnel to be: (1) an applicant who is the designer of the facility for which the AIA applies; and (2) an applicant's primary contractor for the aircraft impact assessment who has designed a nuclear power reactor facility either already licensed or certified by the NRC or currently under review by the NRC.

b. Reactor Core and Spent Fuel Pool Cooling Design Features

   The "reactor core cooling" criterion or "spent fuel pool cooling" criterion in 10 CFR 50.150(a)(1) is satisfied if design features have been included in the design of the plant to specifically perform that cooling function with reduced use of operator action.

c. Intact Containment

   The "intact containment" criterion in 10 CFR 50.150(a)(1) is satisfied if the containment: (1) will not be perforated by the impact of a large, commercial aircraft; and (2) will maintain ultimate pressure capability, given a core damage event until effective mitigation strategies can be implemented. Effective mitigation strategies are those that provide, for an indefinite period of time, sufficient cooling to the damaged core or containment to limit temperature and pressure challenges below the ultimate pressure capability of the containment as defined in Section 19 of the DCD, Revision 18.

d. Spent Fuel Pool Integrity

   The "spent fuel pool integrity" criterion in 10 CFR 50.150(a)(1) is satisfied if the impact of a large commercial aircraft on the SFP wall or support structures would not result in leakage through the SFP liner below the required minimum water level of the pool.

e. Reduced Operator Action

   The NRC considers use of operator action to be reduced when: (1) all necessary actions to control the nuclear facility can be performed in the control room or at an alternate station containing equipment specifically designed for control purposes; and (2) a reduced amount of active operator intervention, if any, is required to meet the acceptance criteria in 10 CFR 50.150(a)(1). Reduction in the use of operator action is measured relative to the actions required to address aircraft impact without the AIA rule in place (e.g., similar actions in operational programs in place at current operating reactor sites).

19F.1 Summary of Technical Information

Appendix 19F states that the applicant performed an AIA in accordance with the requirements in 10 CFR 50.150(a)(1) using the methodology described in NEI 07-13. Based on the results of the assessment, the applicant has identified a set of key design features to show that the acceptance criteria in 10 CFR 50.150(a)(1) are satisfied. These key design features are reported in Appendix 19F, along with references to other sections of the DCD that provide additional details. Appendix 19F also includes descriptions of how the key design features show that the acceptance criteria in 10 CFR 50.150(a)(1) are met.

19F.1.1 Description of Key Design Features

The key design features that are credited, their function(s), and references to sections including detailed descriptions of the features are summarized below:

Key Design Features

No.	Feature	DCD Reference	Function
1	structural design of the shield building	Chapter 3	protection of safety systems located inside containment
2	structural design of the auxiliary building	Chapter 3	protection of the SFP liner integrity
3	structural design of the wall along the south end of the turbine building at column line 11.2	Section 3.7.2.8.3	protection of the auxiliary building from the impact of a large, commercial aircraft
4	structural design of the wall along the east end of the annex building	Figure 3.7.2-19	protection of the auxiliary building from the impact of a large commercial aircraft
5	structural design and location of the SFP	Figure 3.7.2-12 Section 9.1.2.2	protection of the SFP from the effects of an impact of a large commercial aircraft
6	passive safety injection portions of the PXS and the ADS valves and spargers of the RCS inside containment	Section 5.4 Section 6.3	core cooling

Key Design Features

No.	Feature	DCD Reference	Function
7	physically separated locations of the main control room (MCR), remote shutdown station (RSS), and secondary DAS panel	Chapter 7	manual actuation of passive safety injection and recirculation for long-term core cooling can be initiated if required
8	supporting equipment required for operation of the squib valves from the MCR, RSS, or DAS panel including Class 1E batteries, control and instrumentation cabinets, cabling, and transfer switches	Section 7.7.1.11	manual actuation of passive safety injection
9	ADS Stage 4 squib valves IRWST injection line squib valves and recirculation line squib valves	Section 6.3	passive safety injection and recirculation for long-term core cooling
10	steel containment vessel	Section 19.40	containment integrity maintained with only air cooling for 24 hours
11	normal residual RNS containment isolation valves	Figure 5.4-7	isolation of the RNS outside of the containment
12	reactor trip equipment including sensors, manual inputs, protection and safety monitoring system cabinets, and reactor trip switchgear	Section 7.2.1	reactor shutdown
13	the design and locations of 3-hour fire barriers within the auxiliary building	Section 9.5.1	protection of equipment needed for manual actuation of systems and equipment potentially required for core cooling

Key Design Features

No.	Feature	DCD Reference	Function
14	specific barriers in the auxiliary building rated to withstand a differential pressure of 34.5 kPa (5 pound(s) per square inch differential (psid))	Section 9.5.1.2.1.1	limitation of the effects of fire damage created by the impact of a large, commercial aircraft

19F.1.2 Description of How Regulatory Acceptance Criteria Are Met

The acceptance criteria in 10 CFR 50.150(a)(1) are that: (1) the reactor core will remain cooled or the containment will remain intact; and (2) SFP cooling or SFP integrity is maintained. The applicant has met 10 CFR 50.150(a)(1) by including features in the AP1000 design that maintain: (1) an intact containment; and (2) SFP integrity following the impact of a large commercial aircraft.

The applicant credits the shield building as a structure that will remain intact following an impact by a large commercial aircraft. Therefore, containment will also be intact. The RPV, PXS, and equipment within the containment will not be damaged by the impact or by exposure to jet fuel. For a postulated impact on the auxiliary building, the applicant credited the design and locations of 3-hour rated fire barriers to limit damages such that manual actuation of core cooling equipment, if necessary, can be achieved.

The AP1000 design also satisfies the SFP integrity acceptance criterion because it is surrounded by barrier walls that protect the SFP liner from adverse effects of an impact by a large commercial aircraft.

19F.2 Evaluation

The staff has reviewed the description of key design features provided by the applicant and the description of how the key design features show that the acceptance criteria in 10 CFR 50.150(a)(1) are met. The staff's evaluation is provided below.

19F.2.1 Reasonably Formulated Assessment

The applicant states that its AIA is based on the guidance of NEI 07-13, Revision 7. In a letter dated August 6, 2010, in response to RAI-SRP19F-AIA-07, the applicant confirmed that the AP1000 assessment does not take exceptions to portions of NEI 07-13 guidance that apply to the AP1000 design. In a revised RAI response dated September 15, 2010, the applicant further stated that an analytical evaluation and experimental verification has been performed for the first-of-a-kind steel-concrete modular design feature subjected to the aircraft impact loading in accordance with the recommendation set forth in Section 2.4.1(4) of NEI 07-13. Based on the applicant's use of NRC-endorsed guidance document, NEI 07-13, Revision 7, by qualified personnel, the staff finds that the applicant has performed a reasonably formulated assessment.

19F.2.2 Key Design Features for Core Cooling

The staff found the initial description of design features and functional capabilities for core cooling to be incomplete. In RAI-SRP19F-AIA-01, the staff identified specific areas in the DCD that needed to be augmented with additional information. The staff's review of the applicant's response to RAIs pertaining to core cooling is discussed below.

In RAI-SRP19F-AIA-01, the staff requested that the applicant identify and describe the specific design features relied upon to maintain core cooling following impact of a large commercial aircraft during power operation. In its response dated September 17, 2010, the applicant identified the following key design features: safety-related passive safety injection and long-term recirculation cooling systems, specific squib valves that need to actuate and equipment that supports actuation of the squib valves, including Class 1E batteries, control and instrumentation cabinets, cabling, and transfer switches. These design features are fully described in DCD Section 6.3 and parts of Section 7.

The staff reviewed the descriptions of these design features and found that the passive safety injection and long-term recirculation cooling system, have been designed specifically to maintain core cooling functions following design-basis events initiated during power operation. The staff considered the descriptions of the features, as well as the ability of these features to perform their design basis safety functions following impact of a large commercial aircraft, including conditions involving loss of coolant from the RCS, and finds that they are suitable for maintaining core cooling following an impact of a large commercial aircraft,. The staff also considered that since the AP1000 AIA credited the shield building to remain intact upon an aircraft impact, the components of the passive safety injection and long-term recirculation systems that are located within the containment structure would not be exposed to jet fuel damage. Furthermore, should this design feature fail to initiate automatically, it can be initiated or operated either from the MCR, the RSS, or the secondary DAS panel, and require no further operator intervention to maintain the core cooling function. This function can be achieved with the key design features identified in the table above as Numbers 1, 6, 8, and 9. On this basis, the staff finds the applicant's description of the key design features for core cooling to be adequate. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

In RAI-SRP19F-AIA-02, the staff requested that the applicant identify and describe the specific design features that are relied on to maintain core cooling following impact of a large commercial aircraft while the plant is shut down and the reactor is being cooled by the normal RNS. In its response dated August 6, 2010, the applicant states that should this occur, one of two sets of RNS containment isolation valves located inside containment can be closed from the MCR to terminate leakage from the RCS. These valves and the spatial separation between their location and the location of the MCR are identified as key design features. Core cooling is provided by gravity injection from the IRWST, initially, and the containment recirculation system in the long term. These two systems, including their squib valves, are identified in the DCD as key design features.

AP1000 DCD Section 19.E.2.3.3.1 describes use of these features for core cooling following a loss of RNS during shutdown in MODE 5 with the RCS open. The staff's review of this section of the DCD is described in Chapter 19 of NUREG-1793. The applicant has identified appropriate design features that have been shown to be effective in providing core cooling when the RNS is not available. Based on the above, the staff finds the applicant's description of the key design features for core cooling to be adequate. In a subsequent revision to the

AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

To conform to the guidance in NEI 07-13, applicants must consider whether the impact of large commercial aircraft would cause damage that could prevent the reactor from shutting down in the unlikely event that operators did not manually trip the reactor prior to impact. In RAI-SRP19F-AIA-03, the staff requested that the applicant describe those design features that assure the reactor will be shut down following an aircraft impact, including any features that protect equipment needed for reactor shutdown. In its response dated August 6, 2010, the applicant stated that the equipment needed for reactor shutdown is described in DCD Section 7.2.1 and is considered a key design feature(s). They also indicated that the design of this equipment is such that the reactor trip function will fail in a safe manner (control rods drop into the reactor by the force of gravity) if any of this equipment should become damaged by an aircraft impact. The fail-safe design of this equipment is described in DCD Section 7. Based on the above the staff finds that the applicant has adequately described how the reactor will be shut down should equipment normally relied upon for reactor shutdown be damaged by aircraft impact. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

In its initial submittal, the applicant identified the locations of the MCR, RSS and the secondary DAS panel as key design features. In RAI-SRP19F-AIA-04, the staff requested that the applicant describe the roles these features play in satisfying the acceptance criteria in the rule. The staff also requested that the applicant clarify which SSCs in these locations are being credited for actuation of the core cooling equipment. In its response dated August 6, 2010, the applicant stated that manual initiation of core cooling requires operator action from the MCR, RSS, or secondary DAS panel and that each location contains equipment capable of initiating core cooling design features. The applicant also stated that the AIA shows that no single strike from a large commercial aircraft can simultaneously damage the equipment at all three locations. Thus, the degree of separation between these specific facilities is a key feature of the plant design that enables the core cooling acceptance criterion in the rule to be met. The applicant included similar statements in DCD Appendix 19F.4.2. The applicant also added a description of the equipment in these locations needed to actuate core cooling design features. This equipment includes the Class 1E batteries, the supporting PMS control and instrumentation cabinets and cabling for the equipment identified in Appendix 19F.4.3, the transfer switch to isolate the MCR and transfer controls to the remote shutdown room, and the DAS cabling for the squib valve control cabinet.

The staff reviewed detailed descriptions of equipment needed for safe shutdown of the facility in DCD Section 7 and compared them with the set of SSCs cited by the applicant as needed to actuate core cooling design feature. The staff found that the applicant has adequately described key design features needed for actuating core cooling. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

19F.2.3 Key Design Features that Protect Core Cooling Design Feature

Structures

In Appendix 19F, the applicant states that the robust shield building design, as described in DCD Chapter 3, is a key design feature that would provide protection for the core cooling key design feature. It also states that the AP1000 assessment concluded that a strike upon the shield building by a large commercial aircraft would not result in perforation of the shield building and the containment vessel. Because the passive safety injection and long-term recirculation cooling systems that are credited as key design features for core cooling are located inside the containment vessel, it is expected that they will not be damaged, either from an aircraft impact or from exposure to jet fuel.

Fire Protection

The key design features that protect the core cooling key design feature also include the 3-hour rated barriers around and within the auxiliary building as described in DCD Sections 9.5.1 and 9A. The design and locations of fire barriers within the auxiliary building are credited to confine the spread of fire damage resulting from a large commercial aircraft impact. The applicant also credited 5 specific 34.5 kPa (5 psid) fire barriers, as described in DCD Section 9.5.1.2.1.1, to further limit fire spread. The AP1000 assessment determined that no aircraft impact scenario would cause perforation and subsequent fire propagation into the containment where the core cooling equipment is located. Neither would any scenario simultaneously destroy all three redundant locations where support equipment for manual actuation of the core cooling function is located. These key design features are identified in the table above as Numbers 1, 7, 13, and 14. On this basis, the staff finds the applicant's description of the key design features for protecting safety systems required to maintain core cooling to be adequate, as these systems are physically separated and protected by robust structural barriers.

19F.2.4 Containment Intact

The applicant states that the shield building and the protected steel containment vessel as described in DCD Chapter 3 are key design features for maintaining containment intact. Appendix 19F also states that the AP1000 assessment concluded that an aircraft strike upon the shield building would not result in perforation of the shield building and, therefore, the steel containment vessel is not affected. Based on the AP1000 beyond design basis calculation, air-only cooling of containment is sufficient to allow containment integrity to be maintained for 24 hours. This capability is achievable by key design features 1 and 10 as described above. Based on the above, the staff finds the applicant's description of the key design features for maintaining containment intact to be adequate as the containment: (1) will not be perforated by the impact of a large, commercial aircraft; and (2) will maintain ultimate pressure capability.

19F.2.5 Integrity of the Spent Fuel Pool

The key design features credited to maintain the integrity of the SFP are its location and structural design, as described in DCD Section 9.1.2.2 and Figure 3.7.2-12. The applicant indicates that the location and design of the SFP structure are such that it can withstand the effects of an impact of a large, commercial aircraft. The staff finds the applicant's description of the key design features for ensuring SFP integrity to be adequate.

19F.3 Conclusion

The staff finds that the applicant has performed an AIA that is reasonably formulated to identify design features and functional capabilities to show, with reduced use of operator action, that the acceptance criteria in 10 CFR 50.150(a)(1) are met. The staff finds that the applicant adequately describes the key design features and functional capabilities credited to meet 10 CFR 50.150, including descriptions of how the key design features show that the acceptance criteria in 10 CFR 50.150(a)(1) are met. Therefore, the staff finds that the requirements of 10 CFR 50.150(b) are met.

22. REGULATORY TREATMENT OF NON-SAFETY SYSTEMS

22.5.6 Post-72-Hour Actions and Equipment

The staff issued a request for additional information (RAI) on equipment that may be needed 72 hours after an accident (RAI‑SRP19.0‑SPLA‑20). Westinghouse Electric Company, LLC, (the applicant) responded in a letter dated July 15, 2009 (Agencywide Documents Access and Management System (ADAMS) Accession No. ML091980042), clarifying the description of ancillary equipment for the AP1000.

The AP1000 design relies on the following safety functions 72 hours after an accident:

- core cooling, inventory, and reactivity control
- containment cooling and ultimate heat sink
- main control room habitability
- post-accident monitoring
- spent fuel pool cooling

To support these functions, the AP1000 design includes nonsafety-related ancillary equipment. Connections are provided for generators and pumping equipment that can be brought to the site to back up the installed equipment. The ancillary equipment (alternatively, the transportable equipment) is capable of supporting extended operation of the passive safety systems.

- Electrical power is required to supply the following loads:

  – post-accident monitoring instrumentation

  – spent fuel pool monitoring instrumentation

  – ventilation for the main control room, instrumentation and control room, and direct current equipment room

  – power to replenish the passive containment cooling water storage tank (PCCWST) using motor-driven pumps

- After the energy stored in the 1E batteries is depleted, ancillary diesel generators in the annex building provide alternating current (ac) power. A fuel tank stores sufficient fuel for 4 days of operation (both trains). Power from each ac generator is fed to a distribution panel, from which it supplies the associated 1E battery recharger and passive containment cooling system (PCS) recirculation pump, as well as local services (heating for the ancillary diesel fuel tank and lighting for the ancillary diesel space). All of this equipment is in the seismically qualified portion of the annex building, which is also designed to withstand high winds and associated missiles.

- The seismically qualified portion of the annex building is accessible through the auxiliary building, which is a safety-related, seismic Category I structure. Seven days are available for plant operators to restore at least one path to the outside, through which the fuel tank can be refilled or a transportable generator can be connected to the distribution panel described above.

- Makeup water is required for the PCCWST, which provides water for the following:

  - containment cooling
  - firefighting
  - spent fuel pool cooling by maintaining the inventory of water in the pool

- The initial inventory of the PCCWST is adequate for 72 hours. An additional 4-day supply of water is stored in the passive containment cooling ancillary water storage tank, which is a seismic Category II structure, and designed to withstand high winds and associated missiles. One of two recirculation pumps in the PCS pumps this water to the PCCWST. If normal power is not available, an associated ancillary diesel generator can power each of the PCS recirculation pumps.

- A nonsafety-related connection is provided for external makeup to the PCCWST. It is compatible with available firefighting equipment and accessible from the yard outside the auxiliary building ("plant west" of the auxiliary building). Through this connection, any additional water required can be injected at the safety-related return line from the PCS recirculating pump and heater to the PCCWST.

The staff concludes that the design features described above provide adequate assurance that required safety functions can be maintained in the long term (beyond 72 hours post-accident) and after seismic events. This is consistent with the Commission's staff requirements memoranda on SECY-94-084 and SECY-95-132, both titled "Policy and Technical Issues Associated with the Regulatory Treatment of Non-Safety Systems in Passive Plant Designs," dated March 28, 1994, and May 22, 1995, respectively, and NUREG-0800, "Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants." Therefore, the design described above is acceptable.

22.5.9 Short-Term Availability Controls

AP1000 design control document (DCD) Tier 2, Table 16.3-2, "Investment Protection Short-Term Availability Controls," identifies short-term availability controls for nonsafety-related structures, systems, and components (SSCs) that are subject to regulatory treatment.

There are no limiting conditions for operation if the completion times for required actions are not met (i.e., there is no requirement to bring the plant to a safe-shutdown condition when operability requirements are not fulfilled). The staff finds this acceptable since these nonsafety-related systems do not meet any of the four criteria specified in Title 10 of the *Code of Federal Regulations* (10 CFR) 50.36(c)(2)(ii), "Technical specifications," that would require a limiting condition for operation:

(1) installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary

(2) a process variable, design feature, or operating restriction that is an initial condition of a design-basis accident or transient analysis that either assumes the failure of, or presents a challenge to, the integrity of a fission product barrier

(3) an SSC that is part of the primary success path and that functions or actuates to mitigate a design-basis accident or transient that either assumes the failure of, or presents a challenge to, the integrity of a fission product barrier

(4) an SSC that operating experience or probabilistic risk assessment has shown to be significant to public health and safety

In addition, inspections, tests, analyses, and acceptance criteria, (ITAAC) as described in DCD Tier 1, Section 3.7, "Design Reliability Assurance Program," address these SSCs. They are described in DCD Tier 2, Section 17.4, "Design Reliability Assurance Program," and identified in Table 17.4-1, "Risk-Significant SSCs Within the Scope of D-RAP"; therefore, the staff finds the administrative controls for regulatory treatment of nonsafety systems in DCD Tier 2, Table 16.3-2, to be acceptable.

In DCD Tier 2, Section 16.3.2, "Combined License Information," the applicant stated that combined license (COL) applicants referencing the AP1000 will develop a procedure to control the operability of investment protection SSCs in accordance with DCD Tier 2, Table 16.3-2. In DCD Tier 2, Section 13.5, "Plant Procedures," the applicant described the commitment to address operational and maintenance programmatic issues. The staff finds that COL Information Item 13.5-1 provides an acceptable method for ensuring that licensees will develop a procedure to control the operability of nonsafety-related SSCs subject to regulatory treatment.

23. DESIGN CHANGES PROPOSED IN ACCORDANCE WITH ISG-11

Westinghouse has submitted information in support of its design certification (DC) amendment application that Westinghouse considers "proprietary" within the meaning of the definition provided in Title 10 of the *Code of Federal Regulations* (10 CFR) 2.390(b)(5). Westinghouse has requested that this information be withheld from public disclosure and the Nuclear Regulatory Commission (NRC) staff agrees that the submitted information sought to be withheld includes proprietary commercial information and should be withheld from public disclosure. This chapter of the NRC staff's evaluation includes proprietary information that has been redacted in order to make the evaluation available to the public. The redacted information appears within "square brackets" as follows:

[   ]

The complete text of this chapter, including proprietary information, can be found at Agencywide Documents Access and Management System (ADAMS) Accession Number ML112091879 and can be accessed by those who have specific authorization to access Westinghouse proprietary information.

23. Introduction

This chapter addresses new design changes proposed by Westinghouse (the applicant) that were included in Revision 18 of the AP1000 design control document (DCD). The design changes that are evaluated in this chapter do not constitute all of the changes that the applicant proposed to include in the DCD, Revision 18. Rather, the design changes evaluated in this chapter are in addition to those that the applicant has submitted to the NRC as responses to requests for additional information (RAIs) or safety evaluation report (SER) open items.

The applicant proposes that the DCD be changed by adding new, more detailed design information that expands upon the design information already included in the DCD. This information would be used by every combined license (COL) application that references the certified AP1000 design. The regulations of 10 CFR 52.63(a)(1), "Finality of standard design certifications," require that the Commission may not modify a DC, whether on its own motion or in response to a petition from any person, unless the Commission determines that the change meets one of seven criteria. The staff finds that each of the changes evaluated in this chapter meets one or more of the seven criteria in 10 CFR 52.63(a)(1). Further, the staff finds that many of the design changes evaluated in this chapter contribute to the increased standardization of the certification information because the design amendment would be applied to all COL applicants that reference the DC rule. Therefore, these changes enhance standardization, and meet the finality criterion for changes in 10 CFR 52.63(a)(1)(vii).

Interim Staff Guidance, DC/COL-ISG-011, "Interim Staff Guidance Finalizing Licensing-basis Information," describes the staff's position regarding the control of licensing-basis information during and following the initial review of applications for DCs. In part, DC/COL-ISG-11 describes the categories of design changes that applicants should not defer until after the issuance of the DC rule. Categories of those changes that should not be deferred include:

- the correction of significant errors in an application;
- changes needed to ensure compliance with NRC regulations;
- changes needed to support other licensing-basis documents (e.g., conforming changes to information in the final safety analysis report (FSAR) supporting technical specifications (TS));
- significant technical corrections associated with the design or program described in the licensing document (i.e., if not changed, would preclude operation within the bounds of the licensing basis, as opposed to proposed alternatives to the described design or program); and
- changes needed to address a significant vulnerability identified by probabilistic risk assessments (PRAs) or other studies (e.g., a change in a PRA insight).

23.A Changes to Component Cooling Water System

23.A.1 Description of Proposed Changes

In letters dated April 26, 2010, and July 29, 2010, the applicant proposed changes to the design of the component cooling water system. The normal residual heat removal system (RNS), component cooling water system (CCS) relief valves increase in size from 2.54 centimeters (cm) x 2.54 cm (1 inch (in) x 1 in) to 7.62 cm x 10.16 cm (3 in x 4 in) to meet required flow capacity requirements. In addition, the CCS surge tank vent-line increases in size from 5.08 cm x 7.62 cm (2 in to 3 in) nominal pipe size (NPS). Tier 2 text in the DCD is modified to include Sections 3.4.1.2.2.2, “Auxiliary Building Flooding Events”; 9.2.2.3.4, “Component Cooling Water System Valves”; 9.2.2.4.5.2, “Leakage into the Component Cooling Water System from a High Pressure Source”; 19E.2.5, “Component Cooling and Service Water Systems”; and Figure 9.2.2-2, “Component Cooling Water System Piping and Instrumentation Diagram.”

23.A.2 Regulatory Basis

The regulatory basis for evaluating the CCS is documented in Section 9.2.2 of NUREG-1793, “Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design.” While the CCS is a nonsafety-related system, it is considered to be important to safety because it supports the normal (defense-in-depth) capability of removing reactor and spent fuel decay heat. It is part of the first line of defense for reducing challenges to passive safety systems in the event of transients and plant upsets, and its cooling function is important for reducing shutdown risk when the reactor coolant system (RCS) is open (e.g., mid-loop condition). The risk importance of the CCS makes it subject to regulatory treatment of nonsafety systems (RTNSS) in accordance with the Commission’s policy for passive reactor plant designs. The staff’s evaluation of the changes that are proposed focused primarily on confirming that the changes will not adversely affect safety-related structures, systems, and components (SSCs) or those that satisfy the criteria for RTNSS; the capability of the CCS to perform its defense-in-depth and RTNSS functions; and the adequacy of inspections, tests, analyses and acceptance criteria (ITAAC), test program specifications, and availability controls that have been established for the CCS. The proposed changes were evaluated using the guidance provided in NUREG-0800, “Standard Review Plan [SRP] for the Review of Safety Analysis Reports for

Nuclear Power Plants," Section 9.2.2, "Reactor Auxiliary Cooling Water System," Revision 4, March 2007, as it pertains to these considerations. Acceptability was based on conformance with the existing AP1000 licensing basis, the guidance specified in NUREG-0800 Section 9.2.2 (as applicable), and the Commission's policy with respect to RTNSS.

23.A.3 Evaluation

During the staff's evaluation of the proposed CCS design changes, it was determined that additional information was required from the applicant. The staff generated RAI-DCP-CN-06-SBP-01 addressing three issues.

Information previously supplied in a letter dated January 20, 2010, for Section 15.6.2, "Failure of Small Lines Carrying Primary Coolant Outside Containment," was omitted from the April 26, 2010 submittal. This information appeared to be relevant but was removed without an explanation. Additional information is needed to justify that a Chapter 15 change is no longer needed.

The basis for the increased CCS surge tank vent line from 5.1 cm x 7.6 cm (2 in to 3 in) (overflow protection due to normal residual heat removal system leakage into CCS) was not described in DCD Section 9.2.2. The applicant should consider adding this information to the DCD.

The flow rate (as measured in liters per minute (Lpm) (gallons per minute (gpm)) of the CCS/RNS relief valve(s) through the waste water system (WWS) was not described as related to the capacity of the auxiliary building sump pumps (concerns for potential building flooding if the relief valve flow rate exceeds the sump pump flow rate). The applicant should consider adding this information to the DCD.

The applicant's response to RAI-DCP-CN-06-SBP-01 provided the following:

1. The information was deleted from this section in the final proposed change because it describes a non-limiting case (i.e., it is bounded by the sample line break). Discussion of the RNS heat exchanger tube leak has been incorporated into Appendix 19E, Section 19E.2.5.

2. The CCS surge tank line vent/overflow line was increased in size from 5.1 cm x 7.6 cm (2 in to 3 in) to eliminate the potential for over-pressurizing the surge tank (designed as an atmospheric tank) in the event of a large RNS heat exchanger tube leak that causes a significant increase in liquid volume in the CCS. The basis for the increase in surge tank vent line size is described in the proposed revision to DCD Section 9.2.2.3.3.

3. The maximum flow rate possible as a result of a double-ended break of one RNS heat exchanger tube is approximately 1968 Lpm (520 gpm). The large relief valve on the RNS heat exchanger cooling water line discharges to the radioactive waste drain system (WRS) auxiliary building equipment and floor drain sump at elevation 20.3 meters (m) (66 feet (ft)-6 in). This sump is pumped to the waste holdup tank by two air-driven sump pumps, each of which has a nominal capacity of 473 Lpm (125 gpm). In the event that the relief valve discharges continuously for an extended period of time, the WRS floor drain sump may overflow into the 20.3 m (66 ft-6 in) level of the auxiliary building. Section 3.4.1.2.2.2 in Tier 2 of the DCD describes auxiliary building flooding events. In the radiologically controlled area of the first level (elevation 20.3 (66 ft-6 in)) there are no

safe shutdown components and the maximum flood elevation has been determined to be 30.5 cm (12 in) or less, assuming that the flooding is identified and isolated within 30 minutes.

Based on the staff's review, the applicant's response for Item 1 was determined to be acceptable since the DCD Tier 2 text that was deleted for Section 15.6.2 (between the January and the April letters) was not a bounding case and did not need to be included as part of DCD Section 15.6.2. The information that was added to Section 19E.2.5 was evaluated by the staff and was found acceptable since the DCD markup added relevant information associated with the RNS heat exchanger and overpressure protection. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

For Item 2, the staff finds the applicant's response to be acceptable since the increase in relief valve size assures that the CCS surge tank does not over-pressurize due to an RNS heat exchanger tube leak. The existing 5.1 cm (2 in) NPS was too small to pass the approximate 1968 Lpm (520 gpm) leakage from the RNS tube rupture. The DCD markup was provided to add this RNS leak-rate value to DCD Tier 2, Section 9.2.2.3.3. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

For Item 3, the staff finds the applicant's response to be acceptable since an overflow of the WRS floor drain sump does not affect safe shutdown components of a RNS heat exchanger tube break. The maximum flooding level on this floor (auxiliary building, elevation 20.3 (66 ft-6 in) was determined to be 30.5 cm (12 in) or less above the floor, assuming flooding is identified and isolated within 30 minutes.

23.A.4 Conclusion

The staff's review concludes that the design changes described above are acceptable since the proposed changes will not adversely affect safety-related SSCs and the capability of the CCS to perform its defense-in-depth and RTNSS functions will not be degraded by the proposed changes. These design changes were evaluated with respect to the adequacy of ITAAC, test program specifications, and availability controls that have been established for the CCS and found acceptable. RAI-DCP-CN-06-SBP-01 is resolved.

23.B Changes to Component Cooling Water System

23.B.1 Description of Proposed Change

In letters dated April 26, 2010, and July 29, 2010, the applicant proposed changes to the design of the CCS. Four piping header systems were added for the RNS/CCS relief valves. DCD Tier 2, Figure 9.2.2-2, was modified to include these piping header systems.

23.B.2 Regulatory Basis

The regulatory basis for evaluating the CCS is documented in Section 9.2.2 of NUREG-1793. While the CCS is a nonsafety-related system, it is considered to be important to safety because it supports the normal (defense-in-depth) capability of removing reactor and spent fuel decay heat. It is part of the first line of defense for reducing challenges to passive safety systems in the event of transients and plant upsets, and its cooling function is important for reducing shutdown risk when the RCS is open (e.g., mid-loop condition). The risk importance of the CCS makes it subject to RTNSS in accordance with the Commission's policy for passive reactor plant designs. The staff's evaluation of the changes that are proposed focused primarily on confirming that the changes will not adversely affect safety-related SSCs or those that satisfy the criteria for RTNSS; the capability of the CCS to perform its defense-in-depth and RTNSS functions; and the adequacy of ITAAC, test program specifications, and availability controls that have been established for the CCS. The proposed changes were evaluated using the guidance provided in NUREG-0800 Section 9.2.2, "Reactor Auxiliary Cooling Water System," as it pertains to these considerations. Acceptability was based on conformance with the existing AP1000 licensing basis, the guidance specified by NUREG-0800 Section 9.2.2 (as applicable), and the Commission's policy with respect to RTNSS.

23.B.3 Evaluation

During the staff's evaluation of the proposed CCS design changes, it was determined that additional clarification to the description of the design changes was required from the applicant; therefore, the staff generated RAI-DCP-CN-09-SBP-01.

The applicant's response to RAI-DCP-CN-09-SBP-01 is as follows:

> The "Eliminate the RNS …" statement should be replaced with "Larger pressure relief valves have been added to the CCW system." The reason for this design change is further clarified by:
>
> The original (1" x 1") thermal relief valves provided for the RNS and SFS heat exchangers were intended to discharge to the floor of the CCS valve room, where the discharge would be collected by a nearby floor drain. Now that much higher capacity relief valves are needed for the RNS heat exchanger cooling water lines to meet ASME VIII equipment overpressure protection requirements, the larger valves needed for the RNS heat exchanger (V302A/B) are piped to a dedicated drain collection funnel located in the valve room to minimize the potential release of large quantities of vapor and water spray to the room in the event that a high capacity discharge occurred. The smaller valves (V342A/B) are also provided with their own collection header that discharges near the existing room floor drain. These changes are shown in the revised sheet 3 of Tier 2 DCD Figure 9.2.2-2.

Based on the staff's review, the applicant's response was determined to be acceptable since the design includes a collection piping header and dedicated drain funnel to handle the potential release of large quantities of vapor and water spray to the room in the event of a high capacity relief valve discharge. This discharge connects to the main drain header in the auxiliary building. The previous design allowed relief valve discharge to the floor with water collection to the nearest floor drain. The DCD markup was provided to add this design improvement to DCD Tier 2, Figure 9.2.2-2. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

23.B.4 Conclusion

The staff' concludes that the design changes described above are acceptable since the proposed changes will not adversely affect safety-related SSCs and the capability of the CCS to perform its defense-in-depth and RTNSS functions will not be degraded by the proposed changes. These design changes were evaluated with respect to the adequacy of ITAAC, test program specifications, and availability controls that have been established for the CCS and found acceptable. RAI-DCP-CN-09-SBP-01 is resolved.

23.C Changes to Component Cooling Water System

23.C.1 Description of Proposed Changes

In a letter dated June 18, 2010, the applicant proposed changes to the design of the CCS. The proposed changes increase the size of the relief valves on four cooling water lines associated with the reactor coolant pumps (RCPs), and one chemical and volume control system (CVS). Specifically, the RCP cooling water line relief valves V253/A/B/C/D are changed from 7.6 cm x 10.2 cm (3 in x 4 in) to 10.2 cm x 15.2 cm (4 in x 6 in) with the associated branch lines L253A/B/C/D changed from 7.6 cm (3 in) to 10.2 cm (4 in). Also the CVS letdown cooling water line relief valve V222 is changed from 5.1 cm x 7.6 cm (2 in x 3 in) to 7.6 cm x 10.2 cm (3 in x 4 in) with the associated branch line size of L222 changed from 5.1 cm (2 in) to 7.6 cm (3 in). The basis for the change is to prevent over-pressurization of the CCS piping systems. DCD Tier 2, Figure 9.2.2-2 was modified to include these changes.

23.C.2 Regulatory Basis

The regulatory basis for evaluating the CCS is documented in Section 9.2.2 of NUREG-1793. While the CCS is a nonsafety-related system, it is considered to be important to safety because it supports the normal (defense-in-depth) capability of removing reactor and spent fuel decay heat. It is part of the first line of defense for reducing challenges to passive safety systems in the event of transients and plant upsets, and its cooling function is important for reducing shutdown risk when the RCS is open (e.g., mid-loop condition). The risk importance of the CCS makes it subject to RTNSS in accordance with the Commission's policy for passive reactor plant designs. The staff's evaluation of the changes that are proposed focused primarily on confirming that the changes will not adversely affect safety-related SSCs or those that satisfy the criteria for RTNSS; the capability of the CCS to perform its defense-in-depth and RTNSS functions; and the adequacy of ITAAC, test program specifications, and availability controls that have been established for the CCS. The proposed changes were evaluated using the guidance provided in NUREG-0800 Section 9.2.2, "Reactor Auxiliary Cooling Water System," as it pertains to these considerations. Acceptability was based on conformance with the existing AP1000 licensing basis, the guidance specified in NUREG-0800 Section 9.2.2 (as applicable), and the Commission's policy with respect to RTNSS.

23.C.3 Evaluation

Based on the staff's review, these design changes were determined to be acceptable. The changes to the five relief valves and associated branch piping are necessary to prevent over-pressurization of the CCS due to a postulated tube leak in the RCP and CVS heat exchangers with the cooling water lines isolated. The larger relief valves, 10.2 cm x 15.2 cm (4 in x 6 in) for the RCPs and 7.6 cm x 10.2 cm (3 in x 4 in) for CVS, and associated piping have been adequately sized for the required relief flow, thus preventing possible damage to the CCS. The DCD markup was provided to address these changes to DCD Tier 2, Figure 9.2.2-2. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

23.C.4 Conclusion

The staff's review concludes that the design changes described above are acceptable since the proposed changes will not adversely affect safety-related SSCs and the capability of the CCS to perform its defense-in-depth and RTNSS functions will not be degraded by the proposed changes. These design changes were evaluated with respect to the adequacy of ITAAC, test program specifications, and availability controls that have been established for the CCS and found acceptable.

23.D Changes to Ancillary Diesel Generator System

23.D.1 Description of Proposed Changes

In letters dated May 10, 2010, July 29, 2010, and August 5, 2010, The applicant proposed changes to the design of the ancillary diesel generator system. These design change apply to the nonsafety-related ancillary diesel generators and include the following changes:

- Increase the rating (from 35 kilowatts (kW) to 80 kW) and physical size of the ancillary diesel generators
- Increase the size of the diesel fuel oil storage tank and change principal construction code to the American Society of Mechanical Engineers (ASME) Code, Section VIII
- Revise certain circuit breaker sizes
- Revise corresponding physical drawings and electrical one line diagrams
- Revise design of the heating, ventilation, and air conditioning (HVAC) system for ancillary diesel generator and oil storage tank rooms

23.D.2 Regulatory Basis

Sections 8.3.1.3 and 9.5.4 of NUREG-1793 address the function and acceptability of the ancillary diesel generators for the AP1000. No regulatory basis documents are identified as applicable to the ancillary diesel generators since they are nonsafety-related, commercial grade equipment. Acceptability of these design changes were based on conformance with the existing AP1000 licensing basis.

23.D.3 Evaluation

The ancillary diesel generators are designed to provide the post-72 hour power requirements following an extended loss of onsite power sources. The ancillary diesel generators are not safety-related but provide electric power for Class 1E post-accident monitoring, main control room (MCR) lighting, MCR and Division B and C instrumentation and controls (I&C) room ventilation and for refilling the passive containment cooling system (PCS) water storage tank and the spent fuel pool (SFP) when no other sources of power are available. The ancillary diesel generators are not required to perform these functions for the first 72 hours following a loss of all other alternating current (ac) power sources. As stated in the proposed design changes submittal, the design of the anchorage for these skid-mounted package units is consistent with the safe-shutdown earthquake (SSE) design of equipment anchorages of seismic Category II equipment. The off-skid fuel oil piping and fuel oil storage tank are analyzed to show that they withstand an SSE.

During the staff's evaluation of the proposed design changes to the ancillary diesel generator design, it was determined that additional information was required from the applicant to complete the staff's evaluation. The staff generated RAI-DCP-CN-59-SBP-01 requesting clarification of the design changes and justification for the changes to the ventilation system for cooling the diesel. In addition, the description of the design changes did not appear to be consistent with the changes made to the DCD description for this system.

The heat removal arrangement for the operating diesels was changed to include ducting from the discharge of the diesel radiators through a backdraft damper to a hurricane-proof louver on an exterior wall of the diesel enclosure building. There is also a damper and recirculation bypass in the cooling exhaust duct that can be closed in cold weather to recirculate engine heat to the diesel generator room for room heating.

The inlet cooling air is admitted to the diesel generator room by opening a personnel access door on an exterior wall of the enclosure building when the diesel generator is operating. The staff questioned the inconsistency between an exhaust protected against hurricanes and an intake that is not protected during operation of the diesel generator.

The applicant response to RAI-DCP-CN-59-SBP-01 provides sufficient clarification of the design change to support the staff's evaluation and also provides proposed additional changes to the DCD to document the clarifications. With respect to the design for hurricane conditions, the applicant stated that a hurricane is only considered to be an initiating event and is postulated to occur when the ancillary diesel generators are not in operation. When the ancillary diesel generators are not operating, the exterior door used to provide intake of engine cooling air will be closed and this door is designed to withstand a hurricane, including windborne missiles. Since no more than a single initiating event hurricane is postulated for the design basis, hurricane protection is not needed when the ancillary diesel generators are operating and the door that provides inlet cooling air is open.

The change in design code for the ancillary diesel fuel oil storage tank from Underwriters Laboratories (UL) to ASME Code Section VIII provides a more rigorous and extensive set of design, fabrication and testing requirements for the tanks, and is, therefore, acceptable to the staff.

The proposed changes to the ancillary diesel generator do not change the ancillary diesel generators' physical or functional relationship to safety-related SSCs and, therefore, do not increase the potential to adversely affect these SSCs. In addition, the proposed DCD changes include a statement that the ancillary diesel generators and associated SSCs are designed to preclude spatial interaction with any other nonseismic SSC that could adversely interact to prevent the functioning of the post-72 hour SSCs following an SSE. The proposed DCD changes as revised in the response to RAI-DCP-CN-59-SBP-01 are acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant proposed to change the size of the ancillary generator from 35 kW to 80 kW because the starting motor current of the PCS recirculation pump, which can draw up to 6.5 times the full load current, was not considered in the generator sizing calculations. In addition, as part of this modification, the applicant proposed to revise the input circuit breaker size for the regulating transformer from 20 amps to 125 amps, the load test breaker from 100 amps to 60 amps, the PCS pump motor from 20 amps to 50 amps, revise Figure 8.3.1-3 of DCD Tier 2, and update Class 1E 208/120 uninterruptible power supply (UPS) one line diagram (Figure 8.3.2-2) to change "Transportable" AC Generator to "Ancillary" AC Generator. In addition, the applicant proposed other associated physical arrangement drawing changes to accommodate the increased size of the ancillary generator.

The staff reviewed the information provided by the applicant and was concerned that the revised rating of the distribution panel and the size of the output breaker for load testing of the ancillary generator were not compatible to accommodate the higher output current from the upgraded ancillary generator. In addition, the staff found that the proposed change to revise the input circuit breaker size for the regulating transformer from 20 amps to 125 amps did not seem to be adequate. In RAI-SRP 8.3.1-EEB-2, the staff requested the applicant provide its basis for the following:

(1) Utilizing a 125 amp breaker to protect 45 kilovolt amps (kVA) regulating transformer.

(2) Adequacy of the distribution panel rating of 100 amps for the 80 kW ancillary ac generators.

(3) Adequacy of the 60 amps breaker for full load testing of the 80 kW ancillary ac generators.

In a letter dated August 5, 2010, the applicant stated that it had reviewed the adequacy and accuracy of both the rating of the distribution panel and size of each of the breakers on the ancillary diesel generator bus. Based on its review, the applicant revised the distribution panel rating and breaker sizes as follows:

The 125 amp breaker to protect the 45 kVA regulating transformer will be changed from 125 amp breaker to 20 amp breaker, as was originally designed, to a breaker size appropriate to the load on the transformer under ancillary diesel generator operating conditions of 20 amps.

(1) The distribution panel rating will be increased from 100 amps to 225 amps so that it will be protected by the generator output breaker. This generator output breaker will be changed from 100 amps to 150 amps so as to be greater than 125 percent of the generator output.

(2) The 60 amp breaker for full load testing of the 80 kW ancillary generators will be replaced with a 150 amp breaker to allow for full testing of the ancillary diesel generator.

(3) The 50 amp breaker to protect PCS motor will be changed to 100 amps in order to avoid spurious tripping of the breaker on PCS motor start.

The staff has reviewed the above information and concludes that the proposed revised rating of the distribution panel and the size of each of the breakers on the ancillary diesel generator bus are compatible with the revised rating of the ancillary diesel generator. Therefore, the staff finds this concern resolved.

23.D.4 Conclusion

The staff's review concludes that the proposed design changes above are acceptable since the proposed changes will not adversely affect safety-related SSCs and the capability of the ancillary diesel generators to perform their post-72 hour function. These design changes were evaluated with respect to conformance with the existing AP1000 licensing basis and found acceptable. RAI-DCP-CN-59-SBP-01 and RAI-SRP 8.3.1-EEB-2 are resolved.

The staff has reviewed the proposed changes to the ancillary diesel generator design and concludes that the ancillary diesel generator distribution panel and the associated load feeder breakers are sized in accordance with the National Electric Code and, therefore, the proposed changes are acceptable. Also, the staff finds the changes made in Figure 8.3.2-2 to be minor and acceptable.

23.E Changes to Potable Water System

23.E.1 Description of Proposed Changes

In letters dated April 26, 2010, and August 2, 2010, The applicant proposed changes to modify the design of the potable water system (PWS) to add a safety-related loop seal in the PWS piping that penetrates the MCR envelope boundary to prevent in-leakage into the MCR envelope during MCR emergency habitability system (VES) operation.

23.E.2 Regulatory Basis

The applicable regulatory requirement and regulatory guidance are as follows:

- 10 CFR Part 50, "Domestic licensing of production and utilization facilities," Appendix A, "General Design Criteria for Nuclear Power Plants," General Design Criterion (GDC) 2, "Design Basis for Protection against Natural Phenomena," as it relates to the capability of the design to maintain and perform its safety function following an earthquake

- Regulatory guide (RG) 1.29, "Seismic Design Classification"

23.E.3 Evaluation

The current PWS is a nonsafety system. The applicant proposed a design modification of the PWS for the consideration of control room envelope integrity under a seismic event. If a pipe break occurs resulting from a seismic event, the current design of the PWS would not maintain the MCR VES pressure boundary. In the proposed design modification, the applicant added an isolation valve, a loop seal, and a vacuum breaker to upgrade portions of the PWS to provide safety-related function for MCR isolation in meeting RG 1.197 for MCR envelope integrity.

To meet the requirements of GDC 2 as it relates to structures and systems being capable of withstanding the effects of natural phenomena including seismic event, acceptance depends on meeting the guidance of the portions of Regulatory Position C.1 of RG 1.29 for the safety-related portions of the system and Regulatory Position C.2 of RG 1.29 for the nonsafety-related portions of the system.

To determine the adequacy of the safety-related function of the system modification, the staff requested more detailed information in RAI-DCP-CN01-SBP-COLP-01. In the RAI, the staff requested the applicant provide additional information pertaining to: (1) a figure and system description for the illustration of the system modification in the DCD; (2) the design basis and maintenance requirements for the loop seal; (3) the DCD changes including both Tier 1 and Tier 2; (4) the single failure discussion for the vacuum breaker; (5) the minimum response time for operator manual actions; (6) flood protection; (7) testing requirements; (8) TS requirements; and (9) MCR envelope integrity.

In a letter dated August 2, 2010, responding to RAI-DCP-CN01-SBP-COLP-01, the applicant provided more detailed information. Based on the review of the additional information, the staff found the following discussion from the RAI responses to form the basis for its finding:

1. Figure 9.2.5-1, “Main Control Room Potable Water System Isolation,” and system description are added in the DCD Tier 1 and Tier 2 to illustrate the portions of the PWS that have safety-related function pertaining to preventing in-leakage into the MCR envelope.

2. The loop seal is designed to maintain MCR isolation providing the operator sufficient time to close the PWS isolation valves in the event that the nonseismic PWS piping broke. The potable water tank is located at a higher elevation that maintains water in the loop seal by design. Therefore, no maintenance requirements are needed for the loop seal.

3. DCD changes were made in Tier 1 Section 2.7.1, Table 2.7.1-1 and Table 2.7.1-2, to include the safety-related portions of the PSW. These two tables are referenced by ITAAC Table 2.7.1-4. In Tier 2, changes were made in Table 3.2-3, Table 3.9-12, Table 3.9-16, Table 3.11-1, Section 9.2.5.1.1, Section 9.2.5.4, and Section 14.2.9.1.6, which address the safety design basis, safety-related portions of the PWS in AP1000 Class C, seismic Category I, ASME III-3, inservice test requirements, and environmental qualification.

4. The vacuum breaker is to help ensure that a break in the nonsafety-related potable water supply piping would not cause water to siphon from the loop seal. These pressure/vacuum relief devices are not required to consider single active failures. This is consistent with the implementation of a single vacuum relief device in the automatic depressurization system and VES.

5. The safety-related portions of the potable water seal assure MCR pressure boundary integrity after a design basis event. Since a seismic event is not assumed in the analysis to occur simultaneously with another design basis event (such as loss-of-coolant accident (LOCA)), there are no radiological conditions that would change MCR habitability. VES actuation occurs when there is sustained loss of electrical power. For this situation, the design basis for VES actuation is to provide breathable air for the MCR occupants. The MCR occupants will have a supply of breathable air for 72 hours and the MCR would remain habitable. The operators would be alerted to a loss of air through the loop seal piping by the low differential pressure alarm for the MCR and would close the potable water manual isolation valves. The time for the operator actions is not a critical parameter for the safety-related function.

6. The nonseismic PWS lines in the MCR are limited to the kitchen and restroom areas with line sizes of 2.5 cm (1 in) and smaller. There are no safety-related components that would be adversely affected by a rupture of the nonseismic PWS piping in the MCR kitchen and bathroom areas.

7. The initial test program and inservice testing included the PWS to ensure the integrity of the MCR pressure boundary; as shown in Tier 2 Section 14.2.9.1.6, Table 3.9.6, and Table 3.9-16.

8. TS, Section 3.7.6, “Main Control Room, Habitability System,” has been updated to include the safety-related isolation valves of the PWS. The MCR pressure boundary includes the PWS water seal that prevents gas flow through the piping. These TS changes were addressed in the response to RAI-SRP-6.4-SPCV-03.

9. The sanitary drainage system (SDS) is one of the systems that penetrate the MCR boundary. Portions of the SDS, including isolation valves and loop seals, have been modified to safety-related and seismic Category I. The modification of the PWS, DCD Tier 1 and Tier 2 information pertaining to the SDS was revised accordingly. The integrity of the AP1000 MCR boundary was addressed in the response to RAI-SRP-6.4-SPCV-03.

The staff has determined that the proposed modification meets RG 1.29, Position C.2 for the nonsafety-related PSW based on the information in Items (1) and (6) above – that the change portions of the nonsafety-related PWS will be safety-related, and that a failure of the nonsafety-related portions of the system will not adversely affect any of the safety-related functions. Further, the DCD information discussed in Item (3) above demonstrates that RG 1.29, Position C.1 is met for the safety-related portions of the system because appropriate classification designations are specified for the PWS consistent with the approach described in DCD Tier 2, Section 3.2. Based on meeting the guidance of RG 1.29, Positions C.1 and C.2, the staff has determined that the modified PWS meets GDC 2.

The staff reviewed the response to Items (2) and (4) and agrees with the applicant’s justifications that: (1) no maintenance is required for the loop seal because the elevation of the water tank is sufficient to provide the water seal without maintenance; and (2) the vacuum breaker is not required to consider single active failures because it is consistent with the VES design for the automatic pressure relieve devices.

The staff reviewed the response to Item (5) for the human factors concern of the minimum response time for operator manual actions. The applicant explained that operator action was not credited for any design basis event. The safety-related (seismic) design of the loop seal and surrounding pipe in coordination with other safety-related systems used to manage design basis events ensure that either the hazardous environment that would necessitate control room isolation is prevented and/or that the control room isolation function is maintained. The manual valves were installed as a defense-in-depth measure to address longer-term evaporation of the water in the loop seal, and for deterministic beyond-design-basis evaluations that simply considered the loop seal to be unavailable. There is no regulation or regulatory guidance applicable to operator manual actions used in this manner.

In reviewing Items (7) through (9), the staff finds that there is sufficient information to address the need for testing the isolation valves and establishing their TS to ensure the integrity of the MCR pressure boundary. The review of the integrity of the MCR pressure boundary is under

NUREG-0800 Section 6.4. The proposed changes were found acceptable in SER Section 6.4.1.3 because the overall effectiveness of the control room envelope is demonstrated through the testing associated with the control room integrity program.

Based on the above, the staff has determined that sufficient information is provided to address the staff's questions posed in RAI-DCP-CN01-SBP-COLP-01 and that sufficient details are provided in the DCD markups to address the safety-related function of the PWS. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

23.E.4 Conclusion

The staff's review concludes that the design changes described above are acceptable because they meet the requirements and guidance of GDC 2, RG 1.29. RAI-DCP-CN01-SBP-COLP-01 is resolved.

23.F Changes to Reactor Coolant Pressure Boundary Leakage Detection

23.F.1 Description of Proposed Changes

In letters dated January 20, 2010, and July 29, 2010, the applicant proposed changes to revise the licensing basis for unidentified RCS leak detection by removing the N13/F18 containment atmosphere radiation monitor and replacing it with the Flourine-18 (F-18) particulate monitor. The TS Limiting Condition for Operation (LCO) 3.4.9a, and the related discussions in TS Bases B 3.4.7 and B 3.4.9, are revised to reflect the change from the "N13/F18 gaseous monitor" to an "F18 particulate monitor."

In the process of reviewing this proposed design change, the staff identified an operating issue pertaining to RCS leakage detection. Operating experiences at Davis Besse (NRC Bulletin 2002-01, "Reactor Pressure Vessel Head Degradation and Reactor Coolant Pressure Boundary Integrity") indicated that prolonged low-level unidentified reactor coolant leakage inside containment could cause material degradation that could compromise the integrity of a system leading to the gross rupture of the reactor coolant pressure boundary.

23.F.2 Regulatory Basis

The applicable regulatory requirement and regulatory guidance are as follows:

- GDC 30, "Quality of Reactor Coolant Pressure Boundary," as it relates to providing means for detecting and, to the extent practical, identifying the location of the source of reactor coolant leakage

- 10 CFR 52.79(a)37, "Contents of applications; technical information in final safety analysis report," as it relates to "information necessary to demonstrate how operating experience insights have been incorporated into the plant design"

- RG 1.45, Revision 1, as it relates to "Guidance on Monitoring and Responding to Reactor Coolant System Leakage"

The regulatory basis for evaluating the generic technical specifications (GTS) is documented in Chapter 16 of NUREG-1793. The staff's evaluation of the proposed changes focused primarily on confirming that the changes to the GTS reflect the containment atmosphere radioactivity monitoring system design information as described in DCD Sections 5.2.5 and 11.5. The proposed changes were evaluated using the guidance provided in NUREG-0800 Chapter 16, "Technical Specifications – Revision 3, March 2010." Acceptability was based on conformance with the guidance specified in NUREG-0800 Chapter 16.

23.F.3 Evaluation

GDC 30 requires that means shall be provided for detecting and, to the extent practical, identifying the location of the source of reactor coolant leakage. RG 1.45 describes acceptable methods for implementing GDC 30.

<u>F18 Particulate Monitor</u>

The staff reviewed the proposed design changes, including changes in DCD Tier 2, Appendix 1A, Sections 3.1.4, 3.6.3.3, 5.2.5.3.3, and 11.5.2.3.1, and TS LCO 3.4.9, Sections B.3.4.7 and 3.4.9. The proposed design changes revise the licensing basis for unidentified RCS leak detection by removing the N13/F18 containment atmosphere radiation monitor and replacing it with an F-18 particulate monitor.

<u>Detector Sensitivity</u>

In the review, the staff determined that the applicant did not provide sufficient information to demonstrate that the newly proposed F-18 particulate radiation monitor (PSS-JE-RE027) sensitivity is capable of detecting the RCS leak rate of 1.9 lpm (0.5 gpm) according to the TS. Therefore, in RAI-SRP11.5-CHPB-05, the staff requested additional information on the analysis demonstrating the sensitivity of the proposed radiation monitor.

Although this design change specifies the radiation monitor sensitivity for particulate radioactivity, the change does not provide an analysis to demonstrate that the specified monitor sensitivity is capable of satisfying the technical basis of using realistic radioactive concentrations in the RCS, as described in RG 1.45, Revision 1.

In a May 14, 2010, response to RAI-SRP11.5-CHPB-05, the applicant provided the analysis demonstrating that the monitor can detect a RCS leak rate [ ] lower than that specified in the AP1000 TS. Based on its review, the staff found that the results of the applicant's analysis were highly and directly dependent upon the F-18 concentration in the reactor coolant and the fraction of F-18 assumed to enter the containment atmosphere.

The applicant derived the coolant concentration from two references [ ] and to be conservative and to minimize the amount of radioactivity leaked from the RCS, the applicant used the lower value in its analysis. The staff's own literature review of F-18 in pressurized-water reactor (PWR) reactor coolant indicated that the concentration could be 0.014 uCi/ml, [ ] which is lower than that used by the applicant.

The applicant estimated the amount of F-18 entering the containment atmosphere to be [ ] a small fraction of the total leaked from the RCS. The applicant derived this fraction from an analysis that estimated the fraction flashed into the space between a RCS coolant pipe and the insulation surrounding the pipe, and the fraction escaping from the insulation into the containment atmosphere. The applicant estimated the fraction flashed into the space between the pipe and insulation using a method described in NUREG-1320, "Nuclear Fuel Cycle Facility Accident Analysis Handbook," dated May 1988. Using an aerosol transport code, the applicant then calculated the fraction escaping the insulation into the containment atmosphere. The staff independently verified the flash fraction calculation using the method described in NUREG-1320. The staff also concluded that the final escape fraction calculated by the aerosol transport model was conservative because almost all aerosols larger than 1 micron diameter fail to escape into the containment atmosphere, thus greatly reducing the amount of radioactivity reaching the monitor.

Based on its review and independent verification, the staff concludes that the proposed monitor is sufficiently sensitive to detect the TS leak rate. Hence, the staff closed RAI-SRP11.5-CHPB-05.

Response Time

In the letter dated March 12, 2010, the applicant proposed to change the radiation monitor response time for the leak detection from 1.9 Lpm (0.5 gpm) within one hour to 1.9 Lpm (0.5 gpm) within two hours. However, in a May 14, 2010, response to RAI-SRP11.5-CHPB-05, the applicant stated that the radiation particulate monitor is capable of detecting a 1.9 Lpm (0.5 gpm) leak in one hour, and the applicant provided corresponding Tier 2 DCD changes. In a teleconference on July 29, 2010, the applicant clarified that the letter dated May 14, 2010, superseded the early letter regarding the response time. The staff has determined that the response time of detecting 1.9 Lpm (0.5 gpm) leakage in one hour as specified in the May 14, 2010, letter is consistent with the certified design of DCD Revision 15. Based on the clarification and the updated DCD Tier 2 changes, the staff has determined that no change in the response time for the radiation monitor is necessary and, therefore, detecting 1.9 Lpm (0.5 gpm) leakage within one hour is acceptable.

Based on the above, the staff has determined that the proposed F-18 particulate radiation monitor sensitivity and response time pertaining to the RCS detection function are acceptable. Further, using a particulate radiation monitor as one of the leakage detection instruments is consistent with the guidance in RG 1.45, Revision 1. Therefore, the staff has determined that the proposed F-18 particulate radiation monitor is acceptable.

With respect to proposed changes to GTS 3.4.9 and their associated bases, the staff finds these changes, as modified by the applicant's response to RAI-SRP11.5-CHPB-05 acceptable because they reflect the system design and operating information described in DCD Sections 5.2.5 and 11.5.

Davis Besse Operating Experience with RCS Leakage Detection

NRC Bulletin 2002-01 described that the operating experience at Davis Besse in 2002 indicated that prolonged low-level unidentified reactor coolant leakage resulting from nozzle cracking of the control rod drive mechanism inside containment could cause material degradation that could compromise the integrity of a system leading to the gross rupture of the reactor coolant pressure boundary. The question was raised regarding licensees' practices for identifying and resolving degradation of the reactor coolant pressure boundary. Pursuant to 10 CFR 52.79(a)37, relating to the requirement to provide "information necessary to demonstrate how operating experience insights have been incorporated into the plant design," in RAI-DCP-CN45-SBP-01, the applicant was requested to address this issue.

<u>COL Information Item</u>

In a letter dated July 29, 2010, responding to RAI-DCP-CN45-SBP-01, the applicant revised DCD to add a new COL information item, COL Information Item 5.2-3, and a new Section 5.2.6.3 to describe COL Information Item 5.2-3 as follows:

> 5.2.6.3 Response to Unidentified Reactor Coolant System Leakage Inside Containment
>
> The Combined License applicant will provide information to address prolonged low-level unidentified reactor coolant leakage inside containment which could cause material degradation such that it could potentially compromise the integrity of a system leading to the gross rupture of the reactor coolant pressure boundary. This issue could be addressed by operating procedures. The procedures should address operator actions in response to prolonged low level unidentified reactor coolant leakage conditions that exist above normal leakage rates and below the Technical Specification (TS) limits to provide operator sufficient time to take actions before the TS limit is reached. The procedures should address identifying, monitoring, trending, and repairing prolonged low-level leakage. The procedures should also define the alarm setpoints and demonstrate that the setpoints are sufficiently low to provide an early warning for operator actions prior to Technical Specification limits. In addition, the procedures should address converting the instrument output to a common leakage rate.

The staff reviewed the RAI-DCP-CN45-SBP-01 response and determined it to be acceptable because the description of the COL information item in DCD Section 5.2.6.3 markups is consistent with the guidance in RG 1.45, Revision 1, pertaining to managing the prolonged low-level reactor coolant system leakage. Therefore, GDC 30 is met based on the conformance to RG 1.45. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

23.F.4 Conclusion

The staff's review concludes that the design changes described above are acceptable because they meet the requirements and guidance of GDC 30 and RG 1.45, Revision 1. In addition, this design change was evaluated with respect to the adequacy of TS that have been established for the RCS leak detection instrumentation system and found acceptable. COL applications that incorporate by reference the DCD must address the new COL information item described in DCD Section 5.2.6.3. RAI-SRP11.5-CHPB-05 and RAI-DCP-CN45-SBP-01 are resolved.

23.G Changes to Spent Fuel Flood-up Valves Remote Position Indication

23.G.1 Description of Proposed Changes

In letters dated April 26, 2010, and August 3, 2010, the applicant proposed changes to the spent fuel flood-up valves remote position indication. AP1000 DCD, Revision 17 requires several valves that connect to the refueling cavity to have their position status monitored during plant shutdowns to prevent draining of the refueling cavity and the SFP. Tier 1 Table 2.3.7-1 presents a list of these valves. These valves are also designed as seismic Category I components and identified as such in Tier 1 of the DCD. The applicant has identified in these proposed design changes that the spent fuel pool cooling system (SFS) valves SFS-PL-V031 and SFS-PL-V033 are also required to have their position status monitored during plant shutdowns to prevent draining of the refueling cavity and the SFP, but were not identified as such in the DCD. This design change proposes to modify Tier 1 Table 2.3.7-1 to require that these valves have their position status displayed in the MCR. In addition, a previous design change identified that valve SFS-PL-V075 is required to be locked open during normal operation to provide a flow path during scenarios requiring containment flood-up. During refueling, V075 provides the same function of preventing the draining of the refueling cavity and the SFP as V031 and V033. This design change proposes to modify Tier 1 Table 2.3.7-1 to require valve V075 to have its position indicated in the MCR as well. This design change proposes to add two external Class 1E limit switches (open/closed) to the following isolation valves:

- SFS refueling cavity drain to steam generator system (SGS) compartment isolation valve (SFS-PL-V031)

- SFS refueling cavity drain to compartment sump isolation valve (SFS-PL-V033)

- SFS containment floodup isolation valve (SFS-PL-V075)

23.G.2 Regulatory Basis

The regulatory basis for evaluating these proposed design changes are documented in Section 7.5 and Section 9.1.2 of NUREG-1793. In particular, GDC 61, “Fuel Storage and Handling and Radioactivity Control,” requires the fuel storage system to be designed for adequate safety under anticipated operating and accident conditions. The system must be designed with the capability to prevent a significant reduction in fuel storage coolant inventory under accident conditions. During refueling operations the reactor cavity is connected to the SFP, and failure of the valves and piping sections identified above could drain the water from the refueling cavity and from the SFP. Acceptability of the proposed design changes was based on conformance with the existing AP1000 licensing basis and the guidance specified in NUREG-0800 Section 9.1.2 (as applicable).

Reviews of the changes are also based on meeting the relevant requirements of 10 CFR 50.55a(h), “Codes and standards,” and 10 CFR 52.47, “Contents of applications; technical information.” The changes must also conform to the requirements of GDC 13, “Instrumentation and Control,” and GDC 19, “Control Room,” in 10 CFR Part 50, Appendix A, and should meet guidance in RG 1.97, “Criteria for Accident Monitoring Instrumentation for Nuclear Power Plants.” The proposed changes were evaluated using the guidance provided in NUREG-0800 Section 7.5, “Information Systems Important to Safety.” Acceptability was also based on conformance with the existing AP1000 licensing basis and criteria specified in NUREG-0800 Section 7.5 (as applicable).

23.G.3 Evaluation

During the staff’s evaluation of these proposed design changes, it was determined that additional information was required from the applicant. The staff identified that the markup of DCD pages affected by the proposed design changes included changes that were not directly related to the justification provided in the design change submittal. In RAI-DCP-CN55-SBP-01.a and RAI-DCP-CN55-SBP-01.b, the applicant was requested to provide justification for these additional changes. In the RAI response letter dated August 3, 2010, the applicant stated that the changes identified by the staff in RAI-DCP-CN55-SBP-01.a were not part of this proposed design change, but were part of RAI-SRP6.4-SPCV-03, R2. The staff found the applicant's response acceptable because these changes were already evaluated by the staff in Section 6.4 of this report. Therefore, RAI-DCP-CN55-SBP-01.a is considered closed.

In response to RAI-DCP-CN55-SBP-01.b, the applicant stated that the deletions in Tier 2 Table 3.9-16 identified by the staff in RAI-DCP-CN55-SBP-01.b were not deleted from the table, but were moved to the next page. Since this represents an editorial change, the staff finds the applicant's response acceptable and RAI-DCP-CN55-SBP-01.b is considered closed.

In RAI-DCP-CN55-SBP-01.c, the staff identified that the Tier 1 drawings depicting this system did not show all the valves mentioned in the design change proposal (DCP). Therefore, the applicant was requested to update the Tier 1 drawings impacted by this design change. In the RAI response letter dated August 3, 2010, the applicant included a markup of Tier 1 Figure 2.3.7-1, which now included valve SFS-PL-V075. Therefore, the staff finds the applicant's response to be acceptable and RAI-DCP-CN55-SBP-01.c is considered closed. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

DCD Tier 2 Section 9.1.3.3.5, "Spent Fuel Pool Cooling System Valves," provides a description of the valve arrangement needed for refueling. It was not clear to the staff if this description was impacted by the proposed change. In RAI-DCP-CN55-SBP-01.d, the applicant was requested to confirm that the configuration description provided in Tier 2 Section 9.1.3.3.5 was still valid and had not been impacted by the proposed change. In the RAI response letter dated August 3, 2010, the applicant stated that the valve configuration description provided in Tier 2 Section 9.1.3.3.5 is still valid and has not been impacted by the proposed change. The staff agrees with the applicant's determination that Tier 2 Section 9.1.3.3.5 is still valid; therefore, RAI-DCP-CN55-SBP-01.d is considered closed.

The staff evaluated Tier 2 Figure 9.1-6 (Sheet 1 of 2) "Spent Fuel Pool Cooling System Piping and Instrumentation Diagram," and identified additional possible refueling cavity drain paths. In RAI-DCP-CN55-SBP-01.e, the applicant was requested to confirm that all refueling cavity drain path isolation boundary piping and components were described in Tier 2 and included in the appropriate Tier 1 sections and tables. In the RAI response letter dated August 3, 2010, the applicant stated that all refueling cavity penetrations and associated isolation valves that are at elevations below the minimum safety level outlined in Tier 2, Chapter 16, TS 3.9.4 are designed as seismic Category I, and have been identified in the appropriate DCD (Tier 1 and Tier 2) section. The applicant also clarified that all refueling cavity penetration lines and associated isolation valves that are not seismic Category I are located at elevations that preclude the possibility of draining the refueling cavity below the minimum safe level for refueling operations. The staff finds that the applicant has properly identified all the possible refueling cavity drain paths in the appropriate DCD sections, and that these drain paths are designed as seismic Category I components. Therefore, RAI-DCP-CN55-SBP-01.e is considered closed.

As documented in NUREG-1793, the staff reviewed and approved the SFS in AP1000 DCD Tier 1 Section 2.3.7 and Tier 2 Section 9.1.3. The staff reviewed the applicant's proposed design changes to the SFS in the AP1000 standard design by using the review procedures described in NUREG-0800 Section 7.5 and requirements of GDC 13 and GDC 19 in 10 CFR Part 50, Appendix A. AP1000 DCD, Revision 17, Tier 1 Table 2.3.7-1 shows that the safety-related display in the MCR is required for the SFS refueling cavity drain to the SGS compartment isolation valve (SFS-PL-V031) and SFS refueling cavity drain to the compartment sump isolation valve (SFS-PL-V033). These two valves are also required to have their position status monitored during plant shutdowns to prevent draining of the SFP. However, in AP1000 DCD, Revision 17, these two valves were designed without limit switches. To achieve the above required safety-related display functions, two external Class 1E limit switches (open/closed) are provided for valve (SFS-PL-V031) and valve (SFS-PL-V033).

The SFS containment floodup isolation valve (SFS-PL-V075) was added to the SFS by a previous DCP. This valve is required to be locked open to provide a flow path during scenarios requiring containment flood-up. Valve SFS-PL-V075, when closed, also provides the function of preventing the refueling cavity from draining. This function requires the status indication displayed for this valve in the MCR. But, the current valve functional requirements do not provide for remote position indication. Therefore, two external Class 1E limit switches (open/closed) have to be provided for the SFS containment floodup isolation valve to achieve the required safety-related display function.

For the specific DCD changes, the applicant added valve SFS-PL-V075 to DCD Tier 1 ITAAC Table 2.3.7-1 and the new SFS containment flood-up line to DCD Tier 1 ITAAC Table 2.3.7-2. The applicant also added the status of the above three valves to DCD Tier 2, Table 3.9-16, “Valve Inservice Test Requirements”; Table 3.11-1, “Environmentally Qualified Electrical and Mechanical Equipment”; Table 3.2-3, “AP1000 Classification of Mechanical and Fluid Systems, Components, and Equipment”; Table 7.5-1, “Post Accident Monitoring System”; and Table 7.5-7, “Summary of Type D Variables.” The staff finds that the proposed design changes described above are acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

23.G.4 Conclusion

The staff evaluated these proposed design changes against conformance with the existing AP1000 licensing basis and the guidance specified in NUREG-0800 Sections 7.5 and 9.1.2 (as applicable). The staff also evaluated these proposed design changes against the requirements of GDC 61, which requires the fuel storage system to be designed for adequate safety under anticipated operating and accident conditions.

The staff concludes that, based on the description provided in these design changes and the RAI responses discussed above, these proposed design changes are in compliance with the requirements of GDC 61 and follow the guidance provided in NUREG-0800 Sections 9.1.2 and 7.5; therefore, the staff finds the proposed changes to be acceptable.

23.H Changes to the AP1000 Steam Generator Thermal-Hydraulic Data Report

23.H.1 Description of Proposed Changes

In letters dated May 10, 2010; August 4, 2010; and August 12, 2010; the applicant proposed the following changes to the AP1000 steam generator (SG) design:

- In DCD Section 5.4.4.3, the pressure drop through the SG flow restrictor at 100 percent steam flow is changed from approximately 103 kiloPascal (kPa) (15 pounds per square inch (psi)) to approximately 138 kPa (20 psi).

- In DCD Table 5.4-5, the SG design fouling factor is changed from 1.937×10^{-5} to 1.586×10^{-5} m^2-°C/watt (W) (1.1×10^{-4} to 9.0×10^{-5} hr-°F-ft^2/British Thermal Unit (BTU)).

- In DCD Table 10.3.2-2 (and TS Table 3.7.1-2), the main steam safety valve (MSSV) lifting settings and relieving capacities are changed as follows:

Valve Nos.		Lift Setting kPa (psig)		Relieving Capacity 10^6 kg/hr (lb/hr)	
		From	To	From	To
MSSV #1	V030A/B	8170 (1185)	8170 (1185)	0.5940 (1.310)	0.5990 (1.320)
MSSV #2	V031A/B	8246 (1196)	8253 (1197)	0.5987 (1.320)	0.6078 (1.340)
MSSV #3	V032A/B	8329 (1208)	8336 (1209)	0.6105 (1.346)	0.6123 (1.350)
MSSV #4	V033A/B	8405 (1219)	8418 (1221)	0.6151 (1.356)	0.6169 (1.360)
MSSV #5	V034A/B	8487 (1231)	8494 (1232)	0.6205 (1.368)	0.6214 (1.370)
MSSV #6	V035A/B	8563 (1242)	8494 (1232)	0.6214 (1.370)	0.6214 (1.370)

The proposed changes to the MSSV lift settings and relieving capacities are in response to an increased pressure drop calculation for the SG steam outlet nozzle, which impacts the MSSV inlet line losses.

23.H.2 Regulatory Basis

The regulatory basis for evaluating the proposed changes to lift settings and relieving capacity is documented in Chapters 10 and 15 of NUREG-1793. GDC 10, “Reactor Design,” and GDC 15, “Reactor Coolant System Design,” respectively, in 10 CFR Part 50, Appendix A, require that the RCS and associated auxiliary, control, and protection systems be designed with sufficient margin to assure that specified acceptable fuel design limits (SAFDLs) and the design conditions of the reactor coolant pressure boundary, respectively, are not exceeded during any condition of normal operation, including anticipated operational occurrences (AOOs). The design basis events in DCD Chapter 15 were analyzed to ensure compliance with GDC 10 and GDC 15.

The regulatory basis for evaluating the GTS is documented in Chapter 16 of NUREG-1793. The staff’s evaluation of the proposed changes focused primarily on confirming that the changes to the GTS reflect the MSSV design and operating information described in DCD Section 10.3. The proposed changes were evaluated using the guidance provided in NUREG-0800 Chapter 16, “Technical Specifications – Revision 3, March 2010.” Acceptability was based on conformance with the guidance in NUREG-0800 Chapter 16.

23.H.3 Evaluation

As discussed in the August 12, 2010, response to RAI-DCP-CN58-SRSB-02, the applicant revised the calculation of the pressure differential across the SG steam outlet nozzle flow restrictor in the thermal-hydraulic data report, which is a document typically provided by the manufacturer to the utility operating the SG. The revised calculation showed an increase of the pressure loss from approximately 103 kPa (15 psi) to 138 kPa (20 psi). Therefore, the applicant proposed to revise DCD Section 5.4.4.3 by stating that the resultant pressure drop through the SG flow restrictor at 100 percent steam flow is approximately 138 kPa (20 psi), rather than approximately 103 kPa (15 psi) in DCD Revision 17. Also, the SG design fouling factor is revised from 1.937×10^{-5} to 1.586×10^{-5} m^2-°C/W (1.1×10^{-4} to 0.9×10^{-5} hr-°F-ft^2/BTU). The applicant stated that this reduction is based on the operating experience of replacement SGs with Alloy 690 tubing since 1989, and SG fouling factor is reduced to offset the increased pressure loss while still maintaining sufficient margin for the SG heat transfer performance. For the Chapter 15 safety analysis, a higher fouling factor was used where reduced heat transfer to the SG is limiting. The proposed lower value of SG design fouling factor provides increased margin. Therefore, there is no effect on the safety analysis.

Because of the increased pressure loss through the SG flow restrictor, the applicant proposed to change the relief capacities and lift settings of the MSSVs in accordance with ASME Code Section III, Subsection NC-7300. The setpoint of MSSV #6 (V035A/B), which is the highest MSSV setpoint, was lowered to account for the increased pressure losses and still maintain the required relieving capacities. In response to RAI-DCP-CN58-SRSB-01, the applicant stated that for the purposes of the AP1000 safety analysis, the significant MSSV setpoints are MSSV #1 (V030A/B) and MSSV #6 (V035A/B). MSSV #1 represents the lowest safety valve setpoint and is used to determine if design transients will challenge the MSSVs. MSSV #6 is the highest valve setpoint and is used to determine the overall steam pressure relief capacity in the safety analysis. In this proposed change, the lift setpoint of MSSV #6 is reduced from 8563 kPa (1242 psig) to 8494 kPa (1232 psig) to account for the impact of the revised SG flow restrictor pressure loss, but the relieving capacity of MSSV remains unchanged. The reduced lift setting resulted in a marginal increase in valve capacity with respect to the safety analysis of the limiting overpressure turbine trip event. Also, the lift setting of MSSV #1 is not changed while its relieving capacity is increased slightly. The setpoints and relieving capacities of MSSV #2 through MSSV #5 are also slightly increased, but they do not affect the safety analyses. Therefore, the proposed slight changes to the MSSV setpoints and relieving capacities have minimal effect on the safety analyses of the overpressure events. For the limiting turbine trip event, the minimum departure from nucleate boiling ratio (DNBR) remains well above the safety analysis DNBR limit, and the RCS pressure and the secondary side steam pressure remain within 110 percent of the respective design pressures.

With respect to proposed changes to TS 3.7.1, the staff finds these changes acceptable because they reflect the MSSV design and operating information described in DCD Section 10.3. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text.

23.H.4 Conclusion

Based on the above evaluation, the staff concludes that the proposed changes are acceptable because these changes have minimal effect on the safety analysis, and GDC 10 and GDC 15 continue to be complied with. These design changes were also evaluated with respect to the adequacy of TS that have been established for the MSSVs. The staff finds these changes acceptable.

23.I Changes Related to the Implementation of P-17 for Rod Withdrawal Prohibit

23.I.1 Description of Proposed Changes

In a letter dated May 10, 2010, the applicant proposed design changes related to the implementation of P-17 logic for rod withdrawal prohibit. The current design requires the P-17 signal coincident with the Beacon Unavailable Signal to generate the automatic rod withdrawal prohibit. The proposed changes would remove the Beacon Unavailable Signal and the associated AND logic gate to enable an automatic rod withdrawal prohibit solely on the rate of change in nuclear power (P-17). The implementation of the P-17 logic to prohibit rod withdrawal is a conservative change from the current design. As a result of this proposed P-17 logic change, the applicant proposed to revise DCD Section 15.4.3.2 by revising the sequence of dropped rod event in DCD Table 15.4-1 and DCD Figures 15.4-1 through 15.4-4 to reflect this change.

23.I.2 Regulatory Basis

The regulatory basis for evaluating the changes related to the implementation of P-17 logic for rod withdrawal prohibit is documented in Chapter 15 of NUREG-1793. The proposed design changes must also conform to the requirements of GDC 10, GDC 13, GDC 20, "Protection System Functions," and GDC 25, "Protection System Requirements for Reactivity Control Malfunctions" in 10 CFR Part 50, Appendix A.

GDC 10 requires that the reactor core and associated coolant, control, and protection systems be designed such that SAFDLs are not exceeded during normal operation, including the effects of AOOs. Control rod withdrawal is an AOO. The fuel cladding is the first barrier of protection against radioactive release. Meeting GDC 10 ensures that the fuel cladding integrity is not challenged during this AOO.

GDC 13 requires the provision of instrumentation that is capable of monitoring variables and systems over their anticipated ranges to ensure adequate safety, and the provision of controls that can maintain these variables and systems within prescribed operating ranges. Meeting GDC 13 ensures that the appropriate controls are provided to maintain these variables and systems within the prescribed operating ranges.

GDC 20 requires that the protective system automatically initiate the operation of the reactivity control system to ensure that fuel design limits are not exceeded as a result of AOOs. The withdrawal of a control assembly significantly impacts local fuel pin power and could lead to cladding failure. Measures are required to ensure that an abnormal rod withdrawal is detected and automatically terminated before fuel design safety limits are violated. Meeting GDC 20 ensures that cladding integrity is not challenged during this AOO.

GDC 25 requires that the reactor protection system be designed to ensure that SAFDLs are not exceeded for any single malfunction of the reactivity control system, such as accidental withdrawal of control rods. A failure of the reactivity control system that would create an unmitigated withdrawal of a control assembly could lead to cladding failure. Meeting GDC 25 ensures that a power transient fostered from a reactivity addition as a result of a single failure of the reactivity control system will be detected and terminated before challenging the fuel cladding integrity.

23.I.3 Evaluation

The proposed changes to enable the P-17 automatic rod withdrawal prohibit solely on the rate of change in nuclear power affect the response to dropped rod control cluster assembly (RCCA) events, described in DCD Section 15.4.3.2.1. A drop of one or more RCCAs from the same group results in an initial reduction in the core power and a perturbation in the power distribution. In the automatic control mode, the plant control system detects the drop in the core power and initiates withdrawal of a control bank, which could result in power overshoot. The implementation of the proposed P-17 logic to prohibit automatic rod withdrawal prevents the potential power overshoot and is, therefore, conservative relative to the current design. Therefore, the safety analysis of dropped RCCA events would be bounded by the existing analysis described in DCD Section 15.4.3.2.1, which demonstrated that the minimum DNBR for one or multiple rod drops from the same group is greater than the DNBR limit.

The applicant has run a spectrum of transients, varying key input parameters to verify that DNBR limits continue to be met with the proposed P-17 logic implementation. The sequence of a rod drop event displayed in DCD Table 15.4-1 is considered to be representative of all of the cases run. The results of a representative dropped RCCA event are provided in revised Figures 15.4.3-1 through 15.4.3-4. DCD Table 15.4-1 is also modified to reflect a representative case where the peak nuclear power occurs at time 21.7 seconds and peak core heat flux occurs at 24.2 seconds.

The staff has reviewed the proposed design changes to implement the P-17 logic for rod withdrawal prohibit. Based on its review, the staff finds that this change does not affect the safety analysis of the dropped RCCA events described in DCD Section 15.4.3.2.1, and the analysis continues to satisfy the acceptance criteria of NUREG-0800 Section 15.4.3 with respect to the minimum DNBR, peak pressure, and fuel cladding integrity. Therefore, the staff concludes that the proposed design changes are acceptable.

23.I.4 Conclusion

Based on the above evaluation, the staff concludes that the AP1000 proposed design changes are acceptable because they meet the requirements of GDC 10, GDC 13, GDC 20, and GDC 25.

23.J Changes Related to Post-Design Basis Accident Transmitters

23.J.1 Description of Proposed Changes

In letters dated May 25, 2010, July 29, 2010, and October 20, 2010, the applicant proposed design changes to relocate seven containment pressure transmitters outside containment and connect to remote pressure sensors inside containment by sealed capillary tubing. These changes require the addition of four new containment penetrations, one for each safety division. The applicant also proposed to relocate 18 Category 1 post accident monitoring system (PAMS) transmitters above the maximum design-basis accident (DBA) flood level. In addition, the applicant proposed to reduce post-accident operability time for 18 Category 2 PAMS transmitters from 4 months to 2 weeks.

23.J.2 Regulatory Basis

The regulatory basis for evaluating the changes to post-DBA transmitter requirements is documented in Chapters 3, 5, 6, 7, and 9 of NUREG-1793.

Reviews of the changes are also based on meeting the relevant requirements of 10 CFR 50.55a(h) and 10 CFR 52.47. The changes must also conform to the requirements of GDC 13 in 10 CFR Part 50, Appendix A, and should meet the guidance in RG 1.11, “Instrument Lines Penetrating Primary Reactor Containment”; RG 1.97, and RG 1.151, “Instrument Sensing Lines.” The proposed changes were evaluated using the guidance provided in NUREG-0800 Section 7.5, “Information Systems Important to Safety.” Acceptability was based on conformance with the existing AP1000 licensing basis and criteria specified by NUREG-0800 Section 7.5 and RG 1.11, RG 1.97, and RG 1.151 (as applicable). The addition of four new containment penetrations was evaluated using the guidance provided in NUREG-0800

Section 6.2.4, “Containment Isolation System”; NUREG-0800 Section 6.2.6, “Containment Leakage Testing”; and the requirements of 10 CFR Part 50, Appendix J, “Containment Leak Rate Testing,” and GDC 52, “Capability for Containment Leak Rate Testing.”

23.J.3 Evaluation

As documented in NUREG-1793, the staff reviewed and approved the post-DBA transmitter requirements in AP1000 DCD, Revision 15. The staff reviewed the applicant’s proposed design changes using the review procedures described in NUREG-0800 Sections 6.2.4, 6.2.6, and 7.5, requirements of GDC 13 and GDC 52 in 10 CFR Part 50, Appendix A; 10 CFR Part 50, Appendix J; and the guidance in RG 1.11, RG 1.97, and RG 1.151.

The applicant proposed to relocate seven containment pressure transmitters outside containment. These changes will allow direct measurement of differential pressure across the containment shell. These changes also allow those seven transmitters to be located in a mild environment. Relocation of the seven transmitters outside of containment could address the LCO in TS that containment pressure shall be maintained between -1.38 kPa (-0.2 psig) to 6.9 kPa (+1.0 psig), which are used in safety analysis.
[

] Relocation of the seven transmitters outside containment allows the plant to operate within TS for containment pressure. Moving the transmitters outside containment also eliminates the need to include a DBA environmental allowance in the determination of channel accuracy and the setpoint for PCS actuation.

Moving seven containment pressure transmitters outside containment and connecting to remote pressure sensors inside containment by sealed capillary tubing requires the addition of four new containment penetrations, one for each safety division. In Divisions A, B and C, the normal-range and wide-range transmitters share one capillary line and penetration. For Division D there is no wide-range transmitter, so the normal-range transmitter is on its own capillary. These four new instrument penetrations, P46, P47, P48, and P46 are identified in marked up DCD Tier 1 Table 2.2.1-1 and Figure 2.2.2-1, “Containment System.” In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

GDC 55, “Reactor Coolant Pressure Boundary Penetrating Containment,” or GDC 56, “Primary Containment Isolation,” usually require each line that penetrates the containment and is either a part of the reactor coolant pressure boundary or that connects directly to the containment atmosphere, to be provided with containment isolation valves. However, NUREG-0800 Section 6.2.4 endorses the containment isolation provisions described in RG 1.11 for instrument sensing lines. RG 1.11 finds sensing lines with no isolation valves acceptable as long as the lines are sized to limit the potential offsite exposure to be below the guidelines of 10 CFR Part 100, “Reactor site criteria.” The capillary tubing meets this criterion.

The four new containment penetrations to accommodate the new instrument capillary tubing will be leak rate tested, as required by GDC 52. The four new penetrations will be Type A tested, which meets the requirements of 10 CFR Part 50, Appendix J and the guidance of NUREG-0800 Section 6.2.6. This leak rate testing commitment will be added to DCD Tier 2, Table 6.2.3-1, “Containment Penetrations and Isolation Valves.” In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The applicant also proposed to move 18 Category 1 PAMS transmitters above the maximum DBA flood level within containment. This change is made to ensure that the 18 Category 1 PAMS transmitters are available following the DBA flood. [

]

The applicant also proposed to change the post-accident operation period for instruments that monitor Category 2 parameters. These changes would not affect Type A, B, or C primary post-accident parameters. These proposed design changes reduce the post-accident operation period from 4 months to 2 weeks. The Category 2 PAMS transmitter instruments are not required long term following a DBA, so their post-accident operation period can be changed from 4 months to 2 weeks. As Category 2 parameters, these parameters are not considered to be primary post-accident parameters for Type A, B, or C and, therefore, are not required to be qualified long-term following a DBA.

In the markup for AP1000 DCD, Tier 1, Table 2.2.2-1, the applicant changed the qualification for harsh environment from “Yes” to “No” for the seven containment pressure sensors. This change is not justified because the seven containment pressure sensors are still inside containment, even though the seven transmitters are moved outside containment. The applicant also failed to identify the 18 Category 1 PAMS transmitters that are proposed to be relocated above the maximum DBA flood level. As a result, the staff issued RAI-DCP-CN64-ICE-01 requesting the applicant to justify the changes in the environmental qualification of the seven containment pressure sensors. Also, the applicant was requested to identify which Category 1 PAMS transmitters are relocated.

In the RAI response, the applicant restored a harsh environment qualification requirement for the seven containment pressure sensors that are still located inside containment. In the response, the applicant also identified all 18 Category 1 PAMS transmitters that are relocated above the maximum DBA flood level. After reviewing all proposed design changes and information provided in the RAI response, the staff finds that the design changes are acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

These proposed changes also affected the TS Bases for Engineered Safety Feature Actuation System Instrumentation, B 3.3.2. The staff found this change acceptable since it provides details of the system design described in the changes to Section 6.2.2 of the DCD.

23.J.4 Conclusion

After reviewing the proposed design changes, markups to DCD Tier 1 and Tier 2 and RAI responses, the staff finds that the proposed design changes meet the post-DBA monitoring requirements for the transmitters. Therefore, the staff concludes that the proposed design changes are acceptable.

23.K Changes to Startup Feedwater System and Chemical and Volume Control System Isolation Logic

23.K.1 Description of Proposed Changes

In letters dated May 10, 2010, and July 29, 2010, the applicant proposed design changes to add an AND logic to the protection and safety monitoring system (PMS) Functional Diagram Sheets 6 and 10 of Figure 7.2-1 in the AP1000 DCD to isolate the startup feedwater system (SFW) and close the CVS isolation valves earlier in the steam generator tube rupture (SGTR) transient sequence in order to maintain the margin to the SG overfill. The SG narrow range level high coincident with reactor trip limiting setpoint is proposed to be changed to 85 percent and the actuation signal added to Table 7.3-1, Table 15.0-6, and TS Table 3.3.2-1 and its Bases. The newly added AND logic is to combine SGS narrow range level high with P-4 reactor trip.

23.K.2 Regulatory Basis

The regulatory basis for evaluating the proposed changes of SFW and CVS isolation on SGS narrow range level high coincident with P-4 reactor trip is documented in Chapter 7 of NUREG-1793.

Reviews of the changes are also based on meeting the relevant requirements of 10 CFR 50.55a(h) and 10 CFR 52.47. The changes must also conform to the requirements of GDC 13 and GDC 20 in 10 CFR Part 50, Appendix A. The proposed changes were evaluated using the guidance provided in NUREG-0800 Section 7.3, “Engineered Safety Features Systems.” Acceptability was based on conformance with the existing AP1000 licensing basis and criteria specified by NUREG-0800 Section 7.3 (as applicable).

23.K.3 Evaluation

As documented in NUREG-1793, the staff reviewed and approved the engineered safety features in Section 7.3 of AP1000 DCD Tier 2. The staff reviewed the applicant’s proposed design changes to the SFW and CVS isolation logic by using the review procedures described in NUREG-0800 Section 7.3 and requirements of GDC 13 and GDC 20 in 10 CFR Part 50, Appendix A.

The containment pressurization backpressure was not considered in the original transient analysis for the DBA of SGTR. However, the increase of the containment pressure resulting from heat transfer to containment via the passive residual heat removal (PRHR) heat exchanger (HX) impacts the boiling temperature of the in-containment refueling water storage tank (IRWST) water and results in a longer duration of SGTR breakflow. The analysis also showed that the SG overfill occurs at 12,739 seconds during a design basis SGTR accident with no operator actions modeled. These design changes have been proposed in order to maintain SG overfill margin without reliance on operator actions.

For the specific DCD changes, the applicant mainly added an AND logic to the PMS software logic (Sheets 6 and 10 of Figure 7.2-1), which combines the existing SG narrow range level high signal from either of the two SGs and P-4 reactor trip signal to isolate SFW and close CVS isolation valves. The narrow range level high signal for each SG results from a coincidence logic of two out of four divisions with bypass functionality. This change meets the reliability and testability requirements in GDC 21, “Protection System Reliability and Testability.”

Sections 7.3.1.2.13 and 7.3.1.2.15 in AP1000 DCD Tier 2 are also revised to include the new isolation signal for the SFW and CVS systems. The SG narrow range level high limiting setpoint at 85 percent and the actuation signal are added to Table 7.3-1, Table 15.0-6 and TS Table 3.3.2-1 and its bases. The staff finds that these design changes are acceptable. In a subsequent revision to the AP1000 DCD, the applicant made changes to the DCD text which are consistent with the proposed changes.

The AP1000 design provides automatic protection actions to mitigate the consequences of a SGTR event. The automatic actions include reactor trip, actuation of the PRHR HX, initiation of core makeup tank flow, termination of pressurizer heater operation, and isolation of CVS and SFW on high SG narrow range water level. The proposed change to add the SG narrow level high coincident with P-4 reactor trip would isolate the CVC and SFW at a relatively lower SG level and is, therefore, conservative during the SGTR. This added trip isolation function would conservatively maintain the SG overfill margin without relying on operator actions.

The staff has reviewed the proposed change to add an AND logic to the PMS software that combines the existing SG narrow range level high alarm and P-4 reactor trip to isolate SFW and CVS. Based on its review, the staff finds that the results of the analysis continue to show that the SG will not overfill with water, the maximum RCS pressure will not exceed 110 percent of design pressure, and the minimum DNBR will remain greater than the safety DNBR limit. Therefore, the staff concludes that this proposed change is acceptable.

The proposed design changes also include the addition of isolation functions to the engineered safety feature actuation system (ESFAS). If a narrow range high SG level signal is received, coincident with a P-4 reactor trip, signals are sent to isolate the CVS and SFW. In the case of CVS, this prevents additional make-up to the RCS in case of a SGTR casualty. The SFW isolation prevents an overfill condition and, therefore, an over cooling condition, if the reactor is tripped and the SFW system is not isolated. These changes affect the TS for ESFAS instrumentation, Table 3.3.2-1, as well as the discussion in bases Sections B 3.3.2 and B 3.4.17. The staff finds these changes acceptable since they conform to the guidance provided in the Standard Technical Specifications (STS) and add appropriate isolation for protection in these events, as discussed in the changes to Section 15.6.3 of the DCD.

23.K.4 Conclusion

After reviewing the proposed design changes and markups to DCD Tier 2 sections and tables, the staff finds that the proposed changes meet the applicable requirements and guidance for the safety-related functions. Therefore, the staff concludes that these design changes are acceptable.

Based on the above evaluation, the staff concludes that the proposed design changes are acceptable because the SGTR analysis continues to show margin to SG overfill, and meet the pressure and core safety DNBR limits, even though they are not required to be met for a SGTR event.

23.L Changes to Passive Core Cooling System Injection Lines

23.L.1 Introduction

In letters dated May 25, 2010; August 2, 2010; and August 20, 2010, the applicant proposed design changes to the passive core cooling system (PXS) injection lines to address gas intrusion, which included the addition of manual vent valves, pipe stubs, manual drain valves, instrumentation, and re-routing accumulator discharge line connections to the direct vessel injection (DVI) lines. These manual vent valves are located in containment rooms that are constructed to permit entry during full power conditions. Analyses have shown that with enough noncondensible gas accumulation, IRWST injection through the affected flow path could be delayed. Therefore, excessive amounts of noncondensible gas accumulation in the high point vents of the IRWST injection lines may potentially impact the passive injection of IRWST borated water into the reactor vessel (RV). However, the presence of a small amount of noncondensible gases does not imply that the IRWST injection capability is immediately inoperable but rather that gases that are accumulating need to be vented. The venting of these gases requires containment entry to manually operate the vent valves. Since gas accumulation is a slow process, plant operators have sufficient time to vent the noncondensible gases upon receiving an alarm. To incorporate the proposed change, the system modification would include revisions to Tier 1 Figure 2.2.3-1, Tier 2 Figures 5.1-5 and 6.3-1, and Tier 2 Tables 3.2-3, 3.9-17, 3.11-1 and 3I.6-3 to identify the new components. In addition, the proposed change includes three new DCD Sections 6.3.6.3, 6.3.6.3.1, and 6.3.6.3.2, which provide a description of the plan to mitigate gas intrusion and accumulation by means of periodic system surveillance and venting procedures, review of pipe layout and routing drawings to identify high-point vent and low-point drain locations, and assessment of system design features. Also, to ensure proper operational implementation of this design change since gas accumulation has the potential to impact safety-related systems, IRWST required actions and surveillance requirements are added to DCD Section 16.1, "Technical Specifications." For controls of IRWST operations, the affected TS sections are TS 3.5.6, TS 3.5.7, and TS 3.5.8 for during Modes 1 through 4, Mode 5, and Mode 6, respectively.

23.L.2 Regulatory Basis

GDC 27, "Combined Reactivity Control Systems Capability" in 10 CFR Part 50, Appendix A, requires that the emergency core cooling system (ECCS) be designed to provide the capability to assure that under postulated accident conditions and with appropriate margin for stuck rods, the capability to cool the core is maintained.

GDC 27 is applicable because upon actuation the ECCS provides rapid injection of borated water to ensure reactor shutdown. Injection of borated water provides negative reactivity to reduce reactor power to residual levels and ensures sufficient cooling flow to the core. Meeting the requirements of GDC 27 for the ECCS augments the protection for the primary fission product barrier by providing a means to ensure that the core, under postulated accident conditions, can be safely shut down and will be maintained in a coolable geometry. Noncondensible gas accumulation has the potential to delay injection of borated water. Such a delay would impact the moderating and heat removal capabilities, thus providing an adverse challenge to the primary fission product barrier and maintenance of coolable core geometry.

GDC 35, "Emergency Core Cooling," requires, among other things, that the ECCS be designed to provide an abundance of core cooling to transfer heat from the core at a rate such that fuel and clad physical damage that could interfere with continued effective core cooling is prevented.

GDC 35 is applicable because following a breach in the reactor coolant pressure boundary; reactor coolant is lost at a rate determined by several factors, including break size and RCS pressure. The ECCSs are relied upon to inject adequate cooling water into the RCS during a LOCA and to circulate the water through the core to provide for core cooling. The ECCS must inject cooling water at a rate sufficient to ensure that the calculated changes in core geometry will be such that the core remains amenable to cooling, and that the calculated cladding oxidation and hydrogen generation meet the specified performance criteria. Based on analysis, noncondensible gas accumulation has the potential to delay injection of borated water; such a delay may adversely affect fuel and cladding physical configuration with potential to challenge the coolability of the core geometry.

The regulatory basis for evaluating the GTS is documented in Chapter 16 of NUREG-1793. The staff's evaluation of the proposed changes focused primarily on confirming that the changes to the GTS reflect the IRWST design and operating information described in DCD Section 6.3. The proposed changes were evaluated using the guidance provided in NUREG-0800 Chapter 16, "Technical Specifications – Revision 3, March 2010." Acceptability was based on conformance with the guidance specified in NUREG-0800 Chapter 16.

23.L.3 Evaluation

Noncondensible gas accumulation effects on the performance of safety related "active" emergency core cooling, residual heat removal, and containment spray systems have been documented based on operating plant experience and system analysis. Some of these events are identified in NRC generic letter (GL) 2008-01, "Managing Gas Accumulation in Emergency Core Cooling, Decay Heat Removal and Containment Spray Systems," which illustrates the need for license holders to review their safety systems to resolve this issue. The focus of this GL is centered on four principal concerns: (1) licensing basis, (2) design, (3) testing, and (4) corrective actions. Also, the GL provides an assortment of pertinent generic communications documents related to this subject, which was helpful in the staff's evaluation. Although the GL refers to active safety systems focusing on gas accumulation effects on pump performance, the applicant expanded its existing design activity to include AP1000 passive safety systems to "integrate the draft Interim Staff Guidance (ISG) document ISG-019 regarding gas intrusion assessment guidance into the design process, helping to confirm that the potential issues identified in" the GL have been addressed in the AP1000 design. However, this safety evaluation is related to proposed design changes that primarily address gas intrusion and accumulation in the PXS.

The proposed changes include the addition of the following components:

- 8 manual maintenance vent valves in 6 PXS passive injection and recirculation line piping high point locations;

- 4 pipe stubs with maintenance vents and associated valves, line routing to tee into core makeup tank (CMT) vent line routing to the reactor coolant drain tank (RCDT);

- Remote pipe stub gas void indications at the outlets of each of the IRWST passive injection squib valves;

- Re-routing the 2 accumulator discharge line connections to both DVI line vertical cold trap (riser) pipes to tee in physically above (in elevation) and downstream of the associated IRWST connection into the DVI riser pipes (instead of locating the accumulator connection upstream of and below the IRWST tee);

- 20 manual maintenance drain valves in 14 PXS passive injection and recirculation piping locations, 5 normal RNS piping locations, and 1 RCS piping location. (Note: The RNS and RCS drains are unrelated to gas intrusion effects but part of design finalization to consolidate required PXS line changes and piping analyses.)

Issues identified during staff review were addressed in three RAIs, identified as RAI-DCP-CN66-SRSB-01 through RAI-DCP-CN66-SRSB-03, with the primary issues summarized below:

1. RAI-DCP-CN66-SRSB-01
   - Explain the exclusion of vent valves to Train B of the containment recirculation.

2. RAI-DCP-CN66-SRSB-02
   - Provide the bases for selecting 5.7 Liter (L) (0.2 cubic feet ($ft^{3)}$) as the noncondensible gas volume limit in the TS surveillance requirements (SR).
   - Describe the volume measuring method of the noncondensible gas.
   - Describe how the 5.7 L (0.2 ft^3) volume of noncondensible gas is accounted for in the safety analyses for LOCA and post-LOCA long term cooling.

3. RAI-DCP-CN66-SRSB-03
   - Provide justification for excluding the new instrumentation and valve components in ITAAC.
   - Describe the calibration frequency of resistance temperature detector (RTD) switches used to measure the volume.
   - Discuss whether the calibration frequency is controlled by TS.

In its August 20, 2010 response to RAI-DCP-CN66-SRSB-01, the applicant stated that containment recirculation Train A and Train B paths have different configurations to avoid other components and piping lines. Whereas, Train A was routed with two high points to circumvent interference with other plant components, Train B layout constraints were less complicated; hence, there are no local high points that could accumulate gas. After further review, the staff finds the RAI response acceptable.

With regard to RAI-DCP-CN66-SRSB-02, the applicant responded that originally the 5.7 L (0.2 ft^3) noncondensible gas volume limit was selected for the CMT inlet high point pipe TS SR 3.5.2.4 because it was slightly larger than the internal volume between the sensors location on the pipe stubs and the first normally closed manual vent valve that was previously evaluated and approved. Since the gas intrusion and accumulation is a slow process and the alarm occurs before voiding is extended into the line, the relocation allows sufficient time for the operators to vent the line before gas buildup could adversely affect the passive safety operability performance. Therefore, initially the PXS volume limit of 5.7 L (0.2 ft^3) was selected to be consistent with the CMT SR requirements since the IRWST injection line high points, pipe stubs, and sensor configuration is similar to that of the CMT. However, based on the applicant's response, the staff concludes that the sensor location not the volume limit is relevant to proper performance of venting the line because the sensor is configured as a level switch, as discussed below. Therefore, the applicant has proposed to remove the reference to the volume limit from TS SRs 3.5.2.4, 3.5.4.3, and 3.5.6.3 and replace it with "has not caused the high-point-water level to drop below the sensor." Also, the corresponding TS Bases would be revised to appropriately reflect the removal of the volume limit. The staff finds this proposed change acceptable because it refers to the correct function of the sensor.

In addition, the applicant stated that the volume is not directly measured but the change of state from liquid to gas provides the mechanism that controls the sensor output. The sensors are thermal dispersion sensors consisting of one heated RTD and one non-heated RTD configured such that the RTDs function as a thermal dispersion level switch where the temperature difference is based on the conductivity of the medium in contact with the two elements. When the RTDs are exposed to gas, the change in the differential temperature of the elements causes the output switch to actuate providing an alarm to the operator. This sensor configuration has been used in other plant applications with reliable results. Therefore, the staff finds this method to be acceptable.

With respect to safety analyses for LOCA and post-LOCA long term cooling, the applicant stated that the proposed volume is not considered in any safety analyses because the pipe stub and sensor configuration allows for sufficient time for venting before the actual injection path begins to void. The staff finds this acceptable because the alarms trip with less than half the volume of gas that could affect the injection flow performance, the rate of gas accumulation is expected to be sufficiently slow, and there are no credible postulated gas intrusion mechanisms for these locations.

In its August 20, 2010, response to RAI-DCP-CN66-SRSB-03, the applicant stated that the proposed instrumentation switches provide pre-event operability confirmation and are not used for reactor trip, safeguards actuation, or post-accident monitoring functions. As such, these switches are not required to be part of ITAAC or TS. Also, since the switches are nonsafety related process instrumentation, there is limited periodic calibration or functional checking requirements. The staff considers acceptable the response that the process switches do not meet the requirements to include them in ITAAC and TS.

The proposed changes also included the addition of two new actions and one SR to TS 3.5.6, TS 3.5.7, and TS 3.5.8 related to one or two IRWST injection line(s) “inoperable due to presence of noncondensible gases” and surveillance of the new sensors indication. Also, the appropriate TS Bases would be revised to reflect this change. The staff reviewed the new actions, SR, and bases, which provide for conditions, required actions, completion times, and SRs. The staff found that these parameters conform to guidance provided in the STS and reflect the IRWST injection line gas intrusion and accumulation process analysis described in DCD Section 6.3. Therefore, the staff finds the TS change, as modified in the response to RAI-DCP-CN66-SRSB-03 noted above, to be acceptable.

In addition, the proposed change would provide for system surveillance and venting procedures, as described in DCD Chapter 13, to include inspection of the passive safety system location equipped with manual vent valves to eliminate any identified gas accumulation. Procedural inclusion of vent component inspection is acceptable to the staff because timely inspections could reduce intrusion and accumulation of gases in the injection lines.

In accordance with NUREG-0800 Section 6.3, the staff’s evaluation of these proposed design changes must ensure that compliance with GDC 27 and GDC 35 is satisfied. As stated in NUREG-0800, meeting the requirements of:

> …GDC 27 for the ECCS augments the protection for the primary fission product barrier by providing a means to ensure that the core, under postulated accident

> conditions, can be safely shut down and will be maintained in a coolable geometry.
>
> …GDC 35 ensures that the ECCS, assuming a single failure, can provide core cooling under accident conditions sufficient to maintain the core in a coolable geometry and to minimize the reaction of water with the fuel cladding.

The staff evaluation of the proposed change concludes that the reliability and performance of PXS is improved. The requirements of GDC 27 and GDC 35 are satisfied based on the following:

- TS requirements that ensure that the PXS is operated in safe condition;
- Adequate procedural inspections to identify and eliminate gas intrusion and accumulation; and
- Sufficient monitoring and alarming features in the control room to ensure timely venting.

23.L.4 Conclusion

Based on the above evaluation, the staff concludes that the proposed changes to provide venting of noncondensible gases in the injection lines enhance the reliability and performance of the PXS to ensure that the core, under postulated accident conditions, can be safely shut down, maintain a coolable geometry, and minimize the reaction of water with the fuel cladding, thus satisfying the requirements of GDC 27 and GDC 35. Therefore, the proposed design changes are acceptable.

23.M Changes to Squib Valve Actuation Time

23.M.1 Description of Proposed Changes

In letters dated April 28, 2010, July 29, 2010, and August 12, 2010, the applicant proposed design changes to the PMS and diverse actuation system (DAS) controls for PXS IRWST injection squib valves actuation by incorporating a 5-second time delay in PXS actuation control for the automatic (and manual) actuation circuitry between the firing of the first and second valve for each pair of squib valves in the same process line. These proposed design changes address the unacceptable design stress on DVI line piping during simultaneous actuation of squib valves in the parallel configuration. The applicant also made similar changes to PMS controls for PXS containment sump recirculation squib valves in parallel path of the same process line. These proposed design changes revise functional diagrams in DCD Figure 7.2-1 by adding Note 5 in Sheet 16, “In-containment Refueling Water Storage Tank Actuation,” and Note 6 in Sheet 20, “Diverse Actuation System Logic, Manual Actuation,” which state that, for redundant components in a parallel configuration, the components use different time delays to prevent simultaneous actuation.

23.M.2 Regulatory Basis

GDC 35 in 10 CFR Part 50, Appendix A, requires that an ECCS be provided to transfer heat from the reactor core following any LOCA at a rate such that: (1) fuel and clad damage that could interfere with continued effective core cooling is prevented; and (2) clad metal-water reaction is limited to negligible amounts. 10 CFR 50.46, "Acceptance criteria for emergency core cooling systems for light-water nuclear power reactors," specifies that the calculated ECCS cooling performance be shown to comply with the acceptance criteria specified in 10 CFR 50.46(b).

The regulatory basis for evaluating the changes in squib valve actuation time is documented in Chapters 6, 7, and 15 of NUREG-1793.

Reviews of the proposed changes are also based on meeting the relevant requirements of 10 CFR 50.55a(h) and 10 CFR 52.47. The changes should also conform to the guidelines of Institute of Electrical and Electronic Engineers (IEEE) Standard 7-4.3.2, "IEEE Standard Criteria for Digital Computers in Safety Systems of Nuclear Power Generating Stations," as endorsed by RG 1.152, "Criteria for Use of Computer in Safety Systems of Nuclear Power Generating Stations," and the staff requirements memorandum (SRM) on SECY-93-087, "Policy, Technical, and Licensing Issues Pertaining to Evolutionary and Advanced Light-Water Reactor (ALWR) Designs." The proposed changes were evaluated using the guidance provided in NUREG-0800 Section 7.3, "Engineered Safety Features Systems," and Section 7.8, "Diverse Instrumentation and Control Systems." Acceptability was based on conformance with the existing AP1000 licensing basis and criteria specified in NUREG-0800 Sections 7.3 and 7.8 (as applicable).

23.M.3 Evaluation

The proposed changes add notes in the PMS and DAS functional diagrams in DCD Figure 7.2-1 to state that the redundant components in a parallel configuration use different time delays to prevent simultaneous actuation from adversely impacting accident timing in the safety analyses. For the automatic depressurization system (ADS) stage-4 squib valves, DCD Table 15.6.5-10 specifies the actuation time delay of 60 seconds between the ADS-4A and ADS-4B squib valves. The proposed change was only required for the IRWST injection and containment recirculation sump squib valves since the ADS stage-4 valves already have a 60-second time delay difference in their automatic actuation circuitry.

In its August 12, 2010, response to RAI-DCP-CN08-SRSB-01, the applicant stated that its proposed 5-second time delay for the actuation of redundant squib valves in each IRWST injection path and containment recirculation flow path, respectively, was included not to correct the system safety performance, but rather to protect the integrity of components, piping and structural and mechanical modules, in relationship to the specific squib valves actuation characteristics. The applicant performed an evaluation of LOCA safety analyses with the 5-second delay and found that the impact is not significant. The AP1000 design has the squib valves actuate a relatively long time before they are needed, on the order of several hundreds of seconds, so that the very short squib valve actuation delay of 5 seconds or reasonably longer time for the second squib valve in each path is not significant to the IRWST injection and/or containment recirculation performance of the plant events. Therefore, the safety analyses have not been revised to implement this 5-second time delay. The staff agrees with this explanation. The existing safety analyses in DCD Section 15.6.5 for the large-break LOCA, small-break LOCA, and long-term cooling remain valid and in compliance with GDC 35 and 10 CFR 50.46. Therefore, this proposed change is acceptable.

As documented in NUREG-1793, the staff reviewed and approved Functional Diagram Sheet 16 of Figure 7.2-1 for PXS IRWST injection and containment recirculation isolation squib valves actuation and Functional Diagram Sheet 20 of Figure 7.2-1 for DAS manual actuations for IRWST injection squib valves. The staff reviewed the applicant's proposed design changes to the two functional diagrams using the review procedures described in NUREG-0800 Sections 7.3 and 7.8.

10 CFR 52.47 requires that an application include a sufficient description and analysis of the SSCs of the facility, with emphasis upon performance requirements, the bases, with technical justification; therefore, upon which these requirements have been established, and the evaluations required to show that safety functions will be accomplished. The description shall be sufficient to permit understanding of the system designs and their relationship to the safety evaluation. The design information provided for the design basis items, taken alone and in combination, should have one and only one interpretation. Hence, the staff issued RAI-DCP-CN08-ICE-02, requesting the applicant provide clarification for the time delay inconsistency between the design change description and marked-up diagrams and also justify the need for a 5 second time delay between the firing of the two IRWST injection squib valves. In the RAI response, the applicant explained that the 5-second time delay is required to prevent a negative structural impact on the supporting bracket from induced vibrations if both squib valves are fired simultaneously. The firing of one of the commonly mounted explosive valves followed by a five second time delay will have no negative impact on operation. The design change provides an improved protection of the safety function of the IRWST injection and containment recirculation by avoiding potential adverse consequences related to the simultaneous firing of the two squib valves physically housed on the same structural frame module. The staff finds that the design changes and response to the RAI are acceptable. Therefore, RAI-DCP-CN08-ICE-02 is considered resolved. In a subsequent revision to the AP1000 DCD, the applicant made changes to the DCD text which are consistent with the proposed changes.

23.M.4 Conclusion

The staff concludes that the proposed changes of adding notes to the PMS and DAS function diagrams in DCD Figure 7.2-1 are acceptable because they have negligible effect on the LOCA safety analysis, and continue to comply with GDC 35 and 10 CFR 50.46.

In addition, the staff concludes that the applicant’s proposed design changes are acceptable because they have no negative impact on operation, and provide improved protection of the integrity of components, piping and structural and mechanical modules.

23.N Changes Related to Anticipatory Reactor Trip in the Event of an Inadvertent Passive Residual Heat Removal Actuation

23.N.1 Description of Proposed Changes

In a letter dated May 10, 2010, and in two letters dated July 29, 2010, the applicant proposed design changes related to anticipatory reactor trip in the event of an inadvertent PRHR actuation. The applicant proposed design changes to the PMS to include one additional reactor trip to mitigate an inadvertent PRHR event caused by the opening of either of the two PRHR HX discharge valves when the reactor is in power operation. In the PMS logic control system, a reactor trip that is to be added will be generated when either of the two PRHR HX discharge valves comes off its fully shut seat while the reactor is at power. Another proposed design change is to adjust the frequency of the inservice test (IST) for the two PRHR HX discharge valves from the current once every quarter to every cold shutdown.

In order to mitigate an inadvertent PRHR actuation event, the applicant proposed changes to add a PRHR actuation reactor trip function, which is based on the PRHR HX control valve (CV) indication, to DCD Chapter 7.2, "Reactor Trip." Related to this design change, a sentence is added to DCD Section 6.3.7.6.1, which states that for the PRHR HX discharge valves, valve position indication is used to initiate a reactor trip upon opening of these valves while the reactor is at power. Also, DCD Section 15.1.6, "Inadvertent Operation of the PRHR Heat Exchanger," is revised to state that to prevent the reactivity increase (as a result of inadvertent actuation of the PRHR HX event) from causing reactor power increase, a reactor trip is initiated when either PRHR discharge valve comes off of its fully shut seat. DCD Section 15.1.6.2 is revised to state that since a reactor trip is initiated as soon as the PRHR discharge valves are not fully closed, this event is essentially a reactor trip from the initial condition and requires no separate transient analysis. In DCD Table 15.0-4a, the reactor trip function on the PRHR discharge valve not closed with a time delay of 1.25 seconds is added, and in DCD Table 15.0-6, this reactor trip function is listed for the inadvertent operation of the PRHR event.

23.N.2 Regulatory Basis

The regulatory basis for evaluating the proposed changes to the AP1000 PMS reactor trip system is documented in Chapters 7, 15, and 16 of NUREG-1793.

Reviews of the changes are also based on meeting the relevant requirements of regulations and guidelines in 10 CFR 50.55a(h); 10 CFR 52.47; and GDC 20 and GDC 21 of 10 CFR Part 50, Appendix A. The proposed changes were evaluated using the guidance provided in NUREG-0800 Section 7.2, "Reactor Trip Systems." Acceptability was based on conformance with the existing AP1000 licensing basis and criteria specified in NUREG-0800 Section 7.2 (as applicable).

GDC 10 in 10 CFR Part 50, Appendix A, specifies that the reactor core and associated coolant, control, and protection systems shall be designed with appropriate margin to assure that SAFDLs are not exceeded during any condition of normal operation, including the effects of AOOs. An inadvertent operation of the PRHR heat exchanger is an AOO and, therefore, must comply with GDC 10.

23.N.3 Evaluation

As documented in NUREG-1793, the staff reviewed and approved the reactor trip system as specified in Section 7.2 of AP1000 DCD, Revision 15. The staff reviewed the applicant's design changes to the reactor trip system using the review procedures described in NUREG-0800 Section 7.2.

If either of the two PRHR HX discharge valves inadvertently comes off its normally fully closed seat while the reactor is at power, it allows a slug of cold water to be introduced into the reactor core through the PRHR HX to cause a marked increase in reactor power, which may exceed the fuel design limits. Therefore, a reactor trip is needed to mitigate this inadvertent PRHR event introduced by the opening of either of the two PRHR HX discharge valves, and prevent the fuel design limits from being exceeded. However, in the event of such an inadvertent PRHR event, the current reactor trip design included in the AP1000 DCD, Revision 17 will not be able to function fast enough to mitigate this inadvertent PRHR event. Therefore, the proposed design changes result in an improved reactor protection system to mitigate the inadvertent PRHR event. In addition, the 2-out-of-4 control logic with bypass capability is also used for this reactor trip condition in this DCP. The staff finds that all those changes meet applicable requirements in

10 CFR 50.55a(h), GDC 20, and GDC 21. The applicant made necessary changes to DCD Tier 1 Section 2.5.2, Tier 2 Section 7.2, and other related tables and figures. The staff finds that the proposed changes to reactor trip logic for an inadvertent PRHR actuation are acceptable because they satisfy the requirements of 10 CFR 50.55a(h), GDC 20, and GDC 21. In a subsequent revision to the AP1000 DCD, the applicant made changes to the DCD text, which are consistent with the proposed changes.

An inadvertent operation of PRHR HX causes an injection of relatively cold water into the RCS, resulting in a reactivity insertion due to a negative moderator temperature coefficient. Currently, several reactor trip functions are available to mitigate the event, including the overpower ΔT and overtemperature ΔT trip functions, to prevent a power increase, which could lead to a DNBR less than the safety analysis DNBR limit. The safety analysis of the limiting inadvertent operation of PRHR HX, presented in DCD Section 15.1.6, shows that, without taking credit for a reactor trip function, the nuclear power rises to about 120 percent temporarily, then drops and reaches a new equilibrium condition at about 108 percent of the nominal value. The RCS pressure and minimum DNBR are within the respective limits.

The proposed design change to add a PRHR actuation reactor trip function will enhance the reactor protection to trip the reactor upon event initiation. In its July 29, 2010, response to RAI-DCP-CN60-SRSB-01, the applicant stated that it has performed an evaluation of the operation of the PRHR HX transient assuming a conservative 1.25 second reactor trip response time, which covers the time to sense the opening of a PRHR valve through initial insertion of control rods. A confirmatory analysis using LOFTRAN shows that the minimum time between the opening of the PRHR valves and any colder water reaching the reactor core inlet is at least 2 seconds. Since the control rods are already inserting into the core before any colder water reaches the core inlet, there will not be an adverse power increase for this transient. Since an inadvertent operation of the PRHR HX event can only be caused by an inadvertent opening of the PRHR HX discharge valves (either by operator error, false actuation signal, or malfunction of a discharge valve), and a reactor trip will be initiated as soon as a PRHR discharge valve comes off the closed seat position, the consequence is mitigated as soon as the inadvertent PRHR HX operation event occurs. The proposed design changes continue to comply with SAFDL and no additional safety analysis is needed.

Each of the two PRHR HX discharge valves has one set of existing Class 1E magnetic valve position indicators (VPIs), one for the open position indication and one for the close position indication. The design change will use the existing close position indicator and add three more Class 1E magnetic VPIs to give a total of four closed signals per valve. This configuration is necessary for the “two out of four” logic required for a reactor trip signal. The proposed change in DCD Section 6.3.7.6.1 merely indicates that the PRHR HX discharge valves’ position indication is used for the reactor trip function, and is, therefore, acceptable.

The applicant’s proposed design changes add a reactor trip signal generated from the opening of valves in the PRHR system. This trip would minimize the effect of the anticipated reactivity excursion due to cold water addition by the PRHR system initiating flow. This change affected the TS for reactor trip system instrumentation, Table 3.3.1-1, as well as discussions in bases Sections B 3.1.1 and B 3.3.1. The additional information included in this change added appropriate descriptions of the trip function and purpose, and created a trip function in Table 3.3.1-1 that provides adequate protection against this event. The staff finds this change acceptable since it conforms to the format and trip functions described in the STS.

The applicant's proposed design changes also include changing the inservice testing full-stroke exercising requirement for the PRHR HX valves PXS-V108a and PXS-V108b from once a quarter to every cold shutdown. Valves PXS-V108a and PXS-V108b are Class 1, Category B air-operated valves that function as discharge valves for the PRHR HX. The inadvertent actuation of the PRHR HX causes an injection of relatively cold water into the RCS. This produces a reactivity insertion in the presence of a negative moderator temperature coefficient. To prevent this reactivity increase from causing reactor power increase, a reactor trip is initiated when either PRHR discharge valve comes off its full shut seat. The staff considers changing the IST full-stroke exercising requirement for valves PXS-V108a and PXS-V108b from once a quarter to every cold shutdown to be acceptable based on the ASME Code (2004E) ISTC-3521(c), which states that if exercising is not practicable during operation at power, it may be limited to full-stroke testing during cold shutdown.

23.N.4 Conclusion

After reviewing the proposed changes and markups to associated DCD Tier 1 and Tier 2 sections, tables, figures, and TS, the staff finds that the proposed changes provide an improvement to the reactor protection system. The staff concludes that the proposed changes to add a PRHR actuation reactor trip function is acceptable because it will trip the reactor as soon as an inadvertent operation of PRHR HX event occurs, thereby ensuring that the SAFDL will not be exceeded. Therefore, the staff concludes that these proposed design changes are acceptable.

23.O Changes to Reactor and Turbine Trips Functional Logic of Diverse Actuation System

23.O.1 Description of Proposed Changes

In letters dated May 20, 2010, and July 29, 2010, the applicant proposed design changes to add a reactor trip and turbine trip to the functional logic of the DAS based on the 2-out-of-2 control logic of the PRHR high hot leg temperature sensor outputs.

23.O.2 Regulatory Basis

The regulatory basis for evaluating these proposed design changes of DAS PRHR high hot leg temperature logic is documented in Chapter 7 of NUREG-1793.

Reviews of the changes are also based on meeting the relevant requirements of regulations and guidelines in 10 CFR 50.55a(h) and 10 CFR 52.47. The changes must also conform to the requirements of GDC 13 and GDC 20 in 10 CFR Part 50, Appendix A. The proposed changes were evaluated using the guidance provided in NUREG-0800 Section 7.8, "Diverse Instrumentation and Control Systems." Acceptability was based on conformance with the existing AP1000 licensing basis and criteria specified in NUREG-0800 Section 7.8 (as applicable).

23.O.3 Evaluation

As documented in NUREG-1793, the staff reviewed and approved the DAS in AP1000 DCD Tier 1 Section 2.5.1 and Tier 2 Section 7.7.1.11. The DAS system in the certified AP1000 DCD, Revision 15, uses the 2-out-of-2 control logic, which is based on the PRA evaluation. The staff reviewed the proposed design changes using the review procedures described in NUREG-0800 Section 7.8 and applicable regulations of GDC 13 and GDC 20 in 10 CFR Part 50, Appendix A.

According to the modeling in the PRA, the original DAS design in the AP1000 DCD should initiate a reactor trip and turbine trip for anticipated transients without scram (ATWS) sequences with the main feedwater available. Since the main feedwater is still available, the low SG water level signal will not be generated to initiate the reactor or turbine trip in the DAS. Therefore, the high hot leg temperature signal is needed in the DAS to trip the turbine or the reactor via the control rod motor-generator (MG) sets.

10 CFR 52.47 requires that an application include a sufficient description and analysis of the SSCs of the facility, with emphasis upon performance requirements, the bases, with technical justification; therefore, upon which these requirements have been established, and the evaluations required to show that safety functions will be accomplished. The description shall be sufficient to permit understanding of the system designs and their relationship to the safety evaluation. The design information provided for the design basis items, taken alone and in combination, should have one and only one interpretation. Hence, the staff issued RAI-DCP-CN63-ICE-01 requesting the applicant provide justification for adding another time delay for opening PRHR discharge valves, which is not explained in the DCP. The applicant's July 29, 2010, RAI response stated that the time delay has been provided in the functional design to support sequencing of the output field devices associated with a system-level control function. This delay time is added to be consistent with the use of timers in the existing functional design (e.g., low SG water level logic). The staff finds that the response to the RAI is acceptable.

After reviewing the proposed design changes and RAI responses, the staff finds that the proposed design changes are acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

23.O.4 Conclusion

After reviewing the proposed design changes, including markups to DCD Tier 1 and Tier 2 and RAI responses, the staff finds that the proposed changes will meet the required DAS functions as modeled in the PRA and related regulatory criteria. Therefore, the staff concludes that these proposed design changes are acceptable.

23.P Changes to Steam Generator System Instrument Piping

23.P.1 Description of Proposed Changes

In a letter dated July 8, 2010, the applicant proposed design changes in the material for the SGS instrument piping. These design changes would modify Figure 10.3.2-1 of the AP1000 DCD to specify stainless steel piping for all AP1000 Quality Classes B and C instrument piping for the SGS. AP1000 Quality Classes B and C are designed and fabricated to ASME Code, Section III, Class 2 and 3, respectively. The main steam supply system (MSSS) includes the AP1000 SGS.

23.P.2 Regulatory Basis

The staff reviewed and evaluated the proposed design changes in accordance with the guidance in NUREG-0800 Section 10.3.6 to ensure that the ASME Code, Class 2 and 3 MSSS components use material specified in Sections II and III of the ASME Code, thereby meeting the requirements of GDC 1, “Quality Standards and Records,” and 10 CFR 50.55a.

23.P.3 Evaluation

Figure 10.3.2-1 modified all of the ASME Code, Section III, Class 2 and 3 SGS instrument lines, which typically are 2.5 cm (1 in) NPS and less, to be a corrosion resistant (stainless steel) material. Section 10.3.6.2 of the AP1000 DCD specifies that the material selection and fabrication for ASME Code, Section III, Class 2 and 3 are in accordance with the requirements of ASME Code, Section III, Class 2 and 3 components outlined in Sections 6.1.1.1 and 6.1.1.2 of the AP1000 DCD. Section 6.1.1.1 of the AP1000 DCD specifies that pressure-retaining materials meet the requirements of Articles NC-2000 and ND-2000 of the ASME Code, Section III for Class 2 and 3 components, respectively. The staff notes that Articles NC-2000 and ND-2000 for ASME Code Classes 2 and 3, respectively, specify that the material be in accordance with Section II of the ASME Code. Based on this information, the staff finds that the use of stainless steel material specified in ASME Code, Section II for ASME Code Classes 2 and 3 SG instrumentation piping, typically 1 NPS or less, is acceptable. The staff’s acceptance is based on the use of stainless steel for the instrumentation piping, which is more corrosion resistant than carbon steel, and that the material will be procured in accordance with ASME Code Section II and fabricated in accordance with ASME Code Section III. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

23.P.4 Conclusion

The staff concludes that the proposed use of stainless steel instrument piping for the SGS provides higher corrosion resistance than carbon steel, and that the material will be procured and fabricated in accordance with ASME Code Sections II and III as specified in the guidance of NUREG-0800 Section 10.3.6 and, therefore, meets the requirements of GDC 1 and 10 CFR 50.55a. The staff concludes that the proposed design changes are acceptable.

23.Q Changes to the Steel Containment Vessel Girder and Polar Crane Rail Clip

23.Q.1 Description of Proposed Changes

In letters dated April 26, 2010; August 26, 2010; and September 16, 2010, the applicant proposed design changes to the steel containment vessel (SCV) girder and polar crane rail clip. These design changes apply to the safety-related structure (containment vessel) and the heavy load handling system (heavy load lifting equipment and support) and include the following changes:

- Increase in the thickness of the girder top plate from 3.8 cm (1.5 in) to 4.45 cm (1.75 in)
- Change in the rail support from Gantrex Pad to a bolted clip design
- Extension of the SCV girder inward by 6.98 cm (2-3/4 in)

23.Q.2 Regulatory Basis

Sections 3.8.2 and 9.1.5 of NUREG-1793, address the function and acceptability of the SCV associated support structures for the overhead heavy load handling system in the AP1000 standard design. Acceptability of the proposed design change is evaluated to determine whether the design meets the relevant requirements specified in 10 CFR Part 50, Appendix A, GDC 2, which requires that SSCs important to safety shall be designed to withstand the effects of natural phenomena such as earthquakes, tornadoes, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions.

23.Q.3 Evaluation

The SCV associated support structures are designed to provide the necessary support for the overhead heavy load handling (polar crane) system in the AP1000 standard design. The polar crane systems are safety-related and are used to handle heavy equipment, such as the integrated head package, SGs, and HXs. As stated in the DCD changes included in this design change, the design of the SCV associated support structures for the polar crane system support is consistent with the SSE design of equipment anchorages of seismic Category I equipment. The girder top plate and the new bolted clip design for the rail support are analyzed to show that the structure can withstand an SSE event.

During the staff's evaluation of the proposed design changes to the SCV associated support structures, it was determined that additional information was required from the applicant to complete the staff's evaluation. The staff generated RAI-DCP-CN-5-SEB-01 requesting: (1) an analysis including materials and design basis loading used to demonstrate that the increase of 0.64 cm (1/4 in) from 3.81 cm (1-1/2 in) to 4.45 cm (1-3/4 in) thick in top plate of the crane girder is adequate to support the design-basis loadings including a seismic load; (2) an analysis to demonstrate the new rail clip design, including clip spacing is sufficient to meet the design-basis load requirements including the seismic load demands; and (3) the basis for determining the extent of the inward extension of the CV girder top plate.

The applicant's response to RAI-DCP-CN-5-SEB-01 provided sufficient information on the design analysis for the proposed design changes to support the staff's evaluation. In addition to evaluating the applicant's proposed design changes and RAI responses, the staff performed two audits.

With respect to the SCV polar crane girder top plate design, the applicant presented a design analysis, which is documented in the technical report APP-MV50-S2C-020, Khanh Do, "Polar Crane Girder Top Plate Analysis." The stress analysis considers a total of 192 load combinations. Using ANSYS 11.0, a commercially available general purpose code, a 3D finite element model was constructed with the boundary conditions fixed at Elevation (El.) 30.5 m (100 ft) (i.e., at the grade level) for the purpose of determining the maximum stress intensities at the top plate. It was found that the maximum stress intensity [

] is well within the allowable stress intensity of 90 kips per square inch (ksi) (620.5 MegaPascal (MPa)) according to ASME NE-3221 in ASME Code Section III, Division 1, Subsection NE, Class MC, 2001 Edition. Accordingly, a 4.45 cm (1.75 in) thick plate is shown to be adequate to support the design-basis loadings, because the maximum stress intensity generated in the top plate is less than the allowable stress intensity the steel plate can offer. The staff reviewed the methodology of the analysis including model construction, boundary and loading conditions, material properties and applicable code; and determined that the design analysis is acceptable, and the use of a 4.45 cm (1.75 in) thick top plate is in compliance with the ASME Code requirements.

With respect to the new rail clip design with the bolted clips, the applicant presented an analysis in PR-08-5020/70587483, Roger Johnson, "Polar Crane Mechanical Calculations," Revision 1, March 5, 2010, to show that the proposed new design is capable of resisting a horizontal wheel load [ ] due to seismic conditions. With the help of MathCad Version 13 and GTSTRUDL 29.1 seismic analysis, it was found that the rated load [ ] governs the main hoist system, whose design meets NUREG-0554, "Single-Failure-Proof Cranes for Nuclear Power Plants" requirements. The new clip design is given in Westinghouse drawing APP-MH01-V2-021 and Westinghouse drawing APP-MH01-V6-041 and is based on the adopted 76.20-cm (30-in) wheel diameter. [ ] With the use of the clip plate [ ] with three slotted holes, the maximum bending stress [ ] is less than the 81 ksi allowable specified by the code. The clip plate is bolted [ ] to the filler plate welded to the girder top plate [ ] and the induced shear [ ] will be within the allowable shear stress of 148.9 MPa (21.6 ksi) based on the American Welding Society (AWS) code (the ASME NOG-1 code allowable is 50 percent higher, i.e., 223.4MPa (32.4 ksi)). The staff reviewed the detailed calculations and found the new design as given in drawings APP-MH01-V2-021 and APP-MH01-V6-041 to be in compliance with the AWS and ASME Codes; thus, it is acceptable to the staff.

The third item of design changes is concerned with the inward extension of 6.98 cm (2-3/4 in) of the CV girder top plate. The reasoning, according to the submittal, is that the tolerance requirement of the polar crane rail is much tighter than the SCV girder. The staff requested the applicant provide the basis to justify that the increase of 6.98 cm (2.75 in) inward of the SCV girder top plate is quantitatively adequate to meet the tolerance requirement. In its response, the applicant provided ASME Code, ASME-NOG-01-1998 (NOG-1) as the basis in the polar crane design documented in Westinghouse calculation APP-GW-GEE-513, DCP3513, "Steel Containment Vessel Girder and Polar Crane Rail Clip Design." The code NOG-1 specifies that the maximum and minimum span between the rails must be no greater or less than the nominal span of the rails +/- 0.76 cm (3/8 in). This tolerance is tighter than the girder, based on construction experts, who specify the tolerance for the radius of the SCV girder to be +/- 4.95 cm (1.95 in). Because of this difference in tolerance requirements, the girder, including top plate, web and bottom plate, must be extended radially inward toward the center of the CV. Figure 5 in Westinghouse calculation APP-GW-GEE-513 provides the new design showing the tolerance stack-up and the required extension of the top plate. Figure 1, Note B and Figure 2 show the associated design changes. The staff reviewed the drawings and the new design, and found the design changes are in compliance with the ASME Code NOG-1, and thus, are acceptable.

The proposed design changes, including DCD markups and RAI responses, are acceptable. RAI-DCP-CN-5-SEB-01 is resolved.

23.Q.4 Conclusion

The staff concludes that the proposed design changes are acceptable because the proposed changes will not adversely affect safety-related SSCs and the capability of the polar crane systems to perform their intended functions of heavy load lifting and transportation. The proposed design changes were evaluated with respect to conformance with the existing AP1000 licensing basis and found acceptable.

23.R Changes to the Reactor Vessel Support System

23.R.1 Description of Proposed Changes

In letters dated May 10, 2010, and September 9, 2010, the applicant proposed design changes related to the structural support system for the RV, which is a safety-related structure. These design changes involve the following modifications of the RV support system:

- Eliminate reliance on the CA04 structural module as part of the reactor pressure vessel (RPV) support system.
- Provide support boxes as RPV supports
- Change the anchor supports from a “bolted into embedded plates” configuration to a “anchored directly to primary shield wall concrete base via steel embedment plates” configuration.
- Increase the length of the RPV support boxes or legs.
- Install wear plates for the RPV bearing and tribological performance (i.e., to support RV and reduce frictional wear due to thermal expansion).

23.R.2 Regulatory Basis

Sections 3.8.3 and 5.4.10 of NUREG-1793, address the function and acceptability of the RPV support structural box in the AP1000 standard design. Acceptability of the design change was evaluated for its conformance with the existing AP1000 licensing basis.

23.R.3 Evaluation

In the AP1000 standard design, the RPV structural support system is designed to provide the necessary support for the RPV. The original anchorage design was bolting into embedded plates of the CA04 structural module. Design finalization analyses determined that the resulting stresses exceed the allowable stresses. As a result, the applicant proposed design changes in which the overstressed CA04 module is not used to support the RPV. Instead, the applicant has proposed a revised design where four support boxes are used to support the RPV. There are four support “boxes” or “legs” located at the bottom of the RPV’s cold leg nozzles. The support boxes are anchored directly to the primary shield wall concrete base via steel embedment plates. As stated in the proposed design changes, the design of the RPV associated support structures is consistent with the SSE design of seismic Category I equipment. The RPV support boxes, including the new anchorage design, are analyzed to show that they can withstand an SSE event.

During the staff’s evaluation of the proposed design changes to the RPV associated support structures, it was determined that additional information was required from the applicant. The staff requested additional information related to: (1) a stress analysis of the proposed design, including materials and design basis loading used to demonstrate that the maximum stresses incurred at the critical sections of the RPV support box structure are lower than those of the previous design, and that the new design is in compliance with the adopted code requirements; (2) specifications of the wear plates, including material, lubricant used, geometric dimensions in size and shape, and performance requirements; and (3) an assurance of satisfactory tribological performance that uneven settlement on the plate's top surface will not deter lateral movement of the RV due to thermal expansion, and that the wear plate can endure the frictional wearing due to cyclic motion of the heavy RPV over its entire design life without loss of its intended design function.

In a letter dated September 9, 2010, the applicant provided sufficient information on the design analysis to support the staff's evaluation. The supporting information also included documentation on the material specifications of the self-lubricating bearings used for the wear plates.

With respect to the RPV support box design, the applicant stated that the design is in compliance with the design specification depicted in APP-SS30-Z0-001, "Design Specification," Revision 1. Thus, the support box design meets the requirements of ASME Code, Section III, Subsection NF, 1998 Edition, up to and including the 2000 Addenda. The support structure is classified as NF Class 1. Allowable stress limits of ASME Code NF-3220 for the Level A, B, C and D load combinations were calculated for the material used [ ] and it was found that the Level D loading condition governs the design. For design analysis, a three-dimensional finite element analysis (FEA) model was constructed using the general purpose FEA computer code ANSYS. Details of the methodology including the modeling techniques, boundary conditions and loading input are documented in the report APP-PH01-Z0C-007, "Finite Element Analysis of the RV Support Structure," Revision 0, May 26, 2010. The resulting stresses, including linearized primary membrane (P_m) and primary membrane plus bending ($P_m + P_b$) stress intensities, were computed from the FEA model. [ ] The resultant stress intensities for the controlling Level D load case [ ] were compared with the allowable stress intensities. The comparisons demonstrate that the Level D loading condition [ ] is less than the allowable. The staff performed audits of a supporting document on design specifications (APP-SS30-Z0-001) and a supporting document on FEA (APP-PH01-Z0C-007). These audits confirmed that the information in the supporting documents was consistent with the applicant's proposed design changes. Therefore, the staff finds the proposed design changes to be acceptable because they satisfy the ASME Code requirements.

In its September 9, 2010, letter, the applicant stated that the RPV support bottom and side wear plates are specified as Lubron wear plates fabricated by Lubron Bearing Systems. [ ] Detailed specifications of the wear plates used were provided by the applicant. Specifications of the bottom and side wear plates are provided in AP1000 RPV support design drawings APP-PH01-V2-211 (General Assembly) and APP-PH01-V2-212 (Component Details). During RPV installation, the bottom wear plate and interfacing thermal plate are assembled with a bluing process to insure a high degree of uniform contact (>75 percent) between mating surfaces. By design, these wear plates are good for up to 55.2 MPa (8,000 psi) bearing pressure and up to 593 °Celsius (C) (1,100 °Fahrenheit (F)). The actual bearing pressure for the AP1000 RPV support for the Level A service condition is approximately 15.9 MPa (2,300 psi), much less than the bearing capacity of 55.2 MPa (8,000 psi). The RPV support, its connection to the foundation, the foundation, and the wear plate connection to the support have all been designed for friction loads during normal plant heat-up and cool down thermal cycles. The staff's review also considered the potential for uneven settlement of the RPV during installation. Tier 1 Table 2.1.3-2 specifies the ITAAC for the reactor system, which includes the RPV. Several ITAAC exist to address this issue, and include acceptance criteria that a report exists and concludes that the as-installed equipment including anchorage is seismically bounded by the tested or analyzed conditions. The staff finds that the proposed design changes are acceptable in terms of structural and tribological performance.

23.R.4 Conclusion

The staff concludes that these proposed design changes are acceptable because the proposed changes will adversely affect neither safety-related SSCs, nor the capability of the RPV support boxes to perform their intended function of supporting the RPV while allowing free lateral movement of the four legs due to thermal expansion. These design changes were evaluated with respect to conformance with the existing AP1000 licensing basis and found acceptable.

23.S Changes to the Passive Containment Cooling System

23.S.1 Description of Proposed Changes

The applicant has proposed changes to the shield building from the Revision 15 DCD to address additional external hazards and to simplify construction. The applicant assessed the impact of these changes to the PCS in APP-GW-GLR-096, "Evaluation of the Effect of the AP1000 Enhanced Shield Building Design on the Containment Response and Safety Analysis," Revision 1, and submitted the report to the NRC in a letter dated August 6, 2010.

This report includes a description of the enhanced shield building design changes, a discussion of how these changes impact design basis test results, and evaluations of the limiting DBA and beyond design basis accidents (BDBA). Appendix A of APP-GW-GLR-096 includes proposed DCD changes. The changes that impact NUREG-1793 Sections 6.2.1, "Containment Functional Design"; 6.2.2, "Containment Heat Removal Systems"; and 6.2.3 "Shield Building Functional Design"; are as follows:

- Update containment response to reflect results of an analysis that incorporates the enhanced shield building design.

- Lower the required reactor decay heat limit for air only cooling.

- Specify the long-term makeup rates the PCS must simultaneously provide to containment and the SFP when the plant is refueling.

These proposed design changes also include revisions to several TS. In TS Table 3.3.2-1, "Engineered Safeguards Actuation System Instrumentation"; TS Table 3.3.5-1, "DAS Manual Controls"; and TS 3.6.7, "Passive Containment Cooling System (PCS) – Shutdown"; the Modes 5 and 6 applicability is revised to reflect the lower reactor decay heat limit for air only cooling mentioned above. In TS 3.7.9, "Fuel Storage Pool Makeup Water Sources," the notes associated with LCO 3.7.9, which list special plant conditions for each available makeup water source, are revised to account for changes to TS 3.6.7 regarding the availability of the passive containment cooling water storage tank (PCCWST) as a makeup water source. The cask loading pit (CLP) is added as a third makeup water source in addition to the PCCWST and the cask washdown pit. Two new surveillance requirements are also added to ensure readiness of water inventory from the PCCWST and the CLP, when needed.

In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue. Proposed changes to Chapter 9 are evaluated in Section 9.1.3 of this report.

23.S.2 Regulatory Basis

The following Commission regulations are related to the evaluation of the enhanced shield building:

- GDC 16, "Containment Design," as it relates to the reactor containment and associated systems being designed to assure that containment design conditions important to safety are not exceeded for as long as postulated accident conditions require

- GDC 38, "Containment Heat Removal," as it relates to the ability of the containment heat removal system to rapidly reduce the containment pressure and temperature following a LOCA and to maintain them at acceptably low levels

- GDC 50, "Containment Design Basis," as it relates to demonstrating sufficient margin in accident analysis

- 10 CFR 52.47(c)(2), as it relates to design certification testing in support of a passive plant design

The regulatory basis for evaluating the GTS is documented in Chapter 16 of NUREG-1793. The staff's evaluation of the proposed changes focused primarily on confirming that the changes to the GTS reflect the PCS and the SFP design and operating information described in DCD Sections 6.2 and 9.1.3 respectively. The proposed changes were evaluated using the guidance provided in NUREG-0800 Chapter 16, "Technical Specifications – Revision 3, March 2010." Acceptability was based on conformance with the guidance in NUREG-0800 Chapter 16.

23.S.3 Evaluation

One of the safety-related functions of the PCS is to provide air flow over the outside of the containment vessel by means of a natural circulation air flow path. Air enters through inlets located at the top of the shield building and then travels downward into the annulus between the inside of the shield building and the air baffle. At the bottom of the baffle wall, the air turns 180 degrees into the riser annulus formed by the baffle and the outside of the containment vessel. Air continues past the top of the containment vessel and exits through the shield building chimney.

In the Revision 15 design, air is admitted into the top of the shield building through 15 large, uniformly distributed openings, with fixed louvers and screens to prevent weather and wildlife from entering the shield building. In the modified design, a steel structure containing 29 uniformly distributed openings with fixed louvers and screens is added around the top outside of the shield building. The flow area in the steel structure is slightly higher than the flow area through the louvered and screened inlet openings in the previous shield building design. Air enters through these openings, collects in the plenum created by the structure and outside of the shield building, and then enters the shield building through 236 inlet ducts. These shield building inlets have a much lower flow area than the louvered and screened inlet openings in the previous shield building design. The enhanced shield building chimney is shorter than the original design; therefore, the buoyant driving head for the PCS flow is expected to decrease. In the enhanced design, two heavy steel grates are added within the chimney region to protect the containment shell from external hazards, which will increase the discharge flow resistance and reduce the discharge flow area.

The NRC approved the functional design of the containment systems for the AP1000 as described in NUREG-1793. The agency based its approval on data from a number of test facilities that were specifically designed to model processes and phenomena of the AP1000 containment design following a major piping rupture within the containment building. These data were used for the qualification of the WGOTHIC computer code, which was then used for the safety analysis of the AP1000. The test series included heat and mass transfer tests, wind tunnel tests, water distribution tests, integral system tests of the PCS, and air flow path characterization tests. All of these tests were to be within the range of the physical conditions predicted for the enhanced shield building design except for the air flow path characterization test which modeled the previous shield building. The flow path pressure drop is expected to increase in the new design; therefore, the applicant repeated the air flow path characterization test on apparatus specific to the revised shield building. The results were used to confirm the local annulus loss coefficients used in the revised WGOTHIC model.

From the phenomena identification and ranking table that was developed for the AP1000 in Westinghouse Commercial Atomic Power (WCAP)-15613, “AP1000 PIRT and Scaling Assessment,” issued February 2001, The applicant identified the high-ranked (most important) phenomena and processes for evaluation of the containment response following a LOCA or main steamline break (MSLB). These include condensation on the inside surface of the containment shell, conduction through the shell, and evaporation from the containment shell liquid film that flows down from the PCS water storage tank to the top outside of the containment building. Air flow through the containment shield building annulus is not listed with the high-ranked phenomena.

The staff agrees that air flow through the shield building need not be highly ranked following a LOCA or MSLB, because in these instances, the PCS will release water over the containment shell to provide evaporative cooling, and evaporative cooling is a much more significant heat removal mechanism than air flow convection. Analyses by the applicant and the staff illustrate this conclusion. APP-GW-GLR-096 describes the Westinghouse analysis based on the WGOTHIC evaluation model that was approved by the staff for the Revision 15 DCD analysis and subsequently modified to incorporate the proposed wet bulb temperature increase to 30 °C (86.1 °F) discussed in Section 6.2.1.1.1 of the DCD along with the pressurizer room changes discussed in Section 6.2.1.2 of the DCD.

To address the enhanced shield building design, the applicant further revised the model to include the addition of the PCS air inlet structure, reduction of the flow areas in the shield building inlet and exit, reduction of the shield building chimney height, and increase to the air flow path resistance. The applicant ran the design basis LOCA and MSLB events with the revised model and the results demonstrated that even though the natural circulation air flow decreased, the effect on containment pressure and temperature was insignificant. Additionally, the pressure at 24 hours following a large cold leg break LOCA was unchanged. The staff reviewed the detailed modeling changes during audits on April 21, 2010 and September 3, 2010. The subject of the audits was APP-SSAR-GSC-746, “Containment

Response Analysis for the AP1000 Shield Building Design Change." The staff found the estimates on loss coefficients, which were made prior to completion of the air flow path characterization test, to be reasonable because they bounded predictions [ ] for a thick orifice. Furthermore, when pressure drops from the air flow path characterization test became available, these estimated loss coefficients were demonstrated to be conservatively high.

The staff performed a confirmatory analysis using the CONTAIN computer code with an AP1000 model developed by the staff during the DCD review. The shield building changes were incorporated and used to evaluate a large cold-leg break LOCA, which is the peak pressure DBA. The results were consistent with the Westinghouse evaluation; the PCS air flow decrease had a negligible impact on peak pressure, peak temperature, and containment pressure after 24 hours.

The applicant proposed changes to incorporate the results of its analysis into the DCD tables summarizing postulated accident values, DCD Tier 2, Tables 6.2.1.1-1 and 6.2.1.1-3. The changes to the LOCA and MSLB results were found acceptable because they are consistent with the enhanced shield building design. Changes made to the external pressure results are evaluated in Section 23.W of this report.

The natural circulation air flow is reduced in the enhanced shield building design; therefore, the amount of heat that can be removed during air only PCS operation will also be reduced. As a result, the applicant proposed lowering the reactor decay heat limit for air only PCS operation from 9 megawatts thermal (MWt) to 6 MWt. APP-GE-GLR-096 describes the supporting WGOTHIC analysis demonstrating the containment pressure could be maintained below the design value of 407 kPa (59 psig) for seven days with no PCS water release (and subsequent evaporative cooling) assuming an initial decay heat rate of 6 MWt.

The staff reviewed the analysis basis during its July 27, 2010, audit of APP-SSAR-GSC-749, "AP1000 Dry PCS Heat Removal Capability." The evaluation model was the previously described LOCA model modified to turn off the PCS water, replace the accident mass and energy forcing functions with decay heat input to the IRWST, and adjust the air flow path loss coefficients to reflect a 30 percent increase over the air flow path characterization test results. The staff finds the loss coefficient values reasonable because they are based on physical measurements with added margin to bound uncertainties in the test results.

The staff ran a confirmatory CONTAIN analysis using the previously described LOCA model modified for no PCS water flow and an initial decay heat rate of 6 MWt.

The results were consistent with the applicant's evaluation; the air flow across the containment shell decreased and the containment pressure increased compared to the original shield building, but containment pressure remained below the design value for the run duration of seven days.

In an additional study, the applicant re-evaluated the containment pressure resulting from the BDBA of a prolonged loss of offsite power concurrent with a complete loss of the passive containment cooling water. For this unlikely event, the PRHR HX transfers reactor decay heat and the system sensible heat into the IRWST pool. When the water in the IRWST is heated to boiling, the steam that is released condenses on the containment internal structures. As the internal structures are heated, the containment pressure rises and heat is transferred through the containment shell to the air traveling up through the shield building annulus. The applicant performed the analysis with a “best estimate” WGOTHIC model. The results showed that even with the reduced natural circulation air flow associated with the enhanced containment building, it will take more than 24 hours for the containment pressure to reach the maximum pressure capability limit of 889 kPa (129 psig) defined in DCD Section 3.8.2. Therefore, the enhanced shield building meets the DCD Section 19.34.2.6 statement that, with air-only cooling, containment failure is predicted to occur more than 24 hours after accident initiation. The staff reviewed the analysis basis during its July 27, 2010, audit of APP-SSAR-GSC-749. The assumptions for the “best estimate” BDBA evaluation model, which included changes to initial temperatures, heat transfer coefficients, and loss coefficients, were found to be reasonable and consistent with evaluations of beyond design basis events.

The PCS has a design commitment to provide containment cooling and SFP makeup simultaneously from post-72 hours to seven days after DBA initiation at the minimum flow rates specified in DCD Tier 2, Table 6.2.2-1. The applicant recognized that the proposed reduction to the maximum reactor decay heat limit for air only containment cooling created a scenario whereby the currently specified minimum SFP supply of 132.5 Lpm (35 gpm) would not be adequate to maintain coverage of the fuel in the SFP. During refueling, when the full core is split such that the reactor decay heat is greater than 6 MWt and the SFP decay heat is less than 7.2 MWt, the PCS water is reserved for containment cooling for the first 72 hours and cannot be used for SFP makeup until after this time. The applicant determined a DBA at this plant condition would require a minimum of 189.3 Lpm (50 gpm) SFP supply. Because the total PCS flow is limited, an increase in the SFP supply requires a reduction to the currently specified containment make-up rate of 378.5 Lpm (100 gpm). The 378.5 Lpm (100 gpm) is based on containment cooling requirements post-72 hours after a limiting DBA occurring at full power. The necessary flow following a DBA during refueling will always be less than this because the reactor must be shut down for 100 hours prior to the start of refueling to provide time for the RCS to cool down and depressurize. The applicant reduced the required flow rate for containment cooling during refueling to 302.8 Lpm (80 gpm). The supporting analysis, APP-SSAR-GSC-750, “WGOTHIC Validation of Post-72 Hour Containment Cooling Flow Rates for Accident Scenarios after Refueling” was audited by the staff on July 30, 2010.

The evaluation considered a loss of power event coincident with the start of refueling, modeled by adding decay heat representative of 100 hours after shutdown to the IRWST to represent the PRHR HX system. The model assumed full PCS flow for the first 72 hours and 302.8 Lpm (80 gpm) flow thereafter. The results demonstrated that the containment pressure remained well below the design limit of 407 kPa (59 psig) for seven days. The staff found the modeling assumptions to be consistent with design basis analysis and the significant margin in the results provided further assurance that this is an acceptable change.

With respect to proposed changes to TS Sections 3.3.2, 3.3.5, 3.6.7 and 3.7.9 and their associated Bases, the staff finds these changes acceptable because they reflect the PCS and the SFP cooling system design and operating information described in DCD Sections 6.2 and 9.1.3, respectively. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

23.S.4 Conclusion

The staff’s review concludes that the design changes described above are acceptable and compliant with GDC 16, GDC 38, GDC 50 and 10 CFR 52.47(c)(2).

23.T Changes to the Main Control Room Emergency Habitability System

23.T.1 Description of Proposed Changes

In letters dated July 29, 2010, and September 22, 2010, the applicant has proposed changes to the minimum amount of stored compressed air in the MCR VES emergency air storage tanks. To increase the margin to the control room operator dose limits and to expand the site dispersion factors that are permitted for the AP1000 design, a passive filtration subsystem design was added to the MCR VES to filter potential contaminated in-leakage. The subsystem incorporates an eductor, which uses the VES compressed air flow to induce recirculation of MCR air through a filtration unit. The performance of the added subsystem allows for 0.42 cubic meter per minute (m^3/m) (15 cubic feet per minute (cfm) of unfiltered in-leakage while maintaining operator dose below 50 millisievert (mSv) (5 roentgen equivalent man (rem)) total effective dose equivalent (TEDE) required by GDC 19. With the addition of the subsystem, the VES provides a filtration unit to capture potential contaminated air that may leak into the MCR envelope. The applicant conducted testing of the passive filtration subsystem at the Westinghouse Waltz Mill facility. The testing was confirmatory testing to show the performance characteristics of the added passive filtration design and to collect data on the performance of the eductor itself. The passive filter train, utilizing the eductor as well as the technical specifications and ITAAC were reviewed and approved in Sections 6.4 and 9.4.1 of this report. However, after the Chapter 6 and Chapter 9 SERs were issued, the applicant identified the need to adjust the TS on quantity of compressed air needed for 72 hours of continuous operation. The quantity of air needed to support 72 hours of operation increased because the pressure regulating valve minimum required operating inlet pressure needed to increase to ensure that the set outlet pressure could be maintained during the duration of system operation.

The minimum amount of required stored compressed air is changed from 8895 standard cubic meter (m^3) (314,132 standard cubic foot (scf)) to 9276 standard m^3 (327,574 scf. Filling the tanks with 9276 standard m^3 (327,574 scf of air will ensure that the tanks are capable of providing 119 standard cubic meters per hour (scmh) (70 standard cubic foot per minute (scfm)) of air for 72 hours. Operability is determined based on the amount of compressed air stored in the tanks as determined from tank pressure and storage room temperature. The new volume of air is provided in both Tier 1 and Tier 2, including the TS. The relationship between tank pressure, room temperature and volume is provided in the TS Bases.

These proposed design changes also modified the instrumentation representation in DCD Figure 6.4-2 (Sheet 2 of 2) to better represent the instrumentation used in the design. The figure changed a flow instrument from an orifice plate with a differential pressure sensor to a thermal dispersion mass flow transmitter.

23.T.2 Regulatory Basis

The applicable regulations for the control room habitability system aspects of these design changes are detailed in NUREG-0800 Section 6.4, “Control Room Habitability System.” For the changes proposed by the applicant, the following are relevant.

- 10 CFR Part 50, Appendix A, GDC 19

- 10 CFR 52.47(b)(1), which requires that a DC application include the proposed ITAAC

The regulatory basis for evaluating the GTS is documented in Chapter 16 of NUREG-1793. The staff's evaluation of the proposed changes focused primarily on confirming that the changes to the GTS and Bases reflect the VES design and operating information described in DCD Section 6.4. The proposed changes were evaluated using the guidance provided in NUREG-0800 Chapter 16, "Technical Specifications – Revision 3, March 2010." Acceptability was based on conformance with the guidance specified in NUREG-0800 Chapter 16.

23.T.3 Evaluation

The proposed design changes were reviewed for compliance with the applicable regulations. This DCP raises the minimum amount of stored compressed air in the VES emergency air storage tanks to ensure the supply of 72 hours of air at the maximum flow rate of 70 scfm. The mission time for the passive safety-related system is 72 hours based on the Commission's policy on passive systems. The design basis requires that 65±5 scfm flow be provided for all DBAs. As a result, there needs to be enough air to provide 72 hours of flow at the maximum flow of 119 scmh (70 scfm).

The change is necessary to accommodate a 1379 kPa (200 psig) pressure regulator minimum inlet pressure instead of 689 kPa (100 psig) prior to the passive filter train. This is done to ensure that downstream pressure and flow are maintained within the required tolerance. The applicant has demonstrated that the new volume of air is adequate to accomplish the design basis functions.

The staff audited APP-VES-M3C-005, "VES Minimum Pressure Calculations," Revision 1. The calculation determines the amount of breathable air required during 72 hours of VES operation. Basic heat transfer equations and air properties were used to determine heat transfer coefficients and transient heat loss from concrete to outside air and the tank package. Cooldown analysis for station blackout during extreme winter weather were used to determine VES tanks pressure decline due to temperature cooldown and air delivery to MCR. Assuming cold conditions is conservative because it minimizes the volumetric flow. The staff has found that the calculations demonstrate there is an adequate amount of gas to maintain pressure above 1379 kPa (200 psig) at the inlet of the pressure regulator. The calculations showed that for the limiting case, there was not much margin. However, because the calculations were done for the limiting cases, small margin is acceptable.

In Chapter 6 of this report, the staff accepted the passive filter train. The staff came to this conclusion, in part, based on there being adequate ITAAC and Technical Specifications to demonstrate that 65±5 scfm flow is provided from the canisters to the eductor and that 600 scfm of control room air would be drawn through the filter train. The COL holder would need to demonstrate prior to plant operation and periodically thereafter that the system would accomplish the design basis functions. Because the passive eductor-driven filter train was new to the nuclear industry, the staff requested that testing be done to prove this design concept was capable of being operated successfully. Prior to the issuance of the Chapter 6 SER, the applicant completed testing to demonstrate that the system was capable of meeting the performance requirements.

When these proposed design changes were submitted by the applicant, the staff wanted to make sure the testing still demonstrated the system was capable of being operated successfully. As such, the staff also audited TS-SEE-111-09-03, "AP1000 VES Air Filtration Test Specification." The testing performed by the applicant had three objectives. The first was to demonstrate 60 scfm is capable of inducing 600 scfm, the second was to determine whether a feed flow rate higher than the design duct flow rate would damage system components, and the third was to demonstrate the system can be operated below maximum allowable noise levels defined in NUREG-0700, “Human-System Interface Design Review Guidelines.” The maximum allowable noise is 65 dB(A).

The staff observed that the testing did demonstrate the system could be built with the necessary performance characteristics. The staff also observed that the test results showed that the combined flow is sensitive to back pressure, feed pressure and feed flow. For example, for the same feed pressure, an increase in backpressure by 0.5 inch of water will reduce combined flow by approximately 170 scmh (100 scfm). Additionally, at the same feed flow an increase in the feed pressure by 34 kPa (5 psi) will reduce combined flow by approximately 170 scmh (100 scfm). As a result, the staff notes that the parameters influencing the induced flow, for example line losses between the regulator and the eductor, will need to be carefully controlled by the COL holder and that the required 1020 scmh (600 scfm) induced flow may not be satisfied at all conditions. The COL holder has the responsibility to ensure that at least 1020 scmh (600 scfm) will be induced by a feed flow rate of at least 1020 scmh (60 scfm).

The two safety-related flow rates will be demonstrated by ITAAC. Additionally, Tier 1 requires the following be demonstrated:

- The VES provides a 72-hour supply of breathable quality air for the occupants of the MCR.
- The airflow rate from VES is at least 60 scfm and not more than 70 scfm.
- The system provides a passive recirculation flow of MCR air to maintain main control room dose rates below an acceptable level during VES operation.
- The air flow rate at the outlet of the MCR passive filtration system is at least 600 cfm greater than the flow measured by VES-FT003A/B.
- The noise at the operator station is limited to 65 dB(A).

The staff has concluded that with the ITAAC to demonstrate the capacity of the system design the system will meet the requirements of GDC 19. Additionally, the ITAAC are sufficient to show the as-built plant will function and, as a result, 10 CFR 52.47(b)(1) is satisfied.

With regard to the change in instrumentation, the staff finds that either type of instrument can acceptably measure flow. The instrument is safety-related and subject to the quality assurance requirements. As a result, the staff finds the instrumentation change acceptable as well.

With respect to proposed changes to TS 3.7.6 and its associated bases, the applicant stated that both tank pressure and room temperature are used to determine the acceptable minimum storage capacity of the air tanks in term of standard cubic feet (scf). The acceptance criteria are presented in new Figures B 3.7.6-1 and B 3.7.6-2 for use in the verification of the minimum storage capacity of the air tanks specified in Required Action D.1 and SR 3.7.6.2, respectively. The staff finds these changes acceptable because they reflect the VES design and operating information described in DCD Section 6.4,

23.T.4 Conclusion

The staff finds that there will be an adequate amount of air for the extreme winter conditions for 72 hours of VES operation and to maintain pressure above 1379 kPa (200 psig) at the inlet of the pressure regulator. The staff has concluded that the proposed design change complies with GDC 19 and the acceptance criteria specified in Section 6.4 of NUREG-0800. Lastly, the staff finds that the ITAAC are sufficient to demonstrate that the system when built will accomplish the safety function.

23.U Changes to Main Steam Isolation Valve Subcompartment

23.U.1 Description of Proposed Changes

In letters dated, August 12, 2010, and September 30, 2010, the applicant proposed design changes that make the vent paths associated with the main steam isolation valve (MSIV) subcompartments larger. The applicant also proposed to change the content of the pipe hazards analysis report described in Tier 2 DCD Section 3.6.2.5 and to remove tables in Section 6.2 of the DCD that report mass and energy releases and compartment differential pressures outside of containment.

NUREG-0800 Section 6.2.1.2 describes subcompartment analyses inside of containment. Additionally, NUREG-0800 Section 6.2.1.4 describes mass and energy release from secondary side breaks inside of containment. In Chapter 3 of NUREG-0800, high energy pipe hazards outside of containment are described. In the certified design, subcompartment analyses and mass and energy data for pipe breaks outside of containment are included in Chapter 6. This is not typical and not consistent with NUREG-0800 or RG 1.206, “Combined License Applications for Nuclear Power Plants.” Additionally, there is a COL holder item in FSAR Chapter 3 that requires the COL to perform a pipe hazards analysis. As a result, there is some confusion in the certified design. In DCD Section 6.2.1.2 entitled, “Containment Subcompartment Analysis,” there are analyses for subcompartments outside of containment. Additionally, in DCD Chapter 3 there is the requirement for another pipe hazards analysis to be performed by the COL holder.

The applicant identified that the rupture of a feedwater pipe may produce more limiting results than the main steam line break that was described in the DCD; therefore, larger vent paths were needed in the main steam valve rooms.

The applicant has proposed to increase the size of the vent paths in the roof of the Auxiliary Building to provide larger vent paths for high-energy hazards. The proposed design changes also modify the structural attachments at the Auxiliary Building roof. The applicant identified a pipe hazard that releases more energy than is currently considered in the hazards analysis. The vent paths are described in Chapter 3. Specifically the applicant has made changes in the doghouse structures on the roof of the Auxiliary Building. Each doghouse structure has a blowout panel and a louvered vent. The blowout panel is 3.04 m (10 ft) by 3.04 m (10 ft) and the louvered vent is 1.82 m (6 ft) by 1.82 m (6 ft).

The applicant has clarified Section 3.6.2.5 to explicitly include subcompartment pressurization of these compartments outside of containment in the pipe hazards analysis report. To eliminate ambiguity in the DCD, the applicant has removed the subcompartment analyses and mass and energy tables for pipe hazards outside of containment from Chapter 6 of the DCD.

23.U.2 Regulatory Basis

For the Chapter 6 changes, the applicable regulations for the containment systems aspects of this design change are detailed in NUREG-0800 Section 6.2.1.2, “Subcompartment Analysis,” and include the following:

- 10 CFR Part 50, Appendix A, GDC 4, "Environmental and Dynamic Effects Design Bases”

- 10 CFR Part 50, Appendix A, GDC 50

However, because the subject subcompartments are not inside the containment, GDC 50 is not applicable.

For the Chapter 3 changes, the applicable regulations for the protection against pipe rupture are detailed in NUREG-0800 Sections 3.6.1, “Plant Design For Protection Against Postulated Piping Failures In Fluid Systems Outside Containment”; 3.6.2, “Determination Of Rupture Locations And Dynamic Effects Associated With The Postulated Rupture Of Piping”; and in Branch Technical Position (BTP) 3-3, “Protection Against Postulated Piping Failures In Fluid Systems Outside Containment.”

23.U.3 Evaluation

The proposed design changes were reviewed for compliance with GDC 4, which requires that structures withstand the effects of high energy hazards. The design of internal compartments must accommodate the effects of, and be compatible with, the environmental conditions associated with postulated accidents or high energy hazards. The internal compartments shall be appropriately protected against dynamic effects.

The proposed design change of increasing the size of the vents improves the room’s or compartment’s ability to relieve pressure if a high energy pipe fails in the compartment. Confirmation that the final as-built design is in compliance with the requirements is the responsibility of the COL holder. This responsibility is clearly described in the COL holder item in DCD Section 3.6.4.1. Section 3.6.2.5 of the DCD outlines the content of the pipe hazards analysis report. The applicant proposed to change Section 3.6.2.5 to include the following statement:

> Evaluate compartment pressurization in the break exclusion zones in the vicinity of containment penetrations due to 1.0 square foot breaks in the main steam and feedwater lines.

The proposed change clarifies that the compartment pressurization in the break exclusion zones needs to be evaluated for 1.0 square foot breaks in the main steam and feedwater lines. The proposed design change is acceptable because it improves the ability of the facility to withstand high-energy pipe breaks. The change to Section 3.6.2.5 is acceptable because it clarifies the content of the high-energy line break analysis necessary. A COL holder item for high-energy line break analysis is an appropriate approach to demonstrate compliance with GDC 4 because much of the pipe hazards analysis is site-specific in nature.

The staff also finds the removal of the peak differential pressures and mass and energy tables from DCD Chapter 6.2 acceptable. Section 6.2 is dedicated solely to containment issues.

Neither NUREG-0800 nor RG 1.206 recommends these items be included in Chapter 6. Outside containment subcompartments are much more appropriate in Chapter 3 under the COL holder item. As a result, the staff finds this change acceptable as well.

The DCD Tier 2 Section 3.8.4.3.1.4 specifies that a differential pressure of 41 kPa (6 psid) be the design limit for subcompartment pressurization in the MSIV rooms. The design finalization shows that a main feedwater line pipe rupture without adequate venting will cause the subcompartment pressurization to exceed the 41 kPa (6 psid) design pressure limit. Accordingly, the applicant decided to enlarge the venting area of the roof of the Auxiliary Building in order to meet the requirements of the DCD. The applicant provided the modified steam vent design with the proposed design changes. In addition, the applicant committed to finalize the design of the two doghouse structures on the roof of the Auxiliary Building in accordance with the design procedure of the critical sections as defined in DCD Section 3.8, its appendices, and in technical report (TR)-57, APP-GW-GLR-045, "Nuclear Island: Evaluation of Critical Sections."

During the staff's evaluation of these proposed design changes, the following additional information was requested from the applicant:

- Engineering drawings of the doghouse structure at the roof, detailing the venting assemblies, blow-out panels, louvered vents, and connections to the Auxiliary Building roof.

- Stress evaluation on the structures, including applied design-basis loading and the resulting maximum stress.

- The basis, including acceptance criteria and performance requirements, upon which the proposed new design is determined to be acceptable.

The applicant's September 30, 2010, response stated that the design will be finalized using the same methodology, specifications for load combinations, and safety factors that are specified in DCD Section 3.8. Because the final design will be consistent with the design procedure of the critical sections as defined in DCD Section 3.8, its appendices, and in TR-57, the staff finds the change to the vent area to be acceptable.

23.U.4 Conclusion

On the basis of its review of Sections 3.6.2 and 6.2, the staff finds the proposed design changes acceptable. The approach chosen by the applicant will ensure compliance with GDC 4.

The staff's review concludes that the proposed design changes are acceptable because they will not adversely affect safety-related SSCs or the capability of the MSIV depressurization subcompartments to perform their intended functions of pressure relief for the postulated high-energy line break.

23.V Changes to the Component Cooling Water System

23.V.1 Description of Proposed Changes

A leak or tube rupture in the RCP external heat exchanger (EHX) would not result in over-pressurization of piping outside containment, since the pressure in the CCS is controlled by the system's atmospheric surge tank. Such an event could result in a reactor trip and a nonisolable flow path from the RCS through the CCS piping and the surge tank vent to the turbine building (interfacing system LOCA). The applicant has proposed design changes intended to add a safety-related means to isolate this potential flow path. The proposed design changes would provide automatic, safety-related isolation of a LOCA caused by the rupture of one of the RCP EHX tubes. This automatic isolation would prevent discharge of reactor coolant to the turbine building through the CCS surge tank vent and would limit offsite doses to values below those already found acceptable in the event of a small break LOCA, as stipulated in 10 CFR 50.34a, "Design objectives for equipment to control releases of radioactive material in effluents—nuclear power reactors."

In letters dated July 28, 2010; September 3, 2010; September 29, 2010; and October 18, 2010, the applicant proposed design changes to the CCS. The proposed design changes relate to the following:

- Instrumentation and Controls – Containment isolation:

  The applicant proposed to modify the closure logic for CCS motor-operated containment isolation valves CCS-PL-V200, CCS-PL-V207, and CCS-PL-V208 to add a requirement to close on generation of the RCP bearing water high temperature pump trip signal. This modification would add a new isolation signal to DCD Tier 2, Table 6.2.3-1, "Containment Mechanical Penetration and Isolation Valves."

  A closure signal to the component cooling system containment isolation valves is derived from a coincidence of two of the four divisions of high RCP bearing water temperature for any RCP. The high temperature setpoint and dynamic compensation are the same as used in the high RCP bearing water temperature RCP trip (Section 7.3.1.2.5, Condition 6), but with the inclusion of preset time delay.

- Instrumentation and Controls – CCS:

  The applicant proposed to remove the automatic isolation of the CCS RCP HX outlet isolation valves (CCS-PL-V256A/B/C/D) to close on high deviation between inlet and outlet flows. Simultaneous flow deviations in both the inlet and outlet lines would generate a flow deviation alarm and not isolate these valves. This alarm would be indicative of RCS leak conditions and would alert plant operators to close the valve on the cooling water outlet line on each RCP to prevent reactor coolant flow throughout the CCS. Both the flow signals and the isolation valves are nonsafety-related.

- CCS:

  The applicant proposed to install a 10.16 cm (4 in) x 15.24 cm (6 in) safety-class relief valve, designated CCS-PL-V270 and CCS-PL-V271, respectively, on each of the 25.40-cm (10-in) CCS supply and return lines (total of two relief valves), just inside the innermost containment isolation valves (CCS-PL-V201 and CCS-PL-V207). In addition, the applicant proposed to change the safety class of the section of line between the innermost containment isolation valves and the Appendix J test valves (CCS-PL-V214 and CCS-PL-V216) from Class ‘0’ to Class ‘C’ to ensure that the relief valves are installed as ASME safety-class piping.

- Technical Specifications:

  The applicant proposed to add an RCP bearing water temperature high trip function to TS Table 3.3.2-1, “Engineered Safeguards Actuation System Instrumentation,” for closure of the CCS containment isolation valves.

These proposed design changes include revisions to the Tier 2 DCD Sections 3.2, 3.9, 3.11, 5.2, 6.2, 7.2, 7.3, 9.2.2, and Chapter 16.

23.V.2 Regulatory Basis

- Instrumentation and Controls – Containment isolation

  The regulatory basis for evaluating the changes to the AP1000 closure logic for CCS motor-operated containment isolation valves is documented in Chapter 7 of NUREG-1793. Review of these proposed design changes is also based on the requirements in 10 CFR 50.55a(h), 10 CFR 52.47, and GDC 20 and GDC 21 of 10 CFR Part 50, Appendix A.

  The applicable regulations for the containment systems aspects of this design change are detailed in NUREG-0800 Section 6.2.4, “Containment Isolation System,” and include the following:

  - GDC 16 requires that the containment isolation system allow the normal or emergency passage of fluids through the containment boundary while preserving the capability of the boundary to prevent or limit the escape of fission products from postulated accidents.

  - GDC 54, "Piping Systems Penetrating Containment," requires that the containment isolation system valves in piping systems that penetrate the containment be designed to close reliably under accident conditions and prevent the uncontrolled release of radioactive materials.

- Instrumentation and Controls – CCS:

  The regulatory basis for evaluating the proposed instrumentation and controls changes is documented in Chapter 7 of NUREG-1793. Both the flow signals and the isolation valves for the CCS RCP HX outlet isolation valves are nonsafety-related and are not relied upon to perform any safety functions. However, they are part of the CCS, which is considered to be important to safety because it supports the normal (defense-in-depth) capability of transferring heat from various plant components and also removing reactor system and spent fuel decay heat. Reviews of the changes are based on meeting the relevant requirements of 10 CFR 50.55a(h), 10 CFR 52.47, GDC 13, and GDC 19 of 10 CFR Part 50, Appendix A.

- CCS:

  The regulatory basis for evaluating the CCS is documented in Section 9.2.2 of NUREG-1793. While the CCS is a nonsafety-related system, it is considered to be important to safety because it supports the normal (defense-in-depth) capability of removing reactor and spent fuel decay heat. It is part of the first line of defense for reducing challenges to passive safety systems in the event of transients and plant upsets, and its cooling function is important for reducing shutdown risk when the RCS is open (e.g., mid-loop condition). The risk importance of the CCS makes it subject to RTNSS in accordance with the Commission's policy for passive reactor plant designs. The staff's evaluation of the changes that are proposed focused primarily on confirming that the changes could not adversely affect safety-related SSCs or those that satisfy the criteria for RTNSS; the capability of the CCS to perform its defense-in-depth and RTNSS functions; and the adequacy of ITAAC, test program specifications, and availability controls that have been established for the CCS. The proposed changes were evaluated using the guidance provided in NUREG-0800 Section 9.2.2, "Reactor Auxiliary Cooling Water System – Revision 4, March 2007," as it pertains to these considerations. Acceptability was based on conformance with the existing AP1000 licensing basis, the guidance specified in NUREG-0800 Section 9.2.2 (as applicable), and the Commission's policy with respect to RTNSS.

  The following regulatory guidance is also applicable to the proposed design changes:

  - RG 1.26, "Quality Group Classifications and Standards for Water-, Steam-, and Radioactive-Waste-Containing Components of Nuclear Power Plants"

  - RG 1.29

  - SECY-90-016, "Evolutionary Light Water Reactor (LWR) Certification Issues and Their Relationships to Current Regulatory Requirements," related to overpressurization of low-pressure piping systems due to RCS boundary isolation failure could result in rupture of the low-pressure piping outside containment. This could result in a core melt accident with an energetic release outside the containment building, potentially causing a significant offsite radiation release.

- Technical Specifications:

  The regulatory basis for evaluating the GTS is documented in Chapter 16 of NUREG-1793. The staff's evaluation of the proposed changes focused primarily on confirming that the changes to the GTS reflect the CCS isolation function design and operating information described in DCD Sections 5.2, 7.3, and 9.2, respectively. The proposed changes were evaluated using the guidance provided in NUREG-0800 Chapter 16, "Technical Specifications – Revision 3, March 2010." Acceptability was based on conformance with the guidance in NUREG-0800 Chapter 16.

23.V.3 Evaluation

During the staff's evaluation of these proposed design changes, additional information was requested from the applicant. In a letter dated September 3, 2010, the applicant responded to the request for additional information. The staff reviewed the applicant's responses and came to the following conclusions.

- The staff determined that the CCS piping system is adequately protected from over-pressurization due to a postulated RCP external heat exchanger tube rupture with the addition of two new relief valves, one near each CCS containment penetration. Both relief valves are designed to ASME Code Section III, Class 3 and have been added to a markup of Table 3.9-16, "Valve In-service Test Requirements," with a test frequency of at least once per 10 years. The failure of a spring-operated safety valve to open on a high pressure condition is excluded as a single active failure; however, two relief valves will see the over-pressurization event since there is no check valve between the cooling water line serving the reactor coolant drain tank. Since each valve has sufficient capacity to prevent system overpressure for the largest expected discharge from the heat exchanger tube rupture event, the staff finds the CCS piping system is adequately protected from over-pressurization. Therefore, the staff finds the proposed design changes to be acceptable.

- The proposed design changes were reviewed for compliance with GDC 16 and GDC 54 pertaining to containment isolation and containment integrity. The proposed design changes modify the closure logic for the motor operated CCS containment isolation valves CCS-PL-V200, CCS-PL-V207, and CCS-PL-V208 by adding a requirement to close on the generation of a RCP bearing water high temperature signal. This modification adds an additional isolation signal to these valves, and has been included in AP1000 DCD, Tier 2, Table 6.2.3-1, "Containment Mechanical Penetration and Isolation Valves."

  Containment isolation valves are required to close reliably under accident conditions and maintain their integrity to prevent the uncontrolled release of radioactive materials from containment. RCP bearing high water temperature would result from a rupture of one of the U-tubes in the RCP-EHX, which is cooled on the shell side by the CCS. The tube rupture would result in both increased temperature and increased pressure in the CCS. Both GDC 16 and GDC 54 require the containment isolation valves to close to prevent the uncontrolled release of radioactive materials from containment. Therefore, the containment isolation valves must operate at the pressure and temperature conditions in the CCS generated by the RCS tube rupture. Additionally, the containment isolation valves must maintain their integrity and remain leak tight when closed.

  Prior to a rupture, the tube side temperature and pressure in the RCP-EHX are approximately 71 °C (160 °F) and 15.5 MPa (2250 pounds per square inch absolute (psia)); whereas, the temperature and pressure on the shell side of the heat exchanger are approximately 36.6° C (98 °F) and 793 kPa (115 psia). The CCS is a 1379 kPa (200 psig) system, including the containment isolation valves and their included piping. Following a tube rupture the CCS pressure and temperature in the containment would increase significantly. The following conditions must be satisfied:

- The 1379 kPa (200 psig) design containment isolation valves CCS PL-V207, PL-V208, PL-V200, and PL–V201 must be able to close against the increased pressure due to the RCP-EHX tube rupture.

- The 1379 kPa (200 psig) design containment isolation check valve CCS-PL-V201 must maintain its integrity at the increased pressure and temperature due to the RCS-EHX tube rupture and remain closed.

- The new safety-class relief valves, CCS-PL-V270 and CCS-PL-V271, must operate under the conditions of flashing fluid at the maximum fluid temperature produced by the RCP-EHX tube rupture event.

The applicant proposed to add a single safety-class relief valve on each of the 25.4 cm (10 in) CCS supply and return lines respectively just inside the innermost containment isolation valves, CCS-PL-V201 and CCS-PL-V207. The safety-class relief valves, with a set pressure of 1379 kPa (200 psig), are intended to limit the CCS pressure at the containment penetrations to the design conditions for a 1379 kPa (200 psig) system.

The applicant performed an analysis, AP1000/ANSALDO RELAP calculation APP-CCS-M3C-164, Revision 0, September 24, 2010, to simulate the occurrence of a postulated double ended tube break in the RCP-EHX in order to evaluate CCS transient and steady state conditions of temperature and pressure at the relief and containment isolation valves.

The results of the analysis for Case 1, which postulates both safety class relief valves providing overpressure protection and opening at the set pressure of 1379 kPa (200 psig), demonstrate the following:

- CCS-PL-V201 reaches a maximum pressure of 1482 kPa (215 psia), a maximum temperature of approximately 193.3 °C (380 °F), and reaches a steady state condition of approximately 1241 kPa (180 psia) and 189 °C (372 °F) at 1000 seconds.

- CCS-PL-V207 reaches a maximum pressure of 1489 kPa (216 psia), a maximum temperature of approximately 193.3 °C (380 °F), and reaches a steady state condition of approximately 1241 kPa (180 psia) and 189.4 °C (373 °F) at 1000 seconds.

The results of the analysis for Case 2, which postulates a single relief valve, V270, opening upon reaching the set pressure of 1480 kPa (200 psig), and a single failure of relief valve V271 to open, demonstrate similar results of temperature and pressure, but reach steady state conditions at 400 seconds.

The AP1000 piping class sheets and standard details, APP-PLO2-Z0-001, Revision 5, p. 120, provide the design pressure and temperature envelope for class JCB and JCC piping and the CCS containment isolation and safety-related relief valves, summarized as follows;

0-37.7 °C (32-100 °F)	65.5 °C (150 °F)	148.8 °C (300 °F)
1965 kPa	1862 kPa	1586 kPa
285 psig	270 psig	230 psig

Except for the CCS temperature of ~193.3 °C (~380 °F), the transient and steady state conditions are well within the pressure and temperature design envelope of the containment isolation valves and piping. In a subsequent revision to the valve and piping data sheets, "AP1000 Piping Class Sheets and Standard Details", APP-PLO2-Z0-001, Revision 5, the applicant made appropriate changes which resolves this issue.

A RELAP calculation by staff confirmed the above transient results from the applicant's analysis, which was submitted in a letter dated October 18, 2010. The staff concludes that the containment isolation valves would be able to close at these pressure and temperature conditions, and maintain their integrity following a tube rupture in the RCP-EHX.

Each of the four CCS containment isolation valves will be explicitly identified in DCD Tier 2, Table 3.9-12 (Sheet 1 of 7) as having both containment isolation and accident mitigation functions. The new safety-related relief valves, V270 and V271, will be explicitly identified as having an accident mitigation function. The conditions applicable for accident mitigation will be added to the valve data sheets as notes pertaining to the specific fluid temperature and pressure conditions for which the valves must remain operable and intact. In a subsequent revision to the valve and piping data sheets, "AP1000 Piping Class Sheets and Standard Details", APP-PLO2-Z0-001, Revision 5, the applicant made appropriate changes which resolves this issue.

RG 1.26 recommends that portions of cooling water systems important to safety and which are designed for the functioning of components important to safety be designed to Quality Group C standards. For piping and valves the applicable standard is ASME Section III, Class 3.

The applicant proposed to install two additional relief valves, CCS-PL-V270 and CCS-PL-V271, one on each of the 25.4-cm (10-in) CCS supply and return lines, just inside the innermost containment isolation valves, CCS-PL-V201 and CCS-PL-V207, respectively. These relief valves are intended to limit the CCS pressure at the containment penetrations to approximately 1379 kPa (200 psig). Since these relief valves are provided to protect the safety-related CCS containment isolation valves and piping, which are designed to Quality Group B standards, they will be designed to Quality Group C criteria, or ASME Code Section III, Class 3. The staff has evaluated this designation, which will be added to the DCD Tier 2, Table 3.2-3, "AP1000 Classification of Mechanical and Fluid Systems, Components, and Equipment," and concludes that it meets the recommendations of RG 1.26.

SSCs of a nuclear power plant designated as seismic Category I and designed to withstand the effects of an SSE and remain functional include components affecting the safety-related function of the primary containment, in accordance with RG 1.29. The relief valves, CCS-PL-V270 and -V271, are provided to protect the operability and long-term integrity of the CCS 25.4-cm (10-in) containment penetrations. Therefore, they will be designed to seismic Category I criteria. The staff has evaluated this designation and concurs that it meets the guidance of RG 1.29. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

For advanced reactor design, the staff stated its position regarding intersystem LOCA (ISLOCA) protection in SECY-90-016. The staff stated that advanced light-water reactor (ALWR) designs should reduce the possibility of a LOCA outside containment by designing, to the extent practicable, all systems and subsystems connected to the RCS to an ultimate rupture strength at least equal to full RCS pressure.

The CCS is a low-pressure system design with an ultimate rupture strength (URS) below RCS operating pressure. Overpressurization of the CCS could occur following a tube rupture in the RCP-EHX. A relief valve has been added to each of the CCS supply and return headers inside the containment isolation valves in containment to prevent overpressurizing the CCS. The adequacy of pressure relief in protecting the operability and integrity of the containment isolation of CCS has been addressed above and found acceptable. Therefore, the staff finds CCS overpressure protection by the two safety-related relief valves meets the intention of the guidance for ISLOCA.

- Since DCD Tier 1 testing of the CCS-PL-V200 and V201 valves is adequately described in Table 2.2.1-1, the staff determined no other Tier 1 changes or ITAAC are required. DCD Tier 2, Section 14.2.9.2.5 adequately addresses CCS testing, which includes proper operations of controls, instrumentation, actuation signals and interlocks. Furthermore, DCD Tier 2, Section 14.2.9.1.10, “Containment Isolation and Leak Rate Testing,” addresses testing for proper operation of safety-related containment isolation valves listed in Table 6.2.3-1. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

  The proposed revision to DCD Section 9.2.2.4.5.2 provides an adequate description of the automatic isolation function. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

  The applicant proposed to modify the closure logic for CCS motor-operated containment isolation valves CCS-PL-V200, CCS-PL-V207, and CCS-PL-V208 to add a requirement to close on generation of the RCP bearing water high temperature pump trip signal. If a tube break occurs at normal (higher) RCS temperatures, the RTDs used for the automatic isolation function sense the temperature of the reactor coolant flowing through the collection header almost immediately after the break initiates. However, for an idled RCP with the RCS at low temperatures, such as near 93 °C (200 °F), RCS flow is much less (as low as 5 percent) than the flow rates seen at 100percent shaft speed. Even with reactor coolant temperature near 93 °C (200 °F), the RTDs will still sense the reactor coolant temperature within minutes and produce the automatic RCP bearing water high temperature trip, which closes the CCS containment isolation valves. Therefore, the staff’s review finds the applicant’s design change to using reactor coolant temperature instruments to initiate CCS containment isolation acceptable.

- The change to add Modes 3 and 4 to Table 3.3.2-1 of the TS is acceptable to the staff since it envelops the possible Modes within which this event is postulated to occur. The staff had additional questions concerning how the applicant would affect this trip in Modes 3 and 4 since the temperature differential between the RCPs and CCS may be so small that a trip signal would be delayed longer than necessary to effectively isolate the system. In its response, the applicant provided further details of the sensor arrangement and flow path of coolant for this event, should it occur in Modes 3 or 4. The staff found this discussion acceptable because it describes how the trip signal will be generated in sufficient time to isolate the system, without the need for permissive or interlocked trip signals. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

- The applicant proposed to add a signal to Functional Diagram 7.2-1 (Sheet 5 of 20) in AP1000 DCD Tier 2 to close the component cooling system containment isolation valves. This closing signal is derived from the existing 2-out-of-4 control logic with bypass capacity of the high RCP bearing water temperature for any RCP. The high temperature setpoint and dynamic compensation for this new closing signal are the same as those used for RCP trips based on the high RCP bearing water temperature, but it will be implemented with a preset time delay. The newly added logic provides safety-related protection system functions and also meets the reliability and test requirements for the safety protection system as required by GDC 20 and GDC 21. Hence, the staff concludes that this change is acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

  The applicant has also proposed to remove the automatic control function to isolate the CCS RCP HX outlet isolation valves on a high delta-flow between the HX inlet and outlet flow. The high delta-flow between the HX inlet and outlet cooling water lines now will only generate a flow deviation alarm in the MCR. The original automatic isolation function is provided by the plant control system (PLS) and non-Class 1E sensors and instrumentation. This nonsafety-related isolation control function is redundant to and is replaced by the automatic closure of the CCS containment isolation valves based on the high RCP bearing water temperature produced through the safety-related PMS using safety-related RCP RTD sensors. In addition, a new alarm for the high delta-flow between the CCS RCP HX inlet and outlet cooling water lines is now provided in the MCR, and also the remote manual operation of CCS RCP HX outlet isolation valves is retained. If annunciated in the MCR, the new alarm would alert plant operators to close the RCP HX outlet isolation valve remotely in the MCR on the cooling water outlet line to prevent reactor coolant flow throughout the CCS. The staff finds that the above changes meet relevant criteria as required in 10 CFR 50.55a(h) and 10 CFR Part 50, Appendix A GDC 13 and GDC 19. The staff, therefore, concludes that these changes are acceptable.

23.V.4 Conclusion

The staff's review concludes that these proposed design changes are acceptable because they will not adversely affect safety-related SSCs; and the capability of the CCS to perform its defense-in-depth and RTNSS functions will not be degraded by the proposed changes. Adequate overpressure protection of the CCS is provided with ASME Code relief valves during a postulated RCP external heat exchanger tube rupture. An automatic signal will be generated to the associated containment isolation valves in the event of a postulated RCP external heat exchanger tube rupture, as shown in TS Table 3.3.2-1.

On the basis of its review of the containment isolation design aspect of the proposed CCS overpressure protection design change, the staff concludes that the design complies with the acceptance criteria in Section 6.2.4 of NUREG-0800, including: GDC 16; GDC 54; RG 1.26; and RG 1.29.

The staff also finds the design change to provide CCS overpressure protection by the two safety related relief valves meets the intention of the guidance for ISLOCA found in SECY-90-016.

23.W Changes to Add a Vacuum Relief System to the Containment

23.W.1 Description of Proposed Changes

In letters dated August 16, 2010; September 29, 2010; and October 15, 2010, the applicant submitted proposed design changes and supporting documentation, which add a containment vacuum relief system to the existing containment air filtration system (VFS) vent line penetration. The NRC staff reviewed the system design, containment external pressure analyses, containment isolation functions, leak rate testing, descriptions of the valve design, qualification and IST programs, I&C, and associated TS.

The applicant's proposed design changes add a vacuum relief system to the existing VFS 40.64-cm (16-in) vent line penetration as seen in DCD Tier 2, Figure 9.4.7-1, "Containment Air Filtration System P&ID", Sheet 1 of 2. The proposed vacuum relief system consists of redundant vacuum relief devices sized to prevent differential pressure between containment and the shield building from exceeding the design value. Each of the two vacuum relief device flow paths consists of a check valve (VFS-PL-V803A/B) inside containment; a motor operated butterfly valve (VFS-PL-V800A/B) outside containment; and associated piping. Each of these four valves also has a containment isolation function. The redundant check valves inside containment share a common inlet line with the vent line penetration and have independent discharge lines into containment. The redundant motor operated butterfly valves outside containment share a common inlet line. Each relief device, consisting of a check valve, connecting piping, and a motor operated valve (MOV), is designed to provide 100 percent of the required capacity to prevent a differential pressure across the containment vessel from exceeding the design value. Each relief flow path provides the required capacity, such that a single failure of any of the relief devices would not limit the flow below what is required to mitigate a containment vacuum relief event.

The normally closed butterfly valves are designed with motor operators that are powered from separate Class 1E direct current (dc) battery sources. They are designed to close within 30 seconds of receipt of either an automatic containment isolation signal, or a manual isolation signal. They are designed to open automatically within 30 seconds when the containment pressure signal reaches Low-2 level and remain open to preclude exceeding the containment external design pressure. While the vacuum relief system MOVs are open, the containment will be at a vacuum and flow will be into containment. Once the vacuum condition inside containment is reduced to near ambient pressure conditions, the open signal would automatically clear. This would allow the vacuum relief system MOVs, VFS-PL-V800A/B, to close automatically in the event that a containment isolation signal or high radiation signal is present. The check valves are balanced to remain closed during normal operations, including containment vessel venting.

The proposed vacuum relief system is being added to the existing VFS. A short description of the vacuum relief system is being added to DCD Section 9.4.7. Additionally, the proposed vacuum relief system design is shown on DCD Tier 2, Figure 9.4.7-1, Sheet 1 of 2, "Containment Air Filtration System P&ID." Since the proposed vacuum relief system valves are also part of the containment isolation design, valves VFS-PL-V800A/B and VFS-PL-V803A/B have been added to DCD Tier 2, Table 6.2.3-1, "Containment Mechanical Penetrations and Isolation Valves," with two notes. The first, Note 8, indicates that the valves VFS-PL-V800A/B close on either a containment isolation signal or a high radiation in containment signal, and open on a Low-2 containment pressure signal. The second, Note 9, indicates that the Type C leak rate testing of the valves VFS-PL-V800A/B would be in the reverse direction and that closure would occur in 30 seconds.

The applicant has changed the containment external design pressure specified in DCD Section 3.8.2.1.1 from 20.0 kPa (2.9 pounds per square inch differential (psid)) to 11.7 kPa (1.7 psid) based on the actuation point of the vacuum relief system. The applicant has also changed the containment external design analysis in DCD Section 6.2.1.1.4 to demonstrate the vacuum relief system is sufficient to mitigate the maximum expected external pressure.

The applicant has also modified AP1000 DCD Tier 2, Table 3.9-16, “Valve Inservice Test Requirements,” to include butterfly valves VFS-PL-V800A/B and check valves VFS-PL-V803A/B. The IST table will specify VFS-PL-V800A/B as motor-operated butterfly valves with safety-related missions to maintain close, transfer close, maintain open, and transfer open; safety functions as active, containment isolation, safety seat leakage, and remote position; ASME Code Class 2 and IST Category A valves; and IST type and frequency as remote position indication and exercise every 2 years, containment isolation leak test, exercise full stroke quarterly and operability test. The IST table will specify check valves VFS-PL-V803A/B as relief valves with safety-related missions as maintain close, transfer close, and transfer open; safety functions as active, containment isolation, and safety seat leakage; ASME Code Class 2 and IST Category AC valves; and IST type and frequency as containment isolation leak test, exercise full stroke every refueling shutdown, and vacuum relief test every 2 years.

The applicant’s proposed design changes include the addition of TS 3.6.10, “Vacuum Relief Valves,” which address the proposed containment vacuum relief valve operation. The proposed design changes add a function to Table 3.3.2-1, “Engineered Safeguards Actuation System Instrumentation,” for the signal which would open the containment vacuum relief valves on a Low-2 containment pressure level. In addition, the proposed changes extend the Mode Applicability for TS 3.6.4, “Containment Pressure,” and TS 3.6.5, “Containment Air Temperature,” to include Modes 5 and 6, which support TS 3.6.10 requirements.

The applicant has also proposed corresponding changes to Tier 1 DCD sections.

23.W.2 Regulatory Basis

The regulatory basis for evaluating the applicant’s proposed design changes and supporting documentation is documented in Chapters 3, 6, 7, 9, and 16 of NUREG-1793.

The applicable regulations for the design, analyses, containment isolation, and containment leak rate testing aspects of the applicant’s proposed design changes are detailed in NUREG-0800 Sections 6.2.1.1.A, “PWR Dry Containments”; 6.2.1, “Containment Functional Design”; 6.2.4, “Containment Isolation System”; 6.2.6, “Containment Leakage Testing”; and 9.4.3, “Auxiliary and Radwaste Area Ventilation System.” Specifically, the following regulatory requirements and guidance apply:

- 10 CFR Part 50, Appendix A, GDC 2
- 10 CFR Part 50, Appendix A, GDC 16
- 10 CFR Part 50, Appendix A, GDC 38

- 10 CFR Part 50, Appendix A, GDC 50
- 10 CFR Part 50, Appendix A, GDC 52
- 10 CFR Part 50, Appendix A, GDC 53, “Provisions for Containment Testing and Inspection”
- 10 CFR Part 50, Appendix A, GDC 54
- 10 CFR Part 50, Appendix A, GDC 56
- 10 CFR Part 50, Appendix J
- 10 CFR 50.34(f), “Contents of applications; technical information,” regarding Three Mile Island (TMI) Action Plan Item II.E4.2, “Containment Isolation Dependability”
- 10 CFR 52.47(b)(1), which requires that a DC application include the appropriate ITAAC
- RG 1.26
- RG 1.141, “Containment Isolation Provisions for Fluid Systems”
- BTP 6-4, “Containment Purging During Normal Plant Operations.”

The applicable regulations for the staff’s review of the functional design, qualification, and IST programs for the valves described in these proposed design changes are detailed in NUREG-0800 Section 3.9.6 (Revision 3), “Functional Design, Qualification, and Inservice Testing Programs for Pumps, Valves, and Dynamic Restraints.” The staff also considered guidance provided in applicable Commission SECY papers, Commission SRM, GLs, RGs, and regulatory issue summaries. Specifically, the following regulatory requirements apply:

- 10 CFR Part 50, Appendix A, GDC 1
- 10 CFR Part 50, Appendix A, GDC 2
- 10 CFR Part 50, Appendix A, GDC 4
- 10 CFR Part 50, Appendix A, GDC 54
- 10 CFR 50.55a(f), which requires that valves whose function is required for safety be assessed for operational readiness in accordance with the applicable revision to the ASME Code for Operation and Maintenance of Nuclear Power Plants (OM Code)
- 10 CFR 50.55a(b)(3), which takes exception to, or supplements, the ASME OM Code provisions for components within the scope of the IST Program

The applicable regulations for the I&C aspects of the applicant’s proposed design changes are detailed in NUREG-0800 Section 7.3, “Engineered Safety Features,” and NUREG-0800

Section 7.5, "Information Systems Important to Safety." Specifically, the following regulatory requirements and guidance apply:

- 10 CFR Part 50, Appendix A, GDC 13
- 10 CFR Part 50, Appendix A, GDC 19
- 10 CFR Part 50, Appendix A, GDC 20
- 10 CFR Part 50, Appendix A, GDC 21
- 10 CFR 50.55a(h), which requires that protection systems must meet the requirements stated in either IEEE Standard 279, "Criteria for Protection Systems for Nuclear Power Generating Stations," or in IEEE Standard 603-1991, "Criteria for Safety Systems for Nuclear Power Generating Stations," and the correction sheet dated January 30, 1995
- RG 1.97

The applicable regulations for evaluating the applicant's proposed TS are detailed in NUREG-0800 Chapter 16, "Technical Specifications – Revision 3, March 2010." The staff's evaluation focused primarily on confirming that changes to the GTS reflect the containment systems design and operating information in DCD Sections 7.3 and 9.4.7, and the containment analyses described in DCD Section 6.2, and that changes to the GTS meet the requirements of 10 CFR 50.36, "Technical specifications."

23.W.3 Evaluation

23.W.3.1 System Design and Analyses

The staff reviewed the proposed design changes for compliance with GDC 16, which requires that the reactor containment and associated systems be designed to assure that containment design conditions important to safety are not exceeded for as long as postulated accident conditions require.

The proposed vacuum relief system includes an interlock with the inboard containment isolation valve for the containment purge line. The interlock prevents the vacuum relief system from opening if the inboard isolation valve is open. The staff requested that the applicant explain how the safety function would be accomplished if the inboard valve was open and the interlock prevented the vacuum relief system from functioning. The applicant responded that the vacuum relief system actuation had priority over the interlock and that if a containment vacuum condition existed, the system would actuate regardless of the interlock. The applicant revised the statements in the DCD to clarify this design feature. Specifically, the new DCD Section 7.6.2.4 states that if a vacuum relief actuation signal is present, the vacuum relief signal takes precedence over the valve closure interlock. This design feature ensures the safety function is accomplished and removes the possibility of a single failure associated with the interlock disabling the system.

The staff also reviewed the revised external pressure analysis in DCD Section 6.2.1 for compliance with GDC 16. Conformance with acceptance criteria from NUREG-0800 Section 6.2.1.1.A formed the basis for concluding whether GDC 16 was satisfied.

In DCD Revision 15, the applicant determined that the worst case event for maximum external pressure was the loss of all ac power sources during extreme cold weather. The analysis was conducted using the WGOTHIC code with the following conservatisms:

- External temperature boundary condition set at the minimum site parameter from DCD Tier 1, Table 5.0-1, -40 °C (-40 °F).
- Initial containment relative humidity set to 100 percent to maximize the vapor content and allow for the greatest reduction in pressure due to steam condensation.
- Loss of ac power event immediately reduces the containment heat load to zero.
- Initial containment temperature set at the maximum temperature LCO from TS 3.6.5, 48.8 °C (120 °F).
- Initial containment pressure set at the minimum pressure LCO from TS 3.6.4, -1.38 kPa (-0.2 psid).
- The velocity of air flowing over the containment shell is set at 7.56 meters per second (m/s) 24.8 feet per second (ft/s), which correlates to an external wind speed of 77.24 kilometers per hour (km/h) (48 miles per hour (mph)).
- No air leaks into containment.

The analysis demonstrated the differential pressure across the containment vessel remained below the design value for one hour, which was found to be sufficient time for plant operators to take action to mitigate the event.

The applicant revised the external pressure evaluation to incorporate the vacuum relief system and eliminate the need for operator action, to remove unnecessary conservatisms associated with the first three bulleted items above (no changes were made to the final four assumptions), and to incorporate design changes associated with the DCD amendment. The analysis was based on the WGOTHIC evaluation model approved by the staff in Section 23.S of this report, modified for use in an external pressure transient. The worst case event remains the loss of all ac power during cold weather. The applicant recognized that an operating reactor does not produce enough heat to raise the internal temperature to the maximum value on a cold day; thus, the combination of the maximum internal temperature and minimum external temperature is non-mechanistic. In order to remove conservatism, the first step in the revised analysis is determining the minimum external temperature that can sustain the internal temperature at 48.8 °C (120 °F). This pre-transient stage of the analysis assumed a heat rate equal to the value used to size the active containment cooling system. In order to minimize the external shell heat transfer coefficient, the annulus air flow was set to natural convection. The applicant used this model to determine equilibrium containment temperatures associated with various external temperatures and found that -3.88 °C (25 °F) is the minimum external temperature capable of maintaining the maximum internal temperature (48.8 °C (120 °F)).

The next step in the analysis is the loss of power transient. In this phase, the initial temperatures of the internal containment volume, containment shell, baffle and shield building were set to the equilibrium values found during the pre-transient run. For the design basis run, the internal temperature is 48.8 °C (120 °F) and the external temperature is -3.88 °C (25 °F), which bounds the proposed LCO for TS 3.6.10 requiring the internal/external temperature differential be less than or equal to 32.2 °C (90 °F). Because the initial conditions exceed the TS LCO, the equilibrium temperatures derived for the shell, shield building and baffle were also found to be bounding.

The original analysis assumed zero heat loss during the transient. This is non-mechanistic because it neglects the contribution of reactor system sensible and decay heat. In order to remove some of this conservatism, the heat load to containment is assumed equal to the sensible heat from a reactor in Mode 3 at normal operating temperature and normal operating pressure. Decay heat is not considered because it is assumed the reactor has never been critical. The staff agrees that these assumptions produce conservatively low heat loads. The applicant stated that the previous assumption of 100 percent relative humidity was also non-mechanistic because the temperature of the containment vessel is below the dew point. As a result, the revised analysis uses a relative humidity of 82 percent, representing a 25 percent margin over the equilibrium value. The staff finds this approach realistically bounds the relative humidity.

During the transient, the external temperature is assumed to decrease -1.11 °C (30 °F) per hour from an initial value of -3.88 °C (25 °F) until it reaches the minimum site value of -40 °C (-40 °F) at 7800 seconds. To demonstrate this assumption is bounding, The applicant evaluated hourly meteorological data gathered at Charlotte, North Carolina from January 1, 1975 to June 24, 1996 and at Duluth, Minnesota between January 1, 1975 and January 1, 2010. Charlotte, North Carolina was chosen by the applicant as a location having typical meteorological behavior for the Southeast Regional Climate Zone. The applicant also chose the Duluth, Minnesota location because it represents the basis for the AP1000 DCD minimum allowable operation temperature of -40 °C (-40 °F). The applicant found that the maximum observed hourly temperature decrease in Charlotte, North Carolina was -6.66 °C (20 °F) (from 22.77 °C (73 °F) to 11.66 °C (53 °F)). The applicant also found that the maximum observed hourly temperature decrease in Duluth, Minnesota, during below-freezing conditions was -8.33 °C (17 °F) (from -7.22 °C (19 °F) to -16.66 °C (2 °F)). The staff finds the applicant's use of a -1.11 °C (30 °F) per hour temperature drop to be reasonable because the applicant's analysis included several recent years worth of data at a typical southeast regional site (Charlotte, North Carolina) and a typical cold weather site (Duluth, Minnesota), and because there is significant margin between the observed values (-6.66 °C (20 °F) for Charlotte, North Carolina and -8.33 °C (17 °F) for Duluth, Minnesota) and the assumed hourly decrease (-1.11 °C (30 °F).

The WGOTHIC model incorporated one 15.2-cm (6-in) valve with a conservatively calculated system resistance, designed to open 20 seconds after the internal containment pressure reached the setpoint of -8.3 kPa (-1.2 psid). The safety analysis limit -8.3 kPa (-1.2 psid) is clearly identified in the DCD and will be used to develop the Low-2 containment pressure setpoint under the TS setpoint methodology program. The 20 seconds required to develop full flow is consistent with the mechanical design requirements identified in Section 9.1.1 of Enclosure #4 of the applicant's October 15, 2010 submittal. Because it is reasonable to expect a butterfly valve to allow significant flow at 60 percent of the stroke, this is also consistent with the proposed acceptance criteria for ITAAC Item 2 from Table 2.7.6-2 requiring the valves to open within 30 seconds.

The transient response demonstrated that the vacuum relief system limits the containment pressure to a minimum value of -11.2 kPa (-1.63 psid), which is bounded by the design value of

-11.7 kPa (-1.7 psid). As described in Enclosure #6 of its October 15, 2010, submittal, the applicant ran additional vacuum relief scenarios at external temperatures of -40 °C (-40 °F) and 10.0 °C (50 °F) and used the results to confirm that the design basis case was limiting. The -40 °C (-40 °F) case, initiated with an internal temperature of 31.11 °C (88 °F), was also used to demonstrate that the internal to external temperature differential LCO is not required if the internal containment temperature is less than 31.11 °C (88 °F). This bounds TS 3.6.10 Required Action B.2 to reduce containment average temperature to ≤ 26.66 °C (≤ 80 °F) when the inside to outside differential air temperature does not meet the LCO.

The staff reviewed the analysis basis during August 27, 2010, and October 3, 2010, audits of APP-SSAR-GSC-112, “AP1000 External Pressure Analysis to Confirm Sizing of the Vacuum Relief System,” Revision 0 and Revision 1. This report states that while various transients were considered for the external pressure evaluation, the loss of ac power event remains the most limiting. This is the same event that was found to be bounding in the original analysis, for the reasons discussed in Section 6.2.1 of NUREG-1793. The staff finds this evaluation remains applicable to the revised design because the proposed design changes will not impact determination of the limiting event.

The analysis applied a 7.56 m/s (24.8 ft/s) annulus velocity during the transient to represent an external wind of 77.24 km/h (48 mph). The staff finds this will produce conservatively high heat transfer coefficients because the basis for the correlation was testing on a prior version of the shield building. As discussed in Section 23.S, there is an increased pressure drop associated with the revised shield building, so the annulus velocity associated with a 77.24 km/h (48 mph) wind speed will be less than 7.56 m/s (24.8 ft/s).

The staff conducted an additional audit on August 30, 2010, on three supporting calculation notes. The staff found the baseline WGOTHIC external pressure model, described in APP-SSAR-GSC-746, Revision 0, acceptable because it used the same methodology as the DCD Revision 15 analysis to transform the LOCA model into an external pressure model. The staff reviewed the calculations for the total system resistance in APP-VFS-M3C-224, “Containment Vacuum Relief System Resistance Calculation,” Revision 0. The analysis was found to be conservative because the resulting value represents the resistance associated with the more limiting single flow path configuration (which assumes two failures) rather than the worst case single failure. It also incorporates a 65 percent margin over the calculated value to account for potential design changes. The staff reviewed the design basis for the minimum heat load into containment as described in APP-SSAR-GSC-003, “Calculation of the Total Loss of RCS Heat from Mode 3 with Station Blackout,” Revision 0. The staff finds this analysis to be conservative because the code used to generate the heat load does not consider contributions from the major component support structures, which are typically large contributors to containment sensible heat.

The staff performed a confirmatory analysis using the CONTAIN computer code and the AP1000 model described in Section 23.S.3 of this report. The model was altered to incorporate one vacuum relief line and to remove the shield building in order to apply the annulus air velocity directly to the external containment shell, producing conservatively high heat transfer coefficients on this surface. The model incorporated the same valve parameters as the applicant except the valve opening delay time was increased to 30 seconds. The staff evaluated the design basis case and the two sensitivity studies. The containment internal pressure transients demonstrated the design basis case, with a minimum negative pressure of -10.8 kPa (-1.56 psid), was limiting. These results are consistent with the applicant’s evaluation.

NUREG-0800 Section 6.2.1.1.A recommends that the margin between the external design pressure and the conservatively calculated minimum pressure be at least 10 percent at the construction permit (CP) or DC stage of review. The requirement at the operating license stage of review is that the maximum calculated value be less than the design value (zero-margin criterion). The more restrictive margin is applied at the CP and DC stage to account for revised or upgraded analytical models or minor changes that may result in a decrease in the margin in the as-built design. The margin in the revised design basis analysis is 4 percent. The applicant concluded that this margin is acceptable because the calculation of the vacuum relief system resistance included a 65 percent margin to accommodate system variances associated with plant construction. The applicant claims this addresses the "as-built" considerations that form the basis for NUREG-0800 recommended 10 percent margin at the DC stage. Furthermore, when the margin was removed from the loss coefficient, the resultant minimum external pressure was 10.1 kPa (1.46 psid), which provides a 14 percentmargin to the design value. The staff agrees this is an acceptable approach because it meets the intent of the NUREG-0800 recommendation. This finding is consistent with the staff evaluation in NUREG-1793 Section 6.2.1 where a zero-margin criterion was deemed acceptable for the AP1000 peak accident pressures at the DC stage.

The staff reviewed the proposed containment vacuum relief design for compliance with the requirements of GDC 2, which requires that the system be capable of withstanding the effects of earthquakes. The new portions of the system are safety-related and seismic Category I and, therefore, meet the requirements of GDC 2. However, in Section 9.4.7 of the DCD, the applicant removed statements that demonstrate the nonsafety-related portions of the VFS system meet GDC 2. The staff requested that the applicant explain how the VFS system meets GDC 2. The applicant revised the discussion in DCD Section 9.4.7 to state that system equipment and ductwork whose failure could affect the operability of the safety-related systems or components are designed to seismic Category II requirements. This conforms to the certified DCD Revision 15 design, and is adequate to demonstrate compliance with GDC 2.

As a result, the staff finds that the design and design features described in the DCD ensure the requirements of GDC 2 and GDC 16 are met. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue. The staff's evaluation of the AP1000 steel containment, including load combinations and design and analysis procedures, is described in Section 3.8.2 of this report.

23.W.3.2 Containment Isolation and Leak Rate Testing

The staff reviewed the proposed vacuum relief system design for compliance with GDC 56, which requires that each line that connects directly to the containment atmosphere and penetrates primary reactor containment be provided with containment isolation valves. One acceptable design includes: one automatic isolation valve inside, and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment. The design of the vacuum relief system complies with the requirements of GDC 56.

10 CFR 50.34(f)(2)(xiv)(B) requires that each non-essential penetration (except instrument lines) shall have two isolation barriers in series. The vacuum relief design consists of two lines, which connect directly with the containment atmosphere and penetrate the primary containment. This design complies with the requirement of GDC 56 by providing each vacuum relief device with a check valve inside containment and a motor operated butterfly valve outside containment. This design complies with the 10 CFR 50.34(f)(2)(xiv)(B) redundancy requirement. If a check

valve failed to close during an accident, the MOVs in series with it would close on a “T” signal (described in DCD Section 6.2.3), thereby providing containment isolation.

To meet the requirements of GDC 56, upon loss of actuating power, automatic isolation valves should take the position of greatest safety. All power-operated isolation valves should have position indications in the MCR. The safe post-accident position for the valves in the vacuum relief system is closed. The motor operated butterfly valves would close on a “T” containment isolation signal. To improve the reliability of the isolation function, these valves also close on a high radiation in containment signal. These valves are each powered by Class 1E batteries to ensure that they would close on these signals. Their position indication in the MCR is shown on DCD Table 6.2.3-1. Valves VFS-PL-V803A and VFS-PL-V803B are self actuated check valves, which would close if a vacuum does not exist inside containment. These check valves would either close or remain closed post-accident. Since the proposed vacuum relief system valves are also part of the containment isolation design, VFS-PL-V800A/B and VFS-PL-V803A/B have been added to DCD Tier 2, Table 6.2.3-1, “Containment Mechanical Penetrations and Isolation Valves,” with two notes. The first, Note 8, indicates that the valves VFS-PL-V800A/B close on either a containment isolation signal or a high radiation in containment signal, and open on a Low-2 containment pressure signal. The second, Note 9, indicates that the Type C leak rate testing of the valves VFS-PL-V800A/B would be in the reverse direction and that closure would occur in 30 seconds. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The staff also reviewed these proposed design changes for compliance with the requirements of GDC 54, as it relates to providing piping systems penetrating the containment with containment isolation capabilities having redundancy and reliability which reflect their importance to safety. To meet the reliability requirements, the components performing a containment isolation function are acceptable if Group B quality standards, as defined in RG 1.26, apply, and the components are designated seismic Category I in accordance with RG 1.29.

The containment isolation section of the vacuum relief design, consisting of the containment isolation valves and the included piping, are designed to ASME Code Section III, Class 2 criteria. The containment penetrations are classified as Quality Group B, as defined in RG 1.26, and seismic Category I. These designations are shown in DCD Tier 2, Figure 9.4.7-1 and Table 6.2.3-1, and Tier 1, Table 2.2.1-1, Table 2.2.1-2, and Figure 2.2.1-1, “Containment Isolation System.” The applicant has selected the appropriate mechanical design classification.

10 CFR 52.47(b)(1) requires that a DC application include the appropriate ITAAC. The ITAAC for the containment isolation MOV closing time are shown in DCD Tier 1, Table 2.7.6-2 and Table 2.2.1-3. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

In meeting the requirements of GDC 54, relating to lines which provide open paths from the containment to the environs, such as containment purge and vent, the closure times of the isolation valves should minimize the release of containment atmosphere to the environs, to mitigate the offsite radiological consequences, and to prevent degradation of emergency core cooling system effectiveness by reduced containment back-pressure. CSB BTP 6-4 provides additional guidance on the design and use of the containment purge systems, which may be used during the normal plant operating modes.

The VFS is used to purge the containment atmosphere of airborne radioactivity during normal plant operation. The proposed containment vacuum relief system is a safety grade system used to mitigate a containment external pressure scenario, and is part of the VFS, sharing the same containment penetration. The purge system is designed in accordance with CSB BTP 6-4. The purge component of the VFS uses 40.6-cm (16-in) supply and exhaust lines and containment isolation valves designed to close in 10 seconds. The vacuum relief component of the VFS uses 15.2-cm (6-in) supply lines and containment isolation valves designed to close in 30 seconds.

In the event of a LOCA, a maximum time of 30 seconds for closure of the 40.6-cm (16-in) valves was assumed for the analysis for the radiological consequences, as seen in DCD Tier 2, Table 15.6.5-2. This closure time is conservative, as the valve design closure time is 10 seconds. This closure time is consistent with the guidance in CSB BTP 6-4, and was found acceptable as an assumed closure time in the radiological analysis in NUREG-1793, Section 6.2.4.13. The 30 second closure times of the two new 15.2-cm (6-in) vacuum relief valves would be bounded by the current design, as the radiological consequences following a LOCA have already been found acceptable for two open 40.6-cm (16-in) valves, closing in 30 seconds.

To analyze the LOCA containment minimum backpressure, containment purge was assumed to be in operation at time zero and air was vented through both the 40.6-cm (16-in) diameter containment purge supply and exhaust lines until the isolation valves fully closed. These valves were modeled to close 12 seconds after the 55.2 kPa (8 psig) closure setpoint was reached, as described in DCD Tier 2, Section 6.2.1.5.3. This closure time was found acceptable as an assumed closure time in the ECCS analysis (reflood backpressure) in NUREG-1793, Section 6.2.4.13. In DCD, Tier 2, Section 9.4.7.2.1, the maximum time for closure of the vacuum relief valves, 30 seconds, was evaluated for its impact on the calculation of the LOCA backpressure. The minimum containment backpressure following two, 15.24-cm (6-in) valves closing in 30 seconds, is expected to be bounded by the containment backpressure resulting from two, 40.64-cm (16-in) valves closing in 12 seconds.

In NUREG-1793, Section 6.2.6, the staff reviewed the applicant’s proposed containment leakage rate testing program for AP1000 facilities described in DCD Tier 2, Section 6.2.5 and in the proposed TS of DCD Tier 2, Chapter 16. The staff reviewed the information in the DCD for conformance to 10 CFR Part 50, Appendix J, and to GDC 52 and GDC 53. GDC 52 requires the containment and associated equipment to be designed such that the periodic containment integrated leakage rate tests can be conducted at containment design pressure. GDC 53 requires that the containment allow periodic inspection, surveillance, and testing of certain SSCs.

The staff used the guidance, staff positions, and acceptance criteria of NUREG-0800 Section 6.2.6 and RG 1.163, “Performance-Based Containment Leak-Test Program,” in conducting its review.

The staff concluded that the AP1000 containment leakage rate testing program complied with the acceptance criteria of Section 6.2.6 of NUREG-0800 by satisfying the containment leakage rate testing requirements of GDC 52 and GDC 53, and Appendix J to 10 CFR Part 50.

The proposed vacuum relief system valves, VFS-PL-V800A/B and VFS-PL-V803A/B are also part of the containment isolation design and have been added to AP1000 DCD Tier 2, Table 6.2.3-1, “Containment Mechanical Penetrations and Isolation Valves.” These new containment isolation valves will be included in the AP1000 containment leak rate test program, and will be Type C tested, as indicated in DCD Tier 2, Table 6.2.3-1. Adding the new containment isolation valves to the already approved containment leak rate test program, meets the acceptance criteria in Section 6.2.6 of NUREG-0800 for containment leak rate testing of the new valves.

With regard to 10 CFR 52.47(b)(1), the applicant has added appropriate ITAAC to Tier 1. The applicant has included ITAAC to verify the valves function in both the open and closed directions. The staff finds the additional ITAAC acceptable.

23.W.3.3 Valve Design, Qualification, and Testing

The staff reviewed the functional design, qualification, and IST program descriptions for the valves to be used in the applicant's proposed containment vacuum relief system. The staff provided comments to the applicant related to the functional design, qualification, and IST program descriptions for the valves to be used in the proposed containment vacuum relief system. The applicant provided responses to all NRC requests for information. The staff also performed audits of the valve design specifications and data sheets referenced in the proposed design changes.

The proposed AP1000 containment vacuum relief system design includes parallel motor-operated butterfly valves VFS-PL-V800A/B outside containment connected by a single pipe line to parallel check valves VFS-PL-V803A/B inside containment. In the event of a vacuum condition within the AP1000 containment, butterfly valves VFS-PL-V800A/B will receive an automatic electric signal to their battery-powered motor actuators to open the valves. As a result, outside air will flow through the connected piping up to check valves VFS-PL-V803A/B that will open upon a preset differential air pressure across the valves and allow air to enter the AP1000 containment to relieve the vacuum condition. During its review of the applicant's submittal, the staff requested that the applicant clarify the design, qualification, and testing requirements for butterfly valves VFS-PL-V800A/B and check valves VFS-PL-V803A/B. The applicant provided this additional information in letters dated September 29, 2010, and October 15, 2010.

In Section 3.9.6 of this report, the staff concluded that the AP1000 DCD continues to provide sufficient information to satisfy 10 CFR Part 50 and 10 CFR Part 52, "License, certifications, and approvals for nuclear power plants," for the design aspects of the functional design, qualification, and IST programs for safety-related valves to be used in the AP1000 reactor. The staff noted in Section 3.9.6 of this report that the operational program aspects regarding the functional design, qualification, and IST programs for safety-related valves will be reviewed as part of the evaluation of a COL application referencing the AP1000 certified design. The modifications to the AP1000 DCD related to the functional design, qualification, and IST programs for valves are addressed in Section 3.9.6.

In response to staff comments, the applicant revised Section 9.1.1, "Mechanical Design Requirements," in Section 9.1, "Outboard Motor Operated Valves VFS-PL-V800A/B," of its submittal to specify that the butterfly valves in the AP1000 containment vacuum relief system will be designed in accordance with AP1000 DCD Tier 2, Section 3.9, "Mechanical Systems and Components." The staff describes its review of the design requirements for safety-related MOVs in Section 3.9.6 of this report. For example, as indicated in the letter dated March 5, 2010, the applicant plans to revise Section 3.9 of the AP1000 DCD Tier 2 to specify that qualification of safety-related valves will be in accordance with ASME Standard QME-1-2007, "Qualification of Active Mechanical Equipment Used in Nuclear Power Plants." The staff accepted the application of ASME Standard QME-1-2007 in Revision 3 to RG 1.100, "Seismic Qualification of Electric and Active Mechanical Equipment and Functional Qualification of Active Mechanical Equipment for Nuclear Power Plants," with certain staff positions. Also in response to staff comments, the applicant revised Section 9.1.1 of its submittal to specify the design requirements for capacity coefficient and stroke time for full flow capacity of these butterfly valves. The staff finds the reference to the provisions in AP1000 DCD Tier 2, Section 3.9, with the valve-specific design requirements in Section 9.1.1 of the applicant's submittal, to be acceptable for the functional design and qualification of the butterfly valves to be used in the proposed containment vacuum relief system with respect to the design aspects of the AP1000 DC amendment as discussed in Section 3.9.6 of this report.

During its review, the staff requested that the applicant describe the availability of adequate power supplies for motor-operated butterfly valves VFS-PL-V800A/B to perform their design-basis functions. Section 9.1.2, "Valve Electrical Requirements," of the applicant's submittal specifies the design requirements for butterfly valves VFS-PL-V800A/B to be powered from separate Class 1E dc battery sources. Section 9.1.2 also specifies that butterfly valves VFS-PL-V800A/B will be designed to stroke twice for their design-basis operation. Section 9.1.2 indicates that the electrical calculations using the methodology described in IEEE Standard 485, "IEEE Recommended Practice for Sizing Lead-Acid Batteries for Stationary Applications," will take into consideration the starting current and stroke time for the MOV operations. Section 8.2, "DC Power Systems," in AP1000 DCD Tier 2 describes the application of IEEE-485 for dc power systems in the AP1000 certified design. In addition, the functional qualification of butterfly valves VFS-PL-V800A/B in accordance with ASME Standard QME-1-2007 as accepted in Revision 3 to RG 1.100 will demonstrate the power capability of these MOVs to perform their design-basis functions. The staff finds that the applicant has described the methodology for providing adequate power availability to butterfly valves VFS-PL-V800A/B in an acceptable manner.

In response to staff comments, the applicant revised Section 9.1.3, "Testing Requirements," of its submittal to specify that butterfly valves VFS-PL-V800A/B will be tested in accordance with AP1000 DCD Tier 2, Section 3.9.6, "Inservice Testing of Pumps and Valves." As discussed above, the staff describes its review of the description of the IST program for safety-related valves in Section 3.9.6 of this report. Therefore, the staff finds the reference in the applicant's submittal to the provisions in AP1000 DCD Tier 2, Section 3.9.6 for the description of the IST program for the butterfly valves to be used in the AP1000 containment vacuum relief system to be acceptable with respect to the design aspects of the AP1000 DC amendment as discussed in Section 3.9.6 of this report. The staff will review the operational aspects for the IST program for safety-related valves as part of the evaluation of a COL application referencing the AP1000 certified design.

Section 9.2.1, "Mechanical Design Requirements," of the applicant's submittal specifies the design requirements for the AP1000 vacuum relief containment isolation check valves. ASME OM Code, Table ISTC-3500-1 states that if a check valve used for pressure relief is capacity certified, then it shall be classified as a pressure or vacuum relief valve. Therefore, check valves VFS-PL-V803A/B are within the scope of ASME Code, Section III, Subsection NC-7000, "Overpressure Protection," as defined in Paragraph NC-7110, and require capacity certification as defined in Paragraph NC-7750. In response to staff comments, The applicant revised Section 9.2.2, "Testing Requirements," of its submittal to specify that VFS-PL-V803A/B are vacuum relief valves that will be designed and qualified in accordance with ASME Code, Section III, Subsection NC-7000. During its review, the staff informed the applicant that the design requirements for check valves VFS-PL-V803A/B should be included in Section 9.2.1 (rather than Section 9.2.2). As a result, the applicant modified Section 9.2.1 to specify:

(1) VFS-PL-V803A/B are vacuum relief valves that will be designed and qualified in accordance with ASME Code, Section III, Subsection NC-7000; (2) the valves will be qualified using the provisions in AP1000 DCD Tier 2, Section 3.9; (3) the valves will be designed with an allowable tolerance for the 1.38 kPa (0.2 psi) differential opening pressure; and (4) the valve flow capacity to relieve vacuum conditions to avoid the containment external design pressure from being exceeded. The staff finds the reference in the applicant's submittal to the provisions in AP1000 DCD Tier 2, Section 3.9 and the ASME Code design requirements, with the valve-specific design requirements specified in Section 9.2.1 of the applicant's submittal, to be acceptable for the functional design and qualification of the check valves to be used in the AP1000 containment vacuum relief system.

Section 9.2.2 of the applicant's submittal specifies the testing requirements for AP1000 vacuum relief containment isolation check valves VFS-PL-V803A/B. Because these check valves provide a vacuum relief function with a design opening pressure, the NRC informed the applicant that its submittal should specify that these valves will be tested in accordance with ASME OM Code, Appendix I, "Inservice Testing of Pressure Relief Devices in Light-Water Reactor Nuclear Power Plants." In response, the applicant revised Section 9.2.2 to specify that these check valves are tested in accordance with AP1000 DCD Tier 2, Section 3.9.6 and ASME OM Code, Appendix I. Section 9.2.2 also states that these check valves will be tested in both directions in light of their safety functions in both the open and close directions. Section 9.2.2 specifies that 1.38kPa (0.2 psid) will be used as an acceptance criterion for the check valve opening test. As discussed above, the staff describes its review of the description of the IST program for safety-related valves in Section 3.9.6 of this report. Therefore, the staff finds the reference in the applicant's submittal to the provisions in AP1000 DCD Tier 2, Section 3.9.6 and ASME OM Code, Appendix I, for the description of the IST program for the check valves to be used in the AP1000 containment vacuum relief system to be acceptable with respect to the design aspects of the AP1000 DC amendment as discussed in Section 3.9.6 of this report. The staff will review the operational aspects regarding the IST program for safety-related valves as part of the evaluation of a COL application referencing the AP1000 certified design.

In response to staff comments, the applicant modified Section 6.0, "Containment Isolation Consideration," of its submittal in the "Position" paragraph for 10 CFR Part 50, Appendix A, GDC 54, to clarify that butterfly valves VFS-PL-V800A/B cannot be tested in the direction of containment leakage. Therefore, these butterfly valves will be tested in the reverse direction of containment leakage. This testing is more conservative because the valves will be installed such that the containment pressure will assist in sealing the valve closed to minimize containment leakage. The applicant's submittal indicates the application of American National Standards Institute/American Nuclear Society (ANSI/ANS) 56.8, "Containment System Leakage Testing Requirements," for containment valve testing as referenced in the AP1000 DCD. The staff requested that the applicant clarify that the butterfly valves will be installed in an orientation that provides for containment pressure to help seal the valve closed. In its response, the applicant revised Section 6.0 of its submittal to specify that the butterfly valves in the containment vacuum relief system will be installed such that containment pressure will assist in sealing the valve closed. The staff finds that the applicant has clarified the orientation of the butterfly valves in the containment vacuum relief system to support the direction of leakage testing for these valves.

As part of its submittal, the applicant plans to modify AP1000 DCD Tier 2, Table 3.9-16, "Valve Inservice Test Requirements," to include butterfly valves VFS-PL-V800A/B and check valves VFS-PL-V803A/B. The IST table will specify VFS-PL-V800A/B as motor-operated butterfly valves with safety-related missions to maintain close, transfer close, maintain open, and transfer open; safety functions as active, containment isolation, safety seat leakage, and remote position; ASME Code Class 2 and IST Category A valves; and IST type and frequency as remote position indication and exercise every 2 years, containment isolation leak test, exercise full stroke quarterly and operability test. The IST table will specify check valves VFS-PL-V803A/B as relief valves with safety-related missions as maintain close, transfer close, and transfer open; safety functions as active, containment isolation, and safety seat leakage; ASME Code Class 2 and IST Category AC valves; and IST type and frequency as containment isolation leak test, exercise full stroke every refueling shutdown, and vacuum relief test every 2 years. During its review, the staff requested that the applicant resolve an apparent inconsistency between the IST table and its Note 39. In a letter dated October 15, 2010, the applicant provided a planned revision to the IST table to clarify that the containment vacuum relief butterfly valves will be exercised quarterly and that the containment vacuum relief check valves will be full stroke exercised every refueling shutdown. The applicant’s submittal indicates that Note 39 to the IST table will justify the extended test interval for the check valves because of their location inside containment. The staff finds the planned provisions for IST activities for the butterfly valves and check valves in the containment vacuum relief system to comply with the requirements in 10 CFR 50.55a and the ASME OM Code and, therefore, to be acceptable. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

The staff requested that the applicant clarify the provisions for inspection and maintenance of the valves in the AP1000 containment vacuum relief system. In its response, the applicant clarified that the inspection and maintenance of butterfly valves VFS-PL-V800A/B and check valves VFS-PL-V803A/B are the same as those for other safety-related valves. These valves are required to satisfy the design, inspection, and testing requirements described in the applicable section of the AP1000 DCD. These valves will be designed for the full lifetime of their service, and will not require inspection following individual actuations. Corrective action will be taken for any identified malfunction. Periodic testing and inspection results will be documented and trended. The plant predictive maintenance program and its associated condition monitoring will include these valves. The staff finds that the applicant has clarified the implementation of plant programs for inspection and maintenance for butterfly valves VFS-PL-V800A/B and check valves VFS-PL-V803A/B that complies with the NRC regulations and, therefore, is acceptable.

The applicant’s submittal indicates that the scope of AP1000 DCD Tier 1, Section 2.2.1, “Containment System,” will be expanded to include butterfly valves VFS-PL-V800A/B and check valves VFS-PL-V803A/B. Table 2.2.1-3, “Inspections, Tests, Analyses, and Acceptance Criteria [ITAAC],” for the containment system specifies ITAAC for piping and component design in accordance with ASME Code Section III; piping, components, and welds satisfying ASME Code, Section III requirements for integrity; seismic design-basis capability; Class 1E environmental qualification; valve operating times; and valve functional qualification. In its letter dated October 15, 2010, the applicant provided a planned change to Table 2.2.1-3 to specify the closing time for the butterfly valves in the AP1000 containment vacuum relief system. The applicant also indicated that Table 2.7.6-2 in AP1000 DCD Tier 1, Section 2.7.6, “Containment Air Filtration System,” will include new ITAAC for the opening time for the butterfly valves in the AP1000 containment vacuum relief system. The staff finds these ITAAC to be acceptable for the butterfly valves and check valves in the AP1000 containment vacuum relief system. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

Section 9.3, "Valve Design Specifications and Datasheets," of the applicant's submittal indicates that the design specifications and data sheets for butterfly valves VFS-PL-V800A/B and check valves VFS-PL-V803A/B were available for review at the Westinghouse office. On September 16, 2010, the staff reviewed the referenced documents at the Westinghouse office. During this audit, the staff found that the referenced valve specifications and data sheets had not been updated to include butterfly valves VFS-PL-V800A/B and check valves VFS-PL-V803A/B. As a result, the applicant revised Section 9.3 in its submittal to describe the data sheets to be prepared for the butterfly valves and check valves to be used in the AP1000 containment vacuum relief system to support the applicable valve design specifications. On October 7, 2010, the staff audited the preliminary valve specifications and data sheets at the Westinghouse office. The staff finds that the applicant has provided an acceptable description of the valve design specifications and data sheets to support the design and qualification of the butterfly valves and check valves to be used in the AP1000 containment vacuum relief system.

ASME Code, Section III, Article NE-7000, "Overpressure Protection," Subsection NE-7150, "Acceptable Pressure Relief Devices," specifies in Article NE-7152 that vacuum relief devices shall meet the construction requirements applicable to Class 2 valves. The ASME Code also states that valve devices intended to provide vacuum relief, and which are operated by indirect means depending upon an external energy source, are not acceptable unless the following conditions are met: (1) at least two independent external power-operated valve and control systems are employed so that the required relieving capacity is obtained if any one of the valve systems should fail to operate when called upon to do so; and (2) at least one self-actuating vacuum relief device of equivalent relieving capacity is provided in series with each of the external power-operated valves. The ASME Code indicates that acceptable self-actuating vacuum relief devices include balanced self-actuating, horizontally installed, swing disk valves, with provisions for adjustment for the differential pressure under which the valves will operate.

For the proposed AP1000 containment vacuum relief system, Sections 9.1.1 and 9.2.1 of the applicant's submittal specify that butterfly valves VFS-PL-V800A/B and check valves VFS-PL-V803A/B will be designed as ASME Code, Class 2 valves. Motor-operated butterfly valves VFS-PL-V800A/B will receive an automatic electric signal to their battery-powered motor actuators to open the valves from separate Class 1E dc battery sources. Check valves VFS-PL-V803A/B will be designed as swing check valves installed in the horizontal direction with a 1.38 kPa (0.2 psi) differential opening pressure. The design of the proposed AP1000 containment vacuum relief system includes parallel check valves VFS-PL-V803A/B in series with the parallel butterfly valves VFS-PL-V800A/B. The staff finds that the design of the vacuum relief devices for the proposed AP1000 containment vacuum relief system satisfies the provisions in Subsection NE-7150 of ASME Code, Section III.

23.W.3.4 Instrumentation and Control

As documented in Chapter 7 of NUREG-1793, the staff reviewed and approved the engineered safety features and safety-related display information as specified in Sections 7.3 and 7.5, respectively, of the AP1000 DCD, Revision 15. The staff reviewed these proposed design changes using the review procedures described in NUREG-0800 Sections 7.3 and 7.5.

The applicant created a new functional diagram Figure 7.2-1 (Sheet 19 of 21) for controlling the proposed containment vacuum relief MOVs from the PMS. The proposed vacuum relief system MOVs are designed to close within 30 seconds by using the existing VFS isolation signal from the PMS, which includes closure from an automatic containment isolation signal, a High-1 containment radiation signal, a manual containment isolation, or a manual containment cooling signal. In accordance with these proposed design changes, the normally closed vacuum relief system MOVs would open automatically during either of the following conditions:

- 2-out-of-4 coincidence logic for a Low-2 containment pressure condition
- manual actuation of either of the two momentary controls

The 2-out-of-4 logic also receives signals that indicate whether divisions have been bypassed. If one division is bypassed for test or maintenance, the logic will automatically be modified to 2-out-of-3 coincidence logic. Actuating either of the two momentary manual controls in the MCR would actuate all applicable divisions. Separate momentary controls are also provided in the MCR for manually resetting the containment vacuum relief system. In these proposed design changes, the open control function has priority over the closing control function for the containment vacuum relief MOVs. In addition, in order to prevent the purge line isolation inside valve from being opened simultaneously with the vacuum relief system MOVs, interlock logic is implemented to make sure that the vacuum relief system MOVs could not be opened unless the purge line isolation inside valve is closed; if open, vacuum relief system MOVs would close.

While the vacuum relief system MOVs are open, the air flow would be into the containment, which is at a vacuum. Once the vacuum condition inside containment is reduced to near ambient pressure conditions, the open signal would automatically clear. This would allow the vacuum relief system MOVs to close automatically in the event that a containment isolation signal or high radiation signal is present.

The applicant included the necessary design change information in the revised Tier 2, Section 7.3.1, Tables 7.3-1 and 7.3-3, new functional diagram Figure 7.2-1 (Sheet 19 of 21), and Tier 1, Table 2.5.2-3 in the DCD. The applicant also added a new Section 7.6.2.4 in Tier 2 to address the interlock for the containment vacuum relief isolation system, which was added to Tier 1, Table 2.5.2-7 as well for the PMS Interlocks. Since the above logic included for the proposed containment vacuum relief system is designed with division redundancy and bypass capability, the staff concludes that the proposed containment vacuum relief system meets the applicable criteria of protection, reliability, and testability as required in 10 CFR 50.55a(h), and GDC 20 and GDC 21. The applicant added the status of the containment vacuum relief MOVs to Table 7.5-1 for post-accident monitoring, and revised Tier 1, Tables 2.5.2-3 and 2.5.2-4 to add the automatic and manual control functions in the PMS for the containment vacuum relief MOVs. The applicant revised Tier 1, Table 2.5.2-5 and Tier 2, Table 18.12.2-1 to include the display and control of the containment vacuum relief MOVs as part of the minimum inventory for the AP1000 DCD. On the basis of its review of the above changes, the staff finds that the design of the new containment vacuum relief system proposed by the applicant meets the applicable instrumentation and control requirements as mandated in GDC 13 and GDC 19, and also complies with the regulatory guidance in RG 1.97.

The staff finds that the proposed instrumentation and controls design changes meet the relevant requirements in 10 CFR 50.55a(h); 10 CFR 52.47; and 10 CFR Part 50, Appendix A, GDC 13; GDC 19; GDC 20; and GDC 21. The proposed design changes also conform to the related guidance in RG 1.97. Therefore, the staff concludes that the instrumentation and controls aspects of the proposed containment vacuum relief system are acceptable.

23.W.3.5 Technical Specifications

With respect to the proposed TS requirements in TS 3.3.2 and TS 3.6.10, and the proposed changes to TS 3.6.4 and 3.6.5, the staff finds these additions and changes acceptable because they conform to guidance in the Westinghouse STS (NUREG-1431, “Standard Technical Specifications — Westinghouse Plants”), and reflect the containment systems design information in DCD Sections 7.3 and 9.4.7, and their associated analyses described in DCD Section 6.2. In a subsequent revision to the AP1000 DCD, the applicant made an appropriate change to the DCD text, which resolves this issue.

23.W.4 Conclusion

On the basis of its review and confirmatory calculations, the staff finds that the external pressure analysis meets the acceptance criteria from NUREG-0800 Section 6.2.1.1.A, and thus satisfies GDC 16.

On the basis of its review of the containment isolation design aspect of the proposed vacuum relief design, the staff concludes that the design complies with the acceptance criteria in Section 6.2.4 of NUREG-0800, including 10 CFR 50.34(f)(2)(xiv), and CSB BTP 6-4.

On the basis of its review, the staff concludes that the proposed addition of the vacuum relief valves to the already certified AP1000 containment leakage rate testing program complies with the acceptance criteria of Section 6.2.6 of NUREG-0800. Compliance with NUREG-0800 acceptance criteria provides adequate assurance that containment leaktight integrity can be verified before initial operation and periodically throughout its service life. Compliance with the criteria in Section 6.2.6 of NUREG-0800 constitutes an acceptable basis for satisfying the containment leakage rate testing requirements of GDC 52, GDC 53, and Appendix J to 10 CFR Part 50.

The staff reviewed the functional design, qualification, and IST program description for the valves to be used in the proposed AP1000 containment vacuum relief system in accordance with the regulatory basis described in this safety evaluation. Based on its review, the staff concludes that the applicant has provided an acceptable description of the design aspects of the functional design, qualification, and IST programs for the valves to be used in the AP1000 containment vacuum relief system. The staff will review the operational aspects regarding the functional design, qualification, and IST programs for safety-related valves as part of the evaluation of a COL application referencing the AP1000 certified design.

The staff finds that the proposed instrumentation and controls design changes meet the relevant requirements in 10 CFR 50.55a(h), and 10 CFR Part 50, Appendix A, GDC 13, GDC 19, GDC 20, and GDC 21.

On the basis of its review, the staff finds that the proposed changes to the TS that have been established for the containment systems meet the requirements of 10 CFR 50.36.

In addition to the specific DCD changes discussed above in this SER section, the applicant proposed additional changes to several sections, tables, and figures in AP1000 DCD Tier 2 Sections 3.2, 3.7, 3.8, 3.9, 3.11, 7.2, 7.7, 18.12, 19.55, 19.59, and Appendices 1A, 3I and 9A to incorporate the design, testing, and operation of the new containment vacuum relief system and its individual components. The staff has reviewed those proposed DCD changes and finds them to reflect the design, testing, and operation of the new containment vacuum relief system in an acceptable manner.

23.X Changes to the Passive Containment Cooling System

23.X.1 Description of Proposed Changes

The applicant has proposed changes to modeling of the Passive Containment Cooling System (PCS) to correct an error in the time for PCS to begin steady state film coverage of the containment vessel shell which is determined using a scaling factor from AP600 full scale 1/8 sector testing. The applicant assessed the impact of these changes to the PCS in APP-GW-GLR-096, "Evaluation of the Effect of the AP1000 Enhanced Shield Building Design on the Containment Response and Safety Analysis," Revision 2, and submitted the report to the NRC in a letter dated March 10, 2011.

This report provides a scaling calculation of the time for PCS to begin steady state film coverage, a discussion of how these changes impact design basis test results, and results of evaluations of the limiting design basis accidents (DBA). Appendix B of APP-GW-GLR-096 contains proposed DCD changes. The changes that impact Section 6.2.1, "Containment Functional Design" of NUREG-1793 are as follows:

- Corrected value of the time for PCS to begin steady state film coverage.
- Update containment response to reflect results of analyses that use the Corrected value of the time for PCS to begin steady state film coverage.

The proposed changes also include revisions to technical specifications (TS). The applicant proposed to change the calculated peak containment internal pressure for the design basis loss of coolant accident to the updated value in TS Bases B 3.6.4, "Containment Pressure," and TS 5.5.8, "Containment Leakage Rate Testing Program".

23.X.2 Regulatory Basis

The following Commission regulations are related to the evaluation of the PCS:

- GDC 38, "Containment Heat Removal," as it relates to the ability of the containment heat removal system to rapidly reduce the containment pressure and temperature following a loss-of-coolant accident (LOCA) and to maintain them at acceptably low levels
- GDC 50, "Containment Design Basis," as it relates to demonstrating sufficient margin in accident analysis
- 10 CFR 52.47(c)(2) and 10 CFR 50.43(e), as they relates to design certification analysis and testing in support of a passive plant design.

The regulatory basis for evaluating the generic technical specifications (GTS) is documented in Chapter 16 of NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design." The staff's evaluation of the proposed changes focused primarily on confirming that the changes to the GTS reflect the PCS design and operating information described in DCD Section 6.2. The proposed changes were evaluated using the guidance provided by Standard Review Plan (SRP) Chapter 16, "Technical Specifications – Revision 3, March 2010." Acceptability was based on conformance with the guidance in by SRP Chapter 16.

23.X.3 Evaluation

As described in APP-GW-GLR-096, Revision 2, the applicant estimated the total time to establish steady state film coverage for the AP1000 containment vessel is estimated to be 400 seconds. The applicant modified the WGOTHIC evaluation model that was used in previous DCD analyses to reflect the updated value of time to establish steady state film coverage. The applicant ran the design basis loss-of-coolant accident (LOCA) and main steam line break (MSLB) event cases using this revised model to determine the impact of the delay in PCS water application on the calculated pressure and temperature responses.

In its March 10, 2011, letter, the applicant states that in addition to the PCS water application delay, containment modeling changes included adding an epoxy top coat on the containment vessel to a wainscot height of 7 feet above the operating floor. The applicant states in the same letter that adding an epoxy top coat was to make the containment model and containment pressure analysis consistent with Section 6.1 of the DCD, which states the design requirement for the epoxy top coat. Applicant's sensitivity calculation has shown that the impact on containment peak pressure from adding an epoxy top coat the containment model was 0.01 psi.

Appendix B to APP-GW-GLR-096, Revision 2, provides DCD markup on tables and figures with calculated results for double-ended cold leg guillotine break LOCA, and full main steam line double-ended rupture (DER) at 30 percent and 101 percent reactor power with failure of main steam isolation valve. The results show that the containment pressure and temperature after a LOCA or MSLB would stay below the containment design pressure and temperature.

Figures 8-7 and 8-8 of APP-GW-GLR-096, Revision 2, show comparisons for a double-ended hot leg guillotine (DEHLG) LOCA containment response. As shown in the Figures 8-7 and 8-8, the increased delay time for the application for PCS flow has little or no impact on the calculated peak containment pressure and temperature for this short-term event because the transient pressure peak occurs before PCS flow is initiated.

During an audit performed at the Westinghouse Office in Rockville, Maryland between February 22 and March 4, 2011, the staff reviewed the applicant's calculation report supporting the results of analyses presented in APP-GW-GLR-096, Revision 2.

Based on its review of APP-GW-GLR-096, Revision 2, the staff determined that after correcting the delay in PCS water application in the containment analysis, the calculated pressure and temperature are below the containment design pressure and temperature, and therefore, acceptable. The audit the staff performed confirmed these conclusions.

The staff determined that the change in the delay in PCS water application in the containment analysis did not affect the staff's conclusions as stated in NUREG-1793 and the design is compliant with GDC 38, GDC 50, 10 CFR 52.47(c)(2), and 10 CFR 50.43(e).

During its review, the staff found the applicant's proposed changes to TS Bases B 3.6.4 and TS 5.5.8 acceptable because they reflect the peak containment pressure following a design-basis accident as given in DCD Tier 2 Section 6.2.

In AP1000 DCD Revision 19, the applicant made changes to the text, which are consistent with the proposed changes in the March 10, 2011 letter.

23.X.4 Conclusion

Based on its review the staff concludes that the design changes described above are acceptable and the design is compliant with GDC 38, GDC 50, 10 CFR 52.47(c)(2), and 10 CFR 50.43(e).

23.Y Changes to WGOTHIC AP1000 Containment Evaluation Model Inputs

23.Y.1 Description of Proposed Changes

The applicant has proposed changes to the WGOTHIC AP1000 containment evaluation model (CEM) inputs to address errors and to make updates. The applicant assessed the impact of these changes to the containment response to DBAs in APP-GW-GLR-096, Revision 3, and submitted the report to the NRC in a letter, dated June 14, 2011. The changes include the following, as stated in Section 7.2 of the report:

- The recalculation of the LOCA mass and energy (M&E) releases

- The removal of the inorganic zinc coatings within the LOCA zone of influence and within the maximum flood elevation inside the containment

- The revision of the specific heat for the inorganic zinc and epoxy coatings

- The revision of the material properties for the containment shell

- The correction of the modeling of heat transfer from the containment vessel shell below the operating deck

- The credit for some existing thermal conductors for platforms/gratings

- The consideration of the accumulator nitrogen gas after injection

Changes to the calculation of LOCA M&E releases are identified in Section 7.3 of APP-GW-GLR-096. They include:

- An increase in the SG pressure at the tube bundle
- An increase in the vessel metal mass
- A reduction in the SG tube heat transfer area
- A reduction in core power
- An increase in the RCS fluid volume
- An increase in the main feedwater flow
- A reduction in the equilibration temperature

Appendix B of APP-GW-GLR-096 contains proposed DCD changes. The changes to the WGOTHIC AP1000 CEM input resulted in a small increase of containment peak containment pressure, which impacts a number of sections of the DCD and Section 6.2.1, “Containment Functional Design” of NUREG-1793. Crediting some existing thermal conductors for platforms/gratings, which were not credited in the CEM before, also impacts Section 21, "Testing and Computer Code Evaluation" of NUREG-1793.

The proposed changes also include revisions to TS. The applicant proposed to change the calculated peak containment internal pressure for the design basis LOCA to the updated value in TS 5.5.8, "Containment Leakage Rate Testing Program," and TS Bases B 3.6.4, "Containment Pressure."

23.Y.2 Regulatory Basis

The Commission regulation related to the evaluation of the proposed changes to the CEM is GDC 50, "Containment Design Basis." GDC 50 requires the demonstration of sufficient margin in the containment for design basis accident analysis. The staff evaluated the proposed changes using the guidance provided in NUREG-0800 Sections 6.2.1.1.A, "PWR Dry Containments, Including Subatmospheric Containments"; and 6.2.1.3, "Mass and Energy Release Analysis for Postulated Loss-of-Coolant Accidents (LOCAs)." Acceptability was based on conformance with the guidance in NUREG-0800 Sections 6.2.1.1.A and 6.2.1.3.

The regulatory basis for evaluating the GTS is documented in Chapter 16 of NUREG-1793. The staff's evaluation of the proposed changes focused primarily on confirming that the changes to the GTS reflect the PCS design and operating information described in DCD Section 6.2. The staff evaluated the proposed changes using the guidance provided by NUREG-0800 Chapter 16, "Technical Specifications." Acceptability was based on conformance with the guidance in NUREG-0800 Chapter 16.

23.Y.3 Evaluation

As described in APP-GW-GLR-096, Revision 3, the applicant modified the WGOTHIC CEM inputs that were used in previous DCD analyses to reflect the corrected and updated values. The applicant ran the design basis LOCA and MSLB event cases using this revised model to determine the impact of the input changes on the calculated pressure and temperature responses.

23.Y.3.1 **LOCA Mass and Energy (M&E) Releases**

The staff reviewed the long-term LOCA M&E release calculations and the methodology as it applies to the AP1000. The long-term LOCA M&E release calculation provides a key input for the containment evaluation model. The blowdown phase M&E releases were calculated using the SATAN-VI computer code, as described in WCAP-10325-P-A (proprietary) and WCAP-10326-A (nonproprietary), May 1983). The staff has previously determined that the SATAN-VI LOCA blowdown computer program is acceptable for use in obtaining LOCA M&E releases for the LOCA blowdown phase for containment analyses. SATAN-VI has been approved by the staff for this purpose, as discussed in NUREG-0800 Section 6.2.1.4. Applicability to the AP1000 is addressed in Section 6.2.1.3 of NUREG-1793.

The LOCA M&E release input data is documented in Tables 6.2.1.3-9 and 6.2.1.3-10 of the DCD. As described in Section 7.3 of APP-GW-GLR-096, a number of input values were corrected in the blowdown portion of the LOCA M&E release calculation, along with one input value in the long-term release spreadsheet calculation. These input changes produced slightly higher LOCA M&E releases to the containment.

The seven specific SATAN model changes made to the DCD, Revision 18 analysis were reviewed by the staff and audits were performed at the Westinghouse office in Rockville, Maryland between May 23 and June 24, 2011, to determine that the changes were appropriate. Each change is described in detail below.

a. *Steam Generator Pressure at the Tube Bundle*

The SATAN-VI model requires an input value for the SG secondary side pressure at the tube bundle. However, the input value that was used to calculate the M&E releases that are documented in DCD Revision 18 was based on the SG secondary side outlet pressure. The value used previously does not maximize the initial stored energy in the SGs secondary side. Correction of this value resulted in a higher calculated containment pressure response. The staff confirmed the code input requirements and the referenced design specifications for SG pressure, and agrees with the applicant that this change is appropriate.

b. *Vessel Metal Mass*

In the M&E calculation for DCD Revision 18, some of the metal mass associated with the reactor vessel core barrel region was not included in the SATAN-VI model. The total mass of the missing metal was approximately five percent of the total reactor vessel metal mass. The lower original input did not maximize the initial stored energy in the RCS metal. Correction of this value resulted in a higher calculated containment pressure response. The staff confirmed the revised input to the SATAN-VI M&E calculation.

c. *Steam Generator Tube Heat Transfer Area*

The tube heat transfer area input value for each SG in the M&E calculation for DCD Revision 18 was approximately seven percent larger than the correct value. Correction of the tube heat transfer area reduces the heat transfer between the RCS and SGs during the blowdown phase, but does not impact the SG energy release rate that is assumed in the long-term spreadsheet calculation. The staff confirmed the revised input to the SATAN-VI M&E calculation and agrees with the applicant that the long-term release rate assumed is unaffected by the change in input area.

d. *Core Power*

The power level input for the LOCA M&E release calculation was changed from the DCD Revision 18 analysis value of 3415 MWt to 3400 MWt. The original value included 15 MWt of RCP energy that is generated when all four pumps are energized. The RCPs are tripped on a LOCA. Additionally, the analysis methodology for a design basis large break LOCA assumes a loss of offsite power coincident with LOCA initiation. With a loss of offsite power, the RCPs would trip and begin coasting down. The SATAN code input for power is the licensed core power plus the plant-specific power uncertainty, which is included for conservatism. The input is used to initialize the reactor decay heat calculation. Including the energy that is equivalent to the energy generated by the RCPs when electrically powered is not necessary for the SATAN input because RCP energy does not contribute to the decay heat from the fuel. The revised core power is the licensed core power. The implemented change does not alter the modeling characteristics of the RCPs from the prior LOCA M&E release analysis or the approved methods in WCAP-10325-P-A. Changing this core power input value results in a slight reduction in the decay heat contribution to the event. With a loss of power, the RCPs will not continue to operate. However, the staff was concerned about the treatment in the analysis of the additional heat contributed by the RCPs upon coastdown. In an audit discussion and subsequently in a letter dated July 7, 2011, the applicant provided further justification for excluding the pump energy from the initial core power. The pump coastdown energy was shown by the applicant to be an extremely small contribution to the total energy release during a LOCA. Independent calculation using design data provided by the applicant confirmed the pump coastdown energy addition and duration. As a result, the staff finds the core power change in SATAN acceptable.

e. Reactor Coolant System Fluid Volume

The LOCA M&E release methodology uses fluid volumes that have been determined from engineering drawings. This is referred to as a “cold” condition, so the fluid volumes that are used as input to the SATAN-VI model were increased to account for thermal expansion and measurement uncertainty. The total fluid volume of the RCS in the original calculation for DCD Revision 18 was slightly underestimated. The applicant has corrected the values in the new M&E calculations and as such the staff finds the change acceptable. Although the change is small and the overall impact is insignificant the correct values are now used.

f. Feedwater Flow Rate

The typical simplifying assumption for large break LOCA M&E releases analyses is that main feedwater flow equals steam flow at full power operation. While performing the transient initialization checks to assure that the correct steam flow was achieved after changing the initial steam pressure in the SGs, the applicant discovered that the value that was used in the previous analysis for the main feedwater flow rate for each SG was about 50 percent too low. Correction of the initial feedwater flow rate input value increases the stored energy in the secondary side of each SG after blowdown. This increased the long term energy release rate and the subsequent calculated containment pressure response. The staff audited the revised calculation, and agreed with the applicant that the effect on the containment pressure results is small. The applicant has corrected the value and the staff finds the revised feedwater flow acceptable.

g. Equilibration Temperature

The long term LOCA M&E release methodology uses a temperature “setpoint” to define the end point for the removal of the stored energy remaining in the primary system metal, the secondary system metal and secondary side system fluid inventory. The equilibration temperature that was used in the previous analysis was higher than the value recommended in Section 14 of WCAP-15846. Reducing the equilibration temperature would increase the long-term LOCA M&E releases and increase the subsequent calculated containment pressure response. During the audits, the staff reviewed the long-term M&E release spreadsheet calculation in which this temperature input is used. The staff confirmed that the appropriate value was used. As such, the staff finds the change acceptable.

23.Y.3.2 **Inorganic Zinc Coatings within LOCA Zone of Influence and Maximum Flood Elevation inside Containment**

The applicant previously made a design change to reduce the potential post-LOCA amount of debris inside containment to support Generic Safety Issue (GSI)-191, “Assessment of Debris Accumulation on PWR Sump Performance” evaluations. This design change replaces the inorganic zinc coatings on surfaces inside containment that are within the zones of influence of a LOCA and within the flood elevation (this does not include the containment vessel) with epoxy. To reflect this change in the CEM input, the applicant replaced the inorganic zinc coating material properties for all of the internal heat sinks in the CEM with those of epoxy paint.

Epoxy has lower volumetric specific heat and thermal conductivity values than inorganic zinc (Table 6.2.1.1-8 of the DCD). The staff finds that replacing the inorganic zinc coating material properties for all of the internal heat sinks in the CEM with those of epoxy paint is conservative and acceptable.

23.Y.3.3 **Specific Heat for the Inorganic Zinc and Epoxy Coatings**

Table 6.2.1.1-8 of the DCD and Table 13-49 of WCAP-15846 list the thermal properties for the various materials that are used in the CEM. The applicant replaced the specific heat values for the inorganic zinc and epoxy coatings materials with the lowest values provided by the vendors.

The staff finds that using the lowest specific heat values for the inorganic zinc and epoxy coatings materials in the CEM is conservative and acceptable.

23.Y.3.4 **Material Properties for the Containment Shell**

Section 6.2.1.1.2 of the DCD states that the containment vessel is designed and constructed in accordance with the ASME Code, Section III, Subsection NE, “Metal Containment,” as described in Section 3.8.2. The applicant updated the containment vessel material properties (density, specific heat, thermal conductivity) to reflect the values specified by the ASME Code and biased for minimum heat removal in the CEM (Table 13-136 of WCAP-15846).

The staff finds that using the ASME Code-specified material properties are consistent with the design of the containment vessel and biasing the property values is conservative and acceptable.

23.Y.3.5 **Heat Transfer from Containment Vessel Shell below Operating Deck**

A portion of the containment shell below the operating deck is incorrectly modeled in the previous CEM as an internal heat sink with heat transfer from both inside and outside surfaces. To correct the incorrect modeling, the applicant proposed to model the surface as insulated, transferring no heat from the outside surface.

The staff finds the above model correction conservative because it ignores any heat transfer to the outside through the portion of containment shell of interest and, therefore, acceptable.

23.Y.3.6 **Crediting Selected, Existing Thermal Conductors**

The applicant has changed the CEM to credit a few of the many existing heat structures in containment that were not credited for heat removal before. This change has the effect of reducing peak containment pressure. Section 1.1 of APP-GW-GLR-096, Revision 3, states the following:

> Some of the existing thermal conductors that are in the containment evaluation model are not credited for heat and mass transfer in the peak pressure/temperature analyses because they were not part of the official design at the time the model was first developed. This includes the platforms and gratings inside containment. As shown in

Section 13 of WCAP-15846 [Reference 2], these thermal conductors were modeled as insulated on both sides to prevent heat and mass transfer to them. As described in Section 7.2, heat and mass transfer to some of these conductors have been “turned on” now in the containment evaluation model for the peak pressure/temperature analyses to help offset the impact of the higher LOCA M&E releases.

Figure 7.2-1 of APP-GW-GLR-096, Revision 3, schematically shows the locations of the existing thermal conductors that are now being credited for heat and mass transfer in the peak pressure/temperature calculations.

Heat transfer to the thermal conductors in the “dead-ended” compartments is allowed only during the initial blowdown phase. The accumulator compartments (PXS-A, PXS-B) are located below the core makeup tank compartment and are only open at the top. This inhibits the circulation of break flow to these compartments and they are described as dead-ended. Table 7.4-2 of APP-GW-GLR-096, Revision 3, lists all the heat sink thermal conductors that are currently credited in the CEM for heat transfer in each dead-ended compartment.

During the calculation audits, the staff requested further justification for crediting heat and mass transfer to the dead-ended compartments below the operating deck during the blowdown phase. In a letter dated July 7, 2011, the applicant provided a discussion of the large scale test (LST) benchmarks and the correlation to the AP1000 containment. In the LST benchmarks, dead-ended compartments were observed to be well-mixed. Although the LST volumes and flow path areas could not be directly correlated to the AP1000 volumes and flow path areas, the staff agrees with the applicant that the results are representative of the actual plant conditions. The staff also examined other experimental containment benchmarks referenced in APP-GW-GLR-096, such as the HDR and Battelle Model Containment tests to confirm that the applicant’s treatment of dead-end compartments is appropriate.

Heat transfer to certain thermal conductors in the compartments above the operating deck and in “flow-through” compartments below the operating deck is allowed for the entire transient. SG, CMT, and vertical access tunnel (VAT) compartments, which have multiple flow paths with large areas from adjacent compartments allowing flow of steam through each compartment, are describes as flow-through compartments. Figure 7.2-1 also shows the paths for circulation between the various compartments below the operating deck. The LOCA break location is assumed to be in the lower east SG compartment. Section 7.4.1 of APP-GW-GLR-096, Revision 3, provides the following reasons for assuming SG, CMT, and VAT compartments as flow-through compartments:

- The steam release is low, as the hot leg and cold legs are located at approximately the 100-ft elevation. The rising jet/plume will help circulate the containment atmosphere.

- The PCS is actuated to provide cooling by sensible heating and evaporation of water that is evenly distributed on top of the external surface of the containment vessel. This will induce falling wall plumes that will help circulate the containment atmosphere.

- The containment atmosphere is well mixed and the temperature field is not stratified during, and just after, the large LOCA blowdown occurs.

- The concrete, sump, and RCS metal heat sources are located low in the containment. The heat release from these sources will induce rising thermal plumes to help circulate the containment atmosphere.

- The SG, CMT, and VAT compartments that are located below the operating deck are connected to one another and are not dead-ended. This promotes circulation and mixing between these compartments and the volume above the operating deck.

The applicant conservatively ignored heat transfer to the floors of all the compartments because the formation of a liquid layer will inhibit condensation heat transfer to those heat sinks. The staff's SER for the CEM originally included the restriction that heat structures in dead-ended compartments below the operating deck be turned off after blowdown. There is greater uncertainty in flow paths below the operating deck and this restriction was imposed, in part, to ensure conservatism in the overall calculation. The applicant has demonstrated that there remains conservatism in the overall calculation when crediting a few of the heat structures below the operating deck. As described in Section 7.2 of APP-GW-GLR-096, Revision 3, the applicant conservatively ignored in the CEM a significant heat conductor sinks that are available in the AP1000 containment. These include about 35,000 pounds of carbon steel in the CMT and VAT compartments and close to 300,000 pounds of carbon steel above the operating deck (the jib crane, the integrated head stand, etc.). In light of the significant mass of heat structures above and below the operating deck that are not credited, the staff finds that crediting a few is acceptable. This approval does not imply additional heat structures below the operating deck will be approved by the NRC in the future.

Based on its review of APP-GW-GLR-096, Revision 3, the staff determined that crediting the existing thermal conductors for heat and mass transfer in the CEM is consistent with the guidance provided in NUREG-0800 Section 6.2.1.1.A and acceptable.

23.Y.3.7 **Release of Accumulator Nitrogen Gas after Coolant Injection**

Energy from the pressurized nitrogen gas inside the accumulators is used to force the water from the accumulators when the RCS pressure drops below 700 psig. The gas will expand into the DVI lines after all of the water from the accumulators has been discharged and collect at the high points in the RCS. Some of the gas will be released into the containment atmosphere. The previous CEM did not account for the contribution of the nitrogen gas to the containment peak pressure in the containment response analyses. The applicant proposed to update the CEM to include the effect of accumulator nitrogen gas released into the containment.

The applicant assumes an isothermal expansion of nitrogen gas from accumulators to the containment, conservatively ignoring heat transfer needed from the containment atmosphere to the nitrogen gas for such an expansion. The nitrogen gas is released directly from the accumulators to the containment atmosphere over a period of 60 seconds after the water discharge ends. Section 7.2 of APP-GW-GLR-096, Revision 3, states that "[t]he model is not sensitive to this assumption since the gas release occurs before the time of peak pressure (typically around 1500 seconds after event initiation)." The staff finds that the containment peak pressure and temperature are not sensitive to the assumed duration of nitrogen release because the peaks occur much later after the accumulators empty for double ended guillotine cold leg break LOCA and much before the accumulators empty for double ended guillotine hot leg break LOCA and MSLB accidents. The staff finds the applicant's proposed modeling of accumulator nitrogen gas released into the containment conservative and, therefore, acceptable.

As a result of making changes to the WGOTHIC AP1000 CEM inputs to address the errors and updates discussed above and the two errors stated in Section 23.X of this report, the calculated containment peak pressure increased from 398.5 kPa (57.8 psig) stated in AP1000 DCD Revision 15 to 402.0 kPa (58.3 psig) (Figure B-2 of APP-GW-GLR-096, Revision 3), which is below the containment design pressure of 406.8 kPa (59 psig). Considering the conservatisms build into the WGOTHIC AP1000 CEM and that the containment peak pressure stays below the containment design value, the staff finds that the updated containment peak pressure of 402.0 kPa (58.3 psig) is acceptable.

During the audits, the staff reviewed the applicant's calculation reports supporting the results of analyses presented in APP-GW-GLR-096, Revision 3.

Based on its review, the staff determined that after making changes to the WGOTHIC AP1000 CEM inputs, the calculated pressure is below the containment design pressure and, therefore, acceptable. The audits the staff performed confirmed these conclusions.

The staff determined that the changes to the WGOTHIC AP1000 CEM inputs did not affect the staff's conclusions as stated in NUREG-1793 and the design is compliant with GDC 50.

During its review, the staff found the applicant's proposed change to TS 5.5.8 is acceptable because it reflects the peak containment pressure following a DBA as given in DCD Tier 2 Section 6.2.

Based on its review, the staff determined that the DCD changes proposed in Appendix B of APP-GW-GLR-096, Revision 3, resulting from changes to the WGOTHIC AP1000 CEM inputs, are acceptable. The staff confirmed that the applicant has made the proposed changes in DCD, Revision 19.

23.Y.4 Conclusion

Based on its review the staff concludes that the design changes described above are acceptable and the design is compliant with GDC 50. During its review, the staff found that applicant's proposed change to TS 5.5.8 is acceptable.

24. CONCLUSION

The U.S. Nuclear Regulatory Commission (NRC) staff has reviewed Westinghouse's changes to the AP1000 design documentation (see Section 1.5 of this report). On the basis of the evaluation described in the AP1000 FSER (NUREG-1793, NUREG-1793 Supplement 1) and this report, the NRC staff concludes that the AP1000 design documentation (up to and including Revision 19 to the AP1000 design control document) is acceptable and that Westinghouse's application for design certification meets the requirements of Subpart B, “Standard Design Certifications,” of Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52 that are applicable and technically relevant to the AP1000 standard plant design.

A. CHRONOLOGY

This appendix contains a chronological listing of routine licensing correspondence between the staff of the U.S. Nuclear Regulatory Commission (NRC) and Westinghouse regarding the review of the amendment to the AP1000 passive plant design under Project No. 711 and Docket No. 52-006. Please note that Westinghouse Technical Reports are listed with the References in Appendix B.

C. ABBREVIATIONS

χ/Q	atmospheric dispersion
µm	micrometer
µm/m	micrometers per meter
µSv/h	microSieverts per hour
2D	two dimensional
2oo2	two-out-of-two
2oo3	two-out-of-three
2oo4	two-out-of-four
3D	three dimensional
ac	alternating current
ACI	American Concrete Institute
ADAMS	Agencywide Documents Access and Management System
ADS	automatic depressurization system
AEA	Atomic Energy Act
AF	Advant Fieldbus
AFCAP	Advanced First Core Analysis Program
AFSE	Advanced Final Safety Evaluation
Ag-In-Cd	silver-indium-cadmium
AIA	aircraft impact assessment
AISC	American Institute of Steel Construction
AISI	American Iron and Steel Institute
ALARA	as low as is reasonably achievable
ALI	annual limit on intake
AlOOH	aluminum oxyhydroxide
ALWR	advanced light-water reactor
AMS	Asset Management Solutions
AMS	Aerospace Material Specification
AMSAC	anticipated transient without scram (ATWS) mitigation systems actuation circuitry
ANS	American National Standard
ANS	American Nuclear Society
ANSI	American National Standards Institute
AOA	axial offset anomaly
AOI	Advant-Ovation Interface
AOO	anticipated operational occurrence
AOP	abnormal operating procedure
AOV	air operated valve
API	American Petroleum Institute
ARP	Alarm Response Procedures
ART	adjusted reference temperature
ASB	auxiliary and shield building
ASCE	American Society of Civil Engineers
ASD	allowable stress design
ASHRAE	American Society of Heating, Refrigerating and Air-Conditioning Engineers
ASME	American Society of Mechanical Engineers

ASTM	American Society for Testing and Materials
ASTRUM	Automated Statistical Treatment of Uncertainty Method
ATWS	anticipated transients without scram
AV	allowable values
AWS	American Welding Society
B&PV	Boiler & Pressure Vessel (ASME B&PV Code)
B&W	Babcock & Wilcox
BAC	bounding analysis curve
BDBA	beyond design basis accident
BELOCA	best estimate large-break loss-of-coolant accident
BPL	bistable processor logic
BTP	Branch Technical Position
Btu	British thermal units
BTU/ft-hr-°F	British thermal unit per foot hour degree Fahrenheit
BWR	boiling-water reactor
C	Celsius
$Ca(PO_4)_2$	calcium phosphate
CAFTA	Computer-Aided Fault-Tree Analysis System
Cal-Sil	calcium silicate
CAS	central alarm station
CASS	cast austenitic stainless steel
CBP	computer-based procedure
CCF	common-cause failure
CCS	component cooling water system
CCW	component cooling water
CCWS	component cooling water system
CDF	core damage frequency
CDF	cumulative distribution function
CDFM	conservative deterministic failure margin
CDI	conceptual design information
CE	Combustion Engineering
CEI/IEC	Commission Electrotechnique Internationale/International Electrotechnical Commission
CET	core exit thermocouple
CEUS	Central and Eastern United States
CFD	computational fluid dynamics
cfm	cubic feet per minute
CFR	*Code of Federal Regulations*
CFS	condensate and feedwater system
CHF	critical heat flux
CIM	component interface module
CIPS	crud-induced power shift
CIS	containment internal structure
CIS	containment isolation system
CL	cold leg
CLP	cask loading pit
cm	centimeter
cm^2	square centimeter
CMT	core makeup tank

COF	coefficient of friction
COL	combined license
COLA	combined license application
COLR	core operating limits report
CP	cathodic protection
CP	construction permit
CPS	Computerized Procedure System
CPU	central processing unit
CQD	Code Qualification Document
CR	control room
CRC	cyclic redundancy check
CRD	control rod drive
CRDM	control rod drive mechanism
CRDS	control rod drive system
CRE	control room envelope
Cr-Mo	chromium-molybdenum
CSA	control support area
CSDRS	certified seismic design response spectra
CTS	custom technical specification
Cu	copper
CV	containment vessel
CV	control valve
CVS	chemical and volume control system
CWO	core-wide oxidation
CWS	circulating water system
DAC	derived air concentration
DAC	design acceptance criteria
DAS	diverse actuation system
DBA	design-basis accident
DBE	design-basis event
DBT	design-basis threat
DC	design certification
dc	direct current
DCD	design control document
DCP	design change proposal
DCP	design change package
DCR	design certification rule
DDS	data display and processing system
DECL	double-ended cold-leg
DECLG	double-ended cold-leg guillotine
DEDVI	double-ended direct vessel injection
D-EHC	digital electrohydraulic control
DEHL	double-ended hot-leg
DFC	diagnostic flow chart
DG	diesel generator
DG	draft guide
DI&C	digital instrumentation and controls
DID	defense-in-depth
DMIMS	digital metal impact monitoring system
DNB	departure from nucleate boiling

DNBR	departure from nuclear boiling ratio
DOF	degree-of-freedom
dP	differential pressure
dpa	displacements per atom
D-RAP	Design Reliability Assurance Program
DVI	direct vessel injection
DWTP	double wide transition panel
EAB	exclusion area boundary
EALF	energy of the average lethargy causing fission
EC	composite cored/stranded electrodes
ECCS	emergency core cooling system
EDF	Electricite de France
EFDS	equipment and floor drainage system
EFPY	effective full-power year
EHX	external heat exchanger
El.	Elevation
EMC	electromagnetic compatibility
ENDF	Evaluated Nuclear Data File
EO	equipment operator
EOF	Emergency Operating Facility
EOL	end-of-life
EOP	emergency operating procedure
EP	expert panel
EPRI	Electric Power Research Institute
EQ	strip electrodes
EQ	environmental qualification
ERO	emergency response organization
ERS	envelope response spectra
ERVC	external reactor vessel cooling
ESF	engineered safety feature
ESFAS	engineered safety feature actuation system
ESP	early site permit
F	Fahrenheit
FAC	flow-accelerated corrosion
FCEP	fuel criterion evaluation process
FEA	finite element analysis
FEM	finite element method
FEMA	Federal Emergency Management Agency
FFT	Fast-Fourier Transforms
FHA	fuel handling area
FHA	fuel-handling accident
FHM	fuel handling machine
FIRS	foundation input response spectra
FIV	flow-induced vibration
FME	foreign material exclusion
FMEA	failure modes and effects analysis
FN	ferrite number
FPDS	flat panel display system
FPGA	field programmable gate array

Fps	feet per second
FPS	fire protection system
FR	firm rock
FR	*Federal Register*
FRN	*Federal Register* Notice
FRS	floor response spectra
FSAR	final safety analysis report
FSER	final safety evaluation report
ft	feet
ft/s	feet per second
ft^2	square feet
ft^3	cubic feet
ft^3/min	cubic feet per minute
g/cm^3	grams per cubic centimeters
GDC	General Design Criteria
GL	Generic Letter
GMAW	gas metal arc welding
GMRS	ground motion response spectra
GOI	generic open item
GOP	general operating procedure
gpm	gallons per minute
gpm/ft^2	gallons per minute per square foot
GRCA	gray rod cluster assembly
GSI	generic safety issue
GTS	generic technical specification
H_2	hydrogen
HA	human action
HAZ	heat affected zone
HCLPF	high confidence in low probability of failure
HDCI	high-duty core index
HDPE	high-density polyethylene
HED	human engineering discrepancy
HEPA	high-efficiency particulate air
HFE	human factors engineering
HFT	hot functional test
HL	hot leg
HMR	hydro-meteorological report
HP	health physics
HR	hard-rock
HRA	human reliability analysis
HRHF	hard rock high frequency
HSI	human-system interface
HSL	high speed link
HVAC	heating, ventilation, and air conditioning
HX	heat exchanger
Hz	Hertz
I&C	instrumentation and control
I/O	input/output

IASCC	irradiation-assisted stress-corrosion cracking
ICET	integrated chemical effect test
ICP	integrated communications processor
ICTN	integral clamp top nozzle
ID	inner diameter
IDI	isolated development infrastructure
IEEE	Institute of Electrical and Electronic Engineers
IFM	intermediate flow mixer
IGSCC	intergranular stress-corrosion cracking
IHP	integrated head package
IIS	in-core instrumentation system
IISS	in-core instrumentation-support structure
IITA	in-core instrument thimble assembly
ILP	integrated logic processor
in	inch
IN	Information Notice
in/h	inch per hour
in/ft	inch per foot
in/in	inch per inch
in^2	square inch(es)
IOZ	inorganic zinc
IPEEE	individual plant examination of external events
IPSAC	Investment Protection Short-Term Availability Control
IRP	important by the regulatory treatment of nonsafety systems (RTNSS) process
IRWST	in-containment refueling water storage tank
ISA	International Society of Automation
ISG	Interim Staff Guidance
ISI	inservice inspection
ISLOCA	intersystem loss-of-coolant accident
ISRS	in-structure response spectra
IST	inservice testing
ISV	integrated system validation
ITAAC	inspection, tests, analyses, and acceptance criteria
ITP	interface and test processor
IV&V	independent verification and validation
JOG	Joint Owners Group
kA	kilo amp
kcf	kips per cubic feet
kg	kilograms
kg/h	kilograms per hour
kg/m^2	kilograms per square meter
kg/m^3	kilograms per cubic meter
kg/s	kilograms per second
kip	kilopounds (1000 pounds)
kJ/h	kilojoules per hour
km	kilometers
km/h	kilometers per hour
kPa	kilopascal
ksf	kilopounds per square foot

ksi	kilopounds per square inch
kV	kilovolt
kVA	kilovolt amps
kW	kilowatts
kW/ft	kilowatts per foot
L	liters
L/D	length to diameter ratio
lb	pound
lb/ft^2	pounds per square foot
lb/ft^3	pounds per cubic foot
lb/h	pounds per hour
lb/s	pounds per second
LBB	leak-before-break
lbf	pounds-force
lbm	pounds-mass
lbm/ft^3	pounds-mass per cubic foot
lbm/s	pounds-mass per second
lbs	pounds
LCL	local coincidence logic
LCO	limiting condition for operation
LCS	local control station
LCSP	lower core support plate
LLHS	light load handling system
LOAC	loss of alternating current power
LOCA	loss-of-coolant accident
LOCADM	Loss-of-Coolant Accident Deposition Model
LOFT	loss-of-fluid test
LOSP	loss of offsite power
Lpm	liters per minute
Lpm/m^3	liters per minute per square meter
LPZ	low population zone
LRF	large release frequency
LRFD	load and resistance factor design
LSB	last stage blade
LSSS	limiting safety system setting
LTOP	low-temperature overpressure protection
LWR	light-water reactor
m	meters
m/s	meters per second
m^2	square meter
m^3	cubic meters
m^3/h	cubic meters per hour
Mbit	megabit
MBtu	million British thermal units
MBtu/hr	million British thermal units/hour
MCC	motor control center
MCR	main control room
MCRE	main control room envelope
MEB	moisture extraction blade

MFIV	main feedwater isolation valve
MG	motor-generator
MHS	mechanical handling system
MI	mineral insulated
MLO	maximum local oxidation
mm	millimeters
mm/m	millimeters per meter
MOV	motor-operated valve
MOX	Mixed Oxide
MPa	megapascal
MPa/m^3	megapascal per cubic meter
mph	miles per hour
mrem/h	millirem per hour
MRI	metal reflective insulation
MSE	mechanically stabilized earth
MSIV	main steam isolation valve
MSL	main steam line
MSLB	main steam line break
MSSS	main steam supply system
MSSV	main steam safety valve
MSV	main steam stop valve
MTBF	mean time between failure
MTC	maintenance and test cabinet
MTIS	maintenance, inspection, test, and surveillance
MTP	maintenance and test panel
MUX	multiplexer
MVA	megavolt amp
MVG	mixing vane grid
MW	megawatt
MWDF/MTU	megawatt-days per metric ton of uranium
MWe	megawatts electric
MWh	megawatt-hour
MWt	megawatts thermal
$NaAlSi_3O_8$	sodium aluminum silicate
NACE	National Association of Corrosion Engineers
NDE	nondestructive examination
NEA	Nuclear Energy Agency
NEI	Nuclear Energy Institute
NF	new fuel
NFPA	National Fire Protection Association
NI	nuclear island
NIS	nuclear instrumentation system
NOP	Normal Operating Procedures
NPP	nuclear power plant
NPS	nominal pipe size
NPSH	net positive suction head
NPSHa	net positive suction head available
NQA	Nuclear Quality Assurance
NRC	Nuclear Regulatory Commission (U.S.)
NRCA	nonradiologically controlled area

NS	non-seismic
NSSS	nuclear steam supply system
OBE	operating-basis earthquake
OCS	operations and control centers system
OCS	operational conditions sampling
OECD	Organization for Economic Cooperation and Development
OER	operating experience review
OHLHS	overhead heavy load handling system
OL	operating license
OM	Operation and Maintenance (ASME OM Code)
OPDMS	Online Power Distribution Monitoring System
OPRAA	operational phase reliability assurance activity
OPΔT	overpower delta-T
O-RAP	operational reliability assurance program
OSA	operational sequence analysis
OTΔT	overtemperature delta-T
P&ID	piping and instrumentation diagram
P&ID	piping and instrumentation drawings
P/F	pass/fail
P/T	pressure-temperature
PA	protected area
Pa	pascal
PABX	private automatic branch exchange
PAMS	post-accident monitoring system
PCCAWST	passive containment cooling ancillary water storage tank
PCCS	passive core cooling system
PCCWST	passive containment cooling water storage tank
PCS	passive containment cooling system
PCT	peak cladding temperature
PDSP	primary dedicated safety panel
PFM	probabilistic fracture mechanics
PGA	peak ground acceleration
PI	plus integral
PLS	plant control system
PLS	plant lighting system
P_m	primary membrane
$P_m + P_b$	primary membrane plus bending
PMF	probable maximum flood
PMP	probable maximum precipitation
PMS	protection and safety monitoring system
PORV	power-operated relief valve
POV	power-operated valve
ppm	parts per million
PRA	probabilistic risk assessment
PRE	pitting resistance equivalent
PRHR	passive residual heat removal
PSAI	plant-specific action item
PSD	power spectral density
psf	pounds per square foot

psi	pounds per square inch
PSI	preservice inspection
psia	pounds per square inch absolute
psid	pounds per square inch differential
psig	pounds per square inch gauge
PTLR	pressure-temperature limits report
PTS	plant-specific technical specification
PVC	plasticized polyvinyl chloride
PWR	pressurized-water reactor
PWS	potable water system
PXS	passive core cooling system
QA	quality assurance
QDPS	qualified data processing system
QG	quality group
QMS	quality management system
RAI	request for additional information
RAP	reliability assurance program
RAT	reserve auxiliary transformer
RAW	risk achievement worth
RC	reinforced concrete
RCCA	rod cluster control assembly
RCDT	reactor coolant drain tank
RCL	reactor coolant loop
RCP	reactor coolant pump
RCPB	reactor coolant pressure boundary
RCS	reactor coolant system
RDP	refueling disconnect panel
rem	roentgen equivalent man
REMP	Radiological Environmental Monitoring Program
RESAR	Reference Safety Analysis Report
RETS	radiological effluent technical specifications
RG	regulatory guide
RHR	residual heat removal
RIM	required input motion
RIS	Regulatory Issue Summary
RLE	review-level earthquake
RM	refueling machine
RMI	reflective metallic insulation
RMS	radiation monitoring system
RNC	remote node controller
RNS	residual heat removal system
RO	reactor operator
RPV	reactor pressure vessel
RRAS	repair, replacement, and automation services
RRS	required response spectra
RRW	risk reduction worth
RSA	response spectrum analysis
RSC	remote shutdown console
RSR	remote shutdown room

RSS	remote shutdown station
RSW	remote shutdown workstation
RTCB	reactor trip circuit breaker
RTD	resistance temperature detector
RTD	resistance thermowell detector
RTDP	revised thermal design procedure
RTNSS	regulatory treatment of nonsafety systems
RTP	rated thermal power
RT_{PTS}	reference temperature-pressurized thermal shock
RTS	reactor trip system
RV	reactor vessel
RVH	reactor vessel head
RVIS	reactor vessel insulation system
RWS	raw water system
SAFDL	specified acceptable fuel design limit
SAM	startup administrative manual
SAMDA	severe accident mitigation design alternative
SAMG	severe accident management guidance
SAR	safety analysis report
SAS	secondary alarm station
SAT	systems approach to training
SC	steel and concrete composite
SCC	stress-corrosion cracking
scf	standard cubic foot
scfm	standard cubic feet per minute
scmh	standard cubic meters per hour
SCP	setpoint control program
SCV	steel containment vessel
SDOE	secure development and operational environment
SDS	sanitary drainage system
SE	safety evaluation
SEP	Systematic Evaluation Program
SER	safety evaluation report
SF	spent fuel
SFHM	spent fuel pool handling machine
SFHT	spent fuel handling tool
SFP	spent fuel pool
SFS	spent fuel pool cooling system
SFW	startup feedwater system
SG	steam generator
SGI	safeguards information
SGS	steam generator system
SGTR	steam generator tube rupture
SHA	software hazards analysis
SL	safety limit
SLC	software lifecycle
SM	soft-to-medium (soil)
SMA	seismic margin analysis
SMS	special monitoring system
SOE	sequence of events

SPC	steam and power conversion
SPD	self-powered detector
SPHSE	self-priming high-solids epoxy
SPM	Software Program Manual
SPS	signal processing system
SR	soft rock
SR	surveillance requirement
SRM	Staff Requirements Memorandum
SRNC	safety remote node controller
SRP	standard review plan
SRSS	square root of the sum of the squares
SS	soft soil
SS	stainless steel
SSA	signal selector algorithm
SSCs	structures, systems and components
SSE	safe shutdown earthquake
SSI	soil-structure interaction
SSSI	structure-soil-structure interaction
STA	shift technical advisor
STD	Standard
Std.	Standard (IEEE Standard)
STS	standard technical specifications
Sv	sievert
SWCCF	software common-cause failure
SWS	service water system
SWTP	single wide transition panel
T	thickness
TASCS	thermal stratification, cycling or striping
T_{AVG}	average coolant temperature
TC	core inlet temperature signal
TCS	turbine building closed cooling water system
TEDE	total effective dose equivalent
TEM	transmission electron microscopy
TF	transfer functions
TMI	Three Mile Island
TR	technical report
TRS	test response spectra
TS	technical specification
TSC	technical support center
TSP	trisodium phosphate
TSTF	Technical Specification Task Force
UA	heat transfer capacity consisting of the coefficient of heat transfer (U) and required heat transfer area (A)
UAT	unit auxiliary transformer
UBC	Uniform Building Code
UBSM	upper bound soft-to-medium (soil)
UL	Underwriters Laboratories
UMI	upper mounted instrumentations
UNS	unified numbering system

UPS	uninterruptible power supply
URD	Utility Requirements Document
URS	ultimate rupture strength
V	volts
V&V	verification and validation
Vac	volts alternating current
VAS	radiological controlled area ventilation system
VBS	nuclear island nonradioactive ventilation system
VCD	vacuum carbon-deoxidized
VCSNS	Virgil C. Summer Nuclear Station
Vdc	volts direct current
VDU	visual display unit
VES	emergency habitability system
VES	main control room habitability system
VFD	variable frequency drive
VFS	containment air filtration system
VFTP	Ventilation Filter Testing Program
VHS	hot machine shop heating, ventilation, and air conditioning system
VPI	valve position indicator
VRS	radwaste building heating, ventilation, and air conditioning system
Vs	shear wave velocity
VS	void swelling
VTS	turbine building ventilation system
VWS	central chilled water system
VXS	annex/auxiliary buildings nonradioactive heating, ventilation, and air conditioning system
VYS	hot water heating system
VZS	diesel generator building heating and ventilation system
W	watt
WABA	wet annular burnable absorber
WCAP	Westinghouse Commercial Atomic Power
WGS	gaseous radwaste system
WIN	Westinghouse integral nozzle
WLS	liquid radwaste system
WOG	Westinghouse Owners Group
WRS	waste drain system
WSS	solid radwaste system
wt%	weight-percent
WWS	waste water system
ZOI	zone of influence
ZPA	zero period acceleration

UNITED STATES
NUCLEAR REGULATORY COMMISSION
ADVISORY COMMITTEE ON REACTOR SAFEGUARDS
WASHINGTON, DC 20555 - 0001

December 13, 2010

The Honorable Gregory B. Jaczko
Chairman
U.S. Nuclear Regulatory Commission
Washington, DC 20555-0001

SUBJECT: REPORT ON THE FINAL SAFETY EVALUATION REPORT ASSOCIATED WITH THE AMENDMENT TO THE AP1000 DESIGN CONTROL DOCUMENT

Dear Chairman Jaczko:

During the 578th meeting of the Advisory Committee on Reactor Safeguards (ACRS), December 2-4, 2010, we reviewed the NRC staff's Advanced Final Safety Evaluation Report (AFSER) for the pending AP1000 Design Certification Amendment (DCA) application. The amendment is to be reflected in a revision to the AP1000 Design Control Document (DCD). The amendment involves changes to Tier 1 information, and its approval will require rulemaking. We had a number of subcommittee and full committee meetings to review the technical aspects of the amendment. During these meetings, we had the benefit of discussions with representatives of the NRC staff, Westinghouse (WEC), and members of the public. We also had the benefit of the documents referenced.

CONCLUSION AND RECOMMENDATION

The changes proposed in the AP1000 DCA maintain the robustness of the previously certified design. We conclude that there is reasonable assurance that the revised design can be built and operated without undue risk to the health and safety of the public. This conclusion is contingent on the results of our concurrent reviews of the aircraft impact assessment and long-term core cooling issues which will be discussed in separate letters.

This conclusion relies in part on information and commitments provided by WEC during the course of our meetings which have not yet been confirmed to be included in the DCA application. This information and commitments are noted in the discussion following, and the staff should ensure they are appropriately documented as part of the DCA.

BACKGROUND

For its initial design approval and certification of the AP1000 design, the NRC issued NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Design," in September 2004 and published the proposed design certification rule on April 18, 2005. In December 2005, the NRC staff evaluated the conforming Revision 15 to the AP1000 DCD in Supplement 1 to NUREG-1793. The NRC published a final rule certifying the AP1000 standard plant design on January 27, 2006.

Thus, the existing AP1000 certification rule is reflected in DCD Revision 15. Revision 18 was submitted by WEC in a letter dated December 1, 2010, and it includes changes identified in Revision 16, submitted May 26, 2007, and in Revision 17, submitted September 22, 2008, as well as those changes made subsequent to submittal of Revision 17 which are identified in the AFSER, Chapter 23.

In addition, WEC submitted letters to supplement its DCA application dated October 26, November 2, and December 12, 2007, as well as January 11, and 14, 2008. Finally, NuStart Energy Development, LLC and WEC submitted a number of technical reports (TRs) for review. TRs typically address a topical area, such as the design of a component, structure, or process, in support of the AP1000 design.

The DCA application proposes to incorporate changes in the AP1000 certification rule reflecting the following:

- Design standardization, which was enhanced by elimination of numerous combined license (COL) open items currently in the existing rule.
- New regulatory requirements, including requirements related to aircraft impact. (As previously noted, review of compliance with the aircraft impact requirements will be discussed in a separate letter).
- Design finalization, which was required to produce construction drawings and procurement specifications. This includes reduced reliance on design acceptance criteria (DAC).

Significant changes proposed in the DCA application include the following:

- Redesign of the shield building to use a modular, steel concrete composite (SC) structure, replacing the existing reinforced concrete (RC) design. The redesign reduces passive heat removal air flow and affects seismic, aircraft impact, and other loading analyses.
- Redesign of the Reactor Vessel Support System to increase stiffness.
- Increase in the range of foundation soil conditions considered.
- Closure of four digital instrumentation and control (DI&C) DAC, with only one remaining open. Numerous I&C changes were made to reflect design evolution, such as addition of a reactor trip function, implementation of a rod withdrawal prohibit, and modification of the containment isolation logic for the Component Cooling System.
- Closure of four human factors engineering (HFE) DAC, with none remaining open.
- Modification of the reactor coolant pump (RCP) design, including an increase in its rotational inertia.
- Addition of a flow skirt at the inlet to the reactor vessel lower plenum.
- Redesign of the Steam and Power Conversion Systems.

Our review of the DCA application began with a status review by the Full Committee during the 562nd meeting in May 2009. Subsequently, our AP1000 subcommittee held 12 meetings, totaling 21 days of meetings, as listed in the appendix to this letter.

DISCUSSION

Shield Building Redesign

The AP1000 shield building described in AP1000 DCD, Revision 15, is an RC design. In AP1000 DCD, Revisions 16 and 17, WEC proposed a new shield building design. The new design includes provisions to meet the requirements of the new aircraft impact rule, 10 CFR 50.150. (As indicated previously, the results of our review for compliance with the aircraft impact rule will be reported in a separate letter).

The key features of the new shield building are: a cylindrical wall which comprises the bulk of the structure constructed of SC modules; a conical RC roof structure with an integral RC water tank which contains approximately 7 million pounds of water; a tension ring at the intersection of the roof with the cylindrical wall consisting of a built-up closed section of steel plates filled with concrete; and mechanical connections that join the SC wall to the basemat and the RC wall of the auxiliary building.

The tension ring is designed as a steel structure in accordance with the American National Standards Institute/American Institute of Steel Construction (ANSI/AISC) N690. The steel frame for the roof is designed to the applicable building code, ANSI/AISC N690. The concrete roof is designed to American Concrete Institute (ACI) 349 requirements without credit for the steel plate on the bottom of the concrete. The SC modules have not been used previously in nuclear construction in the United States and were a focus of our review.

In the initial design proposed for the new shield building, the SC wall module for the 3-foot thick cylindrical wall consisted of steel faceplates with attached 6-inch long steel studs which are embedded in the 35-inch thick concrete fill between the two plates. In a letter dated October 15, 2009, the NRC staff determined that this design would require modifications to ensure its ability to perform its safety function under design basis loading conditions. Some key issues identified in the letter are listed below:

- The need to demonstrate the adequacy of the design and detailing of the SC module to function as a fully composite unit, as assumed in the WEC design and analysis.
- The need to demonstrate the adequacy of the design and detailing of the connection between the SC module wall and RC wall of the auxiliary building to withstand all design basis loads.
- The need to support the design and analysis of the shield building tension ring (i.e., ring girder) and the air-inlet region with a validated analysis method (i.e., benchmarked to experimental data) or by confirmatory model tests.

Staff concerns focused particularly on the lack of transverse reinforcement that would tie one faceplate to the opposite faceplate to ensure that the SC modules would function as a unit for either out-of-plane demands or in-plane demands.

WEC developed a revised design for the shield building that added tie bars welded to opposite faceplates in the SC wall modules, and also revised the design of the ring girder and the connections between the SC wall module and the RC wall. The revised SC wall module has thicker faceplates, as well as tie bars between the plates to help ensure that the module acts as a composite unit with increased out-of-plane shear strength. The spacing between the tie bars is greater in regions of the wall away from discontinuities and connections, which have low out-of-plane demands, than it is in the regions near discontinuities and the SC to RC connections, where out-of-plane shear demands are higher.

Although design codes for SC modular construction for some applications have been developed in Japan, codes and standards for the design of SC structural components do not exist in the United States. WEC used ACI-349, a design code for RC in nuclear safety-related structures, to guide their design of the SC cylindrical wall modules. Even though the scope of ACI-349 does not include SC construction, the underlying design philosophy, elastic behavior and strength for design basis loads and resilience through ductility for beyond design-basis loads, does apply. Also, the underlying assumptions on composite behavior of steel and concrete materials in RC structural elements do apply to SC structural elements.

To validate this adaptation of ACI-349, WEC conducted a testing program at Purdue University. The tests were intended (1) to demonstrate that the adaptations of ACI-349 proposed by WEC could be used to predict the out-of-plane shear strength, flexural capacity, and in-plane shear strength of SC structures and (2) to investigate the failure behavior of the SC modules.

The test results were also used to benchmark the finite element analyses performed to support the design of the shield building. WEC's approach to developing the design basis involved three levels of analysis with increasing levels of model refinement. Level 1 was used for determining the load magnitudes (seismic demands) imposed on the structure. It was a linear elastic analysis with a fairly coarse mesh that uses simplified models to account for concrete cracking. Level 2 was also a linear elastic analysis with a more refined mesh used for determining the member forces and deformation demands. Level 3 was a nonlinear analysis used to assess the region with high stresses, strains, and displacements in the shield building, such as the connection regions. Detailed submodels were used which included elements such as concrete, steel plates, studs, and tie bars. A strain-based failure criterion was selected to define acceptable limits under design-basis loads. The analysis models were benchmarked against the Purdue tests.

The Office of New Reactors (NRO) requested that the Office of Nuclear Regulatory Research (RES) provide assistance in evaluating the structural analysis, design, construction, and inspection methods for the AP1000. The findings in the RES report were used to inform the evaluation of the shield building design by the staff of NRO. RES engaged outside recognized experts in the field of reinforced concrete structures and composite structures. RES staff assessed and consolidated the inputs from each expert and performed their own independent assessment to develop their report.

The RES staff concluded that the agreement between the experimental results and the predictions of the Level 3 finite element models were adequate to benchmark the models for loads up to and beyond the design-basis safe shutdown earthquake (SSE). The RES staff also concluded that the models would provide useful predictions of SC module behavior for load levels beyond the design-basis level and below the self-imposed analysis strain limits.

The NRO staff concludes that WEC has shown that the models used for the analysis of the shield building predict the observed experimental behavior and response with acceptable accuracy up to the design-basis SSE seismic load level. Also, the staff finds that the design has acceptable stress and strain values in the SC steel plates, tie bars, and studs. The staff also finds that WEC's adaptation of the ACI-349 Code for the design of the SC modules is acceptable. Finally, the staff finds the WEC's confirmatory analysis approach to be acceptable. We concur with the staff's conclusion.

The test specimens representing the SC modules with the closer tie-bar spacing used in regions of high out-of-plane demands failed in a ductile manner in all the tests. Some of the test specimens representing the SC wall modules with the tie-bar spacing used in the regions of low out-of-plane shear demands failed in a non-ductile manner in out-of-plane shear tests. This non-ductile behavior is the basis for a non-concurrence by an NRC staff member on the acceptability of the design of the shield building. In the view of the staff member, the behavior of the modules with increased tie-bar spacing is unacceptable. This non-concurrence was reviewed in both AP1000 Subcommittee and in full committee meetings.

As a matter of principle, structures important to nuclear safety should be designed so that, in the unlikely event the loads acting on the structure are larger than anticipated, the structure would behave in a ductile manner.

The staff member contends that this principle should be met by every element of the structure. WEC contends that it is the structure as a whole, not its elements, that ultimately matters, and that the design of the shield building does provide a structure that will behave in a ductile manner, because the low-ductility elements will approach their elastic limits only after those elements of the structure that do behave in a ductile manner have undergone significant plastic deformation. This approach is consistent with the intent of ACI-349, which requires ductile behavior only where demands are high and plastic deformation is expected to occur.

In the regions of low out-of-plane shear demands, the analysis shows that the out-of-plane shear capacity of the low ductility module is about 5 times greater than the applied shear load under design-basis loads. Indeed, except for some very small regions, the capacity is typically 10 times greater than the demand. Because the structural analysis follows typical seismic engineering practice and the finite element models used to describe the behavior of the SC models have been benchmarked to show satisfactory agreement with experiments even for loads greater than the design-basis loads, the NRO staff finds this margin to be acceptable, despite the uncertainties associated with any seismic analysis. We concur with the staff's conclusion. This conclusion is also consistent with the independent evaluation by the RES staff. All four of the consultants engaged by RES also agreed that the demand-to-capacity ratio was acceptable with sufficient margin. An additional expert consultant engaged by the ACRS, also agreed that margins were sufficient to ensure that the overall structural behavior was ductile.

The effort and scope of analysis and assessment required for the shield building in this case suggests that if SC composites are to be more widely used in nuclear applications, a consensus code should be developed, as has been done for other types of nuclear construction.

Analysis of Containment Vessel Cooling

The Passive Containment Cooling System is a safety-related system which is capable of transferring heat directly from the 130-foot diameter steel containment vessel (CV) to the environment. The Passive Containment Cooling System makes use of both the CV and the shield building surrounding the containment. A water distribution system, with two sets of weirs, is mounted on the outside surface of the steel CV and functions to distribute water flow on the containment exterior. The shield building directs natural draft air flow over the wetted exterior surface of the CV. The redesigned shield building reduces this air flow by about 20%, as compared to the existing, certified RC design.

Our review of WCAP-15846, Volume 1, Revision 1, “WGOTHIC Application to AP600 and AP1000,” revealed that the calculated time required to establish steady state coverage of the water film on the containment surface at prototypical flow rates was underestimated because of incorrect scaling of the 1/8 sector experimental result. This is non-conservative, inasmuch as a shorter time to reach steady state reduces the calculated peak containment pressure. WEC acknowledged the error and stated that correct scaling of the test data would result in a longer time to reach steady state film coverage at prototypical flow rates. However, WEC indicated that the analysis of record is based on an assumed value for the time to reach steady state coverage which is greater than that calculated using the correct scaling. Hence, the error should not impact the calculated peak containment pressure in the analysis of record. The staff should verify that the assumed time to reach steady state film coverage in the analysis of record is indeed longer than the corrected value obtained using the correct scaling.

Reactor Coolant Pump

The AP1000 utilizes four, hermetically sealed, high-rotational inertia, centrifugal canned-motor RCPs. The pump motor and all rotating components are contained inside a robust housing. The pumps circulate large volumes of high temperature, high pressure cooling water through the reactor vessel, loop piping, and steam generators.

In order to provide the rotational inertia necessary for flow coastdown, each pump uses two heavy flywheels of unique design. The flywheels contain high density tungsten alloy segments. A shrink fitting process uses a high strength retaining ring to hold the segments against a heavy-wall stainless steel inner hub. This retaining ring must resist all the centrifugal forces resulting from pump operation. The retaining ring is fabricated from a high strength 18% Cr, 18% Mn, iron based stainless steel (a material commonly used in electric generator applications but not in PWR primary coolant circuits). This assembly is seal-welded within a thin wall Alloy 625 (nickel base) cylindrical enclosure. The primary function of this enclosure is to isolate the tungsten segments and the retaining ring from the primary coolant surrounding the flywheel. After fabrication and inspection, the entire flywheel is then mated to the stainless steel pump shaft by a second shrink-fitting operation.

The design of the AP1000 pump makes it impractical (but not impossible) to perform periodic inservice inspection (ISI) of the Alloy 625 welds to assure that the enclosure remains leak tight. Providing assurance that the flywheel can operate without leaks for the 60-year life of the plant in the absence of ISI, is a daunting challenge. In the absence of a reliable leak detection method, our assessment is that the enclosure must be assumed to leak and that the retaining ring must be capable of operating in the primary water chemistry environment, and at temperatures at which the flywheel is designed to operate. The greatest threat to the integrity of the retaining ring is stress corrosion cracking (SCC).

If the retaining ring is susceptible to SCC, it can fracture after the cracks have reached a critical flaw size, releasing the heavy tungsten segments and causing rotor seizure. Such a seizure could have significant consequences, as discussed in Chapter 15 of the AP1000 DCD, Revision 17, including short term departure from nucleate boiling in the core, potential fuel failures, and offsite dose consequences. Because of the robustness of the pump housing, analysis has shown there is no significant risk of missiles from a flywheel failure exiting the pump.

WEC and the staff have stated that successful operation of the 18% Cr, 18% Mn retaining ring aterial in electric generator applications provides sufficient evidence to assure adequate SCC resistance in the flywheel application. We were not persuaded by this evidence. Electric generator environments are not prototypical of the PWR primary coolant environment. Further, no specific SCC nucleation or crack growth testing of the 18% Cr, 18% Mn retaining ring material has been performed to qualify the material for PWR service. We believe that the use of untested materials in such an important component as the RCP is fundamentally incompatible with General Design Criterion (GDC) 4. Consequently, we were concerned that adequate SCC resistance of the AP1000 flywheel retaining ring had not been demonstrated by testing in the primary water environment in which the flywheel is designed to operate.

WEC has responded to our concerns, and has stated that it will perform a test program to demonstrate the SCC resistance of the retaining ring material. The staff should incorporate this WEC commitment into the regulatory process, and should review the results of this testing with the Committee when available.

Flow Skirt

In the AP1000 DCD, Revisions 16 and 17, WEC proposed a change to its reactor internals. A flow skirt attached to the reactor vessel bottom head was added. The flow skirt is intended to provide a more uniform core inlet flow distribution and reduce the potential for excessive cross-flow, which could result in grid-to-rod fretting and fuel damage. We reviewed the effect of the flow skirt on core flow and flow distribution. Our review concluded that the addition of the flow skirt improves core inlet flow distribution and is satisfactory.

Human Factors Engineering

The staff review of HFE information included in the DCA was thorough, evaluating the HFE program, analyses, and design against the detailed guidelines of NUREG-0711. We are pleased that the four HFE DAC were closed as part of the DCA. This relieves substantial burden in the review of future combined license applications (COLAs). These four HFE DAC are listed below:

- Human Reliability Analysis is integrated with HFE design.
- Task Analysis is performed in accordance with the task analysis implementation plan.
- The human-system interface (HSI) design is performed for the Operation and Control Centers System in accordance with the HSI design implementation plan.
- An HFE program verification and validation implementation plan is developed in accordance with the programmatic level description of the AP1000 human factors verification and validation plan.

The staff review went well beyond the brief acceptance criteria stated in the DAC. For example, when the DAC required that a report exists that concludes the design is in conformance with the implementation plan, the review examined the content of the report, identifying omissions, incomplete analyses, and apparent errors through requests for additional information (RAIs) and open items. The review included staff audits of WEC analysis documents to ensure that all these issues were resolved.

Probabilistic Risk Assessment

The Probabilistic Risk Assessment (PRA) was completed as part of DCD Revision 15 and the most recent revision of the PRA Report is Revision 8 from 2007. DCD Revision 17, Chapter 19 includes very little new PRA information. During the staff review of DCD Revision 17, the staff performed an audit of the PRA at the WEC's headquarters. They reviewed changes to the PRA model that occurred after the submittal of the AP1000 PRA Report, Revision 8, including those related to RAIs and the amended design, as well as how the model had been converted from WEC's proprietary computer code to a more widely used linked-fault-tree code. The audit team explored the PRA by exercising the computer model and reviewing calculation notes documenting the bases for revisions to the PRA model that account for changes in the AP1000 design.

The audit team identified omissions and errors that were documented in open items that now have been closed. They found no other issues that required update of the DCD. In the audit report the staff reiterated their expectation that "before COLs begin to operate, they will develop plant-specific PRAs that conform to the appropriate revision and addenda of ASME/ANS-RA-S."

Digital Instrumentation and Control

The DCA submitted by WEC makes the following major changes to the DI&C System:

- Revised Chapter 7 to delete the use of the Eagle 21 System as an option for the Protection and Safety Monitoring System (PMS) and to provide for the use of the Common Q Platform as the microprocessor based computing platform in a DI&C architecture defined by WEC topical report WCAP-16675, "AP1000 Protection and Safety Monitoring System Architecture Technical Report."
- Revised the Diverse Actuating System (DAS) to be designed using field programmable gate arrays instead of a microprocessor based system.
- Revised the design of the Turbine Generator Overspeed Trip System from redundant, independent mechanical and electrical systems to redundant, independent electrical systems.
- Proposed the closure of DAC associated with the design requirements and system definition phases for the PMS and DAS, based on the more detailed descriptions of the designs provided in the DCA and referenced documents.

We completed a review of the proposed PMS architecture based on evaluating compliance with the four fundamental pillars of reliable DI&C microprocessor based system designs: redundancy, independence, deterministic processing behavior, and diversity and defense in depth (D3). Our review concluded that the redundancy and D3 pillars were met.

The staff found that the AP1000 design for DAS voting logic and diversity met the requirements and was acceptable. However, the staff identified that Automatic Depressurization System (ADS) spurious actuation could be a potential safety concern. WEC resolved this concern by making a change in the DCA to mitigate the potential for spurious ADS actuation. This resolution is acceptable.

During the review, it was noted that the watchdog timers were critical to ensuring that the independence criteria were met and that the PMS would actuate a reactor trip if all of the voting

processors in each division locked up due to a common cause failure (CCF). However, the design architecture for the watchdog timer operations was not clearly defined in the DCA or in referenced documents. Subsequently, WEC provided a detailed description of the watchdog timer design and operation. We consider this additional detail to be necessary and should be included in the DCA.
Our review of deterministic processing behavior noted that the topical report for the Common Q Platform identified that the bus loading in the processor should be limited to less than 70% of its capacity to ensure that deterministic processing was maintained. The DCD Tier 1 Inspections, Tests, Analyses, and Acceptance Criteria (ITAAC) for the PMS did not include a test of the time response of the system from parameter input to control device actuation with the processor loaded to 70% of its capacity. WEC committed to including time response testing to verify system performance at maximum processor loading. We agree with this resolution, which should be reflected in the DCA.

Our review of the Turbine Generator Overspeed Trip System found that there was no specific test to confirm that the trip system would prevent exceeding 120% of rated speed as specified in the note following DCD Tier 2, Table 10.2.2, "Turbine Overspeed Protection." WEC identified two tests in DCD Chapter 14, (100% Load Rejection and Plant Trip from 100% Power) that will demonstrate that the Table 10.2.2 peak transient overspeed value of ≤108% is not exceeded. However, a review of those tests found that the performance criteria did not mention confirming the peak transient overspeed value, and WEC agreed to incorporate the ≤108 % in the performance criteria for these tests. This commitment should be included in the DCA.

The removal of the DAC resulting from these DI&C changes was evaluated by the staff. We agree with the staff resolutions for these DAC.

Diverse Actuating System Out of Service Limits

During the course of our review, we identified a concern which appears to apply to the existing certification, as well as to the proposed amendment. There are two actuation logic modes: automatic and manual. The automatic DAS logic mode functions to logically combine the automatic signals from the two redundant automatic systems on a two-out-of-two basis. The manual DAS is implemented by hard wiring the controls directly to the final loads, bypassing the normal path through the PMS and the DAS automatic logic. The manual DAS has a 30-day Technical Specification out of service (OOS) allowance and the automatic DAS has a 14-day investment protection reporting time for OOS time. The PMS Engineered Safeguards Features Actuation System (ESFAS) is a two-out-of-four system which is designed to fail as-is. The voting units for the system are the same microprocessor based units that are used for the reactor trip functions in the PMS. If a CCF locks up all of the voting units, the system fails as-is and will not perform a safeguards actuation if requested. The backup to PMS is the automatic and manual DAS. As presently specified, both of these backup systems are allowed to be OOS at the same time. If a safeguards action is requested while both are OOS, there is no backup available for independent actuation. We are concerned that allowing both automatic and manual DAS to be OOS at the same time results in an unnecessary and significant reduction in diversity of protection capability which is credited in the AP1000 PRA. Accordingly, we recommend that the staff seek commitments from COL holders to not allow both automatic and manual DAS to be OOS at the same time.

In summary, we agree with the staff's resolution of all of the open items for the AP1000 DCA with respect to the specific safety issues. The changes proposed in the AP1000 DCA maintain the robustness of the previously certified design. We conclude that there is reasonable assurance that the revised design can be built and operated without undue risk to the health and safety of the public. This conclusion is contingent on the results of our concurrent reviews of the aircraft impact assessment and long-term core cooling issues which will be discussed in separate letters.

Additional Comments by ACRS Members Charles H. Brown Jr. and J. S. Armijo

Squib Valve Post Seismic Testing

The Automatic Depressurization System (ADS) ADS-4 squib valves must operate to achieve post LOCA passive long-term cooling. They are actuated by an explosive charge and are one-time-use valves until the internals are replaced. Thus, once installed, they cannot be tested in service.

We asked if the entire valve was operationally tested after being subjected to qualification seismic testing. WEC stated NO, the basis being that the valves are extensively analyzed in accordance with ASME code requirements; motor operated valves (MOV) are not operationally tested after seismic testing; and the critical actuating parts, the charge and tension bolts, are individually tested after seismic testing in simulated prototype fixtures.

We do not agree with this position and recommend that they be operationally tested after seismic testing for the following reasons:

1. Failure of the ADS-4 squib valves due to an unknown common cause mechanism prevents initiation of post LOCA passive long-term cooling.

2. This is a first time application for this service in nuclear power plants.

3. The valve actuation is a one-time pulse that ignites a charge, pushes a piston through the range of a cylindrical channel to rupture a shear cap causing the released cap to rotate about a pin to allow flow to occur. The only force to push the shear cap out of the way other than gravity is the pressure of the fluid. If seismic forces warp the channel, inhibiting or reducing piston travel; or warp the shear cap such that the shear cap does not break cleanly; or bend the pin preventing rotation of the valve disk, then the valve becomes non-operational.

4. An MOV is not a valid basis for comparison since it has a torque applying continuous force to drive a valve open or shut.

5. While an analysis for this unique valve is useful to assess the potential of the design to pass the post seismic test, it has not been validated as being satisfactory for full qualification without actual post seismic qualification operational testing.

Additional Amplifying Discussion

The ability to achieve satisfactory post LOCA passive long-term cooling has been extensively analyzed and tested in excruciating detail relative to types of debris, particulates, chemistry, and environment temperature to ensure sump and other screens do not become clogged. In our opinion, it is incongruous to now conclude that the valves critical to ensuring post LOCA passive long-term cooling will perform satisfactorily without post seismic qualification prototypical operational testing.

UNITED STATES
NUCLEAR REGULATORY COMMISSION
ADVISORY COMMITTEE ON REACTOR SAFEGUARDS
WASHINTON, DC 20555 - 0001

December 20, 2010

The Honorable Gregory B. Jaczko
Chairman
U.S. Nuclear Regulatory Commission
Washington, DC 20555-0001

SUBJECT: LONG-TERM CORE COOLING FOR THE WESTINGHOUSE AP1000 PRESSURIZED WATER REACTOR

Dear Chairman Jaczko:

During the 577th and 578th meetings of the Advisory Committee on Reactor Safeguards (ACRS), November 4-6, and December 2-4, 2010, we reviewed the NRC staff's safety evaluation of the adequacy of long-term core cooling as it applies to the AP1000 design certification amendment application. AP1000 long-term core cooling performance was also reviewed during subcommittee meetings held on November 19-20, 2009, October 5, November 17-19, and December 1, 2010. During these meetings, we had the benefit of discussions with representatives of the NRC staff and the Westinghouse (WEC or applicant). We also had the benefit of the documents referenced.

CONCLUSION AND RECOMMENDATION

1. The regulatory requirements for long-term core cooling for design basis accidents have been adequately met, and the issue is closed for the AP1000 design.

2. This conclusion is based on the cleanliness requirements specified in the amendment. Any future proposed relaxation of these requirements will require substantial additional data and analysis.

BACKGROUND

On May 8, 2008, the Commission issued a Staff Requirements Memorandum (SRM) stating that, "the ACRS should advise the staff and Commission on the adequacy of the design basis long-term core cooling approach for each new reactor design based, as appropriate, on either its review of the design certification or the first license application referencing that reactor design." The main focus of the Commission's concern was the ability of the safety systems to provide adequate core cooling over extended time periods when the Emergency Core Cooling System (ECCS) recirculation mode is activated during a design basis accident (DBA).

The AP1000 is a pressurized light water reactor design that incorporates new passive safety features not found in current operating pressurized water reactors (PWRs). These include a Passive Containment Cooling System (PCS) to transport heat to the ultimate heat sink for accident scenarios.

Many aspects of long-term cooling (LTC), excluding the effects of debris, were considered as part of the AP1000 certification process that was completed in January 2006. This letter report addresses the effect of debris on LTC.

DISCUSSION

For AP1000 LTC, coolant is driven by gravity head through the core. The coolant exits, as a steam-water mixture, mainly through the Automatic Depressurization System (ADS-4) valves. The steam flowing out from the core removes decay heat and is condensed on the inside of the steel containment shell. The condensed water flows down the containment walls, is collected in the In-Containment Refueling Water Storage Tank (IRWST), and is recirculated. Screens placed between the IRWST and the core capture debris. Sump screens are placed in another possible flow path, which is through the loop compartment to the core.

During loss-of-coolant accidents (LOCAs) the level in the IRWST tank drops, redistributing water to the region around the reactor vessel and associated piping, causing much of the piping to be submerged. Breaks in this piping, such as in the cold legs or the direct vessel injection (DVI) lines, can be submerged and provide an unfiltered flow path to the reactor core.

The main sources of debris are: 1) latent containment debris, such as hair and clothing fibers; 2) debris generated by LOCA jets and exposure to post LOCA conditions; and 3) chemical precipitates that form in the recirculating water stream. WEC has taken advantage of what has been learned with regard to the GSI-191 issue for the fleet of operating PWRs. Efforts have been made in the design to minimize LOCA-generated debris by selecting low fiber, low particulate insulation and LOCA resistant qualified coatings. Stringent containment cleanliness requirements have been imposed in the amendment that limit fibrous latent debris and the amount of aluminum that can be submerged. Sump screens have been designed to assure negligible reduction in recirculation flows due to debris accumulation on them.

Because of these actions, any potential problems with LTC would primarily be due to flow blockage in the core which may trap materials that pass through the screens, and more importantly, materials that enter the core directly through submerged breaks. The possibility that unfiltered water, carrying in some cases a major portion of the suspended fibrous and particulate debris, will gain ingress directly to the core is unique to the AP1000 design. Furthermore, the gravity head available in the AP1000 for driving flow through a core in which debris has accumulated is limited. Both of these factors add to the difficulties in determining the adequacy of AP1000 LTC.

In the certified design, the applicant carried out a series of calculations using WCOBRA/TRAC, which had been accepted for analysis of LTC, without considering debris. Resolution of debris effects was deferred to the combined license (COL) stage but is now being addressed in the amendment. In the calculations for the design certification amendment, WCOBRA/TRAC was also used. The effect of debris, which mainly causes in-vessel head losses, was modeled by introducing a constant loss factor at the core inlet. The purpose of these calculations was to determine how the loss factor affected ADS-4 vent qualities (the mass fraction of steam), pressure loss across the debris bed, and mass flux through the core. Based on analysis of the results, the applicant proposed what is effectively an acceptance criterion that requires pressure drop through the debris bed to be less than a specified amount at a specified flow rate. When the criterion was met, the WCOBRA/TRAC results indicated that the ADS-4 vent quality would be less than 50 percent which resulted in acceptable boron concentration. At our request, additional results were obtained with higher loss factors to elucidate the margins inherent in the proposed acceptance criterion with regard to critical heat flux and boron concentrations. These indicated sufficient margin to account for uncertainties, and we agree that the acceptance criterion should be as proposed by the applicant.

To determine whether blockage under representative debris loadings and flow conditions would meet the acceptance criterion, the applicant conducted a series of tests in a pumped flow loop. The loop incorporated a part-length fuel bundle with representative inlet and spacer geometries. Flow rates were varied to simulate the transient mass flux through the core as the debris bed built up, though the lowest flow rates studied were somewhat higher than the value of the flow rate for the acceptance criterion. Fibrous and particulate debris loadings were conservative but were varied over a narrow range. An approved surrogate material was added over a period of time to simulate the effect of chemical precipitates, such as aluminum oxyhydroxide that might form. The reference experimental protocol was selected to follow the sequence of events expected for the long term recirculation phase of a DBA. However, the exact protocol that should be used is unclear, and tests have shown that variations in protocol can result in significant differences in pressure losses. For example, in a test where the protocol was inadvertently varied to follow a non-representative event sequence, a significantly larger debris-bed pressure loss was obtained than for the same case run with the reference protocol. However, the pressure loss still remained within acceptable limits.

For the tests used to determine whether the acceptance criterion could be met, the fibrous debris used was derived from NUKON insulation which may not be typical of the latent debris that might accumulate in the core in an AP1000 DBA. Two tests were conducted with non-reference protocols using debris containing hair and clothing fibers. While the pressure loss behavior was somewhat different from that observed in the NUKON-based test, the pressure losses were within the acceptable range.

Most of the tests were conducted at room temperature. In two exploratory tests, debris-bed pressure losses decreased significantly when the temperature was raised to values closer to those expected during LTC. The lower pressure losses are consistent with the effect of increasing temperatures on water viscosity. However, the net effect of increased temperature on head loss is still uncertain since organic materials may behave differently at LTC temperatures than the NUKON-based debris used in the tests. Absent additional experiments at LTC temperatures using organic fibers (hair, clothing) and prototypical water chemistry, it is not certain that the observed benefit of higher temperature will provide additional margin.

In the tests, the head losses that arose from debris accumulation in the fuel inlet region were rather low when the debris consisted of fibers and particulates alone. However, when the surrogate chemical precipitates were added gradually, head losses rose sharply initially, but generally leveled off as more was added. The effect of the chemical precipitates will depend on the rate of their formation. Although this is uncertain, the rate at which surrogates were added in the tests appears to be conservative.

Radiolysis in the containment atmosphere and doses to cable insulation might form small amounts of nitrogen oxides and hydrogen chloride which may acidify the water condensed on the containment wall. The acidified water may leach zinc from the containment coating. If some zinc does dissolve into the recirculating water stream, the chemical load that should be considered in evaluating debris head losses would be increased. While the experiments indicating that head losses level off with the addition of chemical surrogates suggest that the effect of the possible zinc load could be small, the effect has not been investigated and adds to the uncertainties.

In view of the relatively narrow range of conditions explored in the applicant's test program and the significant uncertainties in the results, a site visit was conducted to better understand the AP1000 related results in the context of in-core debris effects found in the PWR Owner's Group (PWROG) experiments. These cover a wide range of conditions and, while not directly applicable to the AP1000, offer valuable insights into the effects of various experimental parameters.

As a result of the issues arising in subcommittee meetings and the site visit, additional experimental results from the PWROG program at lower flow rates and higher fiber loadings were made available to us.

When the additional WCOBRA/TRAC analyses and the additional experimental results are taken into account, in-core debris bed pressure losses appear to meet the acceptance criterion with sufficient margin to account for the uncertainties, including those due to chemical effects, experimental protocol, and debris constituents. This conclusion is based on the limits on latent debris and submerged aluminum specified in the amendment. These cleanliness specifications should not be relaxed without additional analyses, a much wider range of experiments at prototypical conditions, and NRC review of these findings.

In summary, debris generation during DBAs has been minimized by the choice of LOCA-resistant insulation and coatings. This, together with the large flow area sump screens, results in negligible head losses except in the inlet regions of the core. With regard to in-vessel debris effects, the acceptance criterion established by the applicant is adequate to assure LTC. The criterion is met with sufficient margin to account for uncertainties provided the stringent cleanliness requirements specified in the amendment are maintained. The AP1000 design, therefore, meets the regulatory requirements for LTC during design basis accidents.

Sincerely,

/RA/

Said Abdel-Khalik
Chairman

UNITED STATES
NUCLEAR REGULATORY COMMISSION
ADVISORY COMMITTEE ON REACTOR SAFEGUARDS
WASHINGTON, DC 20555 - 0001

January 19, 2011

The Honorable Gregory B. Jaczko
Chairman
U.S. Nuclear Regulatory Commission
Washington, DC 20555-0001

SUBJECT: REPORT ON THE SAFETY ASPECTS OF THE AIRCRAFT IMPACT ASSESSMENT FOR THE WESTINGHOUSE AP1000 DESIGN CERTIFICATION AMENDMENT APPLICATION

Dear Chairman Jaczko:

During the 579th meeting of the Advisory Committee on Reactor Safeguards, January 13-15, 2011, we reviewed the staff's Safety Evaluation Report (SER) on the Aircraft Impact Assessment (AIA), which is part of the Westinghouse (WEC or the Applicant) AP1000 Design Certification Amendment (DCA) application. Our AP1000 subcommittee held meetings on November 2-3, November 17-19, and December 15-16, 2010, and reviewed the staff's SER and AIA inspection report. During these meetings, we had the benefit of discussions with representatives of the NRC staff and WEC. The AIA was made available to us by the applicant for review prior to our AP1000 subcommittee meeting of November 2-3, 2010. We also had the benefit of the documents referenced. This letter fulfills the requirement of 10 CFR 52.53 that the ACRS report on those portions of the application which concern safety.

CONCLUSION AND RECOMMENDATION

The WEC AIA for the design described in the AP1000 DCA application, as modified to resolve NRC inspection findings, complies with the requirements of 10 CFR 50.150. Analyses show that the containment remains intact following the impact of a large commercial aircraft. The reactor core remains cooled, and spent fuel pool integrity is maintained.

The staff should evaluate information and analyses presented to the ACRS, but not subjected to staff review or inspection, to determine if there is a need for further revision of the design control document (DCD), or a need for further inspections.

BACKGROUND

The results of the AP1000 AIA are a part of the AP1000 DCA application. The AP1000 design was previously certified and the existing AP1000 certification rule references DCD Revision 15. DCD Revision 18 was submitted by WEC in a letter dated December 1, 2010, and it incorporates changes in Revision 16, submitted on May 26, 2007; in Revision 17, submitted on September 22, 2008; as well as those changes made subsequent to the submittal of Revision 17, which are identified in Chapter 23 of the Advanced Final Safety Evaluation Report. We held a series of meetings with the NRC staff and the applicant on the AP1000 DCA application. We wrote a letter, dated December 13, 2010, following our review of the amendment. Our assessment of the AP1000 AIA was not included in the letter.

As required by 10 CFR 50.150, applicants for new nuclear power plants must perform an assessment of the effects of the impact of a large, commercial aircraft. Using realistic analyses, applicants must identify and incorporate into the facility those design features and functional capabilities needed to show that, with reduced use of operator action; (1) the reactor core remains cooled or the containment remains intact, and (2) spent fuel cooling or spent fuel pool integrity is maintained (referred to as the acceptance criteria). Applicants are required to submit a description of the design features and functional capabilities relied upon in the AIA and a description of how these features and capabilities ensure that the acceptance criteria are met. Since the impact of a large, commercial aircraft is a beyond-design-basis event, applicants may use non-safety-related features or capabilities to satisfy the requirements of 10 CFR 50.150.

From September 27, 2010, through October 1, 2010, the staff conducted an inspection of the WEC AP1000 AIA. Based on the results of this inspection, the staff determined that NRC requirements had not been fully met. The inspection revealed that WEC did not use realistic analyses for certain aspects of its AIA and did not fully identify and incorporate into the DCD those design features and functional capabilities credited. WEC responded to the inspection report and proposed corrective actions in its letter to the NRC dated November 12, 2010. The staff issued a letter, dated November 23, 2010, stating that the proposed corrective actions were satisfactory. The staff may review the implementation of the corrective actions during a future inspection to determine that full compliance has been achieved and maintained.

DISCUSSION

The AIA performed by the applicant uses the industry guidance in NEI 07-13, Revision 7, endorsed in Draft Regulatory Guide DG-1176. The results of the AIA show that the modified AP1000 design, described in the application, meets the acceptance criteria of the AIA rule by maintaining containment integrity and spent fuel pool integrity.

The key AP1000 design features identified by WEC to satisfy the requirements of 10 CFR 50.150 include: presenting a small target with a reduced set of safety-related structures, systems, and components (SSCs); a redesigned shield building which protects the steel containment vessel from penetration due to impact[8]; simplified, passive safety equipment for core cooling; no active equipment required for spent fuel pool cooling; and redundancy and defense-in-depth in equipment design. In accordance with 10 CFR 50.150, WEC provided an assessment in the respective technical areas of structures, reactor systems, fire, and shock.

For the structural assessment, WEC used the impulse curve supplied by the NRC and the finite element analysis code LS-DYNA. All of the aircraft strikes analyzed using this code was on the shield building. The redesigned shield building, using a modular, steel concrete composite (SC) structure, reduces passive heat removal air flow. The effects of air flow reduction on containment integrity during accidents were analyzed and shown to be acceptable. Based on the results of the assessment, WEC concluded, and the staff agreed, that both the containment and spent fuel pool remain intact and that core and spent fuel cooling are maintained.

During our November 2-3, 2010 AP1000 subcommittee meeting, we questioned whether the worst-case locations for aircraft impact had been considered. WEC addressed this issue during our November 17-19, 2010, AP1000 subcommittee meeting.

The AP1000 shield building includes a 32 ft. diameter opening in the conical roof which is an essential feature of the passive containment cooling design. This opening is surrounded by the Passive Containment Cooling System water storage tank. During our November 2-3, 2010, subcommittee meeting, issues arose concerning the potential for significant aircraft impact debris to pass through the opening and impact the steel containment vessel. WEC conducted appropriate analyses, which we reviewed during our November 17-19, 2010, subcommittee meeting. Using realistic assumptions for the impact locations of concern, these analyses demonstrated that no significant debris would impact the steel Containment Vessel (CV). In addition, WEC performed a more conservative analysis in which a large mass consisting of debris and the shield plate, was assumed to fall on the steel CV. This impact resulted in only a relatively small amount of plastic deformation and no penetration of the CV.

Our December 13, 2010, letter concerning the AP1000 DCA application describes the SC design, including the addition of tie bars between opposite faceplates of the SC modules. The spacing of these tie bars is smaller in areas of higher, out-of-plane, design basis shear demands - i.e., near discontinuities and connections - than it is in the majority of the shield building wall structure where these demands are lower. Aircraft impacts, unlike design basis events, can impart high out-of-plane shear demands in regions of the shield building wall with greater tie bar spacing. As discussed in our letter of December 13, 2010, these areas can fail in

[8] The shield building redesign is discussed in our letter dated December 13, 2010.

a non-ductile manner under such loads. In order to assure acceptable realism in the analyses, it must be demonstrated that the finite element models used in the AIA adequately describe this non-ductile behavior under high out-of-plane shear loads. WEC provided comparisons of the predictions of the LS-DYNA model with an experiment on a beam representing a SC structure with greater tie bar spacing under high out-of-plane shear loads. The load-deformation behavior predicted by the model agreed well with the results of the experiment; the comparison adequately supports the use of the model for these analyses.

In addition to the possibility of global structural failure, there is also a potential for local failure due to penetration by hard objects such as an engine or landing gear. The AIA analysis included comparisons of the predictions of the LS-DYNA model with penetration tests conducted in Japan on SC structures. The predictions show adequate agreement with the tests. Although the geometry of the specimens in these tests differs from that of the shield building, the comparisons support the use of the model to predict local failures associated with aircraft impact.

WEC demonstrated that AIA requirements with respect to core and spent fuel cooling are met. This is because the systems required for design basis core cooling are located inside containment, which is protected by the redesigned shield building, and there are no active systems required for cooling of spent fuel. In addition, WEC demonstrated that at least one backup water source is always available for cooling.

Similarly, for the fire aspect of AIA, based on the limited systems required for core cooling in the AP1000, and their location within the intact containment, WEC demonstrated that the requirements of 10 CFR 50.150 are met.

Finally, with regard to the effects of shock associated with aircraft impact, WEC demonstrated that these shock loadings are less than those resulting from a design basis seismic event.

The AP1000 AIA was reviewed in parallel with the development of DCD Revision 18, which was submitted on December 1, 2010. Also, the staff conducted an inspection of the AIA and resolved their findings with WEC, as described in a letter dated November 23, 2010. In parallel with these activities, we conducted subcommittee meetings to review the AIA during which WEC responded with information and analyses, some of which may not be reflected in the DCD, as revised, or within the scope of the staff's inspection. In view of these parallel activities, the staff should evaluate information and analyses presented to the ACRS, but not subjected to staff review or inspection, to determine if there is a need for further revision of the DCD, or a need for further inspections.

The AIA for the design described in the AP1000 DCA application, as modified to resolve the staff's inspection findings, complies with the requirements of 10 CFR 50.150. Following the impact of a large commercial aircraft, the containment remains intact, the reactor core remains cooled, and spent fuel pool integrity is maintained.

Sincerely,

/RA/

Said Abdel-Khalik
Chairman

UNITED STATES
NUCLEAR REGULATORY COMMISSION
ADVISORY COMMITTEE ON REACTOR SAFEGUARDS
WASHINGTON, DC 20555 - 0001

May 19, 2011

Mr. R.W. Borchardt
Executive Director for Operations
U.S. Nuclear Regulatory Commission
Washington, DC 20555-0001

SUBJECT: RESPONSE TO THE FEBRUARY 5, 2011, EDO LETTER REGARDING THE FINAL SAFETY EVALUATION REPORT ASSOCIATED WITH THE AMENDMENT TO THE AP1000 DESIGN CONTROL DOCUMENT

Dear Mr. Borchardt:

During the 583rd meeting of the Advisory Committee on Reactor Safeguards, May 12 - 14, 2011, we reviewed your February 5, 2011, letter responding to our December 13, 2010, letter regarding the staff's final Safety Evaluation Report associated with the amendment to the AP1000 Design Control Document (DCD). In our December 13, 2010, letter, we expressed concern that the potential for failure of the reactor coolant pump (RCP) flywheel due to stress corrosion cracking (SCC) should be addressed by demonstrating that the material used is qualified for the primary water environment in which the flywheel is designed to operate. Your letter states that the staff believes this qualification testing is unnecessary because the safety consequences of a RCP flywheel failure have been adequately addressed by designing the pump casing to contain any potential missiles.

Westinghouse has committed to qualification testing as discussed further below. However, we also wish to respond to the rationale provided for the staff's determination that qualification testing of the flywheel material is unnecessary. As noted in our letter, a rotor seizure resulting from flywheel failure "could have significant consequences, as discussed in Chapter 15 of the AP1000 DCD, Revision 17, including short term departure from nucleate boiling in the core, potential fuel failures, and offsite dose consequences." The potential for these effects of a locked rotor accident, and the dynamic forces which would result at the bolted connection of the RCP to the primary system, should be minimized by using flywheel material which has been qualified to be resistant to SCC in the primary system.

Requiring use of available means to reduce the potential for a locked rotor event by using qualified flywheel material is warranted notwithstanding the fact that the flywheel is intended to be protected from exposure to the primary coolant by a surrounding Alloy 625 enclosure, because the integrity of the enclosure is not subject to periodic in-service inspection and therefore cannot be assured.

We have received a copy of the stress corrosion test program to be performed by Westinghouse to demonstrate the SCC resistance of the AP1000 RCP flywheel retaining ring material. We are concerned with the ability of the test program to provide reasonable assurance that the material will be resistant to SCC in the primary coolant environment. Our specific concern is with the proposed use of elastically loaded bent beam samples to demonstrate resistance to the initiation of stress corrosion cracks. This test method has been found to be unreliable for all but highly susceptible materials. For example, testing of hundreds of bent beam specimens for thousands of hours by the General Electric Company in the early 1960s failed to predict the susceptibility of welded Type 304 stainless steel components to SCC in boiling water reactors (BWRs). The crack growth rate (CGR) tests proposed by Westinghouse can provide a sensitive assessment of susceptibility, but the test protocols are not easily standardized. Slow strain rate tests (SSRT) demonstrated SCC susceptibility for BWR environments consistent with in-reactor performance. Today, the SSRT method is widely used to demonstrate resistance to SCC initiation, and a standard protocol is available (ASTM G129-00). Passing this test provides a high degree of assurance that a material is highly resistant to SCC initiation, and SSRT are generally easier and quicker to perform than CGR tests. Furthermore, we consider SSRT to be the most appropriate method for demonstrating SCC resistance of the retaining ring material.

In our December 13, 2010, letter, we also identified a concern that allowing both the automatic and manual modes of actuation of the Diverse Actuation System (DAS) to be out of service at the same time would result in an unnecessary and significant reduction in diversity of the protection capability, which is credited in the AP1000 probabilistic risk assessment (PRA). Thus, we recommended that the staff seek commitments from combined license holders to not allow both automatic and manual DAS to be out of service at the same time. Following review of the staff's response to our letter, we continue to make this recommendation for all the reasons enumerated in our letter. Some compensatory actions should be taken, if both automatic and manual DAS are out of service.

While we understand the logic described by the staff, common cause failure of the Protection and Safety Monitoring System is poorly understood, and no credible reliability models or data are available. Therefore, there is substantial unquantified uncertainty in the PRA results used to evaluate the importance of DAS. We consider both automatic and manual DAS as defense-in-depth measures against a poorly understood set of "common cause" failure mechanisms that could disable a reactor trip. To ensure that the defense-in-depth role is fulfilled, unavailability of manual DAS should be minimized, limited to on the order of no more than 72 hours. The current limiting condition for operation on manual DAS of 30 days is too long. This is in addition to requiring compensatory action in the event that both automatic and manual DAS are out of service, as indicated above.

Sincerely,

/RA/

Said Abdel-Khalik
Chairman
