Docket No. 50-346, License No. NPF-3
Perry Nuclear Power Plant
Docket No. 50-440, License No. NPF-58
FirstEnergy Nuclear Operating Company (FENOC) Expedited Seismic Evaluation
Process (ESEP) Reports, Response to NRC Request for Information Pursuant to
10 CFR 50.54(f) Regarding Recommendation 2.1 of the Near-Term Task Force (NTTF) Review of Insights from the Fukushima Dai-ichi Accident

On March 12, 2012, the Nuclear Regulatory Commission (NRC) issued Reference 1 to all power reactor licensees and holders of construction permits in active or deferred status. Enclosure 1 of Reference 1 requested each addressee to reevaluate the site seismic hazard using updated seismic information and present-day regulatory guidance and methodologies and, if necessary, to perform a risk evaluation.

In Reference 2, the Nuclear Energy Institute (NEI) requested NRC agreement to a path forward to complete the seismic reevaluations. This path forward, an augmented approach to responding to Reference 1, included use of a deterministic ESEP as presented in the Electric Power Research Institute (EPRI) draft report, Seismic Evaluation Guidance: Augmented Approach for the Resolution of Fukushima NearTerm Task Force Recommendation 2.1: Seismic. NEI also proposed that the ESEP reports for Central and Eastern U.S. plants would be submitted to the NRC by December 31, 2014. In Reference 3, the NRC agreed with the path forward and the augmented approach presented in the EPRI report, which was subsequently issued as EPRI Report 3002000704 (Reference 4).

Page 2
FENOC used the guidance in Reference 4 to develop the ESEP reports for Beaver Valley Power Station (BVPS) Unit No. 1, BVPS Unit No. 2, Davis-Besse Nuclear Power Station (DBNPS), and Perry Nuclear Power Plant (PNPP). This guidance allows the use of ground motion response spectra (GMRS) as the review level ground motion (RLGM) seismic demand in lieu of using scaled safe shutdown earthquake (SSE) response spectrum to demonstrate that the resulting high confidence of low probability of failure (HCLPF) values for the expedited seismic equipment list (ESEL) components are acceptable. The rationale that has been used by FENOC for the selection of the RLGM for the ESEPs is illustrated in red on the attached flow chart (Figure 1-2 from Reference 4).

The enclosed ESEP reports for BVPS Unit No. 1, BVPS Unit No. 2, DBNPS, and PNPP (Enclosures A, B, C, and D, respectively) provide the information described in Reference 4 in accordance with the schedule identified in Reference 2.

There are no new regulatory commitments contained in this letter. If there are any questions or if additional information is required, please contact Mr. Thomas A. Lentz, Manager - Fleet Licensing, at 330-315-6810.

I declare under penalty of perjury that the foregoing is true and correct. Executed on December 19, 2014.

Respectfully,

Peter P. Sena III

# EXPEDITED SEISMIC EVALUATION PROCESS REPORT BEAVER VALLEY POWER STATION - UNIT 1 

### 1.0 PURPOSE AND OBJECTIVE

Following the accident at the Fukushima Dai-ichi Nuclear Power Plant (NPP) resulting from the March 11, 2011, Great Tohoku Earthquake, and subsequent tsunami, the Nuclear Regulatory Commission (NRC) established a Near-Term Task Force (NTTF) to conduct a systematic review of NRC processes and regulations and to determine if the agency should make additional improvements to its regulatory system. The NTTF developed a set of recommendations intended to clarify and strengthen the regulatory framework for protection against natural phenomena. Subsequently, the NRC issued a 50.54(f) letter on March 12, 2012 [1], requesting information to assure that these recommendations are addressed by all United States (U.S.) NPPs. The 50.54(f) letter requests that licensees and holders of construction permits under 10 CFR Part 50 reevaluate the seismic hazards at their sites against present-day NRC requirements and guidance. Depending on the comparison between the reevaluated seismic hazard and the current design basis, further risk assessment may be required. Assessment approaches acceptable to the staff include a Seismic Probabilistic Risk Assessment (SPRA), or a Seismic Margin Assessment (SMA). Based upon the assessment results, the NRC staff will determine whether additional regulatory actions are necessary.

This Report describes the Expedited Seismic Evaluation Process (ESEP) undertaken for Beaver Valley Power Station - Unit 1 (BVPS-1). The intent of the ESEP is to perform an interim action in response to the NRC's 50.54(f) letter [1] to demonstrate seismic margin through a review of a subset of the plant equipment that can be relied upon to protect the reactor core following beyond design basis seismic events.

The ESEP is implemented using the methodologies in the NRC endorsed guidance in Electric Power Research Institute (EPRI) 3002000704 [2].

The objective of this Report is to provide summary information describing the ESEP evaluations and results. The level of detail provided in the Report is intended to enable NRC to understand the inputs used, the evaluations performed, and the decisions made as a result of the interim evaluations.

### 2.0 BRIEF SUMMARY OF THE FLEX SEISMIC IMPLEMENTATION STRATEGIES

The Beaver Valley Power Station (BVPS) FLEX strategies for Reactor Core Cooling and Heat Removal, Reactor Inventory Control/Long-term Subcriticality, and Containment Function are summarized below. This summary is derived from the BVPS Overall Integrated Plan (OIP) in response to the March 12, 2012 Commission Order EA-12-049 [17].

During Phase 1, Reactor Core Cooling and Heat Removal is accomplished via steam release from the steam generators with make-up supplied via the Auxiliary Feed Water System (AFW). The primary plant demineralized water storage tank (PPDWST), Turbine Driven Auxiliary Feed Water Pump (TDAFWP), and all needed flow paths for feeding steam generators and the flow paths for steam release from the steam generators and steam supply to the TDAFWP are protected from all hazards. AFW Flow Control Valves and Atmospheric Steam Dump Valves (ASDV) are controlled locally and do not need electricity or air for local control.

During Phase 2, cooling water make-up to the PPDWST is via a FLEX portable pump, with suction from the Ohio River. Make-up water is supplied directly to the PPDWST via a new FLEX connection point.

The same Reactor Core Cooling and Heat Removal strategy applies for Phase 3, except that water purification equipment from the National SAFER Response Center is used to purify the make-up water to the PPDWST.

Reactor Inventory Control is maintained through the use of low leakage reactor coolant pump (RCP) seals. Other than installation of the seals, there are no required plant modifications. With low leakage seals, make-up to the reactor coolant system (RCS) is not required during Phase 1.

During Phase 2, Reactor Inventory Control/Long-term Subcriticality is maintained by pumping borated water from the Boric Acid Storage Tanks (BAST) to the RCS using a FLEX high pressure portable pump and new FLEX connection points at the BASTs and downstream of the Charging Pumps.

The same Reactor Inventory Control/Long-term Subcriticality strategy applies for Phase 3, except National SAFER Response Center equipment is used to mix borated water to replace the contents of the BASTs.

Key parameters are available in the control room and communications will be available between the control room and operators that are controlling the valves locally. Electrical components required to maintain the key parameter indication during Phase 1 include the installed safety related batteries, inverters, vital Alternating Current (AC) and Direct Current (DC) buses, instrument racks and control room indicators that are needed for monitoring key reactor parameters in the control room. A load shed strategy is employed to increase the battery life.

During Phase 2, a FLEX portable generator supplies power to the battery chargers through a new FLEX connection point to maintain key parameter indication. The generator back feeds power through the safety related 480 Voltage Alternating Current (VAC) electrical distribution system to the battery chargers.

There are no FLEX actions needed to maintain containment integrity. Low leakage RCP seals minimize the energy input into containment from the RCS. Containment pressure remains less than 5 pounds per square inch gauge ( psig ) after 7 days post event. Containment temperature and pressure are addressed in recovery actions.

### 3.0 EQUIPMENT SELECTION PROCESS AND ESEL

### 3.1 Equipment Selection Process and ESEL

The selection of equipment to be included on the Expedited Seismic Equipment List (ESEL) was based on installed plant equipment credited in the FLEX strategies during Phases 1, 2, and 3 mitigation of a Beyond Design Basis External Event (BDBEE), as outlined in the BVPS OIP in Response to the March 12, 2012, Commission Order EA-12-049 [3]. The OIP provides the BVPS FLEX mitigation strategy and serves as the basis for equipment selected for the ESEP.

The scope of "installed plant equipment" includes equipment relied upon for the FLEX strategies to sustain the critical functions of core cooling and containment integrity consistent with the BVPS OIP [3]. FLEX recovery actions are excluded from the ESEP scope per EPRI 3002000704 [2]. The overall list of planned FLEX modifications and the scope for consideration herein is limited to those required to support core cooling, reactor coolant inventory and subcriticality, and containment integrity functions. Portable and pre-staged FLEX equipment (not permanently installed) are excluded from the ESEL per EPRI 3002000704 [2].

The ESEL component selection followed the EPRI guidance outlined in Section 3.2 of EPRI 3002000704.

1. The scope of components is limited to that required to accomplish the core cooling and containment safety functions identified in Table 3-2 of EPRI 3002000704. The instrumentation monitoring requirements for core cooling/containment safety functions are limited to those outlined in the EPRI 3002000704 guidance, and are a subset of those outlined in the BVPS OIP [3].
2. The scope of components is limited to installed plant equipment, and FLEX connections necessary to implement the BVPS OIP [3] as described in Section 2.0.
3. The scope of components assumes the credited FLEX connection modifications are implemented, and are limited to those required to support a single FLEX success path; i.e., either "Primary" or "Back-up/Alternate".
4. The "Primary" FLEX success path is to be specified. Selection of the "Back-up/Alternate" FLEX success path must be justified.
5. Phase 3 coping strategies are included in the ESEP scope, whereas recovery strategies are excluded.
6. Structures, systems, and components (SSC) excluded per the EPRI 3002000704 [2] guidance are:

- Structures (e.g., Containment, Reactor Building [RB], Control Building [CNTB], Auxiliary Building [AUX], etc.).
- Piping, cabling, conduit, heating, ventilation, and air-conditioning (HVAC), and their supports.
- Manual valves and rupture disks.
- Power-operated valves not required to change state as part of the FLEX mitigation strategies.
- Nuclear steam supply system components (e.g., reactor pressure vessel and internals, RCPs, and seals, etc.)

7. For cases in which neither train was specified as a primary or back-up strategy, then only one train component (generally 'A' train) is included in the ESEL.

### 3.1.1 ESEL Development

The ESEL was developed by reviewing the BVPS OIP [3] to determine the major equipment involved in the FLEX strategies. Further reviews of plant drawings (e.g., Process and Instrumentation Diagrams [P\&ID] and Electrical One-Line Diagrams) were performed to identify the boundaries of the flowpaths to be used in the FLEX strategies and to identify specific components in the flowpaths needed to support implementation of the FLEX strategies. Boundaries were established at an electrical or mechanical isolation device (e.g., isolation amplifier, valve, etc.) in branch circuits / branch lines off the defined strategy electrical or fluid flowpath. P\&IDs were the primary reference documents used to identify mechanical components and instrumentation. The flow paths used for FLEX strategies were selected and specific components were identified using detailed equipment and instrument drawings, piping isometrics, electrical schematics and one-line drawings, system descriptions, design basis, and documents, etc., as necessary.

### 3.1.2 Power-Operated Valves

Page 3-3 of EPRI 3002000704 [2] notes that power-operated valves not required to change state are excluded from the ESEL. Page 3-2 also notes that "functional failure modes of electrical and mechanical portions of the installed Phase 1 equipment should be considered (e.g., reactor core isolation cooling ([RCIC]/AFW trips)." To address this concern, the following guidance is applied in the BVPS ESEL for functional failure modes associated with power-operated valves:

- Power-operated valves that remain energized during the Extended Loss of all Alternating Current Power (ELAP) events (such as DC powered valves), were included on the ESEL.
- Power-operated valves not required to change state as part of the FLEX mitigation strategies were included on the ESEL, but indicated as screening out of evaluation. The seismic event also causes the ELAP event; therefore, the valves are incapable of spurious operation as they would be de-energized.
- Power-operated valves not required to change state as part of the FLEX mitigation strategies during Phase 1, and are re-energized and operated during subsequent Phases 2 and 3 strategies, were not evaluated for spurious valve operation as the seismic event that caused the ELAP has passed before the valves are re-powered.

### 3.1.3 Pull Boxes

Pull boxes were deemed unnecessary to add to the ESELs, as these components provide completely passive locations for pulling or installing cables. No breaks or connections in the cabling are included in pull boxes. Pull boxes were considered part of conduit and cabling, which are excluded in accordance with EPRI 3002000704 [2].

### 3.1.4 Termination Cabinets

Termination cabinets, including cabinets necessary for FLEX Phase 2 and Phase 3 connections, provide consolidated locations for permanently connecting multiple cables. The termination cabinets and the internal connections provide a completely passive function; however, the cabinets are included in the ESEL to ensure industry knowledge on panel/anchorage failure vulnerabilities is addressed.

### 3.1.5 Critical Instrumentation Indicators

Critical indicators and recorders are typically physically located on panels/cabinets and are included as separate components; however, seismic evaluation of the instrument indication may be included in the panel/cabinet seismic evaluation (rule-of-the-box).

### 3.1.6 Phase 2 and Phase 3 Piping Connections

Item 2 in Section 3.1 above notes that the scope of equipment in the ESEL includes "...FLEX connections necessary to implement the BVPS OIP [3] as described in Section 2." Item 3 in Section 3.1 also notes that "The scope of components assumes the credited FLEX connection modifications are implemented, and are limited to those required to support a single FLEX success path (i.e., either "Primary" or "Back-up/Alternate")."

Item 6 in Section 3.0 above goes on to explain that "piping, cabling, conduit, HVAC, and their supports" are excluded from the ESEL scope in accordance with EPRI 3002000704 [2].

Therefore, piping and pipe supports associated with FLEX Phase 2 and Phase 3 connections are excluded from the scope of the ESEP evaluation. However, any active valves in FLEX Phase 2 and Phase 3 connection flow path are included in the ESEL.

### 4.0 GROUND MOTION RESPONSE SPECTRUM

### 4.1 Plot of GMRS Submitted by the Licensee

The BVPS-1 major structures are founded in the Pleistocene Terrace deposits or on compacted granular structural backfill at foundation elevations varying between 637 feet ( ft ) for the Intake Structure (INTS) to 735 ft for the Diesel Generator Building (DGB). The design basis analysis applies the safe shutdown earthquake (SSE) ground motion at the respective building foundations. Therefore, the SSE, and the ground motion response spectra (GMRS), control point elevation is taken to be at the base of the Reactor Containment Structure (RCBX), elevation (EL) 681. The bedrock immediately underlying the RCBX foundation (EL 561) is characterized by shear wave velocities $\left(\mathrm{V}_{\mathrm{S}}\right)$ of about 5,000 feet per second ( $\mathrm{ft} / \mathrm{s}$ ).

Figure 4-1 presents the GMRS at the control point EL 681 and compares this to the GMRS reported in the BVPS-1 March 2014 submittal [3]. The difference is attributed to:

1. The material damping used for the rock material over the upper 500 ft . While the GMRS, reported in the March 2014, submittal is based on the low strain damping of 3.2 percent over a 500 -foot depth of bedrock, the GMRS used in the BV-1 SPRA limits this damping value to the upper 100 ft where the rock is considered as weathered or fractured. Within the depth range of 100 ft to 500 ft , a damping of 1 percent is used based on the unweathered shale dynamic properties from Stokoe et al., [14]. Below a depth of 500 ft , linear material behavior is adopted with the damping value of 0.5 percent is specified consistent with the kappa estimate for the Site.
2. The subsurface profile used in the site amplification analysis. While the GMRS, reported in the March 2014, submittal is based on a profile which extends from the bottom of the RCBX foundation to at depth hard rock, the GMRS used in the SPRA develops from the analysis of the full soil column to plant grade, subsequently truncated to the RB foundation level, in accordance with ISG-17 [18].

Table 4-1 presents the spectral accelerations at selected frequencies defining the GMRS used in the ESEP. The development of this GMRS is more fully described in [3]. This GMRS is also being utilized as basis to obtain fragilities in support of the on-going SPRA. Because the GMRS defines the ground motion at the RCBX foundation, it is also called the RCBX foundation input response spectrum (FIRS).

## Note:

MAFE = mean annual frequency of exceedance.

### 4.2 COMPARISON TO SSE

Figure 4-2 compares the GMRS with the Site SSE at the control point elevation. The SSE horizontal spectrum is characterized by a peak ground acceleration (PGA) of 0.125 acceleration of gravity (g) and a shape derived from the five percent-damped average response spectra of several acceleration records. This shape is similar to that suggested by Newmark, et al., [12]. The comparison presented on Figure 4-2 illustrates that the maximum ratio of spectral accelerations (GMRS/SSE) is about 2.8 at about 10 Hertz (Hz).

## TABLE 4-2

SSE HORIZONTAL GROUND MOTION RESPONSE SPECTRUM FOR BVPS-1

FIGURE 4-2
COMPARISON OF GMRS AND SSE AT CONTROL POINT ELEVATION

### 5.0 REVIEW LEVEL GROUND MOTION

### 5.1 DESCRIPTION OF RLGM SELECTED

The ESEP is being completed as part of the Augmented Approach because the GMRS exceed the SSE in the 1 Hz to 10 Hz range. The ESEP guidance (EPRI-3002000704) allows the use of the GMRS as the review level ground motion (RLGM) in lieu of using scaled SSE response spectrum to demonstrate acceptance of the high confidence low probability of failure (HCLPF) values for the ESEL components.

Because BVPS-1 is currently performing a SPRA, the fragilities developed in support are being used to the extent applicable also to accomplish the ESEP. The SPRA GMRS shown on Figure 4-1 represents the ground motion input used to obtain new seismic demand on the components on the ESEL, and to obtain HCLPF and fragilities for the ESEL components. Table 4-1 presents the spectral accelerations at specific frequencies defining the RLGM.

### 5.2 METHOD TO ESTIMATE ISRS

The process for obtaining in-structure response spectra (ISRS) from the building seismic analysis incorporates the effects of soil structure interaction (SSI) on the seismic response of the building structures. SSI analysis employing the System for Analysis for Soil Structure Interaction (SASSI) code was performed for the buildings of the BVPS-1 because their foundation mat bears on native soils or on Class A Fill. The analytical model for the SSI analysis combines a horizontally layered representation of the subsurface soil column with a finite element (FE) representation of the structure.

Table 5-1 describes the elevations and $\mathrm{V}_{\mathrm{S}}$ of the soil layers that were used to conduct the site response analysis by RIZZO Associates (RIZZO) [3]. This analysis developed strain compatible dynamic properties of the subsurface layers at the Beaver Valley Site, following the normalized curves listed in Table 5-2. These properties are used in the SSI analyses performed with the SASSI code.

## Note:

$\mathrm{G} / \mathrm{G}_{\max }=$ shear modulus $(\mathrm{G})$ normalized by the low strain shear modulus $\left(\mathrm{G}_{\max }\right)$.

A review of existing lumped-mass and stiffness models of the BVPS- 1 structures concluded that these models were not sufficiently adequate to use as basis to scale the building seismic response. Therefore, the building seismic response used in the ESEP (and in the SPRA) is obtained using new FE models of the structures.

The analytical FE models developed here are based on geometric information, such as configuration of floors and walls, dimensions, wall and slab thicknesses, locations, and size of openings, etc., taken from appropriate structure layout drawings and details. The parametric information, such as the material properties, live loads, equipment loads, and boundary conditions are also obtained from drawings, existing reports, and prevalent codes and standards.

The response spectra at the respective foundation levels represent the foundation input ground motion. The seismic Category I structures that have been analyzed are supported at the different foundation depths. Although, the GMRS reported in [3] applies only to the RCBX, the horizontal FIRS were developed for other structures supported at the following elevations:

- EL 713 for the analyses of the AUX, the Service Building (SRV), and the Main Steam Valve and Cable Vault Building (MSVCV)
- EL 723.5 for the analyses of the Fuel Decontamination Building (FDB), the INTS, and the Safeguards Building (SFGB)
- EL 735 for the analysis of the DGB

The seismic response, including the ISRS for the BVPS-1 structures are developed utilizing the time history ( TH ) modal synthesis in which the input time histories represent the horizontal and vertical FIRS at the respective building foundation levels consistent with the GMRS described in Section 4.0.

ISRS at selected locations are obtained separately, due to three directions of input motion (X, Y, and $Z$ ). The resulting response spectra are then combined using the square-root-of-the-sum-of-the-squares (SRSS) method. For example, the three ISRS at a specific location in North-South (NS) direction resulting from ground motion input; respectively, in the NS, East-West (EW), and vertical directions are combined using SRSS.

Subsequently, equipment HCLPF calculations and fragility evaluations are performed based on the conservative deterministic failure margin (CDFM) approach. In accordance with EPRI 1019200 "Seismic Fragility Applications Guide Update," [19] the seismic analyses are performed using Best Estimate (BE) structure stiffness, mass and damping characteristics, and the BE subsurface $\mathrm{V}_{\mathrm{S}}$ profile compatible with the expected seismic shear strains. The resulting ISRS approximately represent the $84^{\text {th }}$ percentile response suitable for use in the CDFM calculations.

Details of the development of the models, inputs, analysis, and results are presented in ABSG Consulting Inc. (ABS Consulting)/RIZZO Report 2734294-R-005, Revision 1, 2014.

### 6.0 SEISMIC MARGIN EVALUATION APPROACH

### 6.1 Summary of Methodologies Used

The seismic margins for components on the ESEL [6] are developed following the EPRI guidelines described in EPRI 6041 [4], EPRI TR-103959 [5] (Methodology for Developing Seismic Fragilities) and EPRI 1002988 (Seismic Fragility Application Guide). Additionally, EPRI 1019200 [19] is used to develop margins using the CDFM approach.

The ESEL is first grouped to identify similar components relative to equipment classes (e.g., Generic Implementation Procedure [GIP]), and then sampled for representative items based on the type of equipment, manufacturer, location, and anchorage, etc. Representative samples in each equipment group are then evaluated to obtain the seismic margins using the EPRI guidelines.

The overall strategy for developing seismic margins for the various SSCs is as follows:

1. Perform screening verification walkdown to document that caveats associated to generic fragilities are met and perform anchorage calculations.
2. Develop the HCLPF capacities based on available experience data, published generic ruggedness spectra, design criteria documents, and design analysis.
3. Rank the components based on preliminary results.
4. Perform improved analysis of selected equipment.

A number of components on the ESEL are breakers and switches that are housed in a "parent" component, such as a motor control center (MCC) or switchgear. For the purposes of this evaluation, calculations are not explicitly performed for these housed components. Instead, their HCLPF is assigned based on the parent component.

Seismic walkdowns as described in EPRI NP 6041 [4] are performed for all "parent" components on the ESEL [6]. Some ESEL components were walked down in February 2013, in
support of SPRA, and these walkdowns were credited, where applicable. The remaining components were walked down in October 2013, during a plant refueling outage.

HCLPF calculations are performed for all "parent" components [6], as described in Section 6.3, which describes the CDFM approach, and the calculation of structural and functional capacities.

### 6.2 HCLPF Screening Process

No components were screened out based on ruggedness. Rather, the screening level HCLPFs provided in Table 2-4 of EPRI 6041 [4] were utilized to develop mounting level capacities. HCLPF values are then calculated for each component on the ESEL, as described in Section 6.3.

### 6.3 SEISMIC Walkdown Approach

### 6.3.1 Seismic Walkdown Approach

The seismic walkdowns of BVPS-1 were performed in accordance with the criteria provided in Section 5 of EPRI 3002000704 [2], which refers to EPRI NP-6041 [7] for the SMA process. The procedures used for different equipment categories are summarized below.

The Seismic Review Team (SRT) reviewed equipment on the equipment walkdown list that were reasonably accessible and in non-radioactive or moderately radioactive environments. For components in high radioactive environments, a smaller team, and more hurried reviews were employed. For components that were not accessible, the equipment inspection relied on alternate means, such as photographs and plant qualification documents.

In the event the walkdown team had a reasonable basis for assuming that a group of components were similar and similarly anchored, a single representative component out of this group was selected for examination. The similarity of a group of items was established based on equipment construction, dimensions, locations, seismic qualification requirement, anchorage type, and configurations. The "similarity basis" was planned to be confirmed during walk-bys, which would also record anomalies in installation or presence of seismic interaction, if any. The representative item was targeted for a thorough review and documentation. All "representative" and "walk by" items were fully documented in Seismic Evaluation Work Sheets (SEWS).

The SRT performed the walkdowns in an ad hoc manner. For each representative component, the SRT performed a thorough inspection and recorded information related to anchorage, load path configuration, and any potential seismic vulnerability associated to the component seismic capacity. These details recorded in SEWS were subsequently used to verify as-built conditions and determine seismic fragilities.

The 100 percent "walk by" is to look for outliers, lack of similarity, anchorage which is different from that shown on drawings or prescribed in criteria for that component, potential SI [Seismic Interaction ${ }^{1}$ ] problems, situations that are at odds with the team members' past experience, and any other areas of serious seismic concern. If any such concerns surface, then the limited sample size of one component of each type for thorough inspection will have to be increased. The increase in sample size, which should be inspected, will depend upon the number of outliers and different anchorages, etc., which are observed. It is up to the SRT to ultimately select the sample size since they are the ones who are responsible for the seismic adequacy of all elements which they screen from the margin review.

Walk bys also serve to provide the SRT with the sufficient degree of confidence in relation to plant maintenance and construction practices. This is especially used to reinforce the engineering judgment applied for the fragility assessment of inaccessible components. However, in case questionable construction practices are observed in the SSCs, then the system or component class must be inspected in closer detail until the systematic deficiency is defined.

For each item on the equipment walkdown list, a specific SEWS was prepared covering the different caveats. Each SEWS consists of:

- General description of the equipment: Equipment ID, Name, Equipment Category, and Building/Floor/Room
- Equipment Evaluation Caveats

[^0]- Equipment Anchorage
- Seismic Interaction Issues

A database of SEWS was developed in an electronic format using iPad Computers to facilitate entry of the information collected during the walkdowns. The database includes the record of equipment qualifications, walkdown observations, and photographs.

### 6.3.2 Application of Previous Walkdown Information

Previous seismic walkdowns were used to support the ESEP seismic evaluations. Some of the components on the ESEL were included in the NTTF 2.3 seismic walkdowns [15] and SPRA seismic walkdowns [16]. Those walkdowns were recent enough that they did not need to be repeated for the ESEP.

Several ESEL items were previously walked down during the BVPS-1 Seismic individual plant examination of external events (IPEEE) program. Those walkdown results were reviewed and the following steps were taken to confirm that the previous walkdown conclusions remained valid.

- A walk by was performed to confirm that the equipment material condition and configuration is consistent with the walkdown conclusions and that no new significant interactions related to block walls or piping attached to tanks exist.
- If the ESEL item was screened out based on the previous walkdown, that screening evaluation was reviewed and reconfirmed for the ESEP.

### 6.3.3 Significant Walkdown Findings

Consistent with the guidance from NP-6041 [7], no significant outliers or anchorage concerns were identified during the BVPS-1 Seismic walkdowns. The following findings were noted during the walkdowns.

- Block walls were identified in the vicinity of the 125 V DC batteries located in the SRV at EL 713. These block walls were assessed for their structural adequacy [6] to withstand the seismic loads associated to the plant's RLGM demand level.

### 6.4 HCLPF CALCULATION PROCESS

ESEL items in the BVPS-1 were evaluated using the criteria in EPRI NP-6041 [4]. Those evaluations included the following steps:

- Performing seismic capability walkdowns for equipment to verify the installed plant conditions
- Performing screening evaluations using the screening tables in EPRI NP-6041 as described in Section 6.2
- Performing HCLPF calculations considering various failure modes that include both structural failure modes (e.g., anchorage, and load path, etc.) and functional failure modes

All HCLPF calculations were performed using the CDFM methodology and are documented in a BVPS-1 Reference [6].

### 6.4.1 CDFM Approach

HCLPF values for functionality and anchorage are calculated for each representative component selected from the ESEL. The functional HCLPF for equipment is based on experience data, Generic Equipment Ruggedness Data (GERS), test response data, and design criteria. The functional evaluation is supplemented with the verification of the equipment anchorage following Seismic Qualification Utility Group (SQUG)/GIP procedures. The seismic demand on the equipment is based on the floor response spectra near the equipment support location, and the component damping values as recommended in EPRI 6041 [4].

The CDFM approach described in EPRI 1019200 [19] is utilized to obtain the component HCLPF values. The HCLPF capacities are stated in terms of a selected ground motion PGA. The CDFM approach is consistent with EPRI NP-6041-SL [4], updated to accommodate the parameters presented in Table 6-1.

The screening level HCLPF values provided in EPRI 6041 [4] Table 2-4 are presented in terms of the 5 Hz spectral acceleration at the foundation level. In accordance with EPRI 1019200 [19], these values are used to develop mounting level capacity assuming a median structure
amplification factor of 1.5. The ISRS described in Section 4.2 are compared with this mounting level capacity to develop HCLPF associated with the GMRS shape. Anchorage checks are performed based on the spectral accelerations at the estimated equipment frequencies.

TABLE 6-1

## SUMMARY OF CONSERVATIVE DETERMINISTIC FAILURE MARGIN APPROACH (EPRI 1019200, TABLE A.1)

| TECHNICAL ISSUE | RECOMMENDED METHOD |
| :--- | :--- |
| Load Combination | Normal + SME. |
| Ground Response <br> Spectrum | Anchor CDFM Capacity to defined response spectrum shape <br> without consideration of spectral shape variability. |
| Seismic Demand | Perform seismic demand analysis in accordance with latest <br> version of American Society of Civil Engineers (ASCE) 4. |
| Damping | Conservative estimate of median damping. |
| Structural Model | BE (Median) + Uncertainty Variation in Frequency. |
| Soil Structure <br> Interaction | BE (Median) + Parameter Variation. |
| In-Structure (Floor) <br> Spectra Generation | Use frequency shifting rather than peak broadening to <br> account for uncertainty plus use conservative estimate of <br> median damping. |
| Material Strength | Code specified minimum strength or 95\% exceedance actual <br> strength if test data are available. |
| Static Strength | Code ultimate strength (ACI), maximum strength (AISC), <br> Service Level D (ASME), or functional limits. If test data <br> are available to demonstrate excessive conservatism of code <br> equation then use 84\% exceedance of test data for strength <br> equation. |
| Inelastic Energy | For non-brittle failure modes and linear analysis, use <br> appropriate inelastic energy absorption factor from <br> ASCE/SEI 43-05 to account for ductility benefits, or perform <br> Absorption <br> levelinear analysis and go to 95\% exceedance ductility |

### 6.4.2 Component Structural Capacity

In general, the CDFM approach:

1. Develops the elastic seismic response for the structures and components for the ground motion.
2. Develops strength margin factor using component capacities as described in Table 6-1.
3. Develops inelastic energy absorption factor based on ASCE 43-05 or at about the 95 percent exceedance probability of ductility levels.
4. Calculates the CDFM capacity as:

$$
\begin{equation*}
H C L P F_{C D F M}=F_{S} \cdot F_{\mu} \cdot P G A \tag{Equation6-1}
\end{equation*}
$$

where,
$F_{S}=$ Strength margin factor,
$F_{\mu}=$ Inelastic energy absorption factor

The strength margin factor is defined as:

$$
F_{S}=\frac{s-D_{n s}}{D_{s}}
$$

(Equation 6-2)
where,
$S=$ Strength of the structural element
$D_{n s}=$ Non-seismic demand (normal operating loads)
$D_{S}=$ Seismic demand

### 6.4.3 Functional Evaluations

The HCLPF capacities for functionality are based on the comparison of the demand (ISRS) with EPRI 6041 [4] screening level HCLPFs, existing analysis, GERS, or test response spectra.

The screening level HCLPF values provided in EPRI 6041 [4] Table 2-4 are presented in terms of the 5 Hz spectral acceleration at the foundation level. In accordance with EPRI 1019200 [19], these values are used to develop mounting level capacity assuming a median structure amplification factor of 1.5. The ISRS described in Section 5.2 are compared with this mounting level capacity to develop HCLPF associated with the GMRS shape. Anchorage checks are performed based on the spectral accelerations at the estimated equipment frequencies.

Available plant specific seismic qualifications tests are biaxial and all of the published GERS are constructed on the basis of the results of previous biaxial tests of similar types of equipment. These tests apply table input motion in one-horizontal direction and in the vertical direction. For most equipment, for which GERS are available, the vertical test response spectrum (TRS) are at least equal to the horizontal TRS. The published GERS define the horizontal component of the table motion, which is, therefore, taken to represent the capacity stated either in terms of the vertical or horizontal input.

The seismic demand on equipment, on the other hand, is typically defined by ISRS in three orthogonal directions, two horizontal and one vertical. The procedure used to develop the functional capacity compares the resultant horizontal and the vertical ISRS separately with the GERS or TRS. The minimum seismic margin is taken to obtain the functional HCLPF capacity.

### 6.5 Functional Evaluations of Relays

The only relays applicable to FLEX mitigating strategies are the relays that automatically start the TDAFWP. All other plant control is local at the component.

The relays deenergize Solenoid-Operated Valves (SOVs) that port instrument air away from two Air-Operated Valves (AOVs) that control the supply of steam to the TDAFWP in parallel steam supply pipes. The AOVs fail open on loss of instrument air. As instrument air is not seismic, the failure of air results in automatic opening of the AOVs regardless of relay function. Therefore, the relays are not included in this evaluation.

These relays are slave relays in the solid state protection system and have no lock out function. Additionally, manual control from the control room is available to the operators, which deenergizes the SOVs directly, without the need for any relays. Finally, if DC is lost, such that
there is no control power available to the control room, the SOVs fail open, porting air from the AOVs and admitting steam to the TDAFWP.

### 6.6 Tabulated ESEL HCLPF Values (Including Key Failure Modes)

Attachment $\boldsymbol{B}$ tabulates the HCLPF values for all components on the ESEL. All HCLPF values exceed the RLGM. The Table in Attachment B also identifies the method used to develop the HCLPF values and the controlling failure mode. Most of the controlling failure modes are either anchorage failure or loss of functionality and do not involve structural integrity. For a limited number of components, the controlling failure mode is the failure of a nearby masonry block wall. These cases are also identified in the Table.

### 7.0 INACCESSIBLE ITEMS

### 7.1 Identification of ESEL items inaccessible for walkdowns

A total of seven items in the ESEL were inaccessible during walkdowns mainly due to their location in confined spaces and high radiation areas. Table 7-1 provides the description of the seven inaccessible components, the reason for their inaccessibility and the criteria implemented to confirm the installed condition and, therefore, evaluate their seismic fragility. The criteria implemented to confirm the installed condition follows EPRI NP 6041 [7], where a number of ways of confirming the installed condition of equipment, including follow up walkdowns, photographic or other confirmatory evidence is provided.

TABLE 7-1
SUMMARY OF INACCESSIBLE ITEMS IN BVPS-1 ESEL

| COMPONENT ID | DESCRIPTION | REASON FOR <br> INACCESSIBLE | RESOLUTION |
| :---: | :--- | :--- | :--- |
| BV-NE-1NI-31 | BF3 Proportional <br> Counter Source <br> Range Detector | High radiation area <br> (RCBX EL 692) | Fragility is calculated based <br> on design documentation and <br> installation drawings [6]. |

### 8.0 ESEP CONCLUSIONS AND RESULTS

The conclusions and results of the ESEP evaluation are presented in this Section, including the identification of any required plant modifications and schedules for any follow up actions.

### 8.1 SUPPORTING INFORMATION

BVPS-1 has performed the ESEP as an interim action in response to the NRC's 50.54(f) letter [1]. The ESEP demonstrates that BVPS-1 has additional seismic margin plant equipment that can be relied upon to protect the reactor core following a beyond design basis seismic event. It was performed using the methodologies in the NRC endorsed guidance in EPRI 3002000704 [2].

The ESEP provides an important demonstration of seismic margin and expedites plant safety enhancements through evaluations and potential near-term modifications of plant equipment that can be relied upon to protect the reactor core following beyond design basis seismic events.

The ESEP is part of the overall BVPS-1 response to the NRC's 50.54(f) letter [1]. On March 12, 2014, Nuclear Energy Institute (NEI) submitted to the NRC results of a study [7] of seismic core damage risk estimates based on updated seismic hazard information as it applies to operating nuclear reactors in the Central and Eastern United States (CEUS). The study concluded that "site-specific seismic hazards show that there has not been an overall increase in seismic risk for the fleet of U.S. plants," based on the reevaluated seismic hazards. As such, the "current seismic design of operating reactors continues to provide a safety margin to withstand potential earthquakes exceeding the seismic design basis."

The NRC's May 9, 2014, NTTF 2.1 Screening and Prioritization letter [9] concluded that the "fleetwide seismic risk estimates are consistent with the approach and results used in the Gl-199 safety/risk assessment." The letter also stated that "as a result, the staff has confirmed that the conclusions reached in $\mathrm{Gl}-199$ safety/risk assessment remain valid and that the plants can continue to operate while additional evaluations are conducted."

An assessment of the change in seismic risk for BVPS-1 was included in the fleet risk evaluation submitted in the March 12, 2014, NEI letter [7], therefore, the conclusions in the NRC's May 9 letter [9] also apply to BVPS-1.

In addition, the March 12, 2014, NEI letter [7] provided an attached "Perspectives on the Seismic Capacity of Operating Plants," which (1) assessed a number of qualitative reasons why the design of SSCs inherently contain margin beyond their design level, (2) discussed industrial seismic experience databases of performance of industry facility components similar to nuclear SSCs, and (3) discussed earthquake experience at operating plants.

The fleet of currently operating NPPs was designed using conservative practices, such that the plants have significant margin to withstand large ground motions safely. This has been borne out for those plants that have actually experienced significant earthquakes. The seismic design process has inherent (and intentional) conservatisms which result in significant seismic margins within SSCs. These conservatisms are reflected in several key aspects of the seismic design process, including:

- Safety factors applied in design calculations
- Damping values used in dynamic analysis of SSCs
- Bounding synthetic THs for ISRS calculations
- Broadening criteria for ISRS
- Response spectra enveloping criteria typically used in SSCs analysis and testing applications
- Response spectra based frequency domain analysis rather than explicit TH based time domain analysis
- Bounding requirements in codes and standards
- Use of minimum strength requirements of structural components (concrete and steel)
- Bounding testing requirements
- Ductile behavior of the primary materials (that is, not crediting the additional capacity of materials, such as steel and reinforced concrete beyond the essentially elastic range, etc.)

These design practices combine to result in margins, such that the SSCs will continue to fulfill their functions at ground motions well above the SSE.

The intent of the ESEP is to perform an interim action in response to the NRC's 50.54(f) letter [1] to demonstrate seismic margin through a review of a subset of the plant equipment that can be relied upon to protect the reactor core following beyond design basis seismic events. Because the SPRA for BVPS-1 is already under way, the GMRS used in the SPRA is also used as the RLGM for the ESEP evaluation. To more fully characterize the risk impacts of the seismic ground motion represented by the GMRS on a plant specific basis, a more detailed seismic risk assessment (SPRA or risk-based SMA) is being performed in accordance with EPRI 1025287 [10]. As identified in the BVPS-1 Seismic Hazard and GMRS submittal [3], BVPS-1 screens in for a risk evaluation. The complete risk evaluation will more completely characterize the probabilistic seismic ground motion input into the plant, the plant response to that probabilistic seismic ground motion input, and the resulting plant risk characterization. BVPS- 1 will complete that evaluation in accordance with the schedule identified in NEI's letter dated April 9, 2013, [8] and endorsed by the NRC in their May 7, 2013, letter [11].

### 8.2 Identification of Planned Modifications

As discussed in Section 6.6 and presented in Attachment $\boldsymbol{B}$, all components on the ESEL have a HCLPF greater than the RLGM $(0.24 \mathrm{~g})$. Therefore, no modifications related to the ESEP are planned.

### 8.3 Modification Implementation Schedule

As no modifications are planned, this Section is not applicable.

### 8.4 SUMMARY OF REGULATORY COMMITMENTS

None

# EXPEDITED SEISMIC EVALUATION PROCESS REPORT BEAVER VALLEY POWER STATION - UNIT 2 

### 1.0 PURPOSE AND OBJECTIVE

Following the accident at the Fukushima Dai-ichi Nuclear Power Plant (NPP) resulting from the March 11, 2011, Great Tohoku Earthquake, and subsequent tsunami, the Nuclear Regulatory Commission (NRC) established a Near-Term Task Force (NTTF) to conduct a systematic review of NRC processes and regulations and to determine if the agency should make additional improvements to its regulatory system. The NTTF developed a set of recommendations intended to clarify and strengthen the regulatory framework for protection against natural phenomena. Subsequently, the NRC issued a 50.54(f) letter on March 12, 2012 [1], requesting information to assure that these recommendations are addressed by all United States (U.S.) NPPs. The 50.54(f) letter requests that licensees and holders of construction permits under 10 CFR Part 50 reevaluate the seismic hazards at their sites against present-day NRC requirements and guidance. Depending on the comparison between the reevaluated seismic hazard and the current design basis, further risk assessment may be required. Assessment approaches acceptable to the staff include a Seismic Probabilistic Risk Assessment (SPRA), or a Seismic Margin Assessment (SMA). Based upon the assessment results, the NRC staff will determine whether additional regulatory actions are necessary.

This Report describes the Expedited Seismic Evaluation Process (ESEP) undertaken for Beaver Valley Power Station - Unit 2 (BVPS-2). The intent of the ESEP is to perform an interim action in response to the NRC's 50.54(f) letter [1] to demonstrate seismic margin through a review of a subset of the plant equipment that can be relied upon to protect the reactor core following beyond design basis seismic events.

The ESEP is implemented using the methodologies in the NRC endorsed guidance in Electric Power Research Institute (EPRI) 3002000704 [2].

The objective of this Report is to provide summary information describing the ESEP evaluations and results. The level of detail provided in the Report is intended to enable NRC to understand the inputs used, the evaluations performed, and the decisions made as a result of the interim evaluations.

### 2.0 BRIEF SUMMARY OF THE FLEX SEISMIC IMPLEMENTATION STRATEGIES

#### Abstract

The Beaver Valley Power Station (BVPS) FLEX strategies for Reactor Core Cooling and Heat Removal, Reactor Inventory Control/Long-term Subcriticality, and Containment Function are summarized below. This summary is derived from the BVPS Overall Integrated Plan (OIP) in response to the March 12, 2012 Commission Order EA-12-049 [17].

During Phase 1, Reactor Core Cooling and Heat Removal is accomplished via steam release from the steam generators with make-up supplied via the Auxiliary Feed Water System (AFW). The primary plant demineralized water storage tank (PPDWST), Turbine Driven Auxiliary Feed Water pump(TDAFWP) and all needed flow paths for feeding steam generators and the flow paths for steam release from the steam generators and steam supply to the TDAFW pump are protected from all hazards. AFW Flow Control Valves and Atmospheric Steam Dump Valves (ASDV) are controlled locally and do not need electricity or air for local control.

During Phase 2, cooling water make-up to the PPDWST is via a FLEX portable pump, with suction from the Ohio River. Make-up water is supplied directly to the PPDWST via a new FLEX connection point.

The same Reactor Core Cooling and Heat Removal strategy applies for Phase 3, except that water purification equipment from the National SAFER Response Center is used to purify the make-up water to the PPDWST.

Reactor Inventory Control is maintained through the use of low leakage reactor coolant pump (RCP) seals. Other than installation of the seals, there are no required plant modifications. With low leakage seals, make-up to the reactor coolant system (RCS) is not required during Phase 1.

During Phase 2, Reactor Inventory Control/Long-term Subcriticality is maintained by pumping borated water from the Boric Acid Storage Tanks (BAST) to the RCS using a FLEX high pressure portable pump and new FLEX connection points at the BASTs and downstream of the Charging Pumps.

The same Reactor Inventory Control/Long-term Subcriticality strategy applies for Phase 3, except National SAFER Response Center equipment is used to mix borated water to replace the contents of the BASTs.

Key parameters are available in the control room and communications will be available between the control room and operators that are controlling the valves locally. Electrical components required to maintain the key parameter indication during Phase 1 include the installed safety related batteries, inverters, vital Alternating Current (AC) \& Direct Current (DC) buses, instrument racks and control room indicators that are needed for monitoring key reactor parameters in the control room. A load shed strategy is employed to increase the battery life.

During Phase 2, a FLEX portable generator supplies power to the battery chargers through a new FLEX connection point to maintain key parameter indication. The generator back feeds power through the safety related 480 Voltage Alternating Current (VAC) electrical distribution system to the battery chargers.

There are no FLEX actions needed to maintain containment integrity. Low leakage RCP Seals minimize the energy input into containment from the RCS. Containment pressure remains less than 5 pounds per square inch gauge ( psig ) after 7 days post event. Containment temperature and pressure are addressed in recovery actions.

### 3.0 EQUIPMENT SELECTION PROCESS AND ESEL

### 3.1 Equipment Selection Process and ESEL

The selection of equipment to be included on the Expedited Seismic Equipment List (ESEL) was based on installed plant equipment credited in the FLEX strategies during Phases 1, 2, and 3 mitigation of a Beyond Design Basis External Event (BDBEE), as outlined in the BVPS OIP in Response to the March 12, 2012, Commission Order EA-12-049 [17]. The OIP provides the BVPS FLEX mitigation strategy and serves as the basis for equipment selected for the ESEP.

The scope of "installed plant equipment" includes equipment relied upon for the FLEX strategies to sustain the critical functions of core cooling and containment integrity consistent with the BVPS OIP [17]. FLEX recovery actions are excluded from the ESEP scope per EPRI 3002000704 [2]. The overall list of planned FLEX modifications and the scope for consideration herein is limited to those required to support core cooling, reactor coolant inventory and subcriticality, and containment integrity functions. Portable and pre-staged FLEX equipment (not permanently installed) are excluded from the ESEL per EPRI 3002000704 [2].

The ESEL component selection followed the EPRI guidance outlined in Section 3.2 of EPRI 3002000704.

1. The scope of components is limited to that required to accomplish the core cooling and containment safety functions identified in Table 3-2 of EPRI 3002000704. The instrumentation monitoring requirements for core cooling/containment safety functions are limited to those outlined in the EPRI 3002000704 guidance, and are a subset of those outlined in the BVPS OIP [17].
2. The scope of components is limited to installed plant equipment and FLEX connections necessary to implement the BVPS OIP [17] as described in Section 2.0.
3. The scope of components assumes the credited FLEX connection modifications are implemented, and are limited to those required to support a single FLEX success path; i.e., either "Primary" or "Back-up/Alternate".
4. The "Primary" FLEX success path is to be specified. Selection of the "Back-up/Alternate" FLEX success path must be justified.
5. Phase 3 coping strategies are included in the ESEP scope, whereas recovery strategies are excluded.
6. Structures, systems, and components (SSC) excluded per the EPRI 3002000704 [2] guidance are:

- Structures (e.g., Containment, Reactor Building [RB], Control Building [CNTB], Auxiliary Building [AUX], etc.).
- Piping, cabling, conduit, heating, ventilation, and air-conditioning (HVAC), and their supports.
- Manual valves and rupture disks.
- Power-operated valves not required to change state as part of the FLEX mitigation strategies.
- Nuclear steam supply system components (e.g., reactor pressure vessel and internals, RCPs, and seals, etc.).

7. For cases in which neither train was specified as a primary or back-up strategy, then only one train component (generally ' A ' train) is included in the ESEL.

### 3.1.1 ESEL Development

The ESEL was developed by reviewing the BVPS OIP [17] to determine the major equipment involved in the FLEX strategies. Further reviews of plant drawings (e.g., Process and Instrumentation Diagrams [P\&ID] and Electrical One-Line Diagrams) were performed to identify the boundaries of the flowpaths to be used in the FLEX strategies and to identify specific components in the flowpaths needed to support implementation of the FLEX strategies. Boundaries were established at an electrical or mechanical isolation device (e.g., isolation amplifier, valve, etc.) in branch circuits / branch lines off the defined strategy electrical or fluid flowpath. P\&IDs were the primary reference documents used to identify mechanical components and instrumentation. The flow paths used for FLEX strategies were selected and specific components were identified using detailed equipment and instrument drawings, piping isometrics, electrical schematics and one-line drawings, system descriptions, design basis, and documents, etc., as necessary.

### 3.1.2 Power-Operated Valves

Page 3-3 of EPRI 3002000704 [2] notes that power-operated valves not required to change state are excluded from the ESEL. Page 3-2 also notes that "functional failure modes of electrical and mechanical portions of the installed Phase 1 equipment should be considered (e.g., reactor core isolation cooling [RCIC]/AFW trips)." To address this concern, the following guidance is applied in the BVPS ESEL for functional failure modes associated with power-operated valves:

- Power-operated valves that remain energized during the Extended Loss of all Alternating Current Power (ELAP) events (such as DC powered valves), were included on the ESEL.
- Power-operated valves not required to change state as part of the FLEX mitigation strategies were included on the ESEL, but indicated as screening out of evaluation. The seismic event also causes the ELAP event; therefore, the valves are incapable of spurious operation as they would be de-energized.
- Power-operated valves not required to change state as part of the FLEX mitigation strategies during Phase 1, and are re-energized and operated during subsequent Phases 2 and 3 strategies, were not evaluated for spurious valve operation as the seismic event that caused the ELAP has passed before the valves are re-powered.

### 3.1.3 Pull Boxes

Pull boxes were deemed unnecessary to add to the ESELs, as these components provide completely passive locations for pulling or installing cables. No breaks or connections in the cabling are included in pull boxes. Pull boxes were considered part of conduit and cabling, which are excluded in accordance with EPRI 3002000704 [2].

### 3.1.4 Termination Cabinets

Termination cabinets, including cabinets necessary for FLEX Phase 2 and Phase 3 connections, provide consolidated locations for permanently connecting multiple cables. The termination cabinets and the internal connections provide a completely passive function; however, the cabinets are included in the ESEL to ensure industry knowledge on panel/anchorage failure vulnerabilities is addressed.

### 3.1.5 Critical Instrumentation Indicators

Critical indicators and recorders are typically physically located on panels/cabinets and are included as separate components; however, seismic evaluation of the instrument indication may be included in the panel/cabinet seismic evaluation (rule-of-the-box).

### 3.1.6 Phase 2 and Phase 3 Piping Connections

Item 2 in Section 3.1 above notes that the scope of equipment in the ESEL includes "... FLEX connections necessary to implement the BVPS OIP [17] as described in Section 2." Item 3 in Section 3.1 also notes that "The scope of components assumes the credited FLEX connection modifications are implemented, and are limited to those required to support a single FLEX success path (i.e., either "Primary" or "Back-up/Alternate")."

Item 6 in Section 3.0 above goes on to explain that "piping, cabling, conduit, HVAC, and their supports" are excluded from the ESEL scope in accordance with EPRI 3002000704 [2].

Therefore, piping and pipe supports associated with FLEX Phase 2 and Phase 3 connections are excluded from the scope of the ESEP evaluation. However, any active valves in FLEX Phase 2 and Phase 3 connection flow path are included in the ESEL.

### 4.0 GROUND MOTION RESPONSE SPECTRUM

### 4.1 Plot of GMRS Submitted by the Licensee

The BVPS-2 major structures are founded in the Pleistocene Terrace deposits or on compacted granular structural backfill at foundation elevations varying between 681 feet ( ft ) for the RB to 725 ft for the Service Building (SRV). The design basis analysis applies the safe shutdown earthquake (SSE) ground motion at the respective building foundations. Therefore, the SSE, and the ground motion response spectra (GMRS), control point elevation is taken to be at the base of the RCBX, elevation (EL) 681. The bedrock immediately underlying the RCBX foundation (EL 561) is characterized by shear wave velocities ( $\mathrm{V}_{\mathrm{S}}$ ) of about 5,000 feet per second ( $\mathrm{ft} / \mathrm{s}$ ).

Figure 4-1 presents the GMRS at the control point EL 681 and compares this to the GMRS reported in the BVPS-2 March 2014 submittal [3]. The difference is attributed to:

1. The material damping used for the rock material over the upper 500 ft . While the GMRS, reported in the March 2014, submittal is based on the low strain damping of 3.2 percent over a 500 -foot depth of bedrock, the GMRS used in the BV-2 SPRA limits this damping value to the upper 100 ft where the rock is considered as weathered or fractured. Within the depth range of 100 ft to 500 ft , a damping of 1 percent is used based on the unweathered shale dynamic properties from Stokoe et al., [14]. Below a depth of 500 ft , linear material behavior is adopted with the damping value of 0.5 percent is specified consistent with the kappa estimate for the Site.
2. The subsurface profile used in the site amplification analysis. While the GMRS, reported in the March 2014, submittal is based on a profile which extends from the bottom of the RCBX foundation to at depth hard rock, the GMRS used in the SPRA develops from the analysis of the full soil column to plant grade, subsequently truncated to the RB foundation level, in accordance with ISG-17 [18].

Table 4-1 presents the spectral accelerations at selected frequencies defining the GMRS used in the ESEP. The development of this GMRS is more fully described in [3]. This GMRS is also being utilized as basis to obtain fragilities in support of the on-going SPRA. Because the GMRS defines the ground motion at the RCBX foundation, it is also called the RCBX foundation input response spectrum (FIRS).

Note:
MAFE = mean annual frequency of exceedance.

### 4.2 COMPARISON TO SSE

Figure 4-2 compares the GMRS with the Site SSE at the control point elevation. The SSE horizontal spectrum is characterized by a peak ground acceleration (PGA) of 0.125 acceleration of gravity (g) and a shape derived from the five percent-damped average response spectra of several acceleration records. This shape is similar to that suggested by Newmark, et al., [12]. The comparison presented on Figure 4-2 illustrates that the maximum ratio of spectral accelerations (GMRS/SSE) is about 2.8 at about $10 \mathrm{Hertz}(\mathrm{Hz})$.

TABLE 4-2

FIGURE 4-2
COMPARISON OF GMRS AND SSE AT CONTROL POINT ELEVATION

### 5.0 REVIEW LEVEL GROUND MOTION

### 5.1 DESCRIPTION OF RLGM SELECTED

The ESEP is being completed as part of the Augmented Approach because the GMRS exceed the SSE in the 1 Hz to 10 Hz range. The ESEP guidance (EPRI-3002000704) allows the use of the GMRS as the review level ground motion (RLGM) in lieu of using scaled SSE response spectrum to demonstrate acceptance of the high confidence low probability of failure (HCLPF) values for the ESEL components.

Because BVPS-2 is currently performing a SPRA, the fragilities developed in support are being used to the extent applicable also to accomplish the ESEP. The SPRA GMRS shown on Figure 4-1 represents the ground motion input used to obtain new seismic demand on the components on the ESEL, and to obtain HCLPF and fragilities for the ESEL components.
Table 4-1 presents the spectral accelerations at specific frequencies defining the RLGM.

### 5.2 METHOD TO ESTIMATE ISRS

The process for obtaining in-structure response spectra (ISRS) from the building seismic analysis incorporates the effects of soil structure interaction (SSI) on the seismic response of the building structures. SSI analysis employing the System for Analysis for Soil Structure Interaction (SASSI) code was performed for the buildings of the BVPS-2 because their foundation mat bears on native soils or on Class A Fill. The analytical model for the SSI analysis combines a horizontally layered representation of the subsurface soil column with a finite element (FE) representation of the structure.

Table 5-1 describes the elevations and $\mathrm{V}_{\mathrm{S}}$ of the soil layers that were used to conduct the site response analysis by RIZZO Associates (RIZZO) [3]. This analysis developed strain compatible dynamic properties of the subsurface layers at the Beaver Valley Site, following the normalized curves listed in Table 5-2. These properties are used in the SSI analyses performed with the SASSI code.

## Note:

$\mathrm{G} / \mathrm{G}_{\text {max }}=$ shear modulus $(\mathrm{G})$ normalized by the low strain shear modulus $\left(\mathrm{G}_{\text {max }}\right)$.

A review of existing lumped-mass and stiffness models of the BVPS-2 structures concluded that these models were not sufficiently adequate to use as basis to scale the building seismic response. Therefore, the building seismic response used in the ESEP (and in the SPRA) is obtained using new FE models of the structures.

The analytical FE models developed here are based on geometric information, such as configuration of floors and walls, dimensions, wall and slab thicknesses, locations, and size of openings, etc., taken from appropriate structure layout drawings and details. The parametric information, such as the material properties, live loads, equipment loads, and boundary conditions are also obtained from drawings, existing reports, and prevalent codes and standards.

The response spectra at the respective foundation levels represent the foundation input ground motion. The seismic Category I structures that have been analyzed are supported at the different foundation depths. Although, the GMRS reported in [3] applies only to the RCBX, the horizontal FIRS were developed for other structures supported at the following elevations:

- EL 681 for the analysis of the RB
- EL 703 for the analyses of the AUX and the CNTB
- EL 713 for the analyses of the DGB, Main Steam Valve and Cable Vault Building (MSVCV), and Safeguards Building (SFGB)
- EL 723.5 for the analyses of the Fuel Decontamination Building (FDB) and SRV

The seismic response, including the ISRS for the BVPS-2 structures are developed utilizing the time history (TH) modal synthesis in which the input time histories (TH) represent the horizontal and vertical FIRS at the respective building foundation levels consistent with the GMRS described in Section 4.0.

ISRS at selected locations are obtained separately, due to three directions of input motion (X, Y, and Z ). The resulting response spectra are then combined using the square-root-of-the-sum-of-the-squares (SRSS) method. For example, the three ISRS at a specific location in North-South (NS) direction resulting from ground motion input; respectively, in the NS, East-West (EW), and vertical directions are combined using SRSS.

Subsequently, equipment HCLPF calculations and fragility evaluations are performed based on the conservative deterministic failure margin (CDFM) approach. In accordance with EPRI 1019200 "Seismic Fragility Applications Guide Update" [19], the seismic analyses are performed using Best Estimate (BE) structure stiffness, mass and damping characteristics, and the BE subsurface $\mathrm{V}_{\mathrm{S}}$ profile compatible with the expected seismic shear strains. The resulting ISRS approximately represent the 84th percentile response suitable for use in the CDFM calculations.

Details of the development of the models, inputs, analysis, and results are presented in ABSG Consulting Inc. (ABS Consulting) Report 2734294-R-012, Revision 1, 2014.

### 6.0 SEISMIC MARGIN EVALUATION APPROACH

### 6.1 Summary of Methodologies Used

The seismic margins for components on the ESEL [6] are developed following the EPRI guidelines described in EPRI 6041 [4], EPRI TR-103959 [5] (Methodology for Developing Seismic Fragilities) and EPRI 1002988 (Seismic Fragility Application Guide). Additionally, EPRI 1019200 [19] is used to develop margins using the CDFM approach.

The ESEL is first grouped to identify similar components relative to equipment classes (e.g., Generic Implementation Procedure [GIP]), and then sampled for representative items based on the type of equipment, manufacturer, location, and anchorage, etc. Representative samples in each equipment group are then evaluated to obtain the seismic margins using the EPRI guidelines.

The overall strategy for developing seismic margins for the various SSCs is as follows:

1. Perform screening verification walkdown to document that caveats associated to generic fragilities are met and perform anchorage calculations.
2. Develop the HCLPF capacities based on available experience data, published generic ruggedness spectra, design criteria documents, and design analysis.
3. Rank the components based on preliminary results.
4. Perform improved analysis of selected equipment.

A number of components on the ESEL are breakers and switches that are housed in a "parent" component, such as a motor control center (MCC) or switchgear. For the purposes of this evaluation, calculations are not explicitly performed for these housed components. Instead, their HCLPF is assigned based on the parent component.

Seismic walkdowns as described in EPRI NP 6041 [4] are performed for all "parent" components on the ESEL [6]. Some ESEL components were walked down in February 2013, in
support of SPRA, and these walkdowns were credited, where applicable. The remaining components were walked down in May 2014, during a plant refueling outage.

HCLPF calculations are performed for all "parent" components [6], as described in Section 6.3, which describes the CDFM approach, and the calculation of structural and functional capacities.

### 6.2 HCLPF Screening Process

No components were screened out based on ruggedness. Rather, the screening level HCLPFs provided in Table 2-4 of EPRI 6041 [4] were utilized to develop mounting level capacities. HCLPF values are then calculated for each component on the ESEL, as described in Section 6.3.

### 6.3 SEISMIC Walkdown Approach

### 6.3.1 Seismic Walkdown Approach

The seismic walkdowns of BVPS-2 were performed in accordance with the criteria provided in Section 5 of EPRI 3002000704 [2], which refers to EPRI NP-6041 [7] for the SMA process. The procedures used for different equipment categories are summarized below.

The Seismic Review Team (SRT) reviewed equipment on the equipment walkdown list that were reasonably accessible and in non-radioactive or moderately radioactive environments. For components in high radioactive environments, a smaller team, and more hurried reviews were employed. For components that were not accessible, the equipment inspection relied on alternate means, such as photographs and plant qualification documents.

In the event the walkdown team had a reasonable basis for assuming that a group of components were similar and similarly anchored, a single representative component out of this group was selected for examination. The similarity of a group of items was established based on equipment construction, dimensions, locations, seismic qualification requirement, anchorage type, and configurations. The "similarity basis" was planned to be confirmed during walk bys, which would also record anomalies in installation or presence of seismic interaction, if any. The representative item was targeted for a thorough review and documentation. All "representative" and "walk by" items were fully documented in Seismic Evaluation Work Sheets (SEWS).

The SRT performed the walkdowns in an ad hoc manner. For each representative component, the SRT performed a thorough inspection and recorded information related to anchorage, load path configuration, and any potential seismic vulnerability associated to the component seismic capacity. These details recorded in SEWS were subsequently used to verify as-built conditions and determine seismic fragilities.

The 100 percent "walk by" is to look for outliers, lack of similarity, anchorage which is different from that shown on drawings or prescribed in criteria for that component, potential SI [Seismic Interaction ${ }^{1}$ ] problems, situations that are at odds with the team members' past experience, and any other areas of serious seismic concern. If any such concerns surface, then the limited sample size of one component of each type for thorough inspection will have to be increased. The increase in sample size, which should be inspected, will depend upon the number of outliers and different anchorages, etc., which are observed. It is up to the SRT to ultimately select the sample size since they are the ones who are responsible for the seismic adequacy of all elements which they screen from the margin review.

Walk bys also serve to provide the SRT with the sufficient degree of confidence in relation to plant maintenance and construction practices. This is especially used to reinforce the engineering judgment applied for the fragility assessment of inaccessible components. However, in case questionable construction practices are observed in the SSCs, then the system or component class must be inspected in closer detail until the systematic deficiency is defined.

For each item on the equipment walkdown list, a specific SEWS was prepared covering the different caveats. Each SEWS consists of:

- General description of the equipment: Equipment ID, Name, Equipment Category, and Building/Floor/Room
- Equipment Evaluation Caveats

[^1]- Equipment Anchorage
- Seismic Interaction Issues

A database of SEWS was developed in an electronic format using iPad Computers to facilitate entry of the information collected during the walkdowns. The database includes the record of equipment qualifications, walkdown observations, and photographs.

### 6.3.2 Application of Previous Walkdown Information

Previous seismic walkdowns were used to support the ESEP seismic evaluations. Some of the components on the ESEL were included in the NTTF 2.3 seismic walkdowns [15] and SPRA seismic walkdowns [16]. Those walkdowns were recent enough that they did not need to be repeated for the ESEP.

### 6.3.3 Significant Walkdown Findings

Consistent with the guidance from NP-6041 [7], no significant outliers or anchorage concerns were identified during the BVPS-2 seismic walkdowns. The SRT did not identify any potential seismic vulnerabilities associated to any of the screened-in ESEL components in BVPS-2.

### 6.4 HCLPF CALCULATION PROCESS

ESEL items in the BVPS-2 were evaluated using the criteria in EPRI NP-6041 [4]. Those evaluations included the following steps:

- Performing seismic capability walkdowns for equipment to verify the installed plant conditions
- Performing screening evaluations using the screening tables in EPRI NP-6041 as described in Section 6.2
- Performing HCLPF calculations considering various failure modes that include both structural failure modes (e.g., anchorage, and load path, etc.) and functional failure modes

All HCLPF calculations were performed using the CDFM methodology and are documented in a BVPS-2 Reference [6].

### 6.4.1 CDFM Approach

HCLPF values for functionality and anchorage are calculated for each representative component selected from the ESEL. The functional HCLPF for equipment is based on experience data, Generic Equipment Ruggedness Data (GERS), test response data, and design criteria. The functional evaluation is supplemented with the verification of the equipment anchorage following Seismic Qualification Utility Group (SQUG)/GIP procedures. The seismic demand on the equipment is based on the floor response spectra near the equipment support location, and the component damping values as recommended in EPRI 6041 [4].

The CDFM approach described in EPRI 1019200 [19] is utilized to obtain the component HCLPF values. The HCLPF capacities are stated in terms of a selected ground motion PGA. The CDFM approach is consistent with EPRI NP-6041-SL [4], updated to accommodate the parameters presented in Table 6-I.

The screening level HCLPF values provided in EPRI 6041 [4] Table 2-4 are presented in terms of the 5 Hz spectral acceleration at the foundation level. In accordance with EPRI 1019200 [19] these values are used to develop mounting level capacity assuming a median structure amplification factor of 1.5 . The ISRS described in Section 4.2 are compared with this mounting level capacity to develop HCLPF associated with the GMRS shape. Anchorage checks are performed based on the spectral accelerations at the estimated equipment frequencies.

TABLE 6-1
SUMMARY OF CONSERVATIVE DETERMINISTIC FAILURE MARGIN APPROACH (EPRI 1019200, TABLE A.1)

| TECHNICAL ISSUE | RECOMMENDED METHOD |
| :--- | :--- |
| Load Combination | Normal + SME. |
| Ground Response <br> Spectrum | Anchor CDFM Capacity to defined response spectrum shape <br> without consideration of spectral shape variability. |
| Seismic Demand | Perform seismic demand analysis in accordance with latest <br> version of American Society of Civil Engineers (ASCE) 4. |
| Damping | Conservative estimate of median damping. |
| Structural Model | BE (Median) + Uncertainty Variation in Frequency. |
| Soil Structure <br> Interaction | BE (Median) + Parameter Variation. |
| In-Structure (Floor) <br> Spectra Generation | Use frequency shifting rather than peak broadening to <br> account for uncertainty plus use conservative estimate of <br> median damping. |
| Material Strength | Code specified minimum strength or 95\% exceedance actual <br> strength if test data are available. |
| Static Strength | Code ultimate strength (ACI), maximum strength (AISC), <br> Service Level D (ASME), or functional limits. If test data <br> are available to demonstrate excessive conservatism of code <br> equations then use 84\% exceedance of test data for strength <br> equation. |
| Inelastic Energy | For non-brittle failure modes and linear analysis, use <br> appropriate inelastic energy absorption factor from <br> ASCE/SEI 43-05 to account for ductility benefits, or perform <br> Aonlinear analysis and go to 95\% exceedance ductility <br> levels. |

### 6.4.2 Component Structural Capacity

In general, the CDFM approach:

1. Develops the elastic seismic response for the structures and components for the ground motion.
2. Develops strength margin factor using component capacities as described in Table 6-1.
3. Develops inelastic energy absorption factor based on ASCE 43-05 or at about the 95 percent exceedance probability of ductility levels.
4. Calculates the CDFM capacity as:
$H C L P F_{C D F M}=F_{S} \cdot F_{\mu} \cdot P G A$
(Equation 6-1)
where,
$F_{S}=$ Strength margin factor,
$F_{\mu}=$ Inelastic energy absorption factor

The strength margin factor is defined as:

$$
F_{S}=\frac{s-D_{n s}}{D_{s}}
$$

(Equation 6-2)
where,
$S=$ Strength of the structural element
$D_{n s}=$ Non-seismic demand (normal operating loads)
$D_{S}=$ Seismic demand

### 6.4.3 Functional Evaluations

The HCLPF capacities for functionality are based on the comparison of the demand (ISRS) with EPRI 6041 [4] screening level HCLPFs, existing analysis, GERS, or test response spectra.

The screening level HCLPF values provided in EPRI 6041 [4] Table 2-4 are presented in terms of the 5 Hz spectral acceleration at the foundation level. In accordance with EPRI 1019200 [19], these values are used to develop mounting level capacity assuming a median structure amplification factor of 1.5 . The ISRS described in Section 5.2 are compared with this mounting level capacity to develop HCLPF associated with the GMRS shape. Anchorage checks are performed based on the spectral accelerations at the estimated equipment frequencies.

Available plant specific seismic qualifications tests are biaxial and all of the published GERS are constructed on the basis of the results of previous biaxial tests of similar types of equipment.

These tests apply table input motion in one-horizontal direction and in the vertical direction. For most equipment, for which GERS are available, the vertical test response spectrum (TRS) are at least equal to the horizontal TRS. The published GERS define the horizontal component of the table motion, which is, therefore, taken to represent the capacity stated either in terms of the vertical or horizontal input.

The seismic demand on equipment, on the other hand, is typically defined by ISRS in three orthogonal directions, two horizontal and one vertical. The procedure used to develop the functional capacity compares the resultant horizontal and the vertical ISRS separately with the GERS or TRS. The minimum seismic margin is taken to obtain the functional HCLPF capacity.

### 6.5 Functional Evaluations of Relays

The only relays applicable to FLEX mitigating strategies are the relays that automatically start the TDAFWP. All other plant control is local at the component.

The relays deenergize Solenoid-Operated Valves (SOVs) that directly control the supply of steam to the TDAFWP. Since the Vital DC power system is safety related and seismic, the SOVs remain energized and closed until the relays signal the SOVs to open and admit steam to the TDAFWP. Therefore, these relays were included for analysis. Both the relays that actuate on undervoltage of the 4 KV busses that supply power to the normal main feed pumps and the relays that actuate on low steam generator water level were included for the AS/G only, as only one success path is required for this evaluation.

These relays are slave relays in the solid state protection system and have no lock out function. Additionally, manual control from the control room is available to the operators, which deenergizes the SOVs directly, without the need for any relays. Finally, if DC is lost, such that there is no control power available to the control room, the SOVs fail open, directly admitting steam to the TDAFWP.

### 6.6 Tabulated ESEL HCLPF Values (Including Key Failure Modes)

Attachment B tabulates the HCLPF values for all components on the ESEL. All HCLPF values exceed the RLGM. The Table in Attachment B also identifies the method used to develop the

HCLPF values and the controlling failure mode. Most of the controlling failure modes are either anchorage failure or loss of functionality and do not involve structural integrity.

### 7.0 INACCESSIBLE ITEMS

### 7.1 Identification of ESEL items inaccessible for walkdowns

A total of seven items in the ESEL were inaccessible during walkdowns, mainly due to their location in confined spaces and high radiation areas. Table 7-1 provides the description of the seven inaccessible components, the reason for their inaccessibility and the criteria implemented to confirm the installed condition and, therefore, evaluate their seismic fragility. The criteria implemented to confirm the installed condition follows EPRI NP 6041 [7], where a number of ways of confirming the installed condition of equipment, including follow up walkdowns, photographic or other confirmatory evidence is provided.

TABLE 7-1
SUMMARY OF INACCESSIBLE ITEMS IN BVPS-2 ESEL

| COMPONENT ID | DESCRIPTION | REASON FOR <br> INACCESSIBLE | RESOLUTION |
| :---: | :--- | :--- | :--- |
| BV-2NMS-NE31 | Neutron Element - <br> Source Range <br> Neutron Monitor | High radiation <br> area (RCBX EL <br> 692) | Fragility is calculated based <br> on design documentation and <br> installation drawings [6]. |

### 8.0 ESEP CONCLUSIONS AND RESULTS

The conclusions and results of the ESEP evaluation are presented in this Section, including the identification of any required plant modifications and schedules for any follow up actions.

### 8.1 SUPPORTING INFORMATION

BVPS-2 has performed the ESEP as an interim action in response to the NRC's 50.54(f) letter [1]. The ESEP demonstrates that BVPS-2 has additional seismic margin plant equipment that can be relied upon to protect the reactor core following a beyond design basis seismic event. It was performed using the methodologies in the NRC endorsed guidance in EPRI 3002000704 [2].

The ESEP provides an important demonstration of seismic margin and expedites plant safety enhancements through evaluations and potential near-term modifications of plant equipment that can be relied upon to protect the reactor core following beyond design basis seismic events.

The ESEP is part of the overall BVPS-2 response to the NRC's 50.54(f) letter [1]. On March 12, 2014, Nuclear Energy Institute (NEI) submitted to the NRC results of a study [7] of seismic core damage risk estimates based on updated seismic hazard information as it applies to operating nuclear reactors in the Central and Eastern United States (CEUS). The study concluded that "site-specific seismic hazards show that there has not been an overall increase in seismic risk for the fleet of U.S. plants," based on the reevaluated seismic hazards. As such, the "current seismic design of operating reactors continues to provide a safety margin to withstand potential earthquakes exceeding the seismic design basis."

The NRC's May 9, 2014, NTTF 2.1 Screening and Prioritization letter [9] concluded that the "fleetwide seismic risk estimates are consistent with the approach and results used in the Gl-199 safety/risk assessment." The letter also stated that "as a result, the staff has confirmed that the conclusions reached in Gl-199 safety/risk assessment remain valid and that the plants can continue to operate while additional evaluations are conducted."

An assessment of the change in seismic risk for BVPS-2 was included in the fleet risk evaluation submitted in the March 12, 2014, NEI letter [7], therefore, the conclusions in the NRC's May 9 letter [9] also apply to BVPS-2.

In addition, the March 12, 2014, NEI letter [7] provided an attached "Perspectives on the Seismic Capacity of Operating Plants," which (1) assessed a number of qualitative reasons why the design of SSCs inherently contain margin beyond their design level, (2) discussed industrial seismic experience databases of performance of industry facility components similar to nuclear SSCs, and (3) discussed earthquake experience at operating plants.

The fleet of currently operating NPPS was designed using conservative practices, such that the plants have significant margin to withstand large ground motions safely. This has been borne out for those plants that have actually experienced significant earthquakes. The seismic design process has inherent (and intentional) conservatisms which result in significant seismic margins within SSCs. These conservatisms are reflected in several key aspects of the seismic design process, including:

- Safety factors applied in design calculations
- Damping values used in dynamic analysis of SSCs
- Bounding synthetic THs for ISRS calculations
- Broadening criteria for ISRS
- Response spectra enveloping criteria typically used in SSCs analysis and testing applications
- Response spectra based frequency domain analysis rather than explicit TH based time domain analysis
- Bounding requirements in codes and standards
- Use of minimum strength requirements of structural components (concrete and steel)
- Bounding testing requirements
- Ductile behavior of the primary materials (that is, not crediting the additional capacity of materials, such as steel and reinforced concrete beyond the essentially elastic range, etc.)

These design practices combine to result in margins, such that the SSCs will continue to fulfill their functions at ground motions well above the SSE.

The intent of the ESEP is to perform an interim action in response to the NRC's 50.54(f) letter [1] to demonstrate seismic margin through a review of a subset of the plant equipment that can be relied upon to protect the reactor core following beyond design basis seismic events. Because the SPRA for BVPS-2 is already under way, the GMRS used in the SPRA is also used as the RLGM for the ESEP evaluation. To more fully characterize the risk impacts of the seismic ground motion represented by the GMRS on a plant specific basis, a more detailed seismic risk assessment (SPRA or risk-based SMA) is being performed in accordance with EPRI 1025287 [10]. As identified in the BVPS-2 Seismic Hazard and GMRS submittal [3], BVPS-2 screens in for a risk evaluation. The complete risk evaluation will more completely characterize the probabilistic seismic ground motion input into the plant, the plant response to that probabilistic seismic ground motion input, and the resulting plant risk characterization. BVPS-2 will complete that evaluation in accordance with the schedule identified in NEI's letter dated April 9, 2013, [8] and endorsed by the NRC in their May 7, 2013 letter [11].

### 8.2 Identification of Planned Modifications

As discussed in Section 6.6 and presented in Attachment B, all components on the ESEL have a HCLPF greater than the RLGM $(0.24 \mathrm{~g})$. Therefore, no modifications related to the ESEP are planned.

### 8.3 Modification Implementation Schedule

As no modifications are planned, this Section is not applicable.

### 8.4 Summary of Regulatory Commitments

None
