Rod Bundle Heat Transfer Facility Steam Cooling with Droplet Injection Experiments Data Report

Office of Nuclear Regulatory Research

AVAILABILITY OF REFERENCE MATERIALS IN NRC PUBLICATIONS

NRC Reference Material

As of November 1999, you may electronically access NUREG-series publications and other NRC records at NRC's Library at www.nrc.gov/reading-rm.html. Publicly released records include, to name a few, NUREG-series publications; *Federal Register* notices; applicant, licensee, and vendor documents and correspondence; NRC correspondence and internal memoranda; bulletins and information notices; inspection and investigative reports; licensee event reports; and Commission papers and their attachments.

NRC publications in the NUREG series, NRC regulations, and Title 10, "Energy," in the *Code of Federal Regulations* may also be purchased from one of these two sources.

1. **The Superintendent of Documents**
   U.S. Government Publishing Office
   Mail Stop IDCC
   Washington, DC 20402-0001
   Internet: bookstore.gpo.gov
   Telephone: (202) 512-1800
   Fax: (202) 512-2104

   1-800-553-6847 or, locally, (703) 605-6000

A single copy of each NRC draft report for comment is available free, to the extent of supply, upon written request as follows:

Address: **U.S. Nuclear Regulatory Commission**
Office of Administration
Publications Branch
Washington, DC 20555-0001
E-mail: distribution.resource@nrc.gov
Facsimile: (301) 415-2289

Some publications in the NUREG series that are posted at NRC's Web site address www.nrc.gov/reading-rm/doc-collections/nuregs are updated periodically and may differ from the last printed version. Although references to material found on a Web site bear the date the material was accessed, the material available on the date cited may subsequently be removed from the site.

Non-NRC Reference Material

Documents available from public and special technical libraries include all open literature items, such as books, journal articles, transactions, *Federal Register* notices, Federal and State legislation, and congressional reports. Such documents as theses, dissertations, foreign reports and translations, and non-NRC conference proceedings may be purchased from their sponsoring organization.

Copies of industry codes and standards used in a substantive manner in the NRC regulatory process are maintained at—

The NRC Technical Library
Two White Flint North
11545 Rockville Pike
Rockville, MD 20852-2738

These standards are available in the library for reference use by the public. Codes and standards are usually copyrighted and may be purchased from the originating organization or, if they are American National Standards, from—

American National Standards Institute
11 West 42nd Street
New York, NY 10036-8002

ABSTRACT

As part of the Nuclear Regulatory Commission safety analysis computer code development efforts, the Rod Bundle Heat Transfer (RBHT) test facility has been designed and constructed at The Pennsylvania State University. The test series described in this report is the steam cooling tests with droplet injection. A total of 85 steady-state steam cooling experiments with prescribed droplet injection was performed in the RBHT. The purpose of the experiments was to examine steady-state dispersed flow film boiling in prototypical rod bundle geometry for computer code model development and validation.

The Rod Bundle Heat Transfer facility is a full length, 3.66 m (12 ft.), 7 by 7 rod array with typical Pressurized Water Reactor rod diameters of 9.49 mm (0.374 in.) and a rod pitch of 12.59 mm (0.496 in.). The heater rods have a top skewed power shape with a peak to average power of 1.5 at the 2.74 m (9 ft.) elevation. The RBHT facility has been designed using prototypical mixing vane spacer grids.

The bundle inlet steam Reynolds number ranged from 2000 to 15,000 with most of the experiments at the lower Reynolds number range. The droplets were injected upward in the center of the sub-channels at the 1.295 m (51 in.) elevation using two or four injection tubes. The injection tubes used a single row, linear hole pattern of four holes per sub-channel and four sub-channels per tube in the center of the bundle. One additional hole was located at the center of the rod gap location to minimize the chance of local boiling in the injection tube. The hole sizes used were 0.381 mm (0.015 in.) and 0.254 mm (0.01 in.). The injection tubes were bench tested before the bundle tests to optimize the performance of the liquid jets such that the injected droplets would flow upwards in the center of the sub-channel. The droplet sizes issuing from the holes were also measured. The selected hole sizes would produce drops that were typical of the drop sizes observed in the RBHT and FLECHT-SEASET reflood experiments.

FOREWORD

A loss-of-coolant accident (LOCA) is one of the primary postulated accidents that must be considered in the design of nuclear power plants. The plant response to such an accident, including the performance of safety systems that are designed to mitigate the accident, is mainly analyzed using computer codes. For effective analyses of accidents and operational transients, the U.S. Nuclear Regulatory Commission (NRC) consolidated earlier thermal-hydraulics analysis codes into one called TRACE.

The NRC is now assessing and improving the TRACE code as weaknesses are identified. One such weakness is inaccurate prediction of peak clad temperatures of fuel rods, particularly in the later stage of a large-break (LB) LOCA, called the reflood phase. Specifically, the reflood models currently employed in the TRACE code are not sufficiently accurate and, consequently, improved models must be developed to provide necessary support for risk-informed regulations. Accurate prediction of the consequences of an LBLOCA is important because this is one of the limiting postulated accidents used to determine whether plant design parameters (such as power densities, equipment sizes, etc.) have been appropriately selected to ensure safety. As the NRC places increasing emphasis on risk-informed regulations, the agency needs a more accurate and reliable computer code to obtain realistic (rather than conservative) predictions.

To develop better computer code models for an LBLOCA, we need detailed, fundamental data that show heat, mass, and momentum exchanges. Some of these detailed data have only recently become possible because of recent advances in instrumentation technology for two-phase flow measurements. Consequently, to acquire detailed, fundamental data for use in developing models for an LBLOCA, the NRC sponsored the construction of a rod bundle heat transfer (RBHT) test facility and completion of four test series; reflood tests, liquid-gas interfacial drag tests, steam cooling tests without liquid droplet injection, and steam cooling tests with liquid droplet injection.

This report presents the results of steam cooling with droplet injection tests. The data from these tests will be used to develop and assess the droplet model which is a component of a LOCA model for the TRACE code. The results of other test series will be reported in separate reports.

With improved data and code models for an LBLOCA, we can more accurately predict the consequences of LBLOCA accidents and provide better technical bases for regulations associated with such accidents. As a result, this study will help to achieve the NRC's strategic performance goals of making the agency's regulations more effective, efficient, and realistic.

EXECUTIVE SUMMARY

As part of the Nuclear Regulatory Commission safety analysis computer code development efforts, the Rod Bundle Heat Transfer (RBHT) test facility has been designed and constructed at The Pennsylvania State University to provide data and associated analysis to help support the code development efforts. This report describes one of the test series in the RBHT which included 85 steady-state steam cooling experiments with prescribed droplet injection. The purpose of the experiments was to examine steady-state dispersed flow film boiling in a prototypical rod bundle geometry for computer code model development and validation.

The Rod Bundle Heat Transfer (RBHT) facility is a full length simulation of a portion of a Pressurized Water Reactor (PWR) fuel assembly. The bundle is a 7 x 7 rod array with four unheated corner rods and 45 heated electrical rod which simulate a 17 x 17 PWR fuel assembly. The Rod Bundle Heat Transfer facility is full length, 3.66 m (12 ft.), with typical PWR rod diameters of 9.49 mm (0.374 in.) and a rod pitch of 12.59 mm (0.496 in.). The heater rods have a top skewed power shape with a peak to average power of 1.5 at the 2.74 m (9 ft.) elevation.

The droplet flow rates were estimated from examination of the RBHT and FLECHT-SEASET reflood experiments so as to obtain approximately the same two-phase quality behavior in the bundle with droplet injection. A droplet injector was designed and tested to provide the prescribed liquid flow rates at or very near the saturation temperature at the pressure of the experiments. It was found that the jet injection behavior was very sensitive to the temperature of the injection temperature or subcooling since high subcoolings would cause condensation and would collapse the droplet jet into a single stream.

The bundle inlet steam Reynolds number ranged from 2000 to 15,000 with most of the experiments at the lower Reynolds number range. The droplets were injected upward in the center of the sub-channels at the 1.295 m (51 in.) elevation using two or four injection tubes. The injection tubes used a single row, linear hole pattern of four holes per sub-channel and four sub-channels per tube such that the injection was in the center sub-channels of the bundle. One additional hole was located at the center of the rod gap location to minimize the chance of local boiling in the injection tube. The hole sizes used were 3.81 mm (0.015 in.) and 0.254 mm (0.01 in.). The injection tubes were bench tested before the bundle tests to optimize the performance of the liquid jets such that the injected droplets would flow upwards in the center of the sub-channel rather than impact the heater rods, causing early rod quench. The droplet sizes issuing from the holes were also measured. The selected hole sizes would produce drops that were typical of the drop sizes observed in the RBHT and FLECHT-SEASET reflood experiments.

The experiments were performed using a constant power rather than simulating the reactor decay power. The use of a constant bundle power enabled the bundle to reach a steady-state condition which then resulted in quasi-steady film boiling over the majority of the bundle length with droplet injection. There were approximately 500 channels of transient data recorded for each test including the bundle power, heater rod temperatures, upper plenum pressure, inlet flow rate, inlet water temperature, superheated vapor temperatures in the bundle, spacer grid temperatures, liquid carryout of the bundle, and the detailed axial bundle pressure drop. The experiments indicated the non-equilibrium behavior of the superheated steam with entrained saturated droplets. The experimental data has been qualified and submitted to the Nuclear Regulatory Data bank for analysis and computer code validation.

APPENDIX A. DATA PLOTS FOR INDIVIDUAL EXPERIMENTS

(CONTINUING FROM TEST 4042G)

RBHT Steam Cooling with Droplet Injection Test SCD-4042-G

Matrix Test # 2c

Test Conditions

Test Date – 11/1/2005
Steady State Time Window: 19620 – 20280
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 55.0 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.7 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.011 kg/s (0.024 lbm/s)
Droplet Injection Hole Diameter: 0.381 mm (.015 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4042-H

Matrix Test # 2d

Test Conditions

Test Date – 11/1/2005
Steady State Time Window: 21180 – 21900
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 55.0 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.7 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0145 kg/s (0.032 lbm/s)
Droplet Injection Hole Diameter: 0.381 mm (.015 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4042-K

Matrix Test # 1c

Test Conditions

Test Date – 11/1/2005
Steady State Time Window: 22860 – 23760
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 28.9 kW
Bundle Inlet Reynolds Number: 2000
Bundle Inlet Steam Flow: 40.86 kg/hr (90 lbm/hr)
Droplet Injection Flow: 0.0108 kg/s (0.024 lbm/s)
Droplet Injection Hole Diameter: 0.381 mm (.015 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4049-A

Matrix test # 6A

Test Conditions

Date – 11/09/2005
Steady state time window: 13320 - 14280 sec
Inlet steam flow: 5.92 m^3/min (209 ft^3/min)
Inlet steam temperature: 417 K (291 °F)
Droplet injection flow: 0.0036 kg/sec (0.0079 lbm/sec)
Droplet injection temperature: 380 K (225 ^oF)
Upper plenum pressure: 138.6 kPa (20.1 psia)
Bundle power: 110.0 kW
Outlet steam temperature: 656 K (721 °F)
Bundle inlet Reynolds number: 15000

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4049-B

Matrix Test # 6b

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 15000 - 18240
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 110 kW
Bundle Inlet Reynolds Number: 15000
Bundle Inlet Steam Flow: 301.6 kg/hr (665 lbm/hr)
Droplet Injection Flow: 0.0072 kg/s (0.016 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4049-C

Matrix Test # 6c

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 18720 - 19140
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 110 kW
Bundle Inlet Reynolds Number: 15000
Bundle Inlet Steam Flow: 301.6 kg/hr (665 lbm/hr)
Droplet Injection Flow: 0.0108 kg/s (0.024 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4049-D

Matrix Test # 6d

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 19440 - 20040
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 110 kW
Bundle Inlet Reynolds Number: 15000
Bundle Inlet Steam Flow: 301.6 kg/hr (665 lbm/hr)
Droplet Injection Flow: 0.0144 kg/s (0.032 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4049-E

Matrix Test # 5a

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 20820 - 21300
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 75 kW
Bundle Inlet Reynolds Number: 10000
Bundle Inlet Steam Flow: 181.4 kg/hr (400 lbm/hr)
Droplet Injection Flow: 0.0036 kg/s (0.008 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4049-F

Matrix Test # 5b

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 21900 - 24000
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 75 kW
Bundle Inlet Reynolds Number: 10000
Bundle Inlet Steam Flow: 181.4 kg/hr (400 lbm/hr)
Droplet Injection Flow: 0.0072 kg/s (0.016 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4049-G

Matrix Test # 5c

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 24600 - 24900
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 75 kW
Bundle Inlet Reynolds Number: 10000
Bundle Inlet Steam Flow: 181.4 kg/hr (400 lbm/hr)
Droplet Injection Flow: 0.0108 kg/s (0.024 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4049-H

Matrix Test # 5d

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 25680 - 25920
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 75 kW
Bundle Inlet Reynolds Number: 10000
Bundle Inlet Steam Flow: 181.4 kg/hr (400 lbm/hr)
Droplet Injection Flow: 0.0144 kg/s (0.032 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4049-I

Matrix Test # 4a

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 26940 - 27360
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 65 kW
Bundle Inlet Reynolds Number: 8000
Bundle Inlet Steam Flow: 144.2 kg/hr (318 lbm/hr)
Droplet Injection Flow: 0.0036 kg/s (0.008 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4049-J

Matrix Test # 4b

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 28440 - 29760
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 65 kW
Bundle Inlet Reynolds Number: 8000
Bundle Inlet Steam Flow: 144.2 kg/hr (318 lbm/hr)
Droplet Injection Flow: 0.0072 kg/s (0.016 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4049-K

Matrix Test # 4c

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 30420 - 30720
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 65 kW
Bundle Inlet Reynolds Number: 8000
Bundle Inlet Steam Flow: 144.2 kg/hr (318 lbm/hr)
Droplet Injection Flow: 0.0108 kg/s (0.024 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4049-L

Matrix Test # 4d

Test Conditions

Test Date – 11/9/2005
Steady State Time Window: 31140 - 31440
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 65 kW
Bundle Inlet Reynolds Number: 8000
Bundle Inlet Steam Flow: 144.2 kg/hr (318 lbm/hr)
Droplet Injection Flow: 0.0144 kg/s (0.032 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4053-A

Matrix Test # 12a

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 11160 - 11820
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 60 kW
Bundle Inlet Reynolds Number: 6000
Bundle Inlet Steam Flow: 122.5 kg/hr (270 lbm/hr)
Droplet Injection Flow: 0.0036 kg/s (0.008 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4053-B

Matrix Test # 12b

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 12300 - 13680
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 60 kW
Bundle Inlet Reynolds Number: 6000
Bundle Inlet Steam Flow: 122.5 kg/hr (270 lbm/hr)
Droplet Injection Flow: 0.0072 kg/s (0.016 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4053-C

Matrix Test # 12c

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 14400 - 14880
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 60 kW
Bundle Inlet Reynolds Number: 6000
Bundle Inlet Steam Flow: 122.5 kg/hr (270 lbm/hr)
Droplet Injection Flow: 0.0108 kg/s (0.024 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4053-D

Matrix Test # 12d

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 15780 - 18120
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 60 kW
Bundle Inlet Reynolds Number: 6000
Bundle Inlet Steam Flow: 122.5 kg/hr (270 lbm/hr)
Droplet Injection Flow: 0.0144 kg/s (0.032 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4053-E

Matrix Test # 11a

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 18120 - 18900
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 55 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0036 kg/s (0.008 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4053-F

Matrix Test # 11b

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 20100 - 21540
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 55 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0072 kg/s (0.016 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4053-G

Matrix Test # 11c

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 22380 - 22920
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 55 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0108 kg/s (0.024 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4053-H

Matrix Test # 11d

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 23940 - 24360
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 55 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0144 kg/s (0.032 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4053-I

Matrix Test # 10a

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 25320 - 25920
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 29 kW
Bundle Inlet Reynolds Number: 2000
Bundle Inlet Steam Flow: 40.82 kg/hr (90 lbm/hr)
Droplet Injection Flow: 0.0036 kg/s (0.008 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4053-J

Matrix Test # 10b

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 26400 - 27600
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 29 kW
Bundle Inlet Reynolds Number: 2000
Bundle Inlet Steam Flow: 40.82 kg/hr (90 lbm/hr)
Droplet Injection Flow: 0.0072 kg/s (0.016 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4053-K

Matrix Test # 10c

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 28200 - 28560
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 29 kW
Bundle Inlet Reynolds Number: 2000
Bundle Inlet Steam Flow: 40.82 kg/hr (90 lbm/hr)
Droplet Injection Flow: 0.0108 kg/s (0.024 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4053-L

Matrix Test # 10d

Test Conditions

Test Date – 11/18/2005
Steady State Time Window: 28800 - 29280
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 29 kW
Bundle Inlet Reynolds Number: 2000
Bundle Inlet Steam Flow: 40.82 kg/hr (90 lbm/hr)
Droplet Injection Flow: 0.0144 kg/s (0.032 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- No steam probes were traversed in this steady state window.

RBHT Steam Cooling with Droplet Injection Test SCD-4055-A

Matrix Test # 13b

Test Conditions

Test Date – 11/23/2005
Steady State Time Window: 13980 - 15660
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 50 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0072 kg/s (0.016 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4055-B

Matrix Test # 13c

Test Conditions

Test Date – 11/23/2005
Steady State Time Window: 16800 - 17880
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 50 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0108 kg/s (0.024 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4055-C

Matrix Test # 13d

Test Conditions

Test Date – 11/23/2005
Steady State Time Window: 19260 - 20280
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 50 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0144 kg/s (0.032 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4055-D

Matrix Test # 13a

Test Conditions

Test Date – 11/23/2005
Steady State Time Window: 21600 - 23700
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 50 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0036 kg/s (0.008 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4076-A

Matrix Test # 14a

Test Conditions

Test Date – 12/13/2005
Steady State Time Window: 12120 - 18300
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 50 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0036 kg/s (0.008 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4076-B

Matrix Test # 14b

Test Conditions

Test Date – 12/13/2005
Steady State Time Window: 19500 - 23700
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 50 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0072 kg/s (0.016 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4076-C

Matrix Test # 14c

Test Conditions

Test Date – 12/13/2005
Steady State Time Window: 24420 - 27600
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 50 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0108 kg/s (0.024 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

RBHT Steam Cooling with Droplet Injection Test SCD-4076-D

Matrix Test # 14d

Test Conditions

Test Date – 12/13/2005
Steady State Time Window: 28200 - 31620
Upper Plenum Pressure: 1.38 bar (20 psia)
Bundle Power: 50 kW
Bundle Inlet Reynolds Number: 4000
Bundle Inlet Steam Flow: 81.65 kg/hr (180 lbm/hr)
Droplet Injection Flow: 0.0144 kg/s (0.032 lbm/s)
Droplet Injection Hole Diameter: 0.254 mm (.010 in)
Droplet Injection Elevation: 1.295 m (51 in)
Bundle Flow Area: 4.656×10^{-3} m^2 (5.012×10^{-2} ft^2)

Test Notes

- Steam probes at 237.57 cm and 254.0 cm (93.53 in. and 100 in.) were traversed in this steady state window.
- Camera focal length was varied in this steady state window

APPENDIX B. UNCERTAINTIES

The measurement errors in the calculations performed for the analysis are described herein. The first section contains the error analysis for temperature, pressure and flow measurements. The next section includes the description of the error analysis performed for the heat transfer calculations. The final section provides uncertainties for the droplet data measurements.

B.1 Measurement Uncertainty

The instrumentation error associated with the data from RBHT test series can be derived either from equipment manufacturers' specifications or system calibration data. Component calibrations are performed to verify that the manufacturers' specifications are met, and these manufacturers' specifications are used to compute the error estimate for the data path. System calibrations are performed when component calibrations are not expedient or when an accuracy improvement could be accomplished with a system calibration. The system calibration data are used to compute an estimate of error for the system response, and calibration data points. The total system error from a system calibration is a function of both system response error and calibration data error.

In all cases of error estimate, the standard deviation has been computed and presented as the most probable error. The manufacturer-specified error is the maximum possible error. The standard deviation error is calculated from the maximum error by the following:

$$\rho^2 = \sum_{i=1}^{n}\left(\frac{E_i^2}{n}\right) \tag{B-1}$$

where,

ρ = data path standard deviation
E_i^2 = component i maximum error
n = number of sources of error

When a system calibration is performed, the standard deviation from the calibration data and that from the calibration equipment can be combined by the following equation to produce the best estimate of error:

$$\rho = \sqrt{E_d^2 + E_c^2} \tag{B-2}$$

where,

E_d = calibration data standard deviation
E_c = calibration equipment standard deviation

The calibration data standard deviation is a measure of the error involved in fitting the calibration data. That is,

$$E_d = \left[\frac{\sum_{i=1}^{n} (Y_i - Y_f)^2}{n} \right]^{1/2} \quad \text{(B-3)}$$

where,

Y_i = calibration point
Y_f = predicted output from the calibrations curve
n = number of calibration points

The calibration equipment standard deviation is a measure of the absolute error of the calibration point. If the calibration point in the above equation is calculated from an equation of the form

$$Y = (x_1)(x_2)(x_3) \quad \text{(B-4)}$$

then

$$\left(\frac{\sigma_y}{y} \right)^2 = \sum_{i=1}^{n} \left(\frac{\sigma_{x_i}}{x} \right)^2 \quad \text{(B-5)}$$

and

$$E_c = \sqrt{\sigma_y^2} \quad \text{(B-6)}$$

The data path has been broken down into three parts called sensor, conditioner, and readout. The sensor is the device whose electrical output is proportional to a physical quantity (temperature, pressure, flow, power). The conditioner is a device which matches the electrical output of the sensor to the input requirements of the readout device. The readout device measures and records the electrical value of the signal from the conditioner. This recorded electrical value is subsequently used to compute the physical quantity it represents. The errors due to the transmission wire errors are very small (±0.001 percent) in comparison to the element errors and are considered negligible.

The error values for sensor, conditioning, and readout are the manufacturers' specifications in engineering units. These numbers are used to compute the most probable error, as previously described. Where systems calibrations are performed, the equipment calibration data provide the standard deviation and maximum error as computed from the calibration data points in fitting the points to a first-order polynomial. The calibration point standard deviation is computed using the method described above. The calibration point maximum error occurs simultaneously in each component of the calibration equation. The overall system standard deviation may then be calculated using Equation (B-2).

The calculated Total Probable errors using Equation (B-2) for each instrumentation channel are shown in the following tables:

Table B-1 - Temperature measurements including the heater rods, grid fluid, grid walls, support rods, steam probe rakes, flow housing walls, flow housing insulation, vessel and piping walls, and quartz windows thermocouples.

Table B-2 - Differential pressure cells (D/P's), static pressure transducers (P's), and vessels liquid label transducers.

Table B-3 - Inlet Mass and exhaust steam flows transmitters (FM)

Table B-4 - Steam probe rakes linear position transmitter.

Table B-5 - Heater Rod Bundle input voltage (V), amperage (Amps), and Power measurements (W).

B.2 Heat Transfer Coefficient Uncertainty Analysis

The purpose of this uncertainty analysis was to estimate the confidence limits in the heat transfer coefficients calculated for heater rods in the Rod Bundle Heat Transfer Facility (RBHT) bundle test series using the uncertainty analysis performed on the FLECHT-SEASET heater rods. It is believed that the uncertainty geometry analysis performed on the FLECHT-SEASET heater rods is applicable to the RBHT heater rods since the construction and materials are the same or very similar.

The uncertainty analysis used the FLECHT-SEASET heat transfer coefficients calculated from test data, using DATARH. The sensitivity of the heat transfer coefficient to variations in the test data and heater rod design was also calculated by the code. This code solves an inverse heat conduction problem using a finite-difference technique.

The uncertainty analysis used standard statistical treatment of independent uncertainty components to establish 1σ and 2σ confidence intervals on the total uncertainty in the heat transfer coefficient. Individual uncertainty components were obtained from either heater rod inspection data, physical informational, or professional experience and judgment. Each component of the total uncertainty was assumed to be independent, and of known variance.

The FLECHT SEASET unblocked bundle test series utilized stainless steel clad, boron nitride filled heater rods with coiled Kanthal wire heating elements (Figure B-1). For the RBHT the cladding was Inconel not stainless steel but the remaining of the heater rod design was the same. The other properties were the same. In the instrumented heated rods, thermocouples were located at several different axial locations on the inside wall of the cladding. The thermocouple output was used in the DATARH code to compute the heat transfer coefficient. The code input requires density, specific heat, and thermal conductivity for the heater rod materials and geometric details of the heater coil.

The heater rod geometric input included clad inside and outside diameters and thermocouple radial location. Code input from the FLECHT SEASET bundle test instruments included thermocouple temperature, bundle pressure, and SCR power output.

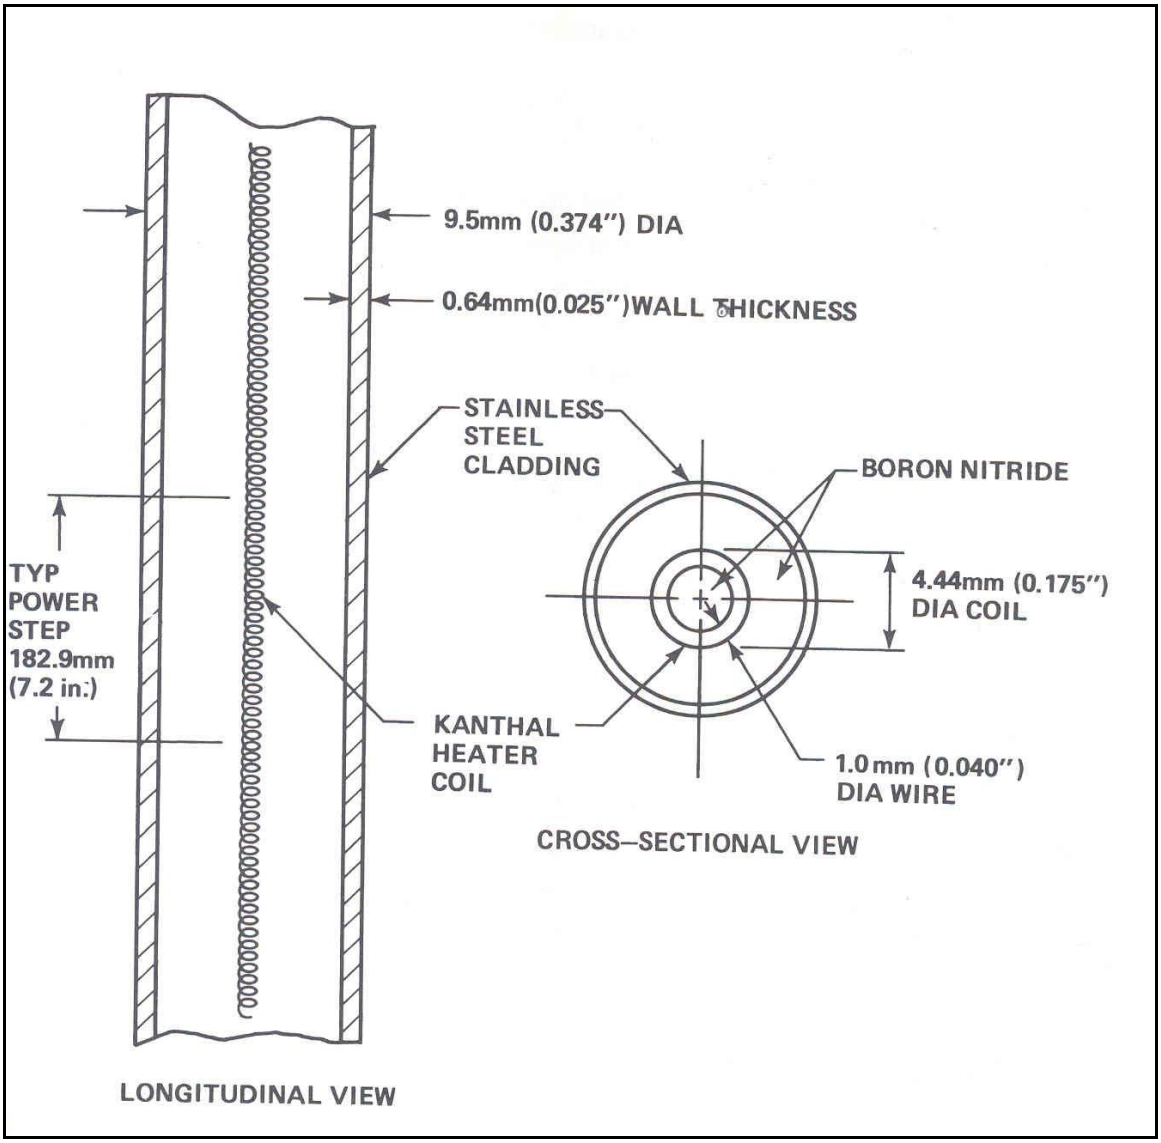

Figure B-1: Heater Rod Design

The heat transfer coefficient may be expressed as

$$h = h[x_1, x_2, ...x_n] \tag{B-7}$$

where x_i (i = 1, 2, . . . n) are the individual parameters that affect the heat transfer coefficient h. The statistical variation of calculated h about its expected value may be expressed by expanding the function $h[x_1,x_2,.....x_n]$ in a multivariable Taylor series.

Including only first-order terms, the result is

$$h[x_1, x_2, ...x_n] - E[h] = \sum_{i=1}^{n} \left(\frac{\partial h}{\partial x_i} \right)_{\bar{x}} \{x_i - E[x_i]\} \quad \text{(B-8)}$$

or

$$\Delta h = \sum_{i=1}^{n} \left(\frac{\partial h}{\partial x_i} \right)_{\bar{x}} \Delta x_i \quad \text{(B-9)}$$

where the derivatives are evaluated using the means of all the random variables x_i (denoted by $\bar{x}$). E[h] is the expected or mean value of the function h, that is, h evaluated at the means of the random variables x_i. Each $(\partial h / \partial x_i)_{\bar{x}} \Delta x_i$ term also is a random variable with a mean of zero and a variance given by

$$\text{var} \left(\frac{\partial h}{\partial x_i} \right)_{\bar{x}} \Delta x_i = \left(\frac{\partial h}{\partial x_i} \right)_{\bar{x}}^2 \sigma_{x_i}^2 = \sigma_{\Delta h_i}^2 \quad \text{(B-10)}$$

where $(\partial h / \partial x_i)_{\bar{x}}$ is constant for given $\bar{x}$.

Assuming the $(\partial h / \partial x_i)_{\bar{x}} \Delta x_i$ terms are independent, the mean of Δh becomes

$$E[\Delta h] = \sum_{i=1}^{n} \left(\frac{\partial h}{\partial x_i} \right)_{\bar{x}} E[\Delta x_i] = 0 \quad \text{(B-11)}$$

and the variance of Δh is

$$\sigma_{\Delta h}^2 = \sum_{i=1}^{n} \sigma_{\Delta h_i}^2 = \sum_{i=1}^{n} \left(\frac{\partial h}{\partial x_i} \right)_{\bar{x}}^2 \sigma_{x_i}^2 \quad \text{(B-12)}$$

Approximating the $(\partial h / \partial x_i)_x$ terms by $(\Delta h / \Delta x_i)_x$, the variance becomes

$$\sigma_{\Delta h}^2 = \sum_{i=1}^{n} \left(\frac{\Delta h_i}{\Delta x_i} \right)_{\bar{x}}^2 \sigma_{x_i}^2 \quad \text{(B-13)}$$

A consequence of the central limit theorem in statistics is that the distribution of the uncertainty calculated above approaches a normal distribution. With a known distribution function, the confidence interval of the uncertainty can be calculated from the variance. The 1σ (70 percent) and 2σ (95 percent) confidence intervals are reported in this evaluation.

These values were obtained by individually perturbing each parameter x_i from its expected value by its estimated standard deviation in numerous runs of the DATARH code. Each perturbation resulted in a new value of calculated h, from which the nominal or expected value was subtracted to provide a Δh_i. Since in these perturbations Δx_i was assumed to be equal to σ_{x_i}, the variance can be evaluated by simply summing the squares of the resultant Δh_i terms:

$$\sigma^2_{\Delta_h} = \sum_{i=1}^{n} \Delta^2_{h_i} \tag{B-14}$$

Positive and negative Δh_i terms $(\Delta h_i^+, \Delta h_i^-)$ were obtained by perturbing each x_i both above and below its expected value. They are indicative of the heat transfer coefficient's sensitivity to uncertainty in each parameter, and were statistically combined to provide bother upper and lower uncertainty bands on calculated h. Differences for each Δh_i^+ and Δh_i^- are due to nonlinearities in the function h [x_1, x_2, . . . x_n].

Uncertainty in the heat transfer coefficient, h, calculated by the DATARH code stems from the following factors:

- Uncertainty in the measured test parameters input to the program
- Uncertainty due to manufacturing tolerances on heater rod dimensions and instrumentation location
- Material property uncertainties

Measured test parameters that are input to DATARH are bundle power, pressure, and clad inside temperature.

The uncertainty in the measured parameters is combined with other sources of uncertainty by summing the variance of each uncertainty component. For the test instruments, the instrument uncertainty was assumed to be uniformly distributed over the uncertainty interval. The variance of a uniformly distributed random variable over the interval $-\alpha < x < \alpha$ is $\alpha^2/_3$. The total instrument uncertainty consists of uncertainty in the sensor, in signal conditioning equipment, and in recording the signal. The variance of each of these components was calculated as described above and summed to get the total variance of the instrument uncertainty. Transducer uncertainty is normally dominant, and thus total uncertainty and transducer uncertainty will be very similar.

The standard deviation (that is, the positive square root of the variance) and maximum uncertainty for each data path are shown in Table B-1 through Table B-5. The maximum uncertainty was calculated by summing the maximum uncertainty of all contributors to the total instrument uncertainty.

Manufacturing tolerances on rod dimensions and instrumentation location also contribute to uncertainty in the calculated heat transfer coefficient h. Heater coil dimensions, clad inside and outside diameters, and thermocouple locations are incorporated in the DATARH geometric heater rod model, because they are possible contributors to uncertainty in h. Uncertainty in the

thermocouple radial location was estimated from X-ray inspection of actual heater rods. Clad outside diameter uncertainty was obtained from the rod inspection data. Uncertainty in clad inside diameter was estimated by combining the uncertainty in clad outside diameter with the uncertainty in clad thickness.

Axial power is also a factor. In FLECHT SEASET heater rods, the number of heater coil turns per inch (coil spacing) is variable (Figure B-1); this changes the length of heater wire per unit length of heater rod. From the X-ray radiographs of the heater rods, the geometry of the axial power steps was determined. Similar approach has been used for the RBHT heater rods.

The rod inspection data do not reflect any variation in the diameter of the Kanthal heater wire. The wire diameter was nominally 0.10 cm (0.040 in.), and small variations in diameter were beyond the resolution of the radiograph. To estimate the uncertainty due to wire diameter variation, the assumption was made that the local variation in wire resistance due to the wire cross-sectional area variation could be approximated from the variation in heater rod resistance between rods.

Uncertainty in the physical properties of the material in the heater rods was based largely on engineering judgment. The boron nitride density uncertainty was based on a sample of five measurements from sections of heater rods that were destructively analyzed.

The input parameters for power factor ($P_{local}/P_{average}$) determination are local step length, total heated length, local step length coil resistance, and total heated length coil resistance. An analysis identical to that discussed was performed for this calculation, varying the input parameters by the estimated standard deviations. Estimated power factor parameter uncertainties are show in Table B-6, and the power factor uncertainty analysis in Table B-7.

Table B-6: Uncertainty of Power

ESTIMATED UNCERTAINTY OF POWER FACTOR CALCULATION

Parameter	Estimated Uncertainty[(a)]	Best-Estimated Value	Reference/ Comments
Step length	±0.06 in.	14.52 in.	Rod inspection data
Step resistance	±0.03%	3.595 Ω	Rod inspection data
Total length	±0.06 in.	144.48 in.	Rod inspection data
Total resistance	±0.03%	21.60 Ω	Rod inspection data

a. All uncertainties are listed at the 1 σ level.

Table B-7 summarizes the certainties of all the parameters used by DATARH to calculate the FLECHT SEASET heat transfer coefficient. These uncertainties were evaluated at the 1Φ level. The uncertainties in Table B-8 for the heater rod material properties are expected to be similar as the same uncertainties used for the RBHT heater rods since the design and materials are similar.

Other sources of uncertainties that could lead to increased uncertainty in the value of h were reviewed; however, for the most part, they were of relatively minor importance and their absence in this analysis would not be significant. Those other factors were as follows:

- Induction and skin effects - These effects of high-frequency components of the chopped ac power were neglected.

- Wire effective length - Analytically, the effective length for a tightly coiled wire is less than the length based on the helix mean radius (which is used in DATARH). However, this source of uncertainty is the same for each wire and will cancel out in the relative power calculation. Therefore, such a correction was not required.

- Electrical resistivity variation with temperature at rod quench - Changes in rod temperature distribution will affect the local. P/P_{avg}. For example, if half the rod is quenched, resistivity in the upper half could be as much as 4 percent greater than that in the lower half, and power would be redistributed within the rod. Since there was no method by which this could be accounted for proportionately, this effect was ignored.

- Kanthal heater helix position - The heater coil may be slightly off center in the rod. This effect was analyzed by varying the coil diameter; however, no coil displacement was examined.

- Thermocouple axial location - The thermocouples were located well within a given power step. Axial conduction in the heater rod in the vicinity of the thermocouples was assumed to be small and axial conduction effects were ignored.

Table B-7: Thermocouple Power Factor Uncertainty Analysis

THERMOCOUPLE POWER FACTOR UNCERTAINTY ANALYSIS

Parameter	Calculated P/P_{avg} (a)	$\Delta(P/P_{avg})^{+}$ (b)	$\Delta(P/P_{avg})^{-}$
Nominal case	1.6561		
Step length + 0.06 in.	1.6493		-0.0068
Step length - 0.06 in.	1.6630	0.0069	
Step resistance + 0.03%	1.6566	0.0005	
Step resistance - 0.03%	1.6556		-0.0005
Total length + 0.06 in.	1.6568	0.0007	
Total length - 0.06 in.	1.6554		-0.0007
Total resistance + 0.03%	1.6556		-0.0005
Total resistance - 0.03%	1.6566	0.0005	

Using values for $\Delta(P/P_{avg})^{+}$:

$\sigma_{P/P_{avg}} = (0.0069^2 + 0.0005^2 + 0.0007^2 + 0.0005^2)^{1/2} = 0.0070$ (absolute)

$= 0.42$ (%)

Using values for $\Delta(P/P_{avg})^{-}$:

$\sigma_{P/P_{avg}} = (0.0068^2 + 0.0005^2 + 0.0007^2 + 0.0005^2)^{1/2} = 0.0069$ (absolute)

$= 0.42$ (%)

a. $\dfrac{P}{P_{avg}} = \left(\dfrac{\text{step resistance}}{\text{step length}}\right)\left(\dfrac{\text{total length}}{\text{total resistance}}\right)$

b. $\Delta(P/P_{avg}) = P/P_{avg} - (P/P_{avg})_{nominal}$

Table B-8: Uncertainties Effecting the Heat Transfer Coefficient Calculations

ESTIMATED UNCERTAINTY OF PARAMETERS AFFECTING CALCULATED HEAT TRANSFER COEFFICIENT

Specific heat	$\pm$3%	

a. All errors or uncertainties are listed at the 1σ level.

b. Touloukian, Y. S., Thermophysical Properties of High Temperature Solid Materials, Macmillan, New York, 1967.

The uncertainty analysis was performed for FLECHT-SEASET test 31504 with the following nominal initial conditions:

-	Pressure	0.28 Mpa (40 psia)
-	Initial clad temperature	871 ^{o}C (1600 ^{o}F)
-	Rod peak power	2.3 kw/m (0.7 kw/ft)
-	Flooding rate	25 mm/sec (1.0 in./sec)
-	□T subcooling	60 ^{o}C (140 ^{o}F)
-	Radial power	Uniform
-	Housing temperature	T_{sat}

These test conditions are similar to the low flooding rate RBHT tests.

The analysis was performed on the heat transfer coefficient calculated for the hot rod 8K at the 1.98 m (78 in) elevation. The calculated value of the heat transfer coefficient from rod 8K was obtained with the best-estimate values of all the parameters in Table B-8. Both positive and negative values of Δh_i were obtained from subsequent DATARH calculations for which the parameters given in Table B-8 were varied. The calculated positive and negative values of Δh_i are listed in Table B-9 as a function of time. They are indicative of the heat transfer coefficient sensitivity for each parameter. The various values of Δh_i^+ and Δh_i^- are statistically combined in Table B-10 and the resulting calculated h values with the estimated 95 percent confidence bands (2σ) are shown in Table B-11.

Examination of the Δh_i values in Table B-9 shows that the measured power, rod outside diameter, clad thickness, and power step factor had the largest effects on the calculated heat transfer coefficient. Other parameters such as the rod properties (except the boron nitride density), rod temperature, and system pressure clearly had second-order effects on the accuracy of the calculated heat transfer.

The method used in this analysis presupposes that the process is linear; higher-order terms in the Taylor series expansion [Equation (B-6)] were neglected. If the method is linear, then the Δh_i values would be of equal magnitude but opposite sign. However, as the Δh_i values listed in Table B-9 indicate, the inverse conduction scheme is not a linear equation and Δh_i values can have different magnitudes if the deviation is taken in either the positive or negative direction from the normal value. Therefore, when the upper and lower bands are calculated as in Table B-10, these bands will not have the same magnitude. One method of compensating for the effect of nonlinearity is to simply average each deviation, both positive and negative values, and obtain an averaged deviation at each time step. This will result in a centered confidence band about the estimated heat transfer coefficient data. The calculations for this approach are given in Table B-11.

Figure B-2, which shows the calculated heat transfer coefficient (h) with the 95 percent confidence limits, indicates that the largest uncertainty in h is early in the transient, particularly at the beginning of reflood. Figure B-3 shows the relative uncertainty for the upper 95 percent confidence band as plotted from Table B-10; it indicates that the relative uncertainty quickly decreased to approximately 10 percent by 30 seconds for this test.

Figure B-3: Relative Uncertainty in Heat Transfer Coefficient as a Function of Time

B.3 Droplet Measurement Uncertainty

This section details testing of the VisiSizer software as completed by Todd at Penn State [4]. A systematic series of tests were performed to characterize the diameter measurement uncertainties and biases of the system. A set of small circles were used in the testing to create images of a known size and location within the optical probe length for VisiSizer to analyze. A set of generalized uncertainties was developed that show the accuracy of VisiSizer along with a method for correcting the measurement bias using a polynomial equation. The effects of calibration bias and changes in operating conditions were also investigated as well as a method for correcting the bias which results from the optical probe length effect.

B.3.1 Testing Methodology

The testing methodology was designed to develop an understanding of system characteristics, and separate the biases and uncertainties for study. The first step involves determining the size of the probe volume with different focus settings. Once this was complete, the uncertainties and biases were investigated. These investigations were broken into five segments, each building upon the previous:

1. Direct droplet measurement uncertainty
2. Calibration bias determination and correction
3. Measurement bias determination and correction
4. Optical probe length effect on measured diameter
5. Effect of optical viewing conditions

Each segment of testing was studied in depth to understand the cause of the uncertainty or bias. Once understood, a generalized uncertainty relation was developed that can apply to all measurements, and bias corrections were developed that remove the effects from the VisiSizer data. These corrections apply when the camera is 66 cm (26 in.) from the optical probe volume.

B.3.2 Test Description

The components of VisiSizer were set up to the desired conditions for testing. However, instead of water droplets – small circles were studied. The circles were studied because the diameter and exact location of each circle in the optical probe was known using a carefully developed experimental procedure. The focus parameter settings and laser pulse duration were each studied as part of the characterization.

B.3.2.1 Calibration Circles

Two sets of circles have been analyzed to determine the diametrical uncertainty of measurements with VisiSizer, where the diameter of each circle was known. The first set of circles was called Patterson graticule circles and these circles were highly accurate coatings on the surface of a microscope reticle. The Patterson graticule circles are typically used to calibrate the optics of a microscope. The second set of circles were attached to a clear polycarbonate

slide. These circles were larger than the graticule circles and were actually screw heads that were inserted into the clear slide. The size of each circle is listed in Table B-12.

Table B-12: Calibration Circle Diameters

Circle no.	diameter [microns (mils)]
1	19.11 (0.7524)
2	35.49 (1.3972)
4	70.98 (2.7945)
6	106.47 (4.1917)
8	144.69 (5.6965)
10	177.45 (6.9862)
12.5	223.86 (8.8134)
15	270.27 (10.6406)
20	360.36 (14.1874)
25	450.45 (17.7343)
A	2383 (93.8)
B	3967 (156.2)

The Patterson graticule circles have numerical labels while the larger set of circles are labeled with letters. The diameter of each Patterson graticule circle was accurate to 0.01 microns ($4.x10^{-04}$ mils) and the circles on the slide were accurate to ± 10 microns (0.4 mils). No suitable objects were available for study in the range of sizes between 450 microns and 2383 microns. The miniscule size of such objects makes them hard to locate and almost impossible to attach to a slide for analysis.

B.3.2.2 Distance from the Camera to Probe Location

The traversing table of a horizontal milling machine was used to hold the reticle and slide during each set of collection sequences. The mill was located in the basement of the Radiation Science and Engineering Center (RSEC) at Penn State and was used because it can accurately move in three dimensions over a very large distance. The x-axis, which was the primary axis used in this investigation, has a range of movement of 122 cm (48 in.).

The procedure for fixing the distance from the camera to the probe location (A) involved moving the circles to the desired location from the camera using the mill traverse handles. Once at the appropriate distance, the camera was carefully focused on the circles. This procedure centered the circles in the optical probe (measurement volume of the system) at the desired distance from the camera. Once set, the camera was not focused again unless the location from camera to the optical probe volume was changed. Typically the digital output on the milling machine was zeroed once the system set-up was complete. The mill then indicated zero when a circle was located in the center of the optical probe.

B.3.2.3 Measurement of Location within the Optical Probe

The milling machine table could be moved when a collection sequence of the circles was desired at a location other than the center of the optical probe. Traversing the mill in the x-direction changes the location of the circles in the probe and the location in the probe was found by reading the digital display of the mill. This reading was referenced to the reading when the center of the optical probe was fixed. The difference between the readings represented the location of the circles within the probe for a collection sequence – where a negative distance indicated the circles had approached the camera.

B.3.2.4 Milling Machine Location Measurement Uncertainty

Under normal circumstances the milling machine table could move in three dimensions with an accuracy of 12.7 microns (0.5 mils). However, a minor problem with the mill table was noted during the testing process. Because of age and heavy use, the traversing measurements were found to have an increased uncertainty in the exact measurement of the table location, which resulted in some erroneous distance measurements. The uncertainty was limited in most cases – but in a few select cases it was noted to be as much as 51 microns (2 mils). When possible, these cases were identified and removed from analysis.

B.3.3 Optical Probe Length Measurement

The dimensions of the optical probe volume were of vital importance when making number and volume flux estimates with VisiSizer for a given experiment. The software reported the height and width of the optical viewing area, but the depth of a frame was not readily known. The depth of a frame was called the optical probe length (OPL), and was the distance towards and away from the camera in which VisiSizer can measure an object. This section investigates the size of the OPL when VisiSizer was in diameter measurement mode with the laser in single pulse mode.

If VisiSizer was focused on a circle and the circle was moved away from the center of the optical probe, there was a finite distance for which the object was in focus for the camera. The optical probe length was a function of the object size, illumination intensity, lens quality, lens configuration (combination of extension tubes, magnification tubes, laser line filter, etc.), and distance from the object to the camera. Finally, the user supplied a focus parameter that instructed VisiSizer on how to discriminate between “in" and "out" of focus images – which directly affected the probe length. A stringent focal test created a very short probe length, while a no focus test allowed circles that were out of focus to be measured by VisiSizer. The reasoning for a focal test was because the out of focus image of a circle appeared smaller than the same circle when it was in focus. Figure B-4 illustrates this point.

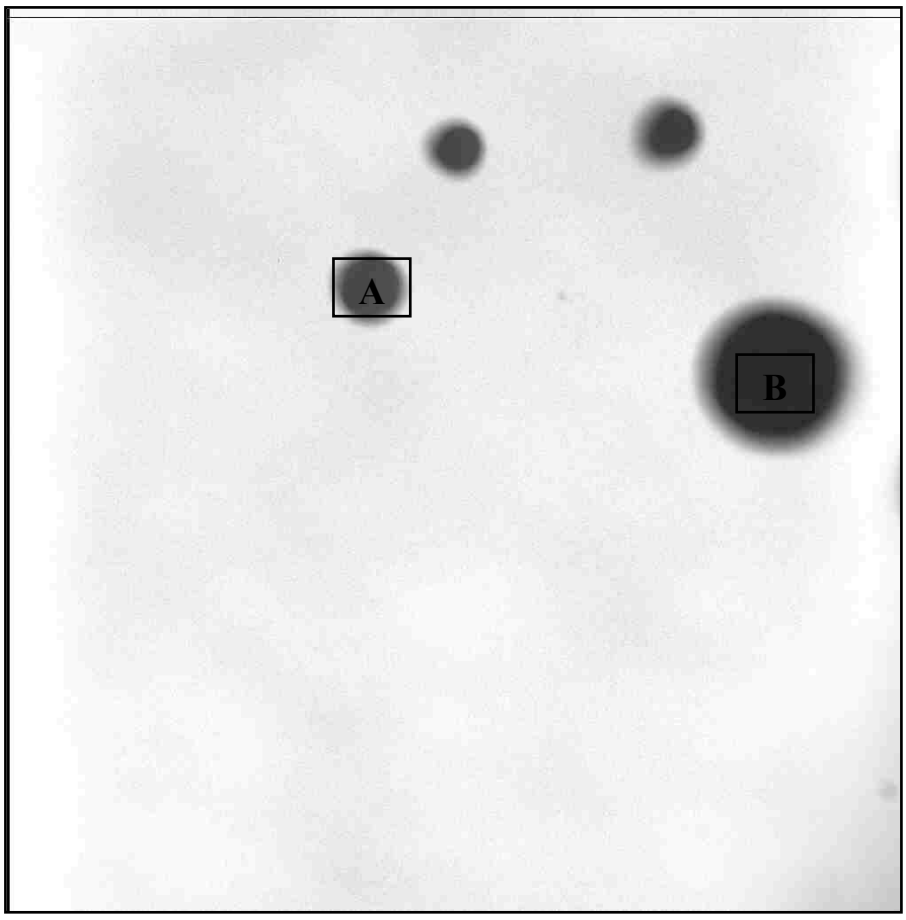

Figure B-4: Sample Frame With Out of Focus Images

Illustrated in this figure is the slide that holds circles A and B. The frame was collected when the images were approximately minus 10 mm (0.39 in.) from the center of the optical probe. The four out of focus images appear fuzzy around the periphery, the fuzziness results in diminished apparent image size when measured by VisiSizer and compared to the same images if they were in focus. This was because VisiSizer assumed some of the pixels in the fuzzy region were not a part of the image.

A selection of circles and focus discrimination settings were investigated to determine the optical probe length for a fixed lens combination, camera distance, and illumination intensity. The circles were moved across the optical probe of the camera by traversing the table. Since the actual size and location of the circles creating each of the images was known, the dependence of circle size and focal parameter could be described for the probe length.

The probe length was determined for each circle size by traversing the mill table across the x-axis. The front and back of the OPL was determined by recording the location of the table where VisiSizer reports about 1 to 2 in focus images of 30 frames captured - with the remainder of the images rejected for focus. The laser pulse duration was set at 7 with the upper threshold set at 200. The threshold differential setting was 30. The results for the optical probe length for each diameter were tabulated in Table B-13 with a range of focus discrimination settings. All data was taken with the camera located 66.0 cm (26.0 in.) from the center of the optical probe.

Table B-13: Optical Probe Length at 66.0 cm (26.0 in) from Camera

Focus Parameter	Optical Probe Length [mm] by Circle Number							
	6	8	10	12.5	15	20	25	A
10								51.0
15		11.2		16.0		18.6	20.3	33.2
20								25.9
25		11.5		12.0		13.1	13.7	19.0
35		9.4		10.1		10.1	9.9	
45		8.9					9.2	8.6
50	3.4	5.0	5.1	5.1	5.4	5.3	5.5	
65	2.8	4.0	3.6	4.0	4.3	4.4	4.6	6.2
75	2.6	3.3	3.4	3.7	4.0	4.0	4.3	
85	1.8	2.7	3.0	3.2	3.4	3.5	3.8	3.5

These measurements were very difficult to perform as they depend upon the ability of the experimenter to locate the region of space in the optical probe where the count rate of in-focus images was small, but not zero. Many competing effects can cause erroneous measurements of the probe length. For instance, the image of a large circle appeared small to VisiSizer when the circle was out of focus. Depending on optical properties and VisiSizer settings, the software may have decided the image was a small in-focus image instead of a large out of focus image. The effect depended on the behavior of the image halo. The data listed in Table B-13 has been carefully screened to remove any overtly erroneous data. A portion of the data in Table B-13 is plotted in Figure B-5. The data for each focus parameter (F) was fit with a logarithmic best-fit line that accurately describes the behavior of the optical probe length vs. circle diameter.

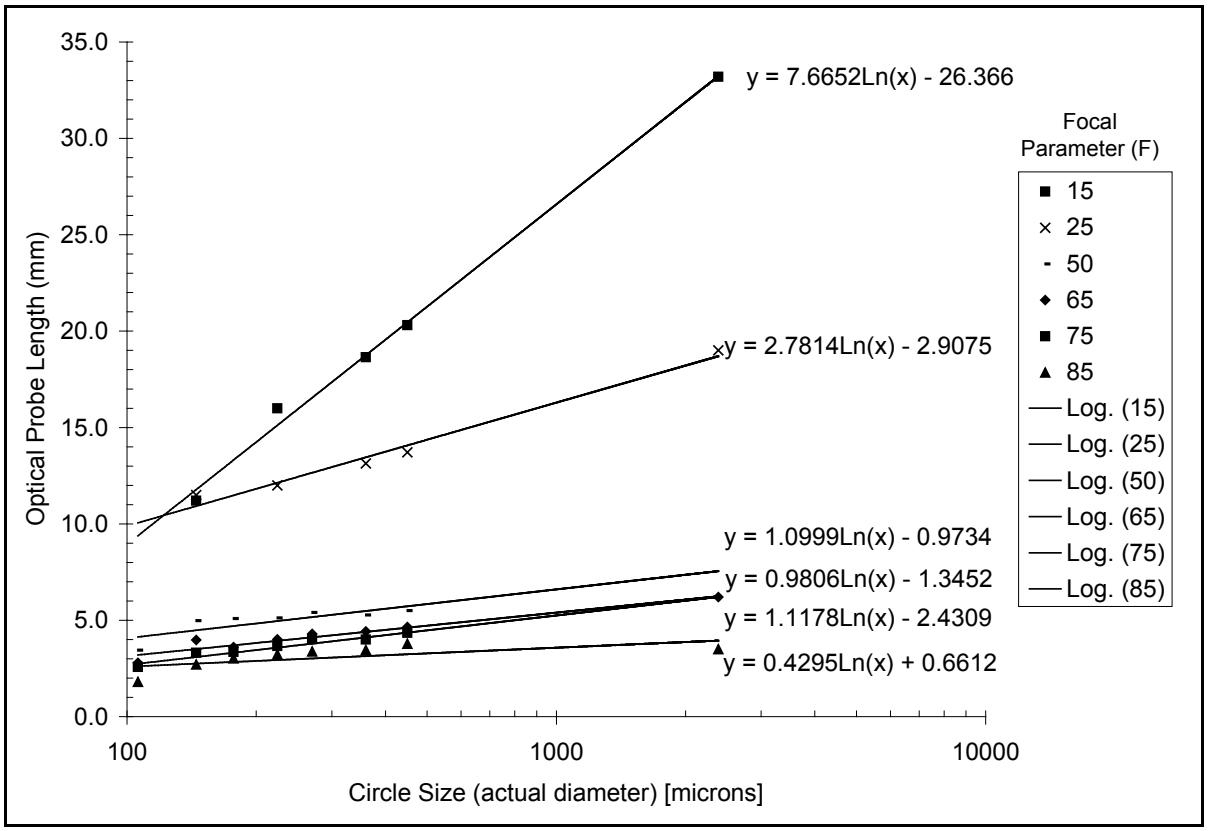

Figure B-5: Plot of the Optical Probe Length vs. Circle Size

The logarithmic best fit for each of the focal parameters was used to describe the behavior of the probe length for each circle size and focus parameter setting. The fits only apply at 66.0 cm (26.0 in.) from the center of the optical probe to the camera. From previous experience, the focal parameter of 25 was known to be the most suitable setting for measuring the velocity of droplets in a reflood experiment because a large probe volume was desired, which enabled the largest amount of information to be captured. The equation for the probe length at a focus parameter of 25 was:

$$OPL_i = 2.7814 \ln(d_i) - 2.9075 \tag{B-15}$$

where:

OPL_i optical probe length for size d_i droplet [mm]

d_i diameter of droplet [microns]

The diameter d_i was the actual diameter of the image that was being measured. Therefore, it was necessary to correct all biases in the measurements prior to finding the optical probe length for a given diameter. Once the probe length was known for a focal discrimination setting, the optical probe volume could be found. Knowing the optical probe volume, estimates of the number and volume flux could be made for a given experiment.

B.3.4 Measurement Bias and Uncertainty

The precision and accuracy of VisiSizer has been investigated using the reticle circles to ascertain the accuracy of the system when used to measure droplet sizes in the RBHT facility. Since each droplet can only be sampled once during a test, VisiSizer must be able to accurately record the droplet diameter with a minimal measurement uncertainty applied to the size of the droplet. Determination of the measurement uncertainty was broken into five portions:

1. direct droplet measurement uncertainty
2. calibration bias
3. measurement bias
4. uncertainty of the location in the optical probe length
5. optical viewing conditions

The direct measurement uncertainty (i.e. measurement precision) was similar to measuring the length of a string many times; fluctuations in the environment, changes in lighting, and dust in the air are all examples of changes that can affect a particular measurement. For VisiSizer, the uncertainty was seen as a variation in the pixel area that the system determines to be in an image. By sampling the number of pixels in an object a large number of times, an estimate of the uncertainty could be made.

Special care must be taken when calibrating VisiSizer. The calibration method involves capturing a frame and inputting the diameter of the largest image in the frame. Typically circle 25 (450 microns) of the reticle was used for calibration and since the direct measurement uncertainty applied to any image that was captured, an uncertainty applied to the image used for calibration. A method was developed to determine what the calibration bias was, and the means to correct the calibration ratio.

Comparisons between the VisiSizer diametrical measurement of a circle and the actual diameter of the circle were made to illustrate the inherent measurement bias of the system that was caused by the optics. Once the bias was characterized, a method for removing it was formulated and was applied to images smaller than 19.5 pixels in diameter.

The optical probe of VisiSizer has a finite measurement volume, of which the optical probe length is the axis along which a droplet moves towards or away from the digital camera, but is still visible. The exact location of a droplet in that length is unknown for a given experiment. Measurement uncertainty results because the apparent diameter of a droplet image that is not in the center of the optical probe length is smaller than the same image if located in the center of the optical probe length. The change in apparent size is a function of the distance of the probe volume from the camera (A) and the location in the optical probe length. A method to correct captured data for this effect was developed for a droplet population that was evenly distributed across the optical probe length.

Finally, the uncertainty from changes in optical viewing conditions was investigated. Optical viewing conditions are related to the intensity of the laser light which exposes the camera CCD. The intensity may vary during a reflood experiment as the conditions inside the test section change. As the experiment progresses the density of the two-phase mixture may vary, resulting in increased or decreased laser absorption in the fluid. To quantify this effect, measurements of the circles were made where the amount of illumination was varied by changing the laser pulse duration, which simulated the possible effect of absorption of laser light

in the two phase flow. The effect was shown to be very small and the same linear effect occurred for all size circles.

B.3.4.1 Direct Measurement Uncertainty

VisiSizer reports all diametrical size measurements in units of microns. But the measurement uncertainty is actually a function of the resolution of a given image, i.e. the number of pixels that are determined to be within the image. VisiSizer can be operated at different distances from the area of study to trade off between good resolution of small droplets and a large optical probe volume with increased counting rates. In order to develop a generalized measurement uncertainty that could apply to all resolutions; the uncertainty was developed using the non-dimensional pixel as a measure of size. The use of pixels enables the user to assume all images with a given pixel area have the same direct measurement uncertainty. This is true no matter the camera location from the probe volume, even though the actual size of the object being imaged is not the same at different camera locations. In the following sections, an integer number of pixels is used to represent the area of a given image, while the equivalent diameter is reported as a real number of pixels that are equivalent to the diameter of the image. The size of a pixel in microns is determined by the calibration ratio. Dividing the area in microns, that is output from VisiSizer, by the calibration ratio (R) squared converts a measurement from microns to pixels, or vise versa.

B.3.4.1.1 Distribution of Individual Measurements

To quantify the direct measurement uncertainty, the image size of each circle is measured a large number of times (>500 times). Each individual measurement is recorded as the number of pixels that are within the image of the circle. As noted before, the measured number of pixels can vary between frames because of random fluctuations. The variations are analyzed to determine the direct measurement uncertainty of the area of each circle. The uncertainty of a large group of measurements for a given circle size should be Gaussian in nature. To illustrate this data from a collection sequence is analyzed to determine the frequency distribution and relative change in pixel area of circle measurements. The analyzed sequence includes eight of the circles on the reticle and the calibration ratio (R) is 20.013 microns (0.8 mils) per pixel for these measurements. The frequency for each of the measurements is plotted in Figures 3-3 and 3-4 for each of the circle sizes. The most probable measured area is assumed to be the center of the distribution and the other measurements are scattered about the most probable size by the relative change in relation to the most probable size.

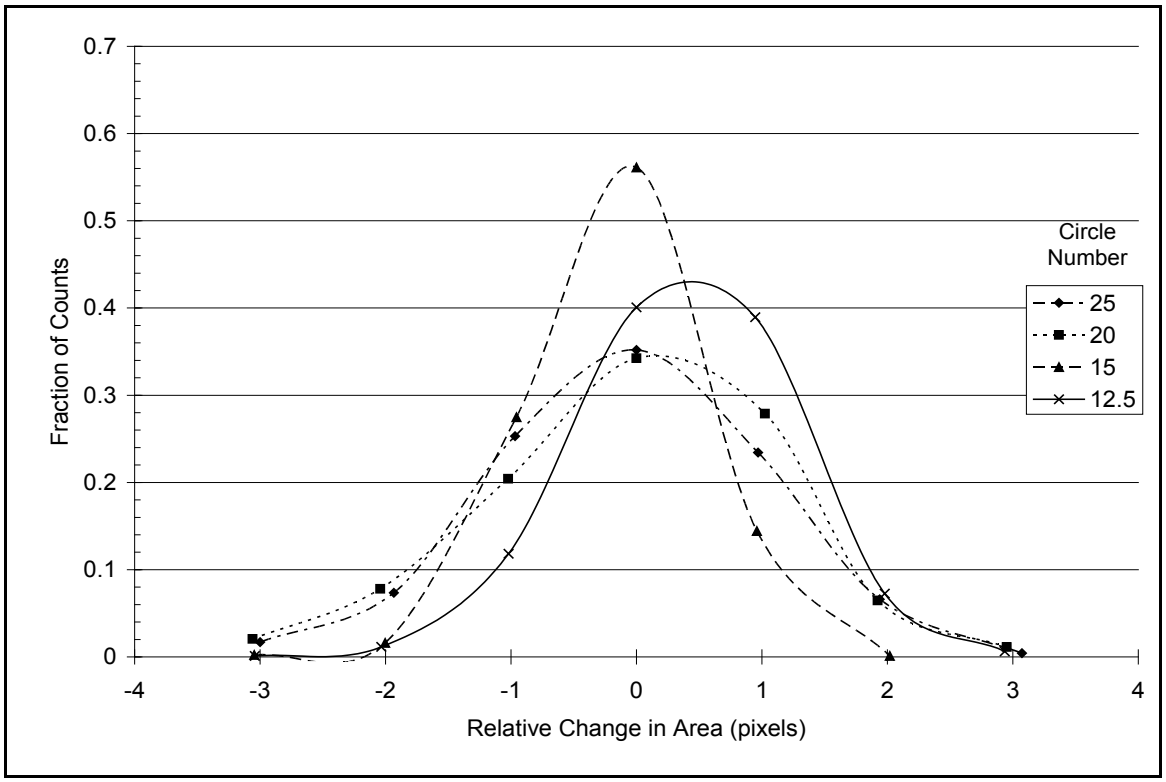

Figure B-6: Distribution of Large Circle Measurements

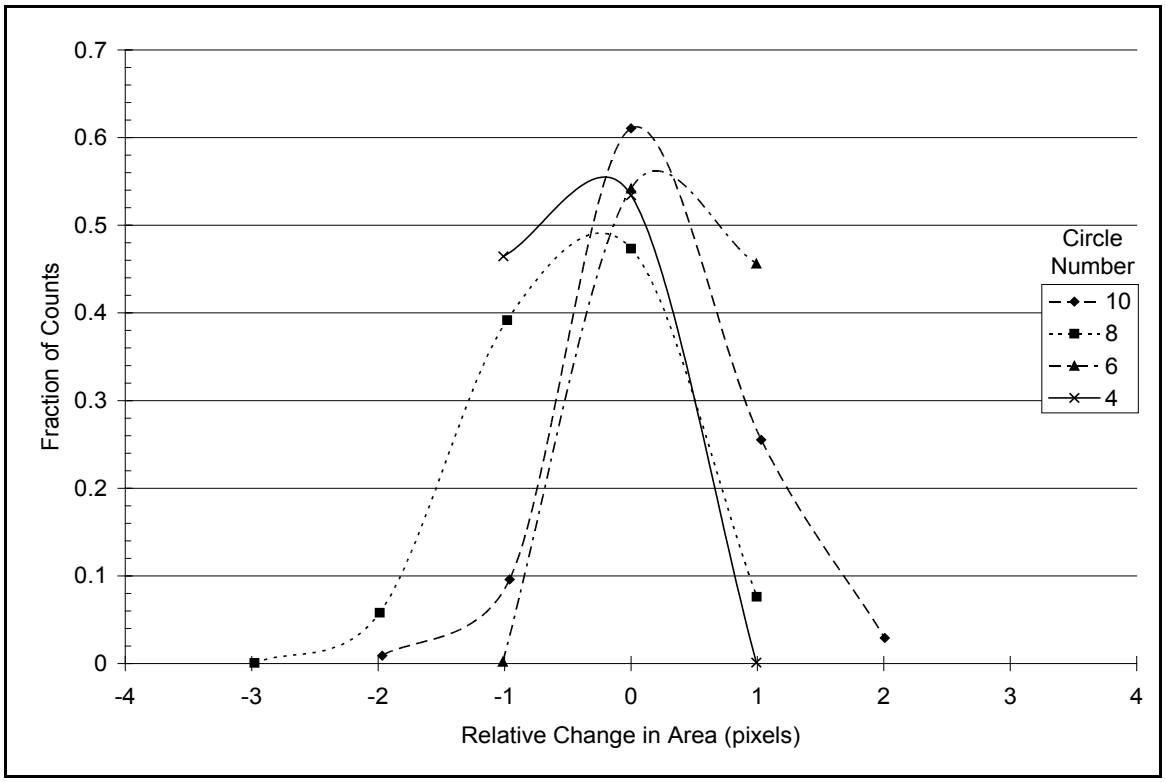

Figure B-7: Distribution of Small Circle Measurements

Figure B-6 and Figure B-7 show that the distribution of measurements for each of the circles is Gaussian in nature, where the percent change for circle 25 (450 microns) is 8.9% from zero to plus two pixels in size. Since the pixel area of each measurement is an integer value, the relative change from the most probable measured size is an integer value. Since the small circles only have about 3-4 pixels of uncertainty, very little data is available to fully illustrate the Gaussian-like distribution function. For the sake of uncertainty analysis, the uncertainty of VisiSizer measurements is assumed Gaussian. The mean area and two sided 95% confidence levels (1.96 σ) for each of the circles are listed in Table B-14, where the method for calculating the mean and 95% confidence are given in Young [8].

Table B-14: Direct Uncertainty of a Sequence of Circle Measurements

Circle Number	Measured Mean Area and 95% Confidence (pixels)
4	2.61 ± 1.09
6	13.47 ± 0.98
8	30.58 ± 1.40
10	51.20 ± 1.34
12.5	87.42 ± 1.67
15	128.84 ± 1.32
20	230.03 ± 2.30
25	365.91 ± 2.13

The 95% confidence has a slight increase in size with increase in pixel area. Reasoning for this behavior can be seen when examining Figure B-6 and Figure B-7 closely. As the actual circle size increases, the width of the measured distribution increases, which results in a larger deviation.

B.3.4.1.2 Investigation of the Effect of Area Variation

Investigating the effect of the variation of an individual measurement from the mean measured value leads to the conclusion that small images are affected more by a variation in the measured area than large images. Figure B-8 is a plot of the pixel area and the percent change that results from increasing the pixel area of an image by one pixel (i.e. a 100% increase in size when increasing from one to two pixels in an image). Also noted on the figure is diameter of two images in microns for comparison, assuming a value of 20.0 microns (0.8 mils) per pixel for the calibration ratio.

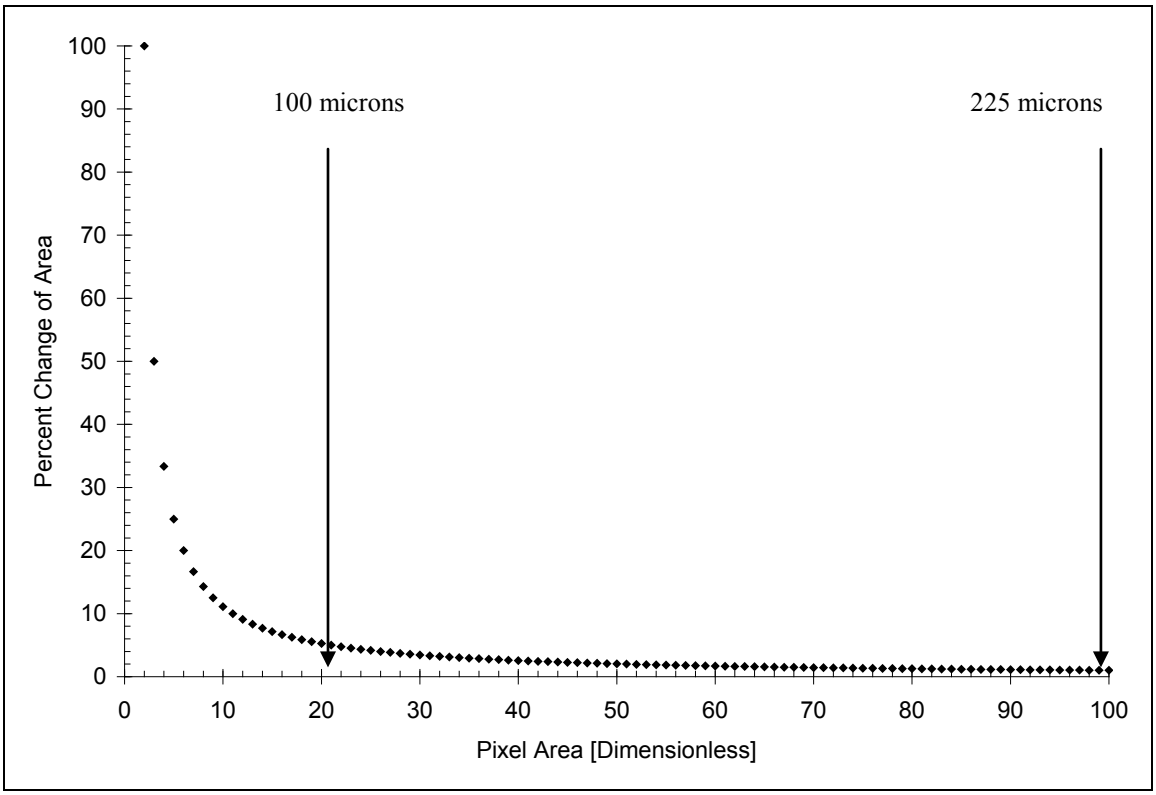

Figure B-8: Effects of Pixel Area Variation

As seen in Figure B-8, the percent change in area is greater than 5% for an area below 21 pixels. The significance of the percent change can be seen in Table B-14 where the measured area of circle number 6 (13.5 pixels in area) has a 95% confidence of one pixel in area. This means the area deviates more than ±5% of the total area of the image. The effect will be more apparent in later sections when the measurement uncertainty is investigated in terms of diametrical uncertainty.

B.3.4.1.3 Generalization of the Uncertainty

The calculated 95% area confidence levels for 228 collection sequences made throughout the testing have been analyzed in order to create a generalized measurement uncertainty for each size of image. Data for each sequence is listed in Appendix A, where each sequence has more than 500 individual circle measurements. The plot of the confidence level vs. image area is seen in Figure B-9, where the data is fit with a logarithmic best fit. A generalized confidence that characterizes all measurements is developed using the deviation about the best fit that bounds 95% of the data using to a one sided Gaussian distribution. See Young [8] for a detailed description of the method.

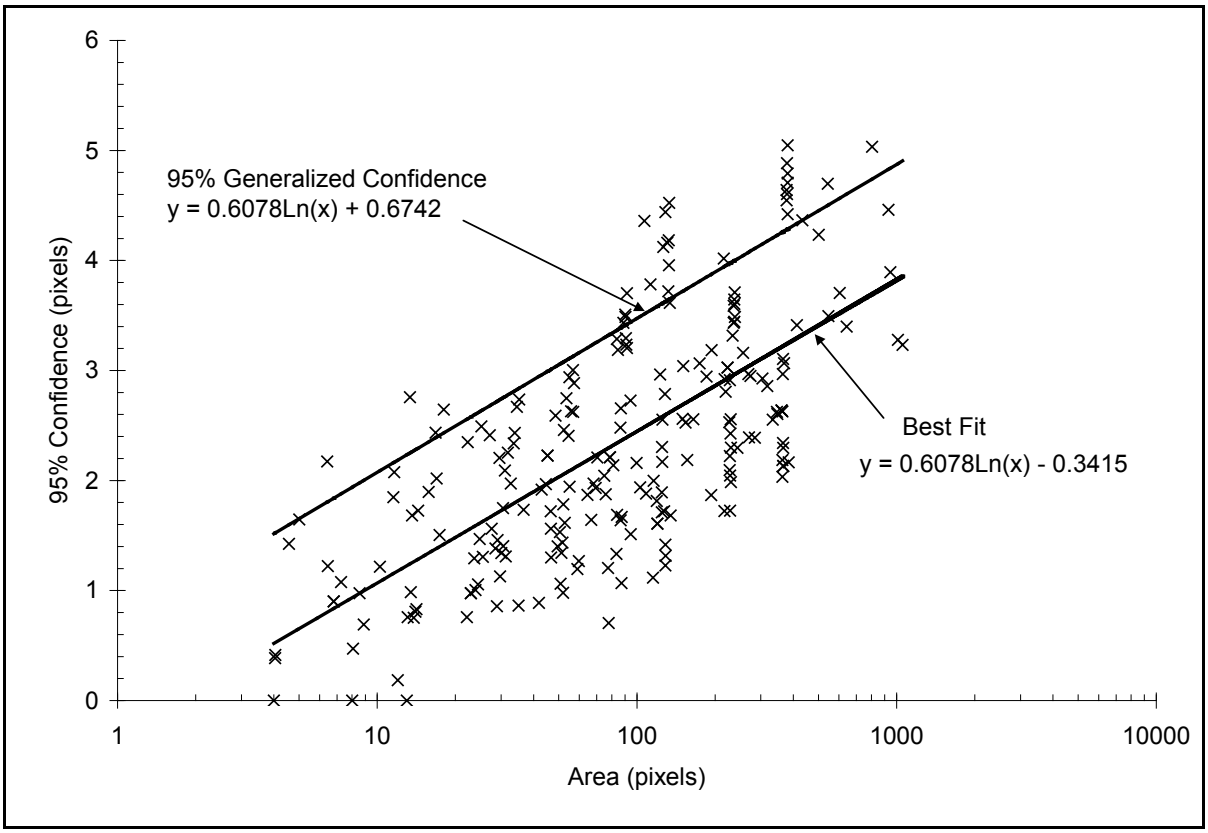

Figure B-9: Generalized 95% Confidence of 228 Measurements

The maximum pixel area of data in Figure B-9 is 1000 pixels. The equivalent diameter is 714 microns (28.56 mils), assuming a calibration ratio of 20.0 microns (0.8 mils) per pixel. Data is not included above this size because the overall percent change in area is miniscule above this size.

The generalized 95% confidence curve in Figure B-9 has the same slope as the best fit line but the magnitude is increased by 1.0157 pixels. Knowing the pixel area of a single droplet measurement in the RBHT Facility, the curve can be used to determine the 95% confidence of that measurement without having to take a large number of samples of the same droplet to create a statistical base. In simple words, there is a 95% chance the mean of a large number of measurements of the same droplet will be within the measured size of the droplet ± the generalized 95% confidence. The best-fit and 95% confidence curves are presented in equation form:

$$best-fit\ deviation$$
$$\sigma_{GA-B} = 0.6078\ln(A) - 0.3415 \quad \text{(B-16)}$$

$$generalized\ 95\%\ confidence:$$
$$\sigma_{GA-95\%} = 0.6078\ln(A) + 0.6742 \quad \text{(B-17)}$$

where:

σ_{GA-B}	best fit of 228 - 95% confidence data points [pixels]
$\sigma_{GA-95\%}$	generalized 95% confidence of an area measurement [pixels]
A	integer number of pixels in an area measurement [pixels]

These relationships can be extrapolated to 10,000 pixels in area with a high degree of confidence. The direct uncertainty of a droplet measurement in the RBHT Facility can now be addressed using the generalized confidence. For the measurement of any droplet the direct measurement uncertainty of the area of the droplet image is ± the generalized confidence, as determined for that particular area. The generalized confidence and best-fit deviation are calculated for a 200 pixel image:

Given a droplet area in pixels from VisiSizer:
A = 200 pixels in area

The uncertainty is calculated from Equation B-16 and B-17:

$$\sigma_{GA-B} = 0.6078\ln(200) - 0.3415 = 2.879 \text{ pixels} \quad \text{(B-18)}$$

$$\sigma_{GA-95\%} = 0.6078\ln(200) + 0.6742 = 3.895 \text{ pixels} \quad \text{(B-19)}$$

Therefore the size of the image with 95% confidence is:

A=200 ± 3.895 pixels

The increasing trend in area confidence noted previously is insignificant when studied in terms of percent deviation of the area. Two extreme cases illustrate the change in percent deviation using the generalized 95% confidence. The first case has an image area of 500 pixels and the second case has an area of 4 pixels (which will later be chosen as the minimum pixel area).

$$\text{percent deviation} = \frac{\sigma_{GA-95\%}}{A} \times 100\% \quad \text{(B-20)}$$

large image:

$$\frac{4.45\,pixels}{500\,pixels} \times 100\% = 0.890\% \quad \text{(B-21)}$$

small image:

$$\frac{1.52\,pixels}{4\,pixels} \times 100\% = 38.00\% \quad \text{(B-22)}$$

There is a significant change in the percent deviation between the cases, with the larger image resulting in less percent change in area.

B.3.4.1.4 Conversion to Diameter

Data from VisiSizer is typically used in terms of the equivalent diameter of a circle. For this reason, the area measurement deviation is revisited in terms of diameter. First, the effect of increasing the size of an area measurement by one pixel has been shown to be more significant for small images than for large images. Fortunately, the increase in area has a less significant effect upon the equivalent diameter of an image than upon the area measurement of the same image. This is seen by converting the area of an image into the equivalent diameter of a circle, and finding the percent change in diameter if the area is increased by one pixel. A 41.42% change in measured diameter occurs when the area of the image is increased from one to two pixels as can be seen in Table B-15.

Table B-15: Effect of Increasing Pixel Area

Pixel Area	% Change in Area	Equivalent Pixel Diameter	% Change in Diameter
1		1.1284	
2	100.0	1.5958	41.42
3	50.0	1.9544	22.47
4	33.3	2.2568	15.47
5	25.0	2.5231	11.80
6	20.0	2.7640	9.54
7	16.7	2.9854	8.01
8	14.3	3.1915	6.90
9	12.5	3.3851	6.07
10	11.1	3.5682	5.41
11	10.0	3.7424	4.88
12	9.1	3.9088	4.45

The percent change is significantly reduced from the 100% effect upon an area measurement as shown in Figure B-8 in the previous section. Table B-15 illustrates the need to use caution when including images that are smaller than 11 pixels in area or 3.74 pixels in diameter in the analyzed data. The reason is because if the same droplet is imaged twice and the two measurements deviate by one pixel in area, the deviation in diameter is greater than 5% between the two measurements. However, since these small droplets are of great interest in a reflood experiment, the large uncertainty is accepted for all images with four or more pixels in area or 2.26 equivalent pixels in diameter. Discrimination of the small images is performed by VisiSizer using the minimum pixel area setting.

VisiSizer reports the equivalent diameter of each droplet, not the area, so the generalized confidence must be reworked for diametrical measurements. The relationship between the area and diametrical uncertainty are derived and manipulated to make use of the 95% generalized confidence that was previously derived for area measurements. The following relationships are used to develop the diametrical uncertainty for both the 95% and best-fit uncertainties:

basic relationship:

$$\mathrm{A}+\sigma_{GA}=\frac{\pi}{4}\left(d+\sigma_{Gd}\right)^2 \tag{B-23}$$

rearranging, where only real positive roots are meaningful:

$$\sigma_{Gd} = \sqrt{d^2 + \frac{4}{\pi}\sigma_{GA}} - d \tag{B-24}$$

NOTE: the term σ_{Gd}^2 cannot be neglected in the derivation because it is at least 10% of the diameter for the smallest sizes.

knowing the best fit area equation and rearranging:

$$\sigma_{Gd-B} = \sqrt{d^2 + 0.7739\ln(d^2) - 0.6218} - d \tag{B-25}$$

knowing the 95% generalized area confidence and rearranging:

$$\sigma_{Gd-95\%} = \sqrt{d^2 + 0.7739\ln(d^2) + 0.6715} - d \tag{B-26}$$

where:

σ_{Gd-B}	best fit diametrical confidence [linear pixels]
$\sigma_{Gd-95\%}$	generalized 95% diametrical confidence [linear pixels]
d	equivalent diameter of an image in pixels

To illustrate the generalized diametrical confidence, the same data in Figure B-9 is plotted in Figure B-10. This new figure shows each of the 228 measured 95% diametrical deviations which are bounded by the generalized 95% diametrical confidence. The best-fit curve from Figure B-9 is also included in Figure B-10 for comparison.

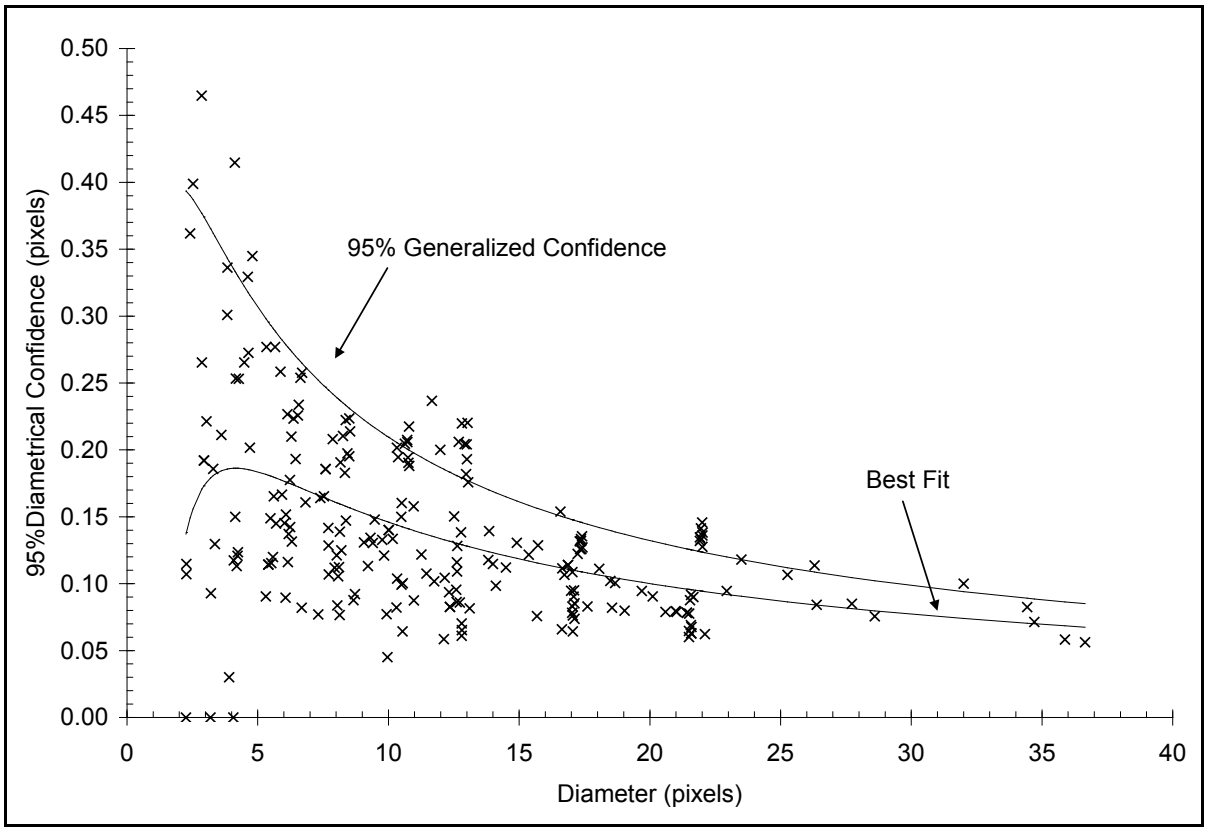

Figure B-10: Diametrical Uncertainty of 228 Data Points

The uncertainty of a measurement decays with increasing diameter. The reason is the fluctuation of one pixel in area has less and less of an effect on the diameter as the diameter increases, and this is because area is related by the square of the diameter. Using Equations B-25 and B-26, the generalized 95% diametrical deviation and the best-fit diametrical uncertainty are calculated for the 200 pixel-area image.

Given a droplet diameter in pixels from VisiSizer:

200 pixel area =15.958 pixels in diameter

The best fit uncertainty is calculated from Equation B-25:

$$\sigma_{Gd-B} = \sqrt{(15.958)^2 + 0.7739\ln((15.958)^2) - 0.6218} - 15.958 = 0.114 \text{ pixels} \qquad \text{(B-27)}$$

The generalized 95% confidence is calculated from Equation B-26:

$$\sigma_{Gd-95\%} = \sqrt{(15.958)^2 + 0.7739\ln((15.958)^2) + 0.6715} - 15.958 = 0.155 \text{ pixels} \qquad \text{(B-28)}$$

Therefore the diameter of the image with 95% confidence is:

$$d = 15.958 \pm 0.155 \text{ pixels}$$

where:

d = diameter of the image [pixels]

Revisiting the percent deviation from Equation B-20, converting the area of the images to diameter and finding the generalized 95% diametrical deviation:

large image (500 pixel area):

$$\frac{0.112\,pixels}{25.231\,pixels}\times 100\% = 0.444\% \tag{B-29}$$

small image (4 pixel area):

$$\frac{0.394\,pixels}{2.257\,pixels}\times 100\% = 17.457\% \tag{B-30}$$

After conversion to diameter, the percent deviation of the large image decreases from 0.89% to 0.44%, while the effect on the small image is even greater, 38% for the area deviation versus 17% for the same image using the diameter deviation. The Sauter Mean Diameter from FLECHT-SEASET [5] was about 1 mm (0.39 in.) and this size has approximately 0.13% deviation.

B.3.4.1.5 Direct Uncertainty Conclusions

The generalized 95% diametrical confidence is necessary because repeated sampling of a droplet is not possible during an experiment. With the generalized deviation of each measurement, the average deviation of the entire population can be found through statistical combination. The generalized 95% confidence is applied to a droplet measurement prior to any other statistical treatment because this uncertainty is directly related to the apparent diameter seen by the camera, not actual diameter of the droplet. When analyzing data in a “class” type structure, the generalized uncertainty for the entire class is determined using the lower class bounds as a conservative approximation.

B.3.4.2 Calibration Bias

VisiSizer measures the area of the image in pixels, calculates the equivalent diameter and determines a ratio (R) that relates the pixel size to the input calibration size of the object. The ratio (R) is in microns per pixel and remains constant while the camera focus remains unchanged. As described in the previous section, there is a direct measurement uncertainty of the size of each individual image measurement, and this includes the image of the object used for calibration.

A large sequence of data is collected of the calibration circle once VisiSizer is satisfactorily calibrated. A diametrical mean is calculated from the sequence, where the mean represents the best estimate of the size of the circle. The mean is then used to remove any remaining calibration bias. The calibration bias is propagated by the calibration ratio (R), where

the ratio can fluctuate proportionally with the uncertainty of the calibration image. The bias only affects data that is listed in microns, not data listed in pixels. The bias correction is developed as follows:

the ratio is found:

$$d_C \sqrt{\frac{4}{\pi} A_C} \tag{B-31}$$

$$R = \frac{d_{CI}}{d_C} \tag{B-32}$$

but the calibration bias is as follows:

$$\Delta d = \frac{\overline{d}}{R} - d_C = \frac{\overline{d} - d_{CI}}{R} \tag{B-33}$$

so the corrected ratio is:

$$R_C = \frac{d_{CI}}{d_C - \Delta d} \tag{B-34}$$

Substituting:

$$R_C = \frac{d_{CI} R}{\overline{d}} \tag{B-35}$$

where:

A_C integer pixel area of calibration image
d_C measured calibration image diameter [pixels]
d_{CI} input calibration image diameter [microns]
R calculated microns per pixel ratio
Δd difference between measured calibration size and mean diameter of sequence [pixels]
$\overline{d}$ mean diameter of calibration image sequence [microns]
R_C corrected microns per pixel ratio

The corrected ratio (R_c) is the ratio that VisiSizer would use if it were exactly calibrated on the mean size of the circle image. The work performed in the previous sections to determine the direct measurement uncertainty was non-dimensionalized into pixels by using the uncorrected ratio (R). But once all corrections are finished, the results will be re-dimensionalized using the corrected ratio (R_c) to remove the calibration bias.

B.3.4.3 Measurement Bias

To determine if any measurement biases are present in a VisiSizer measurement, several sets of data are plotted as actual diameter vs. measured diameter in pixels. These cases are prototypical - the illumination, location in the optical probe length, and distance from the camera to the optical probe are all kept constant. The data is acquired by imaging eight of the reticle circles simultaneously and plotting the circle data for each sequence. Figure B-11 is the resulting plot used to determine the measurement bias.

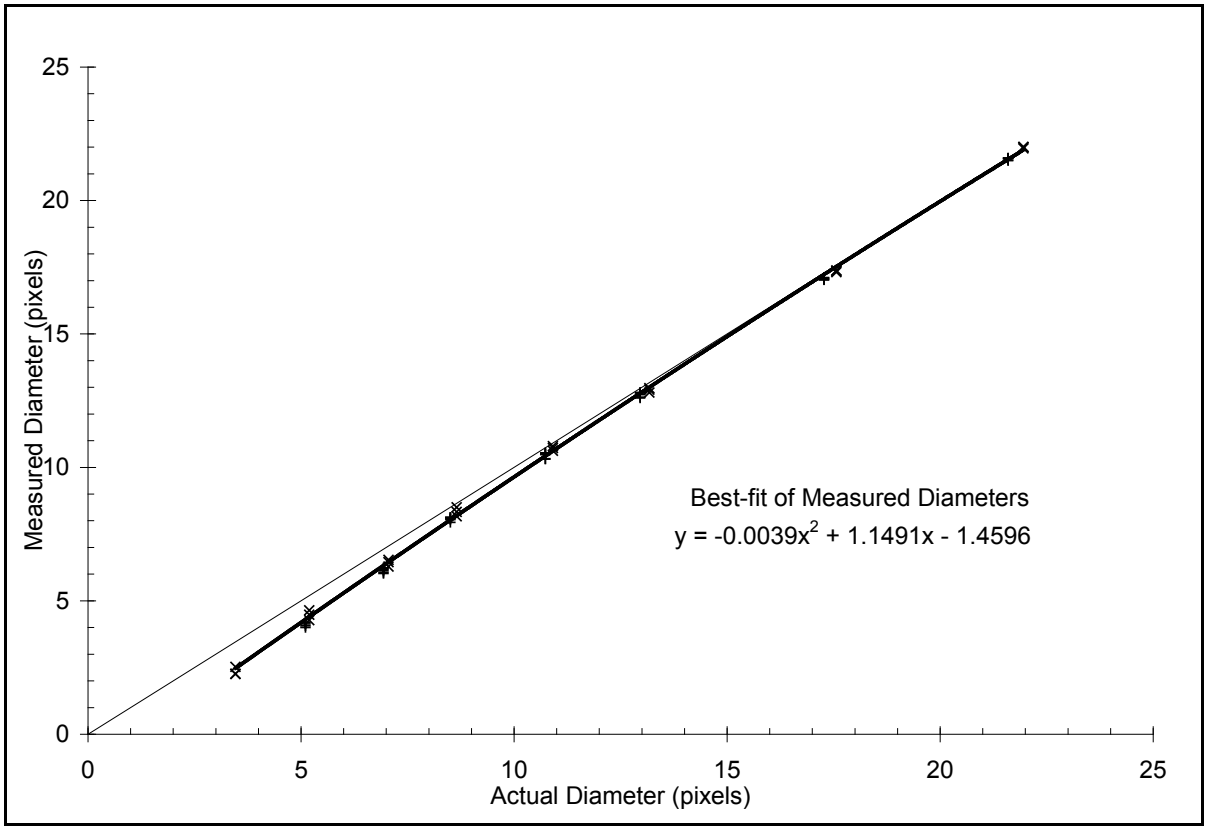

Figure B-11: Actual Versus Measured Diameters to Determine Bias

A measurement bias is present in the VisiSizer system. The trend of small circles to appear smaller than the actual circle size is apparent where the small circles deviate from the 45° perfect agreement line. The data points are fit with a second order polynomial, which will be used later to develop a bias correction.

The pixel diameter is found by dividing the measured diameter by the uncorrected ratio (R). This is because the equivalent pixel diameter in an image is the reported diameter in microns divided by the uncorrected ratio – not the corrected ratio. The actual diameter of a circle is converted to pixels by dividing by the corrected ratio. By calculating the actual diameter in this way, the difference between actual and measured diameter for the 450 micron circle is essentially zero since it is the circle used for calibration. A typical value for the uncorrected ratio is 20.0 microns (0.8 mils) per pixel.

The bias is a result of laser light diffracting around the circles. The effect of laser diffraction is more profound with decreasing size, resulting in a seemingly exponential decay in the difference between actual and measured size as seen in Figure B-12. (In other words, as the size decreases, the difference between the actual and measured diameters increases – a phenomenon seen in Figure B-11.)

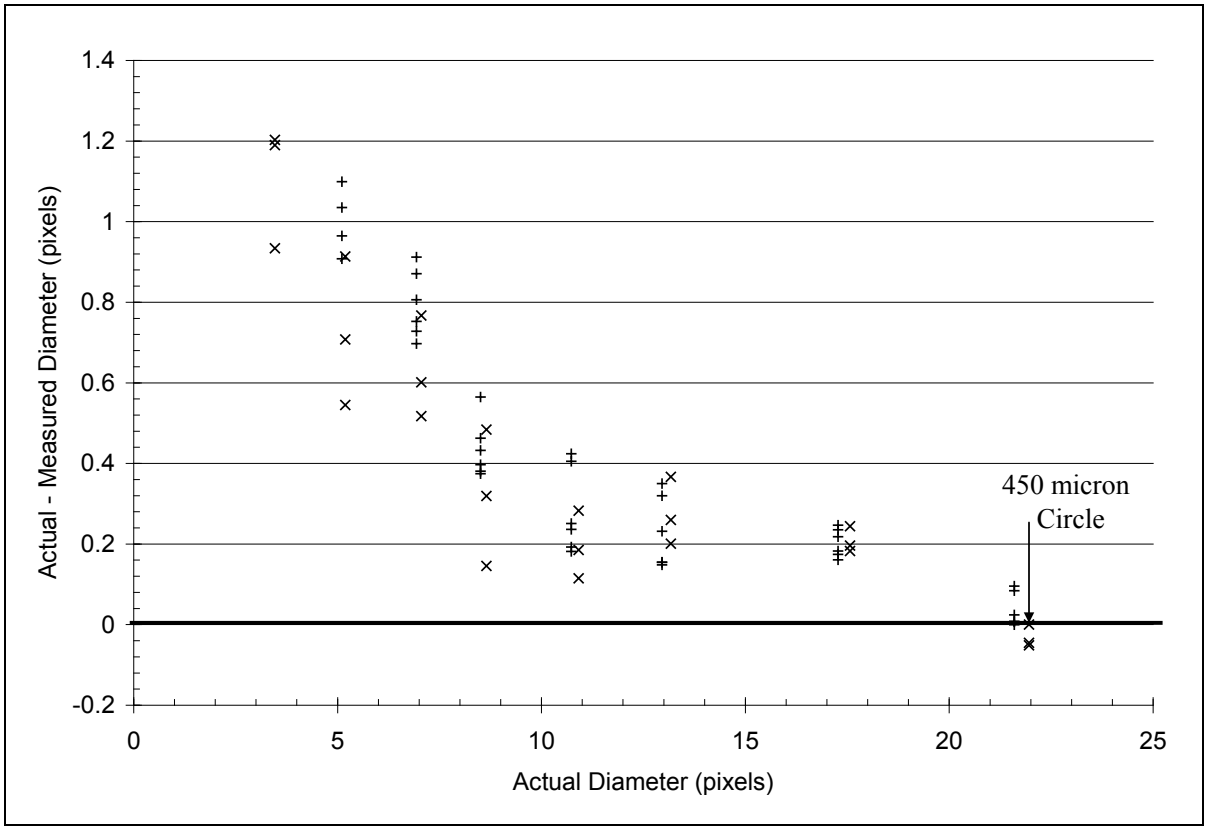

Figure B-12: Comparison of Actual and Measured Diameter

To eliminate the bias, the best fit polynomial found in Figure B-11 is inverted so the measured diameter is input as d_m and the result is the corrected diameter d_N which compensates for the measurement bias. The bias correction is given as

$$d_N = 0.0034 d_m^2 + 0.8678 d_m + 1.3091 \quad \text{(B-36)}$$

where:

d_N = corrected diameter of an image [pixels]

d_m = measured diameter output by VisiSizer [pixels]

The data used for Figure B-11 and Figure B-12 is corrected using the bias correction and the resulting diameters (d_N) are plotted in Figure B-13.

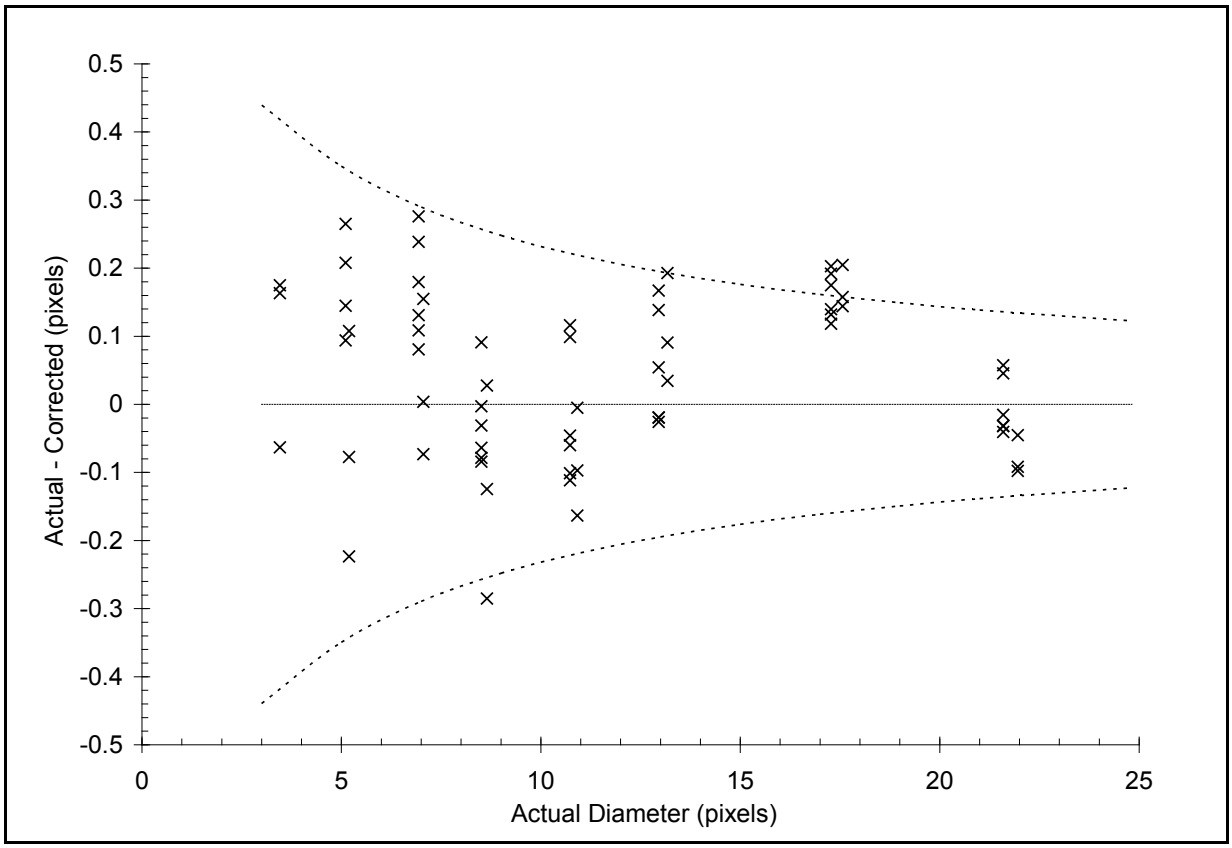

Figure B-13: Data after Bias Correction

The data now falls nicely around zero, indicating no bias. Also included in the figure is the generalized 95% diametrical confidence curve for the range of diameters. Notice nearly all the data falls within the 95% confidence. It must be noted however that this particular correction applies only to the case where the laser is 114 cm (45 in.) ± 5 cm (2 in.) away from the area of study. Also, the laser pulse duration must be set so eight of the ten reticle circles are visible so as to not over or under expose each frame. These limitations are in place because the effect of diffraction changes as the location and intensity of the laser changes. The effects of laser intensity are discussed later.

The bias correction is only applicable for diametrical sizes below 19.5 pixels (390 pixels with R=20.0 microns per pixel). Images larger than 19.5 pixels do not show the bias seen in the smaller images. This is confirmed by maintaining calibration from the reticle to the slide – where VisiSizer is calibrated with the 450 micron (22.5 pixel) circle, and the 3967 micron (198.2 pixel) circle is imaged. The resulting measurement is 3960 microns (197.9 pixels) in diameter. The slight variation in size is reasoned to result from minor variations in experimental conditions caused by the use of the slide versus the reticle.

B.3.4.4 Variation of Diameter in Probe Length

If a droplet is at the front of the optical probe (close to the camera) it should appear to be larger than if at the back of the optical probe. This is intuitively obvious – an object viewed at a close proximity should always appear larger than the same object when viewed farther away. However, another effect competes with the apparent change in size to determine the effect of location within the probe. As the droplet moves from the center of the optical probe it becomes out of focus, resulting in a decrease in apparent size.

Since VisiSizer cannot determine the location of the droplet within the probe, no correction for the size can be made directly by the system. Also, no predictive models for droplet location within a sub-channel are available for a reflood test - so a correction cannot be developed with a known droplet location distribution. The result is that the effect of droplet location in the probe must be studied using an assumed distribution.

B.3.4.4.1 Apparent Change in Diameter

Initially, the uncertainty of a diameter measurement can be quantified by investigating the change in apparent diameter for a given object that is varying within the optical probe length. The location uncertainty is quantified by calculational techniques assuming no effects resulting from the image being out of focus. Knowing the distance from the camera (A), the optical probe length (L), and the diameter of an object (D), the apparent change in diameter can be calculated for objects as they vary in the probe length:

Known:

A	Distance from Camera to Center of Optical Probe
D	Diameter of Object at Distance A
L(A,D)	Optical Probe Length, Function of A and D
l	Distance from Center of Optical Probe to Location of Object

Find:

D_1	Diameter of Object at Distance A-l
D_2	Diameter of Object at Distance A+ e

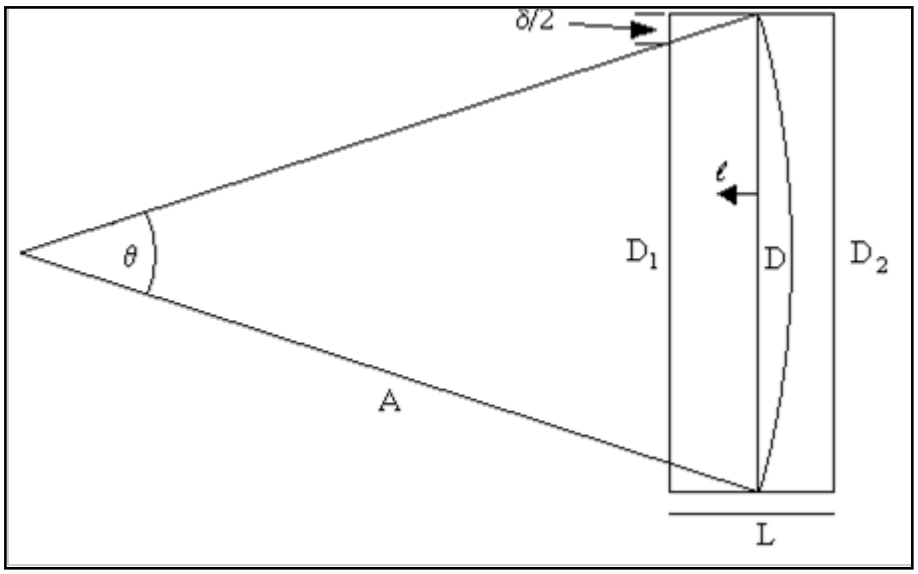

Figure B-14: Schematic of OPL effect

Assume:

A>>D so no curvature of d

$D_1 = D + \delta$

Identity:

$d = A \bullet \theta$ (B-37)

where:

θ is the angle in radians

So:

$D_1 = (A-l) \bullet \theta$ (B-38)

$$\frac{D}{A} = \frac{D-\delta}{A-l} \quad \text{(B-39)}$$

Rearranging:

$$\delta = l \cdot \frac{D}{A} \quad \text{(B-40)}$$

Maximum where l is L/2

$$\delta = \frac{L}{2} \times \frac{d}{A} \quad \text{(B-41)}$$

Where δ represents the apparent change in diameter of an object of size D that approaches the camera location by a distance of *l*. The effect of the change in location within the optical probe length is shown below, where Equation B-41 is investigated for a 450 micron circle at the extremes of the optical probe length listed in Table B-13 for a focus parameter of 25.

Using the values

D = 450.45 microns
A = 660 mm (26 in.)
F =15

From Table B-13:

L =13.7 mm

using Equation B-41 (above):

$$\delta = \frac{13.7mm}{2} \cdot \frac{450.45microns}{660mm} = 4.68 \text{ microns} \quad \text{(B-42)}$$

At the extreme near and far sides of the optical probe length:

D = 450.45 ± 4.68 microns

This calculation illustrates the intuitive variation with location, but it does not entirely represent the change in size within the probe length. However, it does indicate a small (about 1%) change for a 450 micron circle.

B.3.4.4.2 Effect of Focus on Diameter

If an object moves from the center of the probe length, it appears out of focus to the camera. As an image becomes out of focus it begins to diminish in apparent size because less pixels are determined to be in the image as measured by VisiSizer. When considering a case where the apparent diameter does not change as described in Equation B-41, the effect of moving from the center of the optical probe is a decrease in size. The decrease occurs as the object moves towards and away from the camera in relation to the center of the probe because the image goes out of focus.

B.3.4.4.3 Investigation of VisiSizer Data

The change in measured diameter resulting from moving the reticle circles along the optical probe length is seen in data sequences collected by VisiSizer. Table B-16 lists the corrected diameter of each circle measured at several locations along the optical probe length. The information is collected at 66.0 cm (26 in.) from the camera.

Table B-16: Effect of Traversing OPL on Corrected Diameter [pixels]

Circle Number	Location in OPL (mm)							
	-7.87	**-4.98**	**-2.07**	**0.83**	**3.72**	**6.63**	**9.46**	**12.43**
6			4.523	4.482	3.285			
8		4.864	6.702	6.654	5.881			
10	3.285	7.522	8.563	8.553	8.229	6.219		
12.5	6.540	10.009	10.785	10.935	10.666	9.348	5.034	
15	10.462	12.610	13.106	13.141	12.814	11.973	9.851	
20	16.282	17.298	17.656	17.387	17.295	16.828	15.900	13.417
25	21.397	22.015	22.143	21.872	21.798	21.681	20.956	19.681

The information in Table B-16 has been corrected to remove the measurement bias. The center of the probe is at zero millimeters and the measured diameter decreases for each circle as it moves away from the center of the optical probe length (OPL), where negative distances denote movement towards the camera. Initially the measured size of each circle does not decrease as quickly as when approaching the camera as when it moves away from the camera. This is a result of the two competing effects discussed earlier; the apparent change in size and the effect of being out of focus. The effect can clearly be seen in Figure B-15, where the information in Table B-16 is plotted as the diameter at the center of the OPL minus the local diametrical measurement.

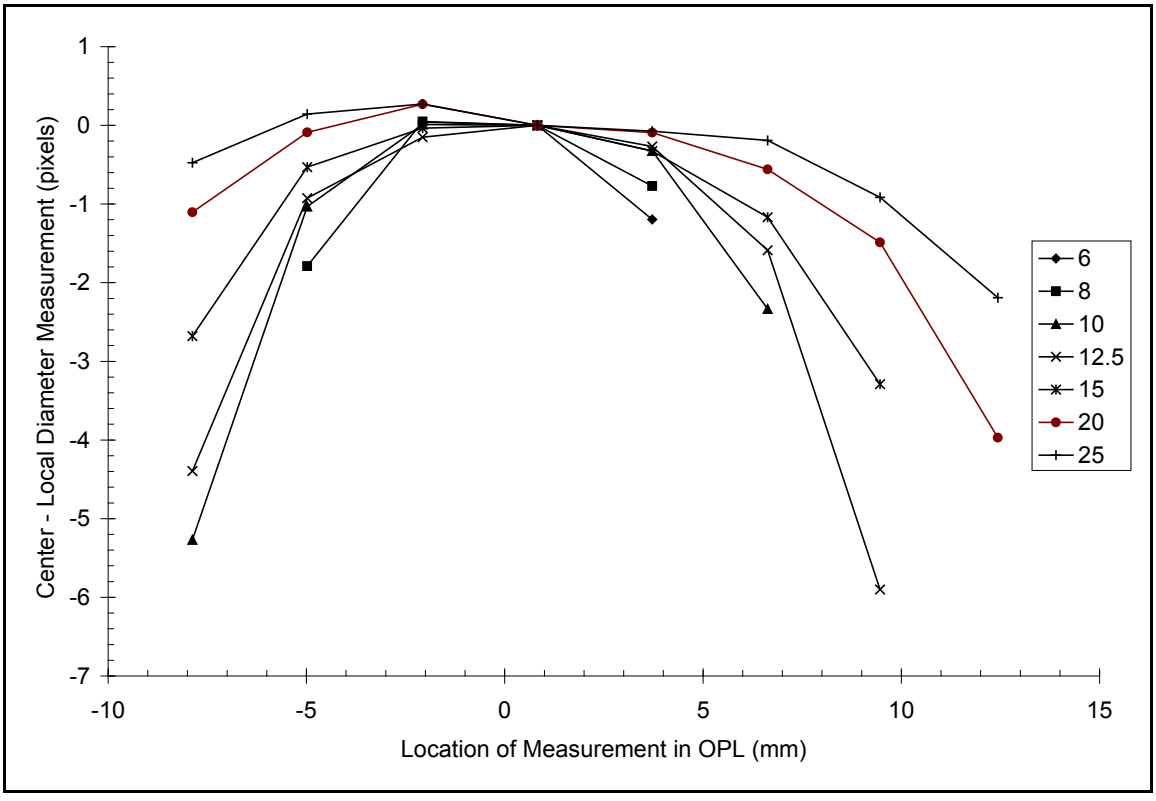

Figure B-15: Difference of Corrected Local Diameter from Diameter at the Center of the OPL

A polynomial best fit of each of the curves in Figure B-15 is developed to characterize the change in size with change in the optical probe location. The curves are listed in Equations B-43 to B-49.

Circle Number:	Equation:	
6	$\Delta d\left(d_6, x\right) = -0.056377x^2 - 0.117970x$	(B-43)
8	$\Delta d\left(d_8, x\right) = -0.044400x^2 - 0.016817x$	(B-44)
10	$\Delta d\left(d_{10}, x\right) = -0.001091x^4 + 0.001048x^3 - 0.01047x^2 - 0.010368x$	(B-45)
12.5	$\Delta d\left(d_{12.5}, x\right) = -0.0007470x^4 + 0.001485x^3 - 0.01295x^2 - 0.001366x$	(B-46)
15	$\Delta d\left(d_{15}, x\right) = -0.0003621x^4 + 0.001465x^3 - 0.01410x^2 - 0.03925x$	(B-47)
20	$\Delta d\left(d_{20}, x\right) = -0.0002179x^4 + 0.001154x^3 - 0.002066x^2 - 0.05398x$	(B-48)
25	$\Delta d\left(d_{25}, x\right) = -0.0001000x^4 + 0.0009038x^3 + 0.002046x^2 - 0.05530x$	(B-49)

where:

$\Delta d\left(d_i, x\right)$ difference of local diameter at x from the diameter at center of circle number i [pixels]

x location in OPL referenced to the center of OPL [mm]

The data shown in Figure B-15 and represented by the polynomial Equations B-43 to B-49 illustrates a bias that results from using a low setting for the focus parameter setting (F). A low setting allows a large optical probe, and the size of droplet images in the probe undergo a decrease in measured diameter as they move away from the center of the probe.

To illustrate the bias, a simple case of data with mono-sized droplets evenly distributed across the OPL is considered. A distribution of droplet sizes is present where the change in size is a result of the location of each droplet in the OPL, assuming no measurement error. The variation in size is more pronounced for sequences which use a low focus parameter (F). A high setting would result in a measured size distribution that is essentially mono-sized, which is the true size of the droplets.

B.3.4.4.4 Bias Correction of OPL Effect

A correction is developed to account for the size of a droplet image decreasing as the image deviates from the center of the OPL. To do this, a probability function $p(d_i, x)$ is defined that describes the probability that a droplet of diameter d_i is found at location x in the OPL. Once the function is defined a correction can be developed where the change of diameter with x is known from Equations B-43 to B-49 and the length of the optical probe is known from Equation B-15. The correction effectively assumes a population of mono-sized droplets and is developed as follows:

known:

$\Delta d\left(d_i, x\right)$ (from Equations B-43 to B-49)

$p\left(d_i, x\right)$ (given)

$L_i = 2.7814 \cdot \ln(d_i) - 2.9075$ (from Equation B-15)

averaging:

$$\Delta\overline{d}_i = \frac{1}{L_i}\int \Delta d\left(d_i, x\right) p\left(d_i, x\right) dx \qquad \text{(B-50)}$$

integrating from: $-L_i/2$ to $L_i/2$

and:

$$d_{OPLi} = d\left(d_i, 0\right) - \overline{d}_i \qquad \text{(B-51)}$$

where:

$\Delta\overline{d}_i$ the average deviation from measured diameter at center of OPL [pixels]

$d\left(d_i, 0\right)$ measured diameter at the center of the OPL for size class i

d_{OPLi} corrected diameter which accounts for variaton along the OPL [pixels]

Since Equations B-43 to B-49 are developed from the reticle circles, the assumption of a mono-sized population is accurate. Another assumption is necessary to simplify the analysis. Evaluation of the integral is performed assuming the largest measured diameter occurs in the center of the optical probe length. The assumption is not entirely accurate as can be seen in Figure B-15. The result of using the bias correction for a given measurement sequence of mono-sized droplets with a known distribution results in shifting the mean measured diameter upwards. Once corrected, the mean measured diameter corresponds with the diameter measured at the center of the probe, which is the location of calibration as mentioned in a previous section.

As was discussed previously, no predictions for the probability function $p(d_i, x)$ are available. However, the function can be over-estimated as unity for all d_i and all x. This allows the development of a generalized correction that can be applied to all sizes of droplets. The average deviation can now be found for each of the circles by integrating Equations B-43 to B-49 and finding the average across the probe for each size using the roots in Table B-17:

General Form of Equations

$$\Delta d\left(d_i, x\right) = -A_i \cdot x^4 + B_i \cdot x^3 - C_i \cdot x^2 + D_i \cdot x \tag{B-52}$$

Averaging from -L/2 to L/2 and simplifying

$$\Delta \bar{d}_i = \frac{1}{L}\left[\frac{-2A_i}{5}\left(\frac{L}{2}\right)^5 - \frac{2C_i}{3}\left(\frac{L}{2}\right)^3\right] = \frac{-A_i}{80}L^4 - \frac{C_i}{12}L^2 \tag{B-53}$$

where:

A_i and C_i are found from Table B-17 for circle size i

Table B-17: Calibration Circle Diameters

Circle no.	diameter [microns]	A_i	C_i
6	106.47		-0.056377
8	144.69		-0.044400
10	177.45	-0.0010910	- 0.010470
12.5	223.86	-0.0007470	- 0.012950
15	270.27	-0.0003621	- 0.014100
20	360.36	-0.0002179	- 0.002066
25	450.45	-0.0001000	+0.002046

The data in Figure B-16 is found from Equation B-53 for each circle size to determine the average deviation for that circle.

The data has been fit with a line to define a generalized bias correction. The best fit equation in Figure B-16 is listed, along with the bounds for the equation:

Range: 0 to 24.6 pixels

$$\Delta \bar{d}_i = 0.024267 \cdot d_i - 0.597671 \tag{B-54}$$

Above 24.6 pixels in diameter (492 microns (19.68 mils), assuming R=20 microns (0.8 mils) per pixel) the effect of location variation within the OPL is not significant. This is because the reduction in measured size that results in the bias is insignificant along the optical probe length of large images. The best-fit equation can be used to correct data from a sequence of mono-sized, evenly distributed droplet measurements when the diameter of the droplets is known in pixels at the center of the optical probe length. To correct the population, subtract the average deviation found from Equation B-54 for the diameter from the measured mean size of the sequence.

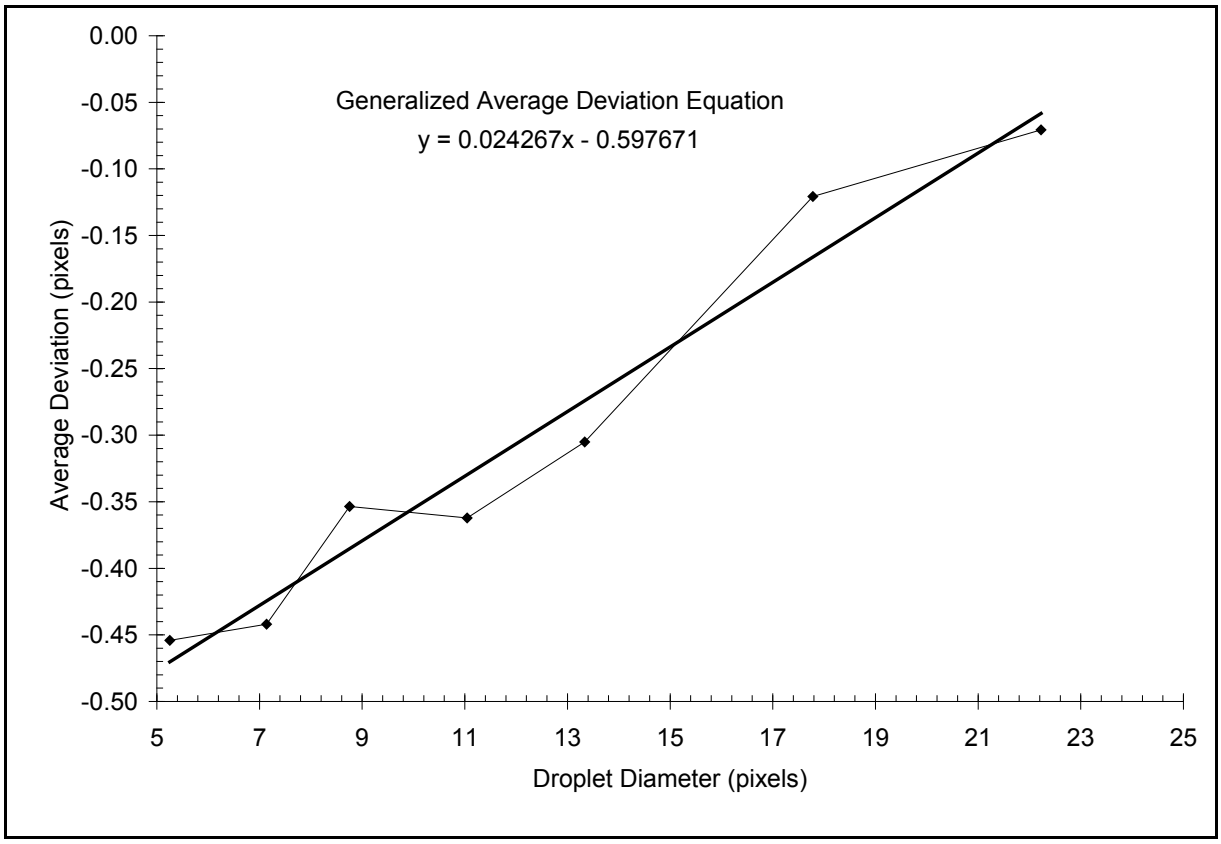

Figure B-16: Average Deviation of Randomly Distributed Population from Actual

The bias correction has been developed for a limited case with mono-sized droplets and a fixed–random distribution of the droplets in the optical probe. Without knowledge of the exact size and location of droplets in a reflood experiment, no bias correction is possible. However, the bias has been shown to only affect droplets smaller than 24.6 pixels in diameter. Assuming a 20.0 microns (0.8 mils) per pixel conversion ratio, the largest droplet affected by the variation in the optical probe length is a 500 micron (20 mils) droplet. Therefore, the effect is not significant for most of the droplet sizes expected in the RBHT facility and can be neglected.

B.3.4.5 Variation of Illumination Intensity

A series of sequences have been collected in which the laser illumination is varied to simulate absorption of the laser light in steam flow during a reflood experiment in the RBHT facility. Under steady state conditions the effect of laser absorption is inconsequential because it can be removed with careful calibration. Since the vapor phase undergoes significant temperature changes during a reflood experiment however, the vapor density, thus laser absorption, changes. The effect of changes in laser intensity are investigated to determine the overall effect on the accuracy of VisiSizer results.

This investigation bounds the expected conditions within the RBHT facility during an experiment, but exact information on the illumination intensity is not available. Figure B-17 shows the measured diameter in pixels for a range of pulse duration settings. The data has been corrected to remove the measurement bias.

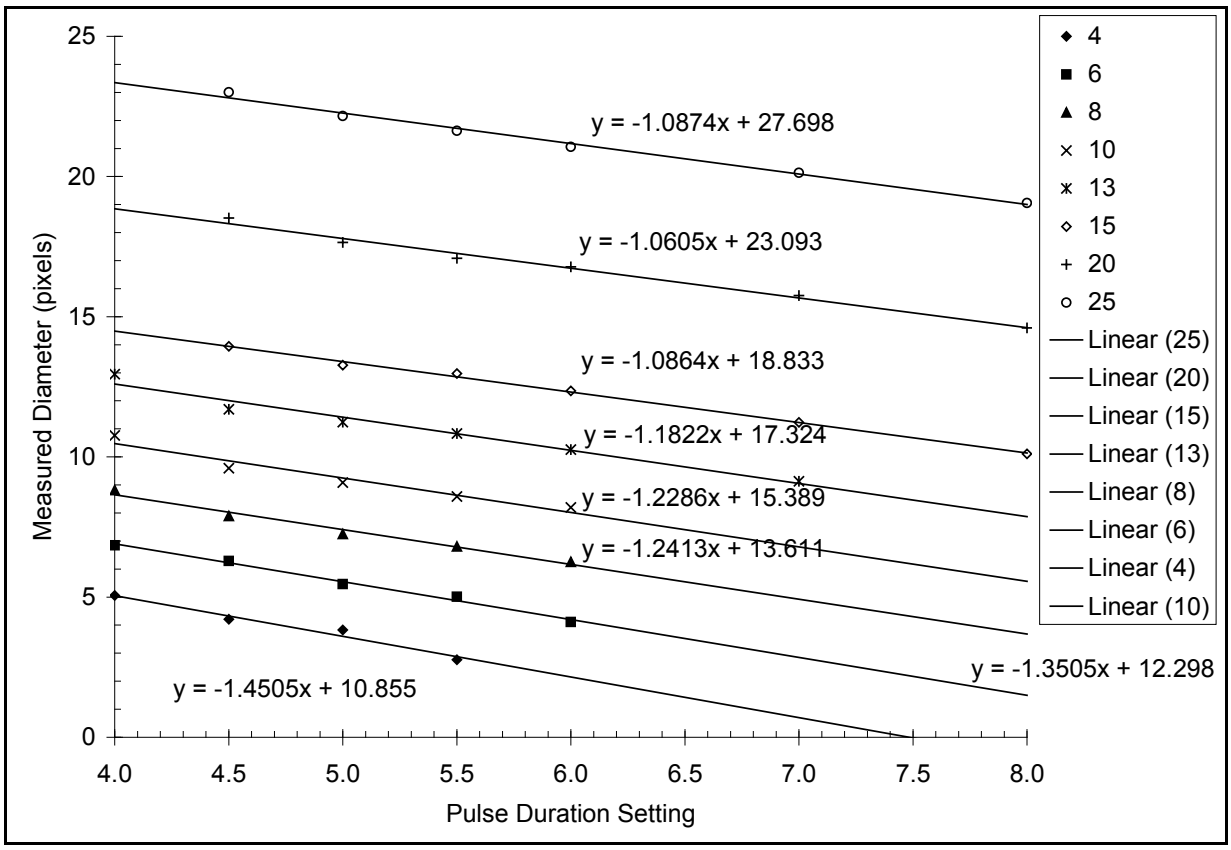

Figure B-17: Effect of Laser Intensity on Diameter Measurement

The diameter change is linear with changes in illumination intensity. This is a significant finding because any changes that affect the illumination intensity during a reflood experiment will not affect the overall distribution of droplet measurements in relation to one another. The distribution will only have an overall increase or decrease in size with respect to the initial calibration.

Currently no method is available to measure the illumination intensity or the relative change in intensity from frame to frame with VisiSizer. A simple bias correction can be developed for frames of data if a method becomes available to measure the change in illumination intensity from the calibration frame.

The results presented in Figure B-17 are collected using the reticle circles and are not entirely prototypical of what occurs with water droplets. Water droplets are semi-transparent and suffer from an over-exposure effect that the opaque circles do not undergo.

11. ABSTRACT (200 words or less)
As part of the Nuclear Regulatory Commission safety analysis computer code development efforts, the Rod Bundle Heat Transfer (RBHT) test facility has been designed and constructed at The Pennsylvania State University. The test series described in this report is the steam cooling tests with droplet injection. A total of 85 steady-state steam cooling experiments with prescribed droplet injection was performed in the RBHT. The purpose of the experiments was to examine steady-state dispersed flow film boiling in prototypical rod bundle geometry for computer code model development and validation. The Rod Bundle Heat Transfer facility is a full length, 3.66 m (12 ft.), 7 by 7 rod array with typical Pressurized Water Reactor rod diameters of 9.49 mm (0.374 in.) and a rod pitch of 12.59 mm (0.496 in.). The heater rods have a top skewed power shape with a peak to average power of 1.5 at the 2.74 m (9 ft.) elevation. The RBHT facility has been designed using prototypical mixing vane spacer grids. The bundle inlet steam Reynolds number ranged from 2000 to 15,000 with most of the experiments at the lower Reynolds number range. The droplets were injected upward in the center of the sub-channels at the 1.295 m (51 in.) elevation using two or four injection tubes. The injection tubes used a single row, linear hole pattern of four holes per sub-channel and four sub-channels per tube in the center of the bundle. One additional hole was located at the center of the rod gap location to minimize the chance of local
