Plant Specific Notes:

1. The terminology "Piping and Piping Components" represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Plant Specific Notes:

1. Material of construction is inhibited Brass which is not susceptible to selective leaching.
2. The terminology “Piping and Piping Components” represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Component Type	Intended Function	Material	Environment	Aging Effect	Aging Management Program	NUREG-2191 Item	NUREG-2192 Table 1	Notes

Plant Specific Notes:

1. Component is constructed of the same material as the fuel oil storage tank. The fuel oil storage tank is not coated on its internal surface. One-time inspection of this component is not required per GALL AMP XI.M30, Element 4.
2. Stainless steel piping embedded in concrete exits the building above grade level. Concrete is not subject to soil or groundwater.

Valve Body	Structural Integrity	Zinc	Air – Indoor Uncontrolled (External)	None	None	VII.J.A-712	3.3.1- 167	A
			Condensation (Internal)	None	None	VII.J.A-712	3.3.1- 167	A

Plant Specific Notes:

1. Cracking of copper alloy (>15% Zn) in indoor air could result from ammonia-based compounds conveyed to external surfaces from bolted joint leakage through insulation. However, cracking of internal surfaces is not expected as these surfaces are not exposed to contamination from external leakage sources.
2. The compresor skid functions as an equivalent anchor for non-safety attached to safety piping.

Plant Specific Notes:

1. Subject component is nickel plated brass valve body.
2. Subject table row represents insulated components in the system.
3. Flow blockage due to fouling is not a concern for components that perform a structural integrity function.
4. The terminology “Piping and Piping Components” represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Table 3.3.2-59 Auxiliary Systems - Liquid Waste Disposal System - Aging Management Evaluation

Component Type	Intended Function	Material	Environment	Aging Effect	Aging Management Program	NUREG-2191 Item	NUREG-2192 Table 1	Notes

Plant Specific Notes:

1. Subject components are for 1,2,3LWD-FL-0017 which are located in the RB Emergency Sump.
2. Subject table row represents insulated components in the system.
3. Flow blockage due to fouling is not a concern for components that perform a structural integrity function.
4. The terminology “Piping and Piping Components” represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Tables 3.3.2-1 through 3.3.2-59 Industry Standard Notes:

A. Consistent with NUREG-2191 item for component, material, environment, and aging effect. AMP is consistent with NUREG-2191 AMP.

B. Consistent with NUREG-2191 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-2191 AMP.

C. Component is different, but consistent with NUREG-2191 item for material, environment, and aging effect. AMP is consistent with NUREG-2191 AMP.

D. Component is different, but consistent with NUREG-2191 item for material, environment, and aging effect. AMP takes some exceptions to the NUREG-2191 AMP.

E. Consistent with NUREG-2191 item for material, environment, and aging effect, but a different AMP is credited or NUREG-2191 identifies a plant-specific AMP.

F. Material not in NUREG-2191 for this component.

G. Environment not in NUREG-2191 for this component and material.

H. Aging effect not in NUREG-2191 for this component, material, and environment combination.

I. Aging effect in NUREG-2191 for this component, material, and environment combination is not applicable.

J. Neither the component nor the material and environment combination are evaluated in NUREG-2191.

3.4 AGING MANAGEMENT OF STEAM AND POWER CONVERSION SYSTEMS

3.4.1 INTRODUCTION

This section provides the results of the aging management review for those components identified in Section 2.3.4, Steam and Power Conversion, as being subject to aging management review. The system or portions of systems which are addressed in this section are described in the indicated sections.

- Condensate System
- Feedwater System
- High Pressure Extraction System
- Heater Vent System
- Low Pressure Extraction System
- Heater Drain System
- Auxiliary Steam System
- Main Steam System
- Turbine and Auxiliaries
- Plant Heating System
- Steam Drain System
- Steam Seal System

3.4.2 RESULTS

The following tables summarize the results of the aging management review for Steam and Power Conversion Systems:

- Table 3.4.2-1, Steam and Power Conversion - Condensate System - Aging Management Evaluation
- Table 3.4.2-2, Steam and Power Conversion - Feedwater System - Aging Management Evaluation
- Table 3.4.2-3, Steam and Power Conversion - Heater Drain System - Aging Management Evaluation
- Table 3.4.2-4, Steam and Power Conversion - High Pressure Turbine Exhaust System - Aging Management Evaluation
- Table 3.4.2-5, Steam and Power Conversion - Heater Vent System - Aging Management Evaluation
- Table 3.4.2-6, Steam and Power Conversion - Low Pressure Turbine Exhaust System - Aging Management Evaluation
- Table 3.4.2-7, Steam and Power Conversion - Auxiliary Steam System - Aging Management Evaluation

- Table 3.4.2-12, Steam and Power Conversion - Steam Seal System - Aging Management Evaluation

3.4.2.1 Materials, Environments, Aging Effects Requiring Management and Aging Management Programs

3.4.2.1.1 Condensate System

Materials

Components in the Condensate System are constructed of the following materials:

* Copper Alloy
* Copper Alloy (>15% Zn)
* Ductile Iron
* Glass
* Gray Cast Iron
* Stainless Steel
* Steel
* Steel w. Nickel Plating
* Steel with Internal Coating/Lining

Environments

Components in the Condensate System are exposed to the following environments:

* Air
* Air – Indoor Uncontrolled
* Air – Outdoor
* Closed-Cycle Cooling Water
* Concrete
* Lubricating Oil
* Raw Water
* Raw Water (Potable)
* Treated Water
* Treated Water >60°C (>140°F)
* Waste Water

Aging Effects Requiring Management

Components in the Condensate System require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage
* Flow Blockage
* Long-Term Loss of Material
* Loss of Coating or Lining Integrity
* Loss of Material
* Loss of Preload
* Reduction of Heat Transfer
* Wall Thinning

Aging Management Programs

The aging effects for components in the Condensate System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)
* Closed Treated Water System (B2.1.12)
* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* Flow-Accelerated Corrosion (B2.1.8)
* Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B2.1.24)
* Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B2.1.27)
* Lubricating Oil Analysis (B2.1.25)
* One-Time Inspection (B2.1.20)
* Open-Cycle Cooling Water System (B2.1.11)
* Selective Leaching (B2.1.21)
* TLAA
* Water Chemistry (B2.1.2)

3.4.2.1.2 Feedwater System

Materials

Components in the Feedwater System are constructed of the following materials:

* Copper Alloy (>15% Zn)
* Galvanized Steel
* Glass
* Polymeric
* Stainless Steel
* Steel
* Steel (with Stainless Steel Cladding)

Environments

Components in the Feedwater System are exposed to the following environments:

* Air – Indoor Uncontrolled
* Air with Borated Water Leakage
* Closed-Cycle Cooling Water
* Closed-Cycle Cooling Water >60°C (>140°F)
* Raw Water (Potable)
* Treated Water
* Treated Water >60°C (>140°F)

Aging Effects Requiring Management

Components in the Feedwater System require aging management to address the following aging effects:

* Cracking
* Cracking or Blistering
* Cumulative Fatigue Damage

* Hardening or Loss of Strength
* Long-Term Loss of Material
* Loss of Material
* Loss of Preload
* Wall Thinning

Aging Management Programs

The aging effects for components in the Feedwater System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)
* Boric Acid Corrosion (B2.1.4)
* Closed Treated Water System (B2.1.12)
* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* Flow-Accelerated Corrosion (B2.1.8)
* Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B2.1.24)
* One-Time Inspection (B2.1.20)
* Selective Leaching (B2.1.21)
* TLAA
* Water Chemistry (B2.1.2)

3.4.2.1.3 Heater Drain System

Materials

Components in the Heater Drain System are constructed of the following materials:

* Copper Alloy
* Copper Alloy (>15% Zn)
* Glass
* Gray Cast Iron
* Stainless Steel
* Steel

Environments

Components in the Heater Drain System are exposed to the following environments:

* Air – Indoor Uncontrolled
* Closed-Cycle Cooling Water
* Closed-Cycle Cooling Water >60°C (>140°F)
* Lubricating Oil
* Raw Water
* Raw Water (Potable)
* Treated Water
* Treated Water >60°C (>140°F)
* Waste Water

Aging Effects Requiring Management

Components in the Heater Drain System require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage

* Long-Term Loss of Material
* Loss of Material
* Loss of Preload
* Wall Thinning

Aging Management Programs

The aging effects for components in the Heater Drain System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)
* Closed Treated Water System (B2.1.12)
* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* Flow-Accelerated Corrosion (B2.1.8)
* Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B2.1.24)
* Lubricating Oil Analysis (B2.1.25)
* One-Time Inspection (B2.1.20)
* Open-Cycle Cooling Water System (B2.1.11)
* Selective Leaching (B2.1.21)
* TLAA
* Water Chemistry (B2.1.2)

3.4.2.1.4 High Pressure Turbine Exhaust System

Materials

Components in the High Pressure Turbine Exhaust System are constructed of the following materials:

* Stainless Steel
* Steel

Environments

Components in the High Pressure Turbine Exhaust System are exposed to the following environments:

* Air – Indoor Uncontrolled
* Treated Water
* Treated Water >60°C (>140°F)

Aging Effects Requiring Management

Components in the High Pressure Turbine Exhaust System require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage
* Long-Term Loss of Material
* Loss of Material
* Loss of Preload
* Wall Thinning

Aging Management Programs

The aging effects for components in the High Pressure Turbine Exhaust System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)

* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* Flow-Accelerated Corrosion (B2.1.8)
* One-Time Inspection (B2.1.20)
* TLAA
* Water Chemistry (B2.1.2)

3.4.2.1.5 Heater Vent System

Materials

Components in the Heater Vent System are constructed of the following materials:

* Stainless Steel
* Steel

Environments

Components in the Heater Vent System are exposed to the following environments:

* Air
* Air – Indoor Uncontrolled
* Air – Outdoor
* Treated Water
* Treated Water >60°C (>140°F)

Aging Effects Requiring Management

Components in the Heater Vent System require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage
* Long-Term Loss of Material
* Loss of Material
* Loss of Preload
* Wall Thinning

Aging Management Programs

The aging effects for components in the Heater Vent System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)
* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* Flow-Accelerated Corrosion (B2.1.8)
* Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B2.1.24)
* One-Time Inspection (B2.1.20)
* TLAA
* Water Chemistry (B2.1.2)

3.4.2.1.6 Low Pressure Turbine Extraction System

Materials

Components in the Low Pressure Turbine Extraction System are constructed of the following materials:

* Nickel Alloy
* Stainless Steel
* Steel

Environments

Components in the Low Pressure Turbine Extraction System are exposed to the following environments:

* Air – Indoor Uncontrolled
* Treated Water
* Treated Water >60°C (>140°F)

Aging Effects Requiring Management

Components in the Low Pressure Turbine Extraction System require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage
* Long-Term Loss of Material
* Loss of Material
* Loss of Preload
* Wall Thinning

Aging Management Programs

The aging effects for components in the Low Pressure Turbine Extraction System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)
* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* Flow-Accelerated Corrosion (B2.1.8)
* One-Time Inspection (B2.1.20)
* TLAA
* Water Chemistry (B2.1.2)

3.4.2.1.7 Auxiliary Steam System

Materials

Components in the Auxiliary Steam System are constructed of the following materials:

* Copper Alloy
* Glass
* Gray Cast Iron
* Stainless Steel
* Steel

Environments

Components in the Auxiliary Steam System are exposed to the following environments:

* Air – Indoor Uncontrolled
* Diesel Exhaust
* Treated Water
* Treated Water >60°C (>140°F)

Aging Effects Requiring Management

Components in the Auxiliary Steam System require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage
* Long-Term Loss of Material
* Loss of Material
* Loss of Preload
* Wall Thinning

Aging Management Programs

The aging effects for components in the Auxiliary Steam System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)
* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* Flow-Accelerated Corrosion (B2.1.8)
* Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B2.1.24)
* One-Time Inspection (B2.1.20)
* Selective Leaching (B2.1.21)
* TLAA
* Water Chemistry (B2.1.2)

3.4.2.1.8 Main Steam System

Materials

Components in the Main Steam System are constructed of the following materials:

* Copper Alloy
* High-Strength Steel
* Stainless Steel
* Steel

Environments

Components in the Main Steam System are exposed to the following environments:

* Air – Indoor Uncontrolled
* Air – Outdoor
* Air with Borated Water Leakage
* Treated Water
* Treated Water >60°C (>140°F)

Aging Effects Requiring Management

Components in the Main Steam System require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage
* Long-Term Loss of Material
* Loss of Material
* Loss of Preload
* Wall Thinning

Aging Management Programs

The aging effects for components in the Main Steam System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)
* Boric Acid Corrosion (B2.1.4)
* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* Flow-Accelerated Corrosion (B2.1.8)
* One-Time Inspection (B2.1.20)
* TLAA
* Water Chemistry (B2.1.2)

3.4.2.1.9 Turbine and Auxiliaries System

Materials

Components in the Turbine and Auxiliaries System are constructed of the following materials:

* High-Strength Steel
* Steel

Environments

Components in the Turbine and Auxiliaries System are exposed to the following environments:

* Air – Indoor Uncontrolled
* Treated Water

Aging Effects Requiring Management

Components in the Turbine and Auxiliaries System require aging management to address the following aging effects:

* Cracking
* Long-Term Loss of Material
* Loss of Material
* Loss of Preload

Aging Management Programs

The aging effects for components in the Turbine and Auxiliaries System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)
* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* One-Time Inspection (B2.1.20)
* Water Chemistry (B2.1.2)

3.4.2.1.10 Plant Heating System

Materials

Components in the Plant Heating System are constructed of the following materials:

* Copper Alloy
* Gray Cast Iron
* Stainless Steel
* Steel

Environments

Components in the Plant Heating System are exposed to the following environments:

* Air – Indoor Uncontrolled
* Air with Borated Water Leakage
* Treated Water
* Treated Water >60°C (>140°F)

Aging Effects Requiring Management

Components in the Plant Heating System require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage
* Long-Term Loss of Material
* Loss of Material
* Loss of Preload
* Wall Thinning

Aging Management Programs

The aging effects for components in the Plant Heating System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)
* Boric Acid Corrosion (B2.1.4)
* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* Flow-Accelerated Corrosion (B2.1.8)
* One-Time Inspection (B2.1.20)
* Selective Leaching (B2.1.21)
* TLAA
* Water Chemistry (B2.1.2)

3.4.2.1.11 Steam Drain System

Materials

Components in the Steam Drain System are constructed of the following materials:

* Glass
* Stainless Steel
* Steel

Environments

Components in the Steam Drain System are exposed to the following environments:

* Air – Indoor Uncontrolled
* Treated Water
* Treated Water >60°C (>140°F)

Aging Effects Requiring Management

Components in the Steam Drain System require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage
* Long-Term Loss of Material
* Loss of Material
* Loss of Preload
* Wall Thinning

Aging Management Programs

The aging effects for components in the Steam Drain System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)

* External Surfaces Monitoring of Mechanical Components (B2.1.23)
* Flow-Accelerated Corrosion (B2.1.8)
* One-Time Inspection (B2.1.20)
* TLAA
* Water Chemistry (B2.1.2)

3.4.2.1.12 Steam Seal System

Materials

Components in the Steam Seal System are constructed of the following materials:

* Ductile Iron
* Stainless Steel
* Steel

Environments

Components in the Steam Seal System are exposed to the following environments:

* Air – Indoor Uncontrolled
* Treated Water
* Treated Water >60°C (>140°F)

Aging Effects Requiring Management

Components in the Steam Seal System require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage
* Long-Term Loss of Material
* Loss of Material
* Loss of Preload
* Wall Thinning

Aging Management Programs

The aging effects for components in the Steam Seal System are managed by the following AMPs:

* Bolting Integrity (B2.1.9)

- External Surfaces Monitoring of Mechanical Components (B2.1.23)
- Flow-Accelerated Corrosion (B2.1.8)
- One-Time Inspection (B2.1.20)
- Selective Leaching (B2.1.21)
- TLAA
- Water Chemistry (B2.1.2)

3.4.2.2 Further Evaluation of Aging Management as Recommended by NUREG-2192

NUREG-2192 provides the basis for identifying those programs that warrant further evaluation by the reviewer in the SLRA. For the Steam and Power Conversion features, those evaluations are addressed in the following sections. Italicized text is taken directly from NUREG-2192.

3.4.2.2.1 Cumulative Fatigue Damage

NUREG-2192

Evaluations involving time-dependent fatigue or cyclical loading parameters may be time-limited aging analyses (TLAAs), as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c)(1). This TLAA is addressed separately in SRP-SLR Section 4.3, "Metal Fatigue," or Section 4.7, "Other Plant-Specific Time-Limited Aging Analyses." For plant-specific cumulative usage factor calculations that are based on stress-based input methods, the methods are to be appropriately defined and discussed in the applicable TLAAs.

Evaluation:

[3.4.1-001] - Fatigue of steam and power conversion systems components is a TLAA, as defined in 10 CFR 54.3. The evaluation of this TLAA is addressed in Section 4.3.3, "Non-Class 1 Piping Fatigue Analyses".

3.4.2.2.2 Cracking Due to Stress Corrosion Cracking in Stainless Steel Alloys

NUREG-2192

Cracking due to stress corrosion cracking (SCC) could occur in indoor or outdoor stainless steel (SS) piping, piping components, and tanks exposed to any air, condensation, or underground environment when the component is: (a) uninsulated; (b) insulated; (c) in the vicinity of insulated components; or (d) in the vicinity of potentially transportable halogens. Cracking can occur in environments containing sufficient halides (e.g., chlorides) in the presence of moisture.

Insulated SS components exposed to indoor air, outdoor air, condensation, or underground environments are susceptible to SCC if the insulation contains certain contaminants. Leakage of fluids through bolted connections (e.g., flanges, valve packing) can result in contaminants present in the insulation leaching onto the component surface or the surfaces of other components below the component. For outdoor insulated SS components, rain and changing weather conditions can result in moisture intrusion into the insulation.

Plant-specific operating experience (OE) and the condition of SS components are evaluated to determine if prolonged exposure to the plant-specific environments has resulted in SCC. SCC in SS components is not an aging effect requiring management if (a) plant-specific OE does not reveal a history of SCC and (b) a one-time inspection demonstrates that the aging effect is not occurring.

In the environment of air-indoor controlled, SCC is only expected to occur as the result of a source of moisture and halides. Inspections focus on the most susceptible locations. The applicant documents the results of the plant-specific OE review in the SLRA.

The GALL-SLR Report recommends further evaluation of SS piping, piping components, and tanks exposed to an air, condensation, or underground environment to determine whether an AMP is needed to manage the aging effect of SCC. The GALL-SLR Report AMP XI.M32, "One-Time Inspection," describes an acceptable program to demonstrate that SCC is not occurring. If SCC is occurring, the following AMPs describe acceptable programs to manage loss of material due to SCC: (a) GALL-SLR Report AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks," for tanks; (b) GALL-SLR Report AMP XI.M36, "External Surfaces Monitoring of Mechanical Components," for external surfaces of piping and piping components; (c) GALL-SLR Report AMP XI.M41, "Buried and Underground Piping and Tanks," for underground piping, piping components and tanks; and (d) GALL-SLR Report AMP XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components," for internal surfaces of components that are not included in other AMPs. The timing of the one-time or periodic inspections is consistent with that recommended in the AMP selected by the applicant during the development of the SLRA. For example, one-time inspections would be conducted between the 50th and 60th year of operation, as recommended by the "detection of aging effects" program element in AMP XI.M32.

The applicant may establish that SCC is not an aging effect requiring management for all components, by demonstrating that a barrier coating isolates the component from aggressive environments. Acceptable barriers include tightly-adhering coatings that have been demonstrated to be impermeable to aqueous solutions and air that contain halides. The GALL-SLR Report AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks," describes an acceptable program to manage the integrity of a barrier coating.

Evaluation:

A review of ONS operating experience confirmed that cracking due to stress corrosion cracking has not been identified in stainless steel piping, piping components, and tanks exposed to air, condensation, or underground environments in ONS steam and power conversion systems.

[3.4.1-002] - ONS has no stainless steel piping, piping components, or tanks exposed to air or condensation in the scope of SLR in steam and power conversion systems. Components in the steam and power conversion system are insulated and are aligned to item 3.4.1-104.

[3.4.1-074] - ONS has no stainless steel or nickel alloy underground piping, piping components, or tanks in an underground environment in the scope of SLR in steam and power conversion systems.

[3.4.1-100] - ONS has no stainless steel tanks within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks" in the scope of SLR in steam and power conversion systems.

[3.4.1-104] – The *One-Time Inspection* (B2.1.20) program will be implemented to confirm cracking due to stress corrosion cracking insulated stainless steel piping, piping components, and tanks exposed to air or condensation is not occurring.

3.4.2.2.3 Loss of Material Due to Pitting and Crevice Corrosion in Stainless Steel and Nickel Alloys

NUREG-2192

Loss of material due to pitting and crevice corrosion could occur in indoor or outdoor SS and nickel alloy piping, piping components, and tanks exposed to any air, condensation, or underground environment when the component is: (a) uninsulated; (b) insulated; (c) in the vicinity of insulated components; or (d) in the vicinity of potentially transportable halogens. Loss of material due to pitting and crevice corrosion can occur on SS and nickel alloys in environments containing sufficient halides (e.g., chlorides) in the presence of moisture.

Insulated SS and nickel alloy components exposed to air, condensation, or underground environments are susceptible to loss of material due to pitting or crevice corrosion if the insulation contains certain contaminants. Leakage of fluids through mechanical connections such as bolted flanges and valve packing can result in contaminants leaching onto the component surface or the surfaces of other components below the component. For outdoor insulated SS and nickel alloy components, rain and changing weather conditions can result in moisture intrusion into the insulation.

Plant-specific OE and the condition of SS and nickel alloy components are evaluated to determine if prolonged exposure to the plant-specific environments has resulted in pitting or crevice corrosion. Loss of material due to pitting and crevice corrosion is not an aging effect requiring management for SS and nickel alloy components if (a) plant-specific OE does not reveal a history of loss of material due to pitting or crevice corrosion; and (b) a one-time inspection demonstrates that the aging effect is not occurring or is occurring so slowly that it will not affect the intended function of the components during the subsequent period of extended operation. The applicant documents the results of the plant specific OE review in the SLRA.

In the environment of air-indoor controlled, pitting and crevice corrosion is only expected to occur as the result of a source of moisture and halides. Inspections focus on the most susceptible locations.

The GALL-SLR Report recommends further evaluation of SS and nickel alloy piping, piping components, and tanks exposed to an air, condensation, or underground environment to determine whether an AMP is needed to manage the aging effect of loss of material due to pitting and crevice corrosion. GALL-SLR Report AMP XI.M32, “One-Time Inspection,” describes an acceptable program to demonstrate that loss of material due to pitting and crevice corrosion is not occurring at a rate that affects the intended function of the components. If loss of material due to pitting or crevice corrosion has occurred and is sufficient to potentially affect the intended function of an SSC, the following AMPs describe acceptable programs to manage loss of material due to pitting or crevice corrosion: (a) GALL-SLR Report AMP XI.M29, “Outdoor and

Large Atmospheric Metallic Storage Tanks," for tanks; (b) GALL-SLR Report AMP XI.M36, "External Surfaces Monitoring of Mechanical Components," for external surfaces of piping and piping components; (c) GALL-SLR Report AMP XI.M41, "Buried and Underground Piping and Tanks," for underground piping, piping components and tanks; and (d) GALL-SLR Report AMP XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components," for internal surfaces of components that are not included in other AMPs. The timing of the one-time or periodic inspections is consistent with that recommended in the AMP selected by the applicant during the development of the SLRA. For example, one-time inspections would be conducted between the 50th and 60th year of operation, as recommended by the "detection of aging effects" program element in AMP XI.M32.

The applicant may establish that loss of material due to pitting and crevice corrosion is not an aging effect requiring management by demonstrating that a barrier coating isolates the component from aggressive environments. Acceptable barriers include tightly-adhering coatings that have been demonstrated to be impermeable to aqueous solutions and air that contain halides. GALL-SLR Report AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks," describes an acceptable program to manage the integrity of a barrier coating.

<u>Evaluation:</u>

A review of ONS OE confirmed that pitting and crevice corrosion has not occurred on surfaces of stainless steel piping, piping components, and tanks exposed to air, condensation, or underground environments in ONS steam and power conversion systems, or in reactor vessel, internals, and reactor coolant system components aligned to this section.

[3.4.1-003] - The *One-Time Inspection* (B2.1.20) program will be implemented to confirm pitting and crevice corrosion of stainless steel piping, piping components, and tanks exposed to air or condensation is not occurring.

[3.4.1-095] - ONS has no stainless steel or nickel alloy piping, piping components, or tanks in an underground environment in the scope of SLR in steam and power conversion systems.

[3.4.1-098] - ONS has no stainless steel or nickel alloy tanks within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks" in the scope of SLR in steam and power conversion systems.

[3.4.1-103] – The *One-Time Inspection* (B2.1.20) program will be implemented to confirm pitting and crevice corrosion of insulated stainless steel piping, piping components, and tanks exposed to air or condensation is not occurring.

3.4.2.2.4 Quality Assurance for Aging Management of Non-Safety Related Components

NUREG-2192

Acceptance criteria are described in Branch Technical Position (BTP) IQMB-1 (Appendix A.2 of this SRP-SLR).

Evaluation:

Quality Assurance provisions applicable to SLR are discussed in Appendix B1.3, Quality Assurance Program and Administrative Controls.

3.4.2.2.5 Ongoing Review of Operating Experience

NUREG-2192

Acceptance criteria are described in Appendix A.4, "Operating Experience for Aging Management Programs."

Evaluation:

The OE process and acceptance criteria are described in Appendix B1.4, Operating Experience.

3.4.2.2.6 Loss of Material Due to Recurring Internal Corrosion

Recurring internal corrosion can result in the need to augment AMPs beyond the recommendations in the GALL-SLR Report. During the search of plant-specific OE conducted during the SLRA development, recurring internal corrosion can be identified by the number of occurrences of aging effects and the extent of degradation at each localized corrosion site. This further evaluation item is applicable if the search of plant specific OE reveals repetitive occurrences. The criteria for recurrence is (a) a 10 year search of plant specific OE reveals the aging effect has occurred in three or more refueling outage cycles; or (b) a 5 year search of plant specific OE reveals the aging effect has occurred in two or more refueling outage cycles and resulted in the component either not meeting plant specific acceptance criteria or experiencing a reduction in wall thickness greater than 50 percent (regardless of the minimum wall thickness).

The GALL-SLR Report recommends that GALL-SLR Report AMP XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components," be evaluated for inclusion of augmented requirements to ensure the adequate management of any recurring aging effect(s). Alternatively, a plant-specific AMP may be proposed. Potential augmented requirements include: (i) alternative examination methods (e.g., volumetric versus external visual); (ii) augmented inspections (e.g., a greater number of locations, additional locations based on risk insights based on susceptibility to aging effect and consequences of failure, a greater frequency of inspections), *and (iii) additional trending parameters and decision points where increased inspections would be implemented.*

The applicant states: (a) why the program's examination methods will be sufficient to detect the recurring aging effect before affecting the ability of a component to perform its intended function, (b) the basis for the adequacy of augmented or lack of augmented inspections, (c) what parameters will be trended as well as the decision points where increased inspections would be implemented (e.g., the extent of degradation at individual corrosion sites, the rate of degradation change), (d) how inspections of components that are not easily accessed (i.e., buried, underground) will be conducted, and (e) how leaks in any involved buried or underground components will be identified.

Plant-specific OE examples should be evaluated to determine if the chosen AMP should be augmented even if the thresholds for significance of aging effect or frequency of occurrence of aging effect have not been exceeded. For example, during a 10 year search of plant-specific OE, two instances of a 360 degree 30 percent wall loss occurred at copper alloy to steel joints. Neither the significance of the aging effect nor the frequency of occurrence of aging effect threshold has been exceeded. Nevertheless, the OE should be evaluated to determine if the AMP that is proposed to manage the aging effect is sufficient (e.g., method of inspection, frequency of inspection, number of inspections) to provide reasonable assurance that the current licensing basis (CLB) intended functions of the component will be met throughout the subsequent period of extended operation. While recurring internal corrosion is not as likely in other environments as raw water and waste water (e.g., treated water), the aging effect should be addressed in a similar manner.

Evaluation:

[3.4.1-061] - A review of plant OE has not identified recurring internal corrosion of metallic piping, piping components, or tanks exposed to raw water or waste water in the steam and power conversion systems.

3.4.2.2.7 Cracking Due to Stress Corrosion Cracking in Aluminum Alloys

NUREG-2192:

SCC is a form of environmentally assisted cracking which is known to occur in high and moderate strength aluminum alloys. The three conditions necessary for SCC to occur in a component are a sustained tensile stress, aggressive environment, and material with a susceptible microstructure. Cracking due to SCC can be mitigated by eliminating one of the three necessary conditions. For the purposes of SLR, acceptance criteria for this further evaluation is being provided for demonstrating that the specific material is not susceptible to SCC or an aggressive environment is not present. Cracking due to SCC is an aging effect requiring management unless it is demonstrated by the applicant that one of the two necessary conditions discussed below is absent.

Susceptible Material: If the material is not susceptible to SCC, then cracking is not an aging effect requiring management. The microstructure of an aluminum alloy, of which alloy composition is only one factor, is what determines whether the alloy is susceptible to SCC. Therefore, determining susceptibility based on alloy composition alone is not adequate to conclude whether a particular material is susceptible to SCC. The temper, condition, and product form of the alloy is considered when assessing if a material is susceptible to SCC. Aluminum alloys that are susceptible to SCC include:

- 2xxx series alloys in the F, W, Ox, T3x, T4x, or T6x temper
- 5xxx series alloys with a magnesium content of 3.5 weight percent or greater
- 6xxx series alloys in the F temper
- 7xxx series alloys in the F, T5x, or T6x temper
- 2xx.x and 7xx.x series alloys
- 3xx.x series alloys that contain copper
- 5xx.x series alloys with a magnesium content of greater than 8 weight percent

The material is evaluated to verify that it is not susceptible to SCC and that the basis used to make the determination is technically substantiated. Tempers have been specifically developed to improve the SCC resistance for some aluminum alloys. Aluminum alloy and temper combination which are not susceptible to SCC when used in piping, piping component, and tank applications include 1xxx series, 3xxx series, 6061-T6x, and 5454-x. If it is determined that a material is not susceptible to SCC, the SLRA provides the components/locations where it is used, alloy composition, temper or condition, product form, and for tempers not addressed above, the basis used to determine the alloy is not susceptible and technical information substantiating the basis.

Aggressive Environment: If the environment to which an aluminum alloy is exposed is not aggressive, such as dry gas or treated water, then cracking due to SCC will not occur and it is not an aging effect requiring management. Aggressive environments that are known to result in cracking due to SCC of susceptible aluminum alloys are aqueous solutions, air, condensation, and underground locations that contain halides (e.g., chloride). Halide concentrations should be considered high enough to facilitate SCC of aluminum alloys in uncontrolled or untreated aqueous solutions and air, such as raw water, waste water, condensation, underground locations, and outdoor air, unless demonstrated otherwise.

Halides could be present on the surface of the aluminum material if the component is encapsulated in a material such as insulation or concrete. In a controlled or uncontrolled indoor air, condensation, or underground environment, sufficient halide concentrations to cause SCC could be present due to secondary sources such as leakage from nearby components (e.g., leakage from insulated flanged connections or valve packing). If an aluminum component is exposed to a halide-free indoor air environment, not encapsulated in materials containing halides, and the exposure to secondary sources of moisture or halides is precluded, cracking due to SCC is not expected to occur. The plant-specific configuration can be used to demonstrate that exposure to halides will not occur. If it is determined that SCC will not occur because the environment is not aggressive, the SLRA provides the components and locations exposed to the environment, description of the environment, basis used to determine the environment is not *aggressive, and technical information substantiating the basis. GALL-SLR Report AMP XI.M32, "One-Time Inspection," and a review of plant-specific OE describe an acceptable means to confirm the absence of moisture or halides within the proximity of the aluminum component.*

If the environment potentially contains halides, the GALL-SLR Report AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks," describes an acceptable program to manage cracking due to SCC of aluminum tanks. The GALL-SLR Report AMP XI.M36, "External Surfaces Monitoring of Mechanical Components," describes an acceptable program to manage cracking due to SCC of aluminum piping and piping components. The GALL-SLR Report AMP XI.M41, "Buried and Underground Piping and Tanks," describes an acceptable program to manage cracking due to SCC of aluminum piping and tanks, which are buried or underground. GALL-SLR Report AMP XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components" describes an acceptable program to manage cracking due to SCC of aluminum components that are not included in other AMPs.

An alternative strategy to demonstrating that an aggressive environment is not present is to isolate the aluminum alloy from the environment using a barrier to prevent SCC. Acceptable barriers include tightly-adhering coatings that have been demonstrated to be impermeable to aqueous solutions and air that contain halides. GALL-SLR Report AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks," describes an acceptable program to manage the integrity of a barrier coating for internal or external coatings.

Evaluation:

[3.4.1-102] – ONS has no in-scope aluminum tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to air, condensation, soil, concrete, raw water or waste water in the steam and power conversion systems.

[3.4.1-105] - ONS has no insulated aluminum piping, piping components, or tanks exposed to air or condensation environments in scope of SLR in steam and power conversion systems.

[3.4.1-109] – ONS has no aluminum alloy piping, piping components, or tanks exposed to air, condensation, raw water or waste water environments in the scope of SLR in steam and power conversion systems.

[3.4.1-112] – ONS has no aluminum underground piping, piping components or tanks in the scope of SLR in steam and power conversion systems.

3.4.2.2.8 Loss of Material Due to General, Crevice or Pitting Corrosion and Cracking Due to Stress Corrosion Cracking

NUREG-2192:

Loss of material due to general (steel only), Crevice, or pitting corrosion and cracking due to SCC (SS only) can occur in steel and SS piping and piping components exposed to concrete. Concrete provides a high alkalinity environment that can mitigate the effects of loss of material for steel piping, thereby significantly reducing the corrosion rate. However, if water intrudes through the concrete, the pH can be reduced and ions that promote loss of material such as chlorides, which can penetrate the protective oxide layer created in the high alkalinity environment, can reach the surface of the metal. Carbonation can reduce the pH within concrete. The rate of carbonation is reduced by using concrete with a low water-to-cement ratio and low permeability. Concrete with low permeability also reduces the potential for the penetration of water. Adequate air entrainment improves the ability of the concrete to resist freezing and thawing cycles and therefore reduces the potential for cracking and intrusion of water, Cracking due to SCC, as well as pitting and crevice corrosion can occur due to halides present in the water that penetrates to the surface of the metal.

If the following conditions are met, loss of material is not considered to be an applicable aging effect for steel: (a) attributes of the concrete are consistent with American Concrete Institute (ACI) 318 or ACI 349 (low water-to-cement ratio, low permeability, and adequate air entrainment) as cited in NUREG-1557; (b) plant-specific OE indicates no degradation of the concrete that could lead to penetration of water to the metal surface; and (c) the piping is not potentially exposed to groundwater. Where these conditions are not met, loss of material due to general (steel only), crevice, or pitting corrosion, and cracking due to SCC (SS only) are identified as applicable aging effects. GALL-SLR Report AMP XI.M41, "Buried and Underground Piping and Tanks," describes an acceptable program to manage these aging effects.

Evaluation:

[3.4.1-051] – The steel components aligned to this item are condensate piping and the main condenser shell. Loss of material of is not considered to be an applicable aging effect for these components based on the following consideration: (a) the concrete in areas containing these components conforms to ACI 349 or ACI 318; (b) review of ONS operating experience did not identify degradation of concrete around embedded components that could lead to penetration of water; and (c) these components are not exposed to a soil environment. Steel components that do not exit the concrete into soil are not potentially exposed to groundwater.

[3.4.1-082] – ONS has no stainless steel piping components exposed to concrete in the scope of SLR in steam and power conversion systems.

3.4.2.2.9 Loss of Material Due to Pitting and Crevice Corrosion in Aluminum Alloys

NUREG-2192:

Loss of material due to pitting and crevice corrosion could occur in aluminum piping, piping components, and tanks exposed to an air, condensation, underground, raw water, or waste water environment for a sufficient duration of time. Environments that can result in pitting and/or crevice corrosion of aluminum alloys are those that contain halides (e.g., chloride) in the presence of moisture. The moisture level and halide concentration in atmospheric and uncontrolled air are greatly dependent on geographical location and site-specific conditions. Moisture level and halide concentration should be considered high enough to facilitate pitting and/or crevice corrosion of aluminum alloys in atmospheric and uncontrolled air, unless demonstrated otherwise. The periodic introduction of moisture or halides into an environment from secondary sources should also be considered. Leakage of fluids from mechanical connections (e.g., insulated bolted flanges and valve packing): onto a component in indoor controlled air is an example of a secondary source that should be considered. Halide concentrations should be considered high enough to facilitate loss of material of aluminum alloys in untreated aqueous solutions, unless demonstrated otherwise. Plant-specific OE and the condition of aluminum alloy components are evaluated to determine if prolonged exposure to the plant-specific air, condensation, underground, or water environments has resulted in pitting or crevice corrosion. Loss of material due to pitting and crevice corrosion is not an aging effect requiring management for aluminum alloys if (a) plant-specific OE does not reveal a history of loss of material due to pitting or crevice corrosion and (b) a one-time inspection demonstrates that the aging effect is not occurring or is occurring so slowly that it will not affect the intended function of the components. The applicant documents the results of the plant-specific OE review in the SLRA.

In the environment of air-indoor controlled, pitting and crevice corrosion is only expected to occur as the result of a source of moisture and halides. Alloy susceptibility may be considered when reviewing OE and interpreting inspection results. Inspections focus on the most susceptible alloys and locations.

The GALL-SLR Report recommends the further evaluation of aluminum piping, piping components, and tanks exposed to an air, condensation, or underground environment to determine whether an AMP is needed to manage the aging effect of loss of material due to pitting and crevice corrosion. GALL-SLR Report AMP XI.M32, "One-Time Inspection," describes an acceptable program to demonstrate that the aging effect of loss of material due to pitting and crevice corrosion is not occurring at a rate that will affect the intended function of the components. If a loss of material due to pitting and crevice corrosion has occurred and is sufficient to potentially affect the intended function of an SSC, the following AMPs describe acceptable programs to manage loss of material due to pitting and crevice corrosion: (i) GALL-SLR Report AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks," for tanks; (ii) GALL-SLR Report AMP XI.M36, "External Surfaces Monitoring of Mechanical Components," for external surfaces of piping and piping components; (iii) GALL-SLR Report AMP XI.M41, "Buried and Underground Piping and Tanks," for underground piping, piping components and tanks; and (iv) GALL-SLR Report AMP XI.M38, "Inspection of Internal Surfaces in Miscellaneous

Piping and Ducting Components," for internal surfaces of components that are not included in other AMPs. The timing of the one-time or periodic inspections is consistent with that recommended in the AMP selected by the applicant during the development of the SLRA. For example, one-time inspections would be conducted between the 50th and 60th year of operation, as recommended by the "detection of aging effects" program element in AMP XI.M32.

An alternative strategy to demonstrating that an aggressive environment is not present is to isolate the aluminum alloy from the environment using a barrier to prevent loss of material due to pitting and crevice corrosion. Acceptable barriers include tightly-adhering coatings that have been demonstrated to be impermeable to aqueous solutions and air that contain halides. The GALL-SLR Report AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks," describes an acceptable program to manage the integrity of a barrier coating.

Evaluation:

[3.4.1-035] – ONS has no aluminum alloy piping, piping components, or tanks exposed to air or condensation in the scope of SLR in steam and power conversion systems.

[3.4.1-094] – ONS has no aluminum underground piping, piping components or tanks in the scope of SLR in steam and power conversion systems.

[3.4.1-097] – ONS has no aluminum tanks (within the scope of AMP XI.M29, Outdoor and Large Atmospheric Metallic Storage Tanks) exposed to air or condensation in the scope of SLR in steam and power conversion systems.

[3.4.1-119] - ONS has no insulated aluminum piping, piping components, or tanks exposed to air or condensation in the scope of SLR in steam and power conversion systems.

[3.4.1-120] – ONS has no aluminum piping, piping components or tanks exposed to raw water or waste water in the scope of SLR in steam and power conversion systems.

Results Tables: Steam and Power Conversion Systems

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-001	Steel piping, piping components exposed to any environment	Cumulative fatigue damage due to fatigue	TLAA, SRP-SLR Section 4.3 Metal Fatigue	Yes (SRP-SLR Section 3.4.2.2.1)	Consistent with NUREG-2191. Fatigue of Steam and Power Systems components is a time-limited aging analysis (TLAA), as defined in 10 CFR 54.3. The evaluation of this TLAA is addressed in Section 4.3. See further evaluation in Section 3.4.2.2.1.
3.4.1-002	Stainless steel piping, piping components, tanks exposed to air, condensation	Cracking due to SCC	AMP XI.M32, “One-Time Inspection,” AMP XI.M36, “External Surfaces Monitoring of Mechanical Components,” AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components,” or AMP XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.2)	Not applicable. ONS has no stainless steel piping, piping components, or tanks exposed to air or condensation in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used. Components in the Steam and Power Conversion system are insulated and are aligned to item 3.4.1-104. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-003	Stainless steel, nickel alloy piping, piping components, tanks exposed to air, condensation	Loss of material due to pitting, crevice corrosion	AMP XI.M32, “One-Time Inspection,” AMP XI.M36, “External Surfaces Monitoring of Mechanical Components,” AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components,” or AMP XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.3)	Consistent with NUREG-2191. The *One-Time Inspection* program (B2.1.20) will be implemented to confirm that loss of material is not occurring in stainless steel components exposed to air-indoor uncontrolled (external) environments. See further evaluation in Section 3.4.2.2.3.
3.4.1-004	Steel external surfaces exposed to air with borated water leakage	Loss of material due to boric acid corrosion	AMP XI.M10, “Boric Acid Corrosion”	No	Consistent with NUREG-2191.
3.4.1-005	Steel piping, piping components exposed to steam, treated water	Wall thinning due to flow-accelerated corrosion	AMP XI.M17, “Flow-Accelerated Corrosion”	No	Consistent with NUREG-2191.
3.4.1-006	Metallic closure bolting exposed to any environment, soil, underground	Loss of preload due to thermal effects, gasket creep, self-loosening	AMP XI.M18, “Bolting Integrity”	No	Consistent with NUREG-2191.
3.4.1-007	High-strength steel closure bolting exposed to air, soil, underground	Cracking due to SCC; cyclic loading	AMP XI.M18, “Bolting Integrity”	No	Consistent with NUREG-2191.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-009	Steel, stainless steel, nickel alloy closure bolting exposed to air-indoor uncontrolled, air-outdoor, condensation	Loss of material due to general (steel only), pitting, crevice corrosion	AMP XI.M18, “Bolting Integrity”	No	Consistent with NUREG-2191.
3.4.1-011	Stainless steel piping, piping components, tanks, heat exchanger components exposed to steam, treated water >60°C (>140°F)	Cracking due to SCC	AMP XI.M2, “Water Chemistry,” and AMP-XI.M32, “One-Time Inspection”	No	Consistent with NUREG-2191. In addition to Steam and Power Conversion Systems, components in Auxiliary Systems are aligned to this item.
3.4.1-012	Steel tanks exposed to treated water	Loss of material due to general, pitting, crevice corrosion, MIC	AMP XI.M2, “Water Chemistry,” and AMP-XI.M32, “One-Time Inspection”	No	Consistent with NUREG-2191. In addition to Steam and Power Conversion systems, components in Auxiliary Systems are aligned to this item.
3.4.1-014	Steel piping, piping components exposed to steam, treated water	Loss of material due to general, pitting, crevice corrosion, MIC (treated water only)	AMP XI.M2, “Water Chemistry,” and AMP-XI.M32, “One-Time Inspection”	No	Consistent with NUREG-2191. In addition to Steam and Power Conversion Systems, components in Reactor Vessel, Internals, And Reactor Coolant System and Auxiliary Systems are aligned to this item.
3.4.1-015	Steel heat exchanger components exposed to treated water	Loss of material due to general, pitting, crevice corrosion, MIC	AMP XI.M2, “Water Chemistry,” and AMP-XI.M32, “One-Time Inspection”	No	Consistent with NUREG-2191. In addition to Steam and Power Conversion Systems, components in Auxiliary Systems are aligned to this item.
3.4.1-016	Copper alloy, aluminum piping, piping components exposed to treated water, treated borated water	Loss of material due to pitting, crevice corrosion, MIC (copper alloy only)	AMP XI.M2, “Water Chemistry,” and AMP-XI.M32, “One-Time Inspection”	No	Consistent with NUREG-2191. In addition to Steam and Power Conversion Systems, components in Auxiliary Systems are aligned to this item.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-018	Copper alloy, stainless steel heat exchanger tubes exposed to treated water	Reduction of heat transfer due to fouling	AMP XI.M2, "Water Chemistry," and AMP-XI.M32, "One-Time Inspection"	No	Consistent with NUREG-2191.
3.4.1-019	Stainless steel, steel heat exchanger components exposed to raw water	Loss of material due to general (copper alloy only), pitting, crevice corrosion, MIC; flow blockage due to fouling	AMP XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-2191 with exceptions. Exceptions apply to the NUREG-2191 recommendations for the *Open-Cycle Cooling Water System* (B2.1.11) program implementation.
3.4.1-020	Copper alloy, stainless steel piping, piping components exposed to raw water	Loss of material due to general (copper alloy only), pitting, crevice corrosion, MIC; flow blockage due to fouling	AMP XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. ONS has no copper alloy, stainless steel piping, piping components exposed to raw water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-022	Stainless steel, copper alloy, steel heat exchanger tubes exposed to raw water	Reduction of heat transfer due to fouling	AMP XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-2191 with exceptions. Exceptions apply to the NUREG-2191 recommendations for the *Open-Cycle Cooling Water System* (B2.1.11) program implementation.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-023	Stainless steel piping, piping components exposed to closed-cycle cooling water >60°C (>140°F)	Cracking due to SCC	AMP XI.M21A, “Closed Treated Water Systems”	No	Consistent with NUREG-2191.
3.4.1-025	Steel heat exchanger components exposed to closed-cycle cooling water	Loss of material due to general, pitting, crevice corrosion, MIC	AMP XI.M21A, “Closed Treated Water Systems”	No	Consistent with NUREG-2191.
3.4.1-026	Stainless steel heat exchanger components, piping, piping components exposed to closed-cycle cooling water	Loss of material due to pitting, crevice corrosion	AMP XI.M21A, “Closed Treated Water Systems”	No	Consistent with NUREG-2191.
3.4.1-027	Copper alloy piping, piping components exposed to closed-cycle cooling water	Loss of material due to pitting, crevice corrosion, MIC	AMP XI.M21A, “Closed Treated Water Systems”	No	Consistent with NUREG-2191.
3.4.1-028	Steel, stainless steel, copper alloy heat exchanger tubes exposed to closed-cycle cooling water	Reduction of heat transfer due to fouling	AMP XI.M21A, “Closed Treated Water Systems”	No	Not applicable. ONS has no steel, stainless steel, or copper alloy heat exchanger tubes exposed to closed-cycle cooling water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-030	Steel tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to soil, concrete, air, condensation	Loss of material due to general, pitting, crevice corrosion, MIC (soil only)	AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks"	No	Not applicable. ONS has no steel tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to soil, concrete, air, condensation in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-032	Gray cast iron, ductile iron piping, piping components exposed to soil	Loss of material due to selective leaching	AMP XI.M33, "Selective Leaching"	No	Not applicable. ONS has no gray cast iron or ductile iron piping, piping components exposed to soil in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-033	Gray cast iron, ductile iron, copper alloy (>15% Zn or >8% Al) piping, piping components exposed to treated water, raw water, closed-cycle cooling water	Loss of material due to selective leaching	AMP XI.M33, "Selective Leaching"	No	Consistent with NUREG-2191.
3.4.1-034	Steel external surfaces exposed to air-indoor uncontrolled, air-outdoor, condensation	Loss of material due to general, pitting, crevice corrosion	AMP XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-2191. In addition to Steam and Power Conversion Systems, components in Reactor Vessel, Internals, And Reactor Coolant System are aligned to this item.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-035	Aluminum piping, piping components, tanks exposed to air, condensation	Loss of material due to pitting, crevice corrosion	AMP XI.M32, “One-Time Inspection,” AMP XI.M36, “External Surfaces Monitoring of Mechanical Components," AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components,” or AMP XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.9)	Not applicable. ONS has no aluminum alloy piping, piping components, or tanks exposed to air or condensation in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-036	Steel piping, piping components exposed to air - outdoor	Loss of material due to general, pitting, crevice corrosion	AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Not applicable. ONS has no steel piping or piping components exposed to air – outdoor in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-037	Steel piping, piping components exposed to condensation	Loss of material due to general, pitting, crevice corrosion	AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components	No	Consistent with NUREG-2191.
3.4.1-038	Steel piping, piping components exposed to raw water	Loss of material due to general, pitting, crevice corrosion, MIC; flow blockage due to fouling	AMP XI.M20, “Open-Cycle Cooling Water System”	No	Not applicable. ONS has no steel piping, piping components exposed to raw water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-040	Steel piping, piping components exposed to lubricating oil	Loss of material due to general, pitting, crevice corrosion, MIC	AMP XI.M39, “Lubricating Oil Analysis,” and AMP XI.M32, “One-Time Inspection”	No	Consistent with NUREG-2191.
3.4.1-041	Steel heat exchanger components exposed to lubricating oil	Loss of material due to general, pitting, crevice corrosion, MIC	AMP XI.M39, “Lubricating Oil Analysis,” and AMP XI.M32, “One-Time Inspection”	No	Not applicable. ONS has no steel heat exchanger components exposed to lubricating oil in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-042	Aluminum piping, piping components exposed to lubricating oil	Loss of material due to pitting, crevice corrosion	AMP XI.M39, “Lubricating Oil Analysis,” and AMP XI.M32, “One-Time Inspection”	No	Not applicable. ONS has no aluminum piping, piping components exposed to lubricating oil in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-043	Copper alloy piping, piping components exposed to lubricating oil	Loss of material due to pitting, crevice corrosion, MIC	AMP XI.M39, “Lubricating Oil Analysis,” and AMP XI.M32, “One-Time Inspection”	No	Consistent with NUREG-2191.
3.4.1-044	Stainless steel piping, piping components, heat exchanger components exposed to lubricating oil	Loss of material due to pitting, crevice corrosion, MIC	AMP XI.M39, “Lubricating Oil Analysis,” and AMP XI.M32, “One-Time Inspection”	No	Not applicable. ONS has no stainless steel piping, piping components, or heat exchanger components exposed to lubricating oil in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-045	Aluminum heat exchanger tubes exposed to lubricating oil	Reduction of heat transfer due to fouling	AMP XI.M39, "Lubricating Oil Analysis," and AMP XI.M32, "One-Time Inspection"	No	Not applicable. ONS has no aluminum heat exchanger tubes exposed to lubricating oil in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-046	Stainless steel, steel, copper alloy heat exchanger tubes exposed to lubricating oil	Reduction of heat transfer due to fouling	AMP XI.M39, "Lubricating Oil Analysis," and AMP XI.M32, "One-Time Inspection"	No	Not applicable. ONS has no stainless steel, steel, or copper alloy heat exchanger tubes exposed to lubricating oil in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-047	Stainless steel piping, piping components, tanks, closure bolting exposed to soil, concrete	Loss of material due to pitting, crevice corrosion, MIC (soil only)	AMP XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. ONS has no stainless steel piping, piping components, tanks, closure bolting exposed to soil or concrete in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-048	Nickel alloy piping, piping components, tanks, closure bolting exposed to soil, concrete	Loss of material due to pitting, crevice corrosion, MIC (soil only)	AMP XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. ONS has no nickel alloy piping, piping components, tanks, or closure bolting exposed to soil, concrete in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-050	Steel piping, piping components, tanks, closure bolting exposed to soil, concrete, underground	Loss of material due to pitting, crevice corrosion, MIC (soil only)	AMP XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. ONS has no steel piping, piping components, tanks, or closure bolting exposed to soil or underground environments in the scope of subsequent license renewal in Steam And Power Conversion systems. Steam And Power Conversion components exposed to concrete are aligned with item 3.4.1-051. The associated NUREG-2191 aging items are not used.
3.4.1-051	Steel piping, piping components exposed to concrete	None	None	Yes (SRP-SLR Section 3.4.2.2.8)	Consistent with NUREG-2191. See further evaluation in Section 3.4.2.2.8.
3.4.1-052	Aluminum piping, piping components exposed to gas	None	None	No	Not applicable. ONS has no aluminum piping, piping components exposed to gas in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-053	Copper alloy, copper alloy (>8% Al) piping, piping components exposed to air with borated water leakage	None	None	No	Not applicable. ONS has no copper alloy, copper alloy (>8% Al) piping, piping components exposed to air with borated water leakage in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-054	Copper alloy piping, piping components exposed to air, condensation, gas	None	None	No	Consistent with NUREG-2191.
3.4.1-055	Glass piping elements exposed to lubricating oil, air, condensation, raw water, treated water, air with borated water leakage, gas, closed-cycle cooling water	None	None	No	Consistent with NUREG-2191.
3.4.1-056	Nickel alloy piping, piping components exposed to air with borated water leakage	None	None	No	Not applicable. ONS has no nickel alloy piping, piping components exposed to air with borated water leakage in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-057	PVC piping, piping components exposed to air - indoor uncontrolled, condensation	None	None	No	Not applicable. ONS has no PVC piping or piping components exposed to air – indoor uncontrolled, or condensation in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-058	Stainless steel piping, piping components exposed to gas	None	None	No	Not applicable. ONS has no stainless steel piping or piping components exposed to gas in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-059	Steel piping, piping components exposed to air - indoor controlled, gas	None	None	No	Not applicable. ONS has no steel piping or piping components exposed to air – indoor controlled or gas in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-060	Metallic piping, piping components exposed to steam, treated water	Wall thinning due to erosion	AMP XI.M17, “Flow-Accelerated Corrosion”	No	Consistent with NUREG-2191.
3.4.1-061	Metallic piping, piping components, tanks exposed to raw water, waste water	Loss of material due to recurring internal corrosion	AMP XI.M20, “Open-Cycle Cooling Water System,” or AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	Yes (SRP-SLR Section 3.4.2.2.6)	Not applicable. Loss of material due to recurring internal corrosion has not been identified within metallic piping, piping components, or tanks exposed to raw water or waste water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-062	Steel, stainless steel or aluminum tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to treated water	Loss of material due to general (steel only), pitting, crevice corrosion, MIC (steel, stainless steel only)	AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks"	No	Not applicable. ONS has no steel, stainless steel or aluminum tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to treated water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-063	Insulated steel, copper alloy (>15% Zn or >8% Al), piping, piping components, tanks, tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to air, condensation	Loss of material due to general, pitting, crevice corrosion (steel only); cracking due to SCC (copper alloy (>15% Zn or >8% Al) only)	AMP XI.M36, "External Surfaces Monitoring of Mechanical Components" AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks"	No	Not applicable. ONS has no copper alloy (>15% Zn or >8% Al), piping, piping components, or tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") in the scope of subsequent license renewal in Steam and Power Conversion systems. Insulated steel piping, piping components or tanks exposed to air or condensation in the Steam and Power Conversion systems are aligned to item 3.4.1-034. The associated NUREG-2191 aging items are not used.
3.4.1-064	Non-metallic thermal insulation exposed to air, condensation	Reduced thermal insulation resistance due to moisture intrusion	AMP XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. ONS has no non-metallic thermal insulation with a thermal resistance intended function in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-066	Any material piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, lubricating oil	Loss of coating or lining integrity due to blistering, cracking, flaking, peeling, delamination, rusting, or physical damage; loss of material or cracking for cementitious coatings/linings	AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Consistent with NUREG-2191 with exceptions. Exceptions apply to the NUREG-2191 recommendations for the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* (B2.1.27) program implementation. In addition, Condensate System components using a different aging management program were aligned to 3.4.1-066 and 3.4.1-067: • Main Condenser outlet waterbox and tubesheet coatings are managed by the *Open Cycle Cooling Water System* (B2.1.11) program. • Powdex and Slurry Tanks coatings are managed by *Water Chemistry* (B2.1.2) program and *One-Time Inspection* (B2.1.20) program.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-067	Any material piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, lubricating oil	Loss of material due to general, pitting, crevice corrosion, MIC	AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Consistent with NUREG-2191 with exceptions. Exceptions apply to the NUREG-2191 recommendations for the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* (B2.1.27) program implementation. In addition, Condensate System components using a different aging management program were aligned to this item. See SRP Item 3.4.1-066 for additional information.
3.4.1-068	Gray cast iron, ductile iron piping, piping components with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, waste water	Loss of material due to selective leaching	AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Not applicable. ONS has no gray cast iron, ductile iron piping, piping components with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, waste water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-070	Stainless steel, steel, nickel alloy, copper alloy closure bolting exposed to lubricating oil, treated water, treated borated water, raw water, waste water	Loss of material due to general (steel; copper alloy in raw water, waste water only), pitting, crevice corrosion, MIC (raw water, waste water environments only)	AMP XI.M18, “Bolting Integrity”	No	Not applicable. ONS has no stainless steel, steel, nickel alloy, copper alloy closure bolting exposed to lubricating oil, treated water, treated borated water, raw water, or waste water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-072	Stainless steel, steel, aluminum piping, piping components, tanks exposed to soil, concrete	Cracking due to SCC (steel in carbonate/ bicarbonate environment only)	AMP XI.M41, “Buried and Underground Piping and Tanks”	No	Not applicable. ONS has no stainless steel, steel, aluminum piping, piping components, tanks exposed to soil, concrete environment, or steel exposed to a carbonate/bicarbonate environment in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-073	Stainless steel closure bolting exposed to air, soil, concrete, underground, waste water	Cracking due to SCC	AMP XI.M18, “Bolting Integrity”	No	Consistent with NUREG-2191.
3.4.1-074	Stainless steel underground piping, piping components, tanks	Cracking due to SCC	AMP XI.M32, “One-Time Inspection,” AMP XI.M41, “Buried and Underground Piping and Tanks,” or AMP XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.2)	Not applicable. ONS has no stainless steel piping, piping components, or tanks in an underground environment in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-075	Stainless steel, steel, aluminum, copper alloy, titanium heat exchanger tubes exposed to air, condensation	Reduction of heat transfer due to fouling	AMP XI.M36, “External Surfaces Monitoring of Mechanical Components”	No	Not applicable. ONS has no stainless steel, steel, aluminum, copper alloy, titanium heat exchanger tubes exposed to air or condensation, where the tubes have a heat transfer intended function, in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-077	Elastomer piping, piping components, seals exposed to air, condensation	Hardening or loss of strength due to elastomer degradation	AMP XI.M36, “External Surfaces Monitoring of Mechanical Components”	No	Not applicable. ONS has no elastomer piping, piping components, seals exposed to air or condensation in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-078	Elastomer piping, piping components, seals exposed to air, condensation	Hardening or loss of strength due to elastomer degradation	AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Not applicable. ONS has no elastomer piping, piping components, seals exposed to air or condensation in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-081	Steel components exposed to treated water, raw water	Long-term loss of material due to general corrosion	AMP XI.M32, “One-Time Inspection”	No	Consistent with NUREG-2191.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-082	Stainless steel piping, piping components exposed to concrete	None	None	Yes (SRP-SLR Section 3.4.2.2.8)	Not applicable. ONS has no stainless steel piping components exposed to concrete in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-083	Stainless steel, nickel alloy tanks exposed to treated water	Loss of material due to pitting, crevice corrosion, MIC	AMP XI.M2, “Water Chemistry,” and AMP XI.M32, “One-Time Inspection”	No	Consistent with NUREG-2191. In addition to Steam and Power Conversion systems, components in Auxiliary Systems are aligned to this item.
3.4.1-084	Stainless steel, nickel alloy piping, piping components exposed to steam	Loss of material due to pitting, crevice corrosion	AMP XI.M2, “Water Chemistry,” and AMP XI.M32, “One-Time Inspection”	No	Not applicable. Steam environments in the Steam and Power Conversion systems are evaluated as treated water and are aligned to Item 3.4-1, 085. The associated NUREG-2191 aging items are not used. The associated NUREG-2191 aging items are not used.
3.4.1-085	Stainless steel, nickel alloy piping, piping components, PWR heat exchanger components exposed to treated water	Loss of material due to pitting, crevice corrosion, MIC	AMP XI.M2, “Water Chemistry,” and AMP XI.M32, “One-Time Inspection”	No	Consistent with NUREG-2191. In addition to Steam and Power Conversion system, components in Reactor Vessel, Internals, and Reactor Coolant System and Auxiliary Systems are aligned to this item.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-086	Stainless steel, steel, aluminum, copper alloy, titanium heat exchanger tubes internal to components exposed to air, condensation	Reduction of heat transfer due to fouling	AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Not applicable. ONS has no stainless steel, steel, aluminum, copper alloy, or titanium heat exchanger tubes internal to components exposed to air or condensation in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-089	Steel, stainless steel, copper alloy piping, piping components exposed to raw water (for components not covered by NRC GL 89-13)	Loss of material due to general (steel, copper alloy only), pitting, crevice corrosion, MIC; flow blockage due to fouling	AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Not applicable. ONS has no steel, stainless steel, or copper alloy piping or piping components exposed to raw water (for components not covered by NRC GL 89-13) in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-090	Steel, stainless steel, copper alloy heat exchanger tubes exposed to raw water (for components not covered by NRC GL 89-13)	Reduction of heat transfer due to fouling	AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Not applicable. ONS has no steel, stainless steel, or copper alloy heat exchanger tubes exposed to raw water (for components not covered by NRC GL 89-13) in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-091	Steel, stainless steel, copper alloy heat exchanger components exposed to raw water (for components not covered by NRC GL 89-13)	Loss of material due to general (steel, copper alloy only), pitting, crevice corrosion, MIC; flow blockage due to fouling	AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Not applicable. ONS has no steel, stainless steel, or copper alloy heat exchanger components exposed to raw water (for components not covered by NRC GL 89-13) in the scope of subsequent license renewal in Steam and Power Conversion systems. Components in a raw water (potable) environment have been aligned to item 3.3.1-088. The associated NUREG-2191 aging items are not used.
3.4.1-092	Copper alloy (>15% Zn or >8% Al) piping, piping components exposed to soil	Loss of material due to selective leaching	AMP XI.M33, “Selective Leaching”	No	Not applicable. ONS has no copper alloy (>15% Zn or >8% Al) piping or piping components exposed to soil in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-094	Aluminum underground piping, piping components, tanks	Loss of material due to pitting, crevice corrosion	AMP XI.M32, “One-Time Inspection,” AMP XI.M41, “Buried and Underground Piping and Tanks,” or AMP XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.9)	Not applicable. ONS has no aluminum underground piping, piping components or tanks in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-095	Stainless steel, nickel alloy underground piping, piping components, tanks	Loss of material due to pitting, crevice corrosion	AMP XI.M32, "One-Time Inspection," AMP XI.M41, "Buried and Underground Piping and Tanks," or AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	Yes (SRP-SLR Section 3.4.2.2.3)	Not applicable. ONS has no stainless steel or nickel alloy piping, piping components, or tanks in an underground environment in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-096	Aluminum tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to soil, concrete	Loss of material due to pitting, crevice corrosion	AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks"	No	Not applicable. ONS has no aluminum tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to soil or concrete in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-097	Aluminum tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to air, condensation	Loss of material due to pitting, crevice corrosion	AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks," AMP XI.M32, "One-Time Inspection," AMP XI.M41, "Buried and Underground Piping and Tanks," or AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	Yes (SRP-SLR Section 3.4.2.2.9)	Not applicable. ONS has no aluminum tanks (within the scope of AMP XI.M29, Outdoor and Large Atmospheric Metallic Storage Tanks) exposed to air or condensation in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-098	Stainless steel, nickel alloy tanks (within the scope of AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks”) exposed to air, condensation	Loss of material due to pitting, crevice corrosion	AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks,” AMP XI.M32, “One-Time Inspection,” AMP XI.M41, “Buried and Underground Piping and Tanks,” or AMP XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.3)	Not applicable. ONS has no stainless steel or nickel alloy tanks within the scope of AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks” in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-099	Stainless steel tanks (within the scope of AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks”) exposed to soil, concrete	Loss of material due to pitting, crevice corrosion, MIC (soil only)	AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks”	No	Not applicable. ONS has no stainless steel tanks (within the scope of AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks”) exposed to soil or concrete in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-100	Stainless steel tanks (within the scope of AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks”) exposed to air, condensation	Cracking due to SCC	AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks,” AMP XI.M32, “One-Time Inspection,” or AMP XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.2)	Not applicable. ONS has no stainless steel tanks within the scope of AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks” in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-101	Stainless steel tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to air, condensation, soil, concrete, raw water, waste water	Cracking due to SCC	AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks"	No	Not applicable. ONS has no stainless steel tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to soil or concrete in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-102	Aluminum tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to air, condensation, soil, concrete, raw water, waste water	Cracking due to SCC	AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks," AMP XI.M32, "One-Time Inspection," or AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	Yes (SRP-SLR Section 3.4.2.2.7)	Not applicable. ONS has no aluminum tanks (within the scope of AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks") exposed to air, condensation, soil, concrete, raw water or waste water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-103	Insulated stainless steel, nickel alloy piping, piping components, tanks exposed to air, condensation	Loss of material due to pitting, crevice corrosion	AMP XI.M29, "Outdoor and Large Atmospheric Metallic Storage Tanks," AMP XI.M32, "One-Time Inspection," AMP XI.M36, "External Surfaces Monitoring of Mechanical Components," or AMP XI.M42, "Internal Coatings/ Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	Yes (SRP-SLR Section 3.4.2.2.3)	Consistent with NUREG-2191. The *One-Time Inspection* program (B2.1.20) will be implemented to confirm that loss of material is not occurring in insulated stainless steel or nickel alloy components exposed to air-indoor uncontrolled (external) environments. In addition to Steam and Power Conversion system, components in Reactor Vessel, Internals, and Reactor Coolant System are aligned to this item. See further evaluation in Section 3.4.2.2.3.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-104	Insulated stainless steel piping, piping components, tanks exposed to air, condensation	Cracking due to SCC	AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks,” AMP XI.M32, “One-Time Inspection,” AMP XI.M36, “External Surfaces Monitoring of Mechanical Components,” or AMP XI.M42, “Internal Coatings/ Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.2)	Consistent with NUREG-2191. The *One-Time Inspection* program (B2.1.20) will be implemented to confirm that cracking due to SCC is not occurring in insulated stainless steel components exposed to air-indoor uncontrolled (external) environments. In addition to Steam and Power Conversion system, components in Reactor Vessel, Internals, and Reactor Coolant System are aligned to this item. See further evaluation in Section 3.4.2.2.2.
3.4.1-105	Insulated aluminum piping, piping components, tanks exposed to air, condensation	Cracking due to SCC	AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks,” AMP XI.M32, “One-Time Inspection,” AMP XI.M36, “External Surfaces Monitoring of Mechanical Components,” or AMP XI.M42, “Internal Coatings/ Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.7)	Not applicable. ONS has no insulated aluminum piping, piping components, or tanks exposed to air or condensation environments in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-106	Copper alloy (>15% Zn or >8% Al) piping, piping components exposed to air, condensation	Cracking due to SCC	AMP XI.M36, “External Surfaces Monitoring of Mechanical Components”	No	Consistent with NUREG-2191.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-107	Copper alloy (>15% Zn or >8% Al) tanks exposed to air, condensation	Cracking due to SCC	AMP XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. ONS has no copper alloy (>15% Zn or >8% Al) tanks exposed to air or condensation environments in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-109	Aluminum piping, piping components, tanks exposed to air, condensation, raw water, waste water	Cracking due to SCC	AMP XI.M32, "One-Time Inspection," AMP XI.M36, "External Surfaces Monitoring of Mechanical Components," AMP XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components," or AMP XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	Yes (SRP-SLR Section 3.4.2.2.7)	Not applicable. ONS has no aluminum alloy piping, piping components, or tanks exposed to air, condensation, raw water or waste water environments in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-112	Aluminum underground piping, piping components, tanks	Cracking due to SCC	AMP XI.M32, "One-Time Inspection," AMP XI.M41, "Buried and Underground Piping and Tanks," or AMP XI.M42, "Internal Coatings/ Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	Yes (SRP-SLR Section 3.4.2.2.7)	Not applicable. ONS has no aluminum underground piping, piping components or tanks in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-114	Titanium heat exchanger tubes exposed to treated water	Cracking due to SCC, reduction of heat transfer due to fouling	AMP XI.M2, "Water Chemistry," and AMP XI.M32, "One-Time Inspection"	No	Not applicable. ONS has no titanium heat exchanger tubes exposed to treated water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-115	Titanium (ASTM Grades 1, 2, 7, 9, 11, or 12) heat exchanger components other than tubes, piping, piping components exposed to treated water	None	None	No	Not applicable. ONS has no titanium (ASTM Grades 1, 2, 7, 9, 11, or 12) heat exchanger components other than tubes, piping, or piping components exposed to treated water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-116	Titanium heat exchanger tubes exposed to closed-cycle cooling water	Cracking due to SCC, reduction of heat transfer due to fouling	AMP XI.M21A, "Closed Treated Water Systems"	No	Not applicable. ONS has no titanium heat exchanger tubes exposed to closed-cycle cooling water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-117	Aluminum piping, piping components, tanks exposed to soil, concrete	Loss of material due to pitting, crevice corrosion	AMP XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. ONS has no aluminum piping, piping components, or tanks exposed to soil or concrete in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-119	Insulated aluminum piping, piping components, tanks exposed to air, condensation	Loss of material due to pitting, crevice corrosion	AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks,” AMP XI.M32, “One-Time Inspection,” AMP XI.M36, “External Surfaces Monitoring of Mechanical Components,” or AMP XI.M42, “Internal Coatings/ Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.9)	Not applicable. ONS has no insulated aluminum piping, piping components, or tanks exposed to air or condensation environments in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-120	Aluminum piping, piping components, tanks exposed to raw water, waste water	Loss of material due to pitting, crevice corrosion	AMP XI.M29, “Outdoor and Large Atmospheric Metallic Storage Tanks,” AMP XI.M32, “One-Time Inspection,” AMP XI.M36, “External Surfaces Monitoring of Mechanical Components,” AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components,” or AMP XI.M42, “Internal Coatings/ Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	Yes (SRP-SLR Section 3.4.2.2.9)	Not applicable. ONS has no aluminum piping, piping components or tanks exposed to raw water or waste water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-122	Elastomer piping, piping components, seals exposed to air	Loss of material due to wear	AMP XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. ONS has no elastomer piping, piping components, or seals exposed to air in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-123	Elastomer piping, piping components, seals exposed to air	Loss of material due to wear	AMP XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. ONS has no elastomer piping, piping components, or seals exposed to air in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-124	PVC piping, piping components, tanks exposed to concrete	None	None	No	Not applicable. ONS has no PVC piping, piping components, or tanks exposed to concrete in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-125	PVC piping, piping components, tanks exposed to soil	Loss of material due to wear	AMP XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. ONS has no PVC piping, piping components, or tanks exposed to soil in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-126	Titanium (ASTM Grades 1, 2, 7, 9, 11, or 12) heat exchanger components other than tubes, piping, piping components exposed to closed-cycle cooling water	None	None	No	Not applicable. ONS has no titanium (ASTM Grades 1, 2, 7, 9, 11, or 12) heat exchanger components other than tubes, piping, or piping components exposed to closed-cycle cooling water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-127	Aluminum piping, piping components, tanks exposed to air with borated water leakage	None	None	No	Not applicable. ONS has no aluminum piping, piping components, or tanks exposed to air with borated water leakage in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-128	Copper alloy piping, piping components exposed to concrete	None	None	No	Not applicable. ONS has no copper alloy piping or piping components exposed to concrete in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-129	Copper alloy piping, piping components exposed to soil, underground	Loss of material due to general, pitting, crevice corrosion, MIC (soil only)	AMP XI.M41, “Buried and Underground Piping and Tanks”	No	Not applicable. ONS has no copper alloy piping or piping components exposed to soil or underground in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-130	Titanium piping, piping components, heat exchanger components other than tubes exposed to raw water	Cracking due to SCC, flow blockage due to fouling	AMP XI.M20, "Open-Cycle Cooling Water System," or AMP XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. ONS has no titanium piping, piping components, or heat exchanger components other than tubes exposed to raw water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-131	Copper alloy (>15% Zn) piping, piping components exposed to air with borated water leakage	Loss of material due to boric acid corrosion	AMP XI.M10, "Boric Acid Corrosion"	No	Not applicable. ONS has no copper alloy (>15% Zn) piping or piping components exposed to air with borated water leakage in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-132	Stainless steel piping, piping components, tanks exposed to air with borated water leakage	None	None	No	Consistent with NUREG-2191.
3.4.1-133	Aluminum piping, piping components exposed to raw water	Flow blockage due to fouling	AMP XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. ONS has no aluminum piping or piping components exposed to raw water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.

Table 3.4.1 Summary of Aging Management Programs for Steam And Power Conversion System Evaluated in Chapter VIII of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.4.1-134	Titanium (ASTM Grades 3, 4, or 5) heat exchanger tubes exposed to raw water	Cracking due to SCC	AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Not applicable. ONS has no titanium (ASTM Grades 3, 4, or 5) heat exchanger tubes exposed to raw water in the scope of subsequent license renewal in Steam and Power Conversion systems. The associated NUREG-2191 aging items are not used.
3.4.1-135	Polymeric piping, piping components, ducting, ducting components, seals exposed to air, condensation, raw water, raw water (potable), treated water, waste water, underground, concrete, soil	Hardening or loss of strength due to polymeric degradation; loss of material due to peeling, delamination, wear; cracking or blistering due to exposure to ultraviolet light, ozone, radiation, or chemical attack; flow blockage due to fouling	AMP XI.M36, “External Surfaces Monitoring of Mechanical Components,” or AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Consistent with NUREG-2191.

Plant Specific Notes:

1. Flow blockage due to fouling is not a concern for components that perform a structural integrity function.
2. Internal surfaces of the main condenser outlet waterboxes and tubesheets will be managed with the Open Cycle Cooling Water AMP.
3. The terminology “Piping and Piping Components” represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Table 3.4.2-2 Steam and Power Conversion Systems - Feedwater System - Aging Management Evaluation

Component Type	Intended Function	Material	Environment	Aging Effect	Aging Management Program	NUREG-2191 Item	NUREG-2192 Table 1	Notes

Plant Specific Notes:

1. Flow blockage due to fouling is not a concern for components that perform a structural integrity function.
2. The terminology "Piping and Piping Components" represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Plant Specific Notes:

1. Flow blockage due to fouling is not a concern for components that perform a structural integrity function.
2. The terminology “Piping and Piping Components” represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Component Type	Intended Function	Material	Environment	Aging Effect	Aging Management Program	NUREG-2191 Item	NUREG-2192 Table 1	Notes

Plant Specific Notes:

1. The terminology "Piping and Piping Components" represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Component Type	Intended Function	Material	Environment	Aging Effect	Aging Management Program	NUREG-2191 Item	NUREG-2192 Table 1	Notes

Plant Specific Notes:

1. The terminology “Piping and Piping Components” represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Plant Specific Notes:

1. The terminology “Piping and Piping Components” represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Plant Specific Notes:

1. The terminology “Piping and Piping Components” represents pipes, pipe fittings (reducers, elbows, tees, etc), and in-line piping components (e.g. valves, traps, strainers, orifices, flow elements, etc.) and is used to identify components with the system that are susceptible to wall thinning (due to erosion or flow accelerated corrosion) or cumulative fatigue damage. Component susceptibility to these aging effects is determined by susceptibility analyses, operating experience, or system design.

Tables 3.4.2-1 through 3.4.2-12 Industry Standard Notes:

A. Consistent with NUREG-2191 item for component, material, environment, and aging effect. AMP is consistent with NUREG-2191 AMP.

B. Consistent with NUREG-2191 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-2191 AMP.

C. Component is different, but consistent with NUREG-2191 item for material, environment, and aging effect. AMP is consistent with NUREG-2191 AMP.

D. Component is different, but consistent with NUREG-2191 item for material, environment, and aging effect. AMP takes some exceptions to the NUREG-2191 AMP.

E. Consistent with NUREG-2191 item for material, environment, and aging effect, but a different AMP is credited or NUREG-2191 identifies a plant-specific AMP.

F. Material not in NUREG-2191 for this component.

G. Environment not in NUREG-2191 for this component and material.

H. Aging effect not in NUREG-2191 for this component, material, and environment combination.

I. Aging effect in NUREG-2191 for this component, material, and environment combination is not applicable.

J. Neither the component nor the material and environment combination are evaluated in NUREG-2191.

3.5 AGING MANAGEMENT OF CONTAINMENTS, STRUCTURES, AND COMPONENT SUPPORTS

3.5.1 INTRODUCTION

This section provides the results of the aging management review for those components identified in Section 2.4, Containments, Structures, and Component Supports, as being subject to AMR. The systems, or portions of systems, which are addressed in this section are described in the indicated sections.

- Auxiliary Building (Section 2.4.1)
- Reactor Building (Section 2.4.2)
- Turbine Building (Section 2.4.3)
- Keowee Hydro Station (Section 2.4.4)
- Electrical Related Structures (Section 2.4.5)
- Earthen Embankments (Section 2.4.6)
- Yard Structures (Section 2.4.7)
- Bulk Commodities (Section 2.4.8)

3.5.2 RESULTS

The following tables summarize the results of the aging management review for Containments, Structures, and Component Supports:

- Table 3.5.2-1, Containments, Structures, and Component Supports - Auxiliary Building - Aging Management Evaluation
- Table 3.5.2-2, Containments, Structures, and Component Supports - Reactor Building - Aging Management Evaluation
- Table 3.5.2-3, Containments, Structures, and Component Supports - Turbine Building - Aging Management Evaluation
- Table 3.5.2-4, Containments, Structures, and Component Supports - Keowee Hydro - Aging Management Evaluation
- Table 3.5.2-5, Containments, Structures, and Component Supports - Electrical Related Structures - Aging Management Evaluation
- Table 3.5.2-6, Containments, Structures, and Component Supports - Earthen Embankments - Aging Management Evaluation
- Table 3.5.2-7, Containments, Structures, and Component Supports - Borated Water Storage Tank Superstructure - Aging Management Evaluation
- Table 3.5.2-8, Containments, Structures, and Component Supports - Essential Siphon Vacuum Building - Aging Management Evaluation
- Table 3.5.2-9, Containments, Structures, and Component Supports - Intake Structure - Aging Management Evaluation
- Table 3.5.2-10, Containments, Structures, and Component Supports - Protected Service Water Building - Aging Management Evaluation
- Table 3.5.2-11, Containments, Structures, and Component Supports - Protected Service Water Conduit Duct Banks - Aging Management Evaluation

- Table 3.5.2-12, Containments, Structures, and Component Supports - Standby Shutdown Facility - Aging Management Evaluation
- Table 3.5.2-13, Containments, Structures, and Component Supports - Radwaste Facility - Aging Management Evaluation
- Table 3.5.2-14, Containments, Structures, and Component Supports - Trenches - Aging Management Evaluation
- Table 3.5.2-15, Containments, Structures, and Component Supports - Technical Support Building - Aging Management Evaluation
- Table 3.5.2-16, Containments, Structures, and Component Supports - Elevated Water Storage Tank Structure - Aging Management Evaluation

3.5.2.1 Materials, Environments, Aging Effects Requiring Management and Aging Management Programs

3.5.2.1.1 Auxiliary Building

Materials

Components in the Auxiliary Building are constructed of the following materials:

- Concrete
- Concrete Block
- Elastomer, Rubber and Other Similar Materials
- Fiber Reinforced Polymer
- Masonry Walls
- Stainless Steel
- Steel

Environments

Components in the Auxiliary Building are exposed to the following environments:

- Air
- Air – Indoor Uncontrolled
- Air – Outdoor
- Air with Borated Water Leakage
- Concrete
- Groundwater/Soil
- Soil
- Treated Borated Water
- Treated Borated Water >60°C (>140°F)
- Water – Flowing

Aging Effects Requiring Management

Components in the Auxiliary Building require aging management to address the following aging effects:

* Cracking
* Cracking or Blistering
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Cumulative Fatigue Damage
* Hardening or Loss of Strength
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Material, Wear, Deformation, Cracking
* Loss of Preload
* Loss of Sealing

Aging Management Programs

The aging effects for components in the Auxiliary Building are managed by the following AMPs:

* Boric Acid Corrosion (B2.1.4)
* Fire Protection (B2.1.15)
* Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B2.1.13)
* Masonry Walls (B2.1.32)
* One-Time Inspection (B2.1.20)
* Structures Monitoring (B2.1.33)
* TLAA
* Water Chemistry (B2.1.2)

3.5.2.1.2 Reactor Building

Materials

Components in the Reactor Building are constructed of the following materials:

* Coatings
* Concrete
* Concrete Block
* Elastomer, Rubber and Other Similar Materials
* Stainless Steel
* Steel
* Steel (with Stainless Steel Cladding)

Environments

Components in the Reactor Building are exposed to the following environments:

* Air
* Air – Indoor Uncontrolled
* Air – Outdoor
* Air with Borated Water Leakage
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Reactor Building require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Cumulative Fatigue Damage

* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Coating or Lining Integrity
* Loss of Leak Tightness
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Material, Wear, Deformation, Cracking
* Loss of Preload
* Loss of Prestress
* Loss of Sealing
* Reduction in Foundation Strength, Cracking

Aging Management Programs

The aging effects for components in the Reactor Building are managed by the following AMPs:

* 10 CFR 50, Appendix J (B2.1.31)
* ASME Section XI, Subsection IWE (B2.1.28)
* ASME Section XI, Subsection IWL (B2.1.29)
* Boric Acid Corrosion (B2.1.4)
* Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B2.1.13)
* Masonry Walls (B2.1.32)
* Protective Coating Monitoring and Maintenance (B2.1.35)
* Secondary Shield Wall Tendon Surveillance Program (B4.1)
* Structures Monitoring (B2.1.33)
* TLAA

3.5.2.1.3 Turbine Building

Materials

Components in the Turbine Building are constructed of the following materials:

* Concrete
* Concrete Block
* Elastomer, Rubber and Other Similar Materials
* Masonry Walls
* Steel

Environments

Components in the Turbine Building are exposed to the following environments:

* Air
* Air – Indoor Uncontrolled
* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Turbine Building require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Cumulative Fatigue Damage
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength

* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Material, Wear, Deformation, Cracking
* Loss of Preload
* Loss of Sealing

Aging Management Programs

The aging effects for components in the Turbine Building are managed by the following AMPs:

* Fire Protection (B2.1.15)
* Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B2.1.13)
* Masonry Walls (B2.1.32)
* Structures Monitoring (B2.1.33)
* TLAA

3.5.2.1.4 Keowee Hydro Station

Materials

Components in the Keowee Hydro Station are constructed of the following materials:

* Concrete
* Concrete Block
* Elastomer, Rubber and Other Similar Materials
* Stainless Steel
* Steel

Environments

Components in the Keowee Hydro Station are exposed to the following environments:

* Air
* Air – Indoor Uncontrolled
* Air – Outdoor
* Concrete
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Keowee Hydro Station require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength

* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Material, Wear, Deformation, Cracking
* Loss of Preload
* Loss of Sealing
* Reduction in Foundation Strength, Cracking

Aging Management Programs

The aging effects for components in the Keowee Hydro Station are managed by the following AMPs:

* FERC Inspections of the Keowee Hydro Station
* Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B2.1.13)
* Inspection of Water-Control Structures Associated with Nuclear Power Plants (B2.1.34)
* Masonry Walls (B2.1.32)
* Structures Monitoring (B2.1.33)

3.5.2.1.5 Electrical Related Structures

Materials

Components in the Electrical Related Structures are constructed of the following materials:

* Aluminum
* Concrete
* Concrete Block
* Elastomer, Rubber and Other Similar Materials
* Stainless Steel
* Steel

Environments

Components in the Electrical Related Structures are exposed to the following environments:

* Air – Indoor Uncontrolled
* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Electrical Related Structures require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength

* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Preload
* Loss of Sealing

Aging Management Programs

The aging effects for components in the Electrical Related Structures are managed by the following AMPs:

* Masonry Walls (B2.1.32)
* Structures Monitoring (B2.1.33)

3.5.2.1.6 Earthen Embankments

Materials

Components in the Earthen Embankments are constructed of the following materials:

* Various

Environments

Components in the Earthen Embankments are exposed to the following environments:

* Air – Outdoor
* Water – Flowing
* Water – Standing

Aging Effects Requiring Management

Components in the Earthen Embankments require aging management to address the following aging effects:

* Loss of Material, Loss of Form

Aging Management Programs

The aging effects for components in the Earthen Embankments are managed by the following AMPs:

* FERC Inspections of the Keowee Earthen Embankments

3.5.2.1.7 Borated Water Storage Tank Superstructure

Materials

Components in the Borated Water Storage Tank Superstructure are constructed of the following materials:

* Concrete
* Steel

Environments

Components in the Borated Water Storage Tank Superstructure are exposed to the following environments:

* Air – Indoor Uncontrolled
* Air – Outdoor
* Air with Borated Water Leakage
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Borated Water Storage Tank Superstructure require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Preload

* Reduction in Foundation Strength, Cracking

Aging Management Programs

The aging effects for components in the Borated Water Storage Tank Superstructure are managed by the following AMPs:

* Boric Acid Corrosion (B2.1.4)
* Structures Monitoring (B2.1.33)

3.5.2.1.8 Essential Siphon Vacuum Building

Materials

Components in the Essential Siphon Vacuum Building are constructed of the following materials:

* Concrete
* Steel

Environments

Components in the Essential Siphon Vacuum Building are exposed to the following environments:

* Air – Indoor Uncontrolled
* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Essential Siphon Vacuum Building require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Preload

Aging Management Programs

The aging effects for components in the Essential Siphon Vacuum Building are managed by the following AMPs:

* Structures Monitoring (B2.1.33)

3.5.2.1.9 Intake Structure

Materials

Components in the Intake Structure are constructed of the following materials:

* Concrete
* Steel

Environments

Components in the Intake Structure are exposed to the following environments:

* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Intake Structure require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Preload
* Reduction in Foundation Strength, Cracking

Aging Management Programs

The aging effects for components in the Intake Structure are managed by the following AMPs:

* Inspection of Water-Control Structures Associated with Nuclear Power Plants (B2.1.34)
* Structures Monitoring (B2.1.33)

3.5.2.1.10 Protected Service Water Building

Materials

Components in the Protected Service Water Building are constructed of the following materials:

* Concrete
* Elastomer, Rubber and Other Similar Materials
* Steel

Environments

Components in the Protected Service Water Building are exposed to the following environments:

* Air
* Air – Indoor Uncontrolled
* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Protected Service Water Building require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking

* Loss of Material, Wear, Deformation, Cracking
* Loss of Preload
* Loss of Sealing
* Reduction in Foundation Strength, Cracking

Aging Management Programs

The aging effects for components in the Protected Service Water Building are managed by the following AMPs:

* Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B2.1.13)
* Structures Monitoring (B2.1.33)

3.5.2.1.11 Protected Service Water Conduit Duct Banks

Materials

Components in the Protected Service Water Conduit Duct Banks are constructed of the following materials:

* Concrete
* Steel

Environments

Components in the Protected Service Water Conduit Duct Banks are exposed to the following environments:

* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Protected Service Water Conduit Duct Banks require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Preload
* Reduction in Foundation Strength, Cracking

Aging Management Programs

The aging effects for components in the Protected Service Water Conduit Duct Banks are managed by the following AMPs:

* Structures Monitoring (B2.1.33)

3.5.2.1.12 Standby Shutdown Facility

Materials

Components in the Standby Shutdown Facility are constructed of the following materials:

* Concrete
* Elastomer, Rubber and Other Similar Materials
* Steel

Environments

Components in the Standby Shutdown Facility are exposed to the following environments:

* Air
* Air – Indoor Uncontrolled
* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Standby Shutdown Facility require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Material, Wear, Deformation, Cracking

* Loss of Preload
* Loss of Sealing
* Reduction in Foundation Strength, Cracking

Aging Management Programs

The aging effects for components in the Standby Shutdown Facility are managed by the following AMPs:

* Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B2.1.13)
* Structures Monitoring (B2.1.33)

3.5.2.1.13 Radwaste Facility

Materials

Components in the Radwaste Facility are constructed of the following materials:

* Concrete
* Concrete Block
* Elastomer, Rubber and Other Similar Materials
* Steel

Environments

Components in the Radwaste Facility are exposed to the following environments:

* Air – Indoor Uncontrolled
* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Radwaste Facility require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Preload

* Loss of Sealing

Aging Management Programs

The aging effects for components in the Radwaste Facility are managed by the following AMPs:

* Masonry Walls (B2.1.32)
* Structures Monitoring (B2.1.33)

3.5.2.1.14 Trenches

Materials

Components in the Trenches are constructed of the following materials:

* Concrete
* Steel

Environments

Components in the Trenches are exposed to the following environments:

* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Trenches require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Preload
* Reduction in Foundation Strength, Cracking

Aging Management Programs

The aging effects for components in the Trenches are managed by the following AMPs:

* Structures Monitoring (B2.1.33)

3.5.2.1.15 Technical Support Building

Materials

Components in the Technical Support Building are constructed of the following materials:

* Concrete
* Steel

Environments

Components in the Technical Support Building are exposed to the following environments:

* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Technical Support Building require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Preload
* Reduction in Foundation Strength, Cracking

Aging Management Programs

The aging effects for components in the Technical Support Building are managed by the following AMPs:

* Structures Monitoring (B2.1.33)

3.5.2.1.16 Elevated Water Storage Tank Structure

Materials

Components in the Elevated Water Storage Tank Structure are constructed of the following materials:

* Steel

Environments

Components in the Elevated Water Storage Tank Structure are exposed to the following environments:

* Air – Outdoor

Aging Effects Requiring Management

Components in the Elevated Water Storage Tank Structure require aging management to address the following aging effects:

* Loss of Material
* Loss of Preload

Aging Management Programs

The aging effects for components in the Elevated Water Storage Tank Structure are managed by the following AMPs:

* Structures Monitoring (B2.1.33)

3.5.2.1.17 Microwave House Structure

Materials

Components in the Microwave House Structure are constructed of the following materials:

* Aluminum
* Concrete
* Elastomer, Rubber and Other Similar Materials
* Steel

Environments

Components in the Microwave House Structure are exposed to the following environments:

* Air – Indoor Uncontrolled
* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Microwave House Structure require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking

* Loss of Preload
* Loss of Sealing

Aging Management Programs

The aging effects for components in the Microwave House Structure are managed by the following AMPs:

* Structures Monitoring (B2.1.33)

3.5.2.1.18 Manholes

Materials

Components in the Manholes are constructed of the following materials:

* Concrete
* Steel

Environments

Components in the Manholes are exposed to the following environments:

* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Manholes require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Preload
* Reduction in Foundation Strength, Cracking

Aging Management Programs

The aging effects for components in the Manholes are managed by the following AMPs:

* Structures Monitoring (B2.1.33)

3.5.2.1.19 Condenser Circulating Water Discharge Pipe

Materials

Components in the Condenser Circulating Water Discharge Pipe are constructed of the following materials:

- Steel

Environments

Components in the Condenser Circulating Water Discharge Pipe are exposed to the following environments:

- Air – Outdoor
- Groundwater/Soil
- Water – Flowing

Aging Effects Requiring Management

Components in the Condenser Circulating Water Discharge Pipe require aging management to address the following aging effects:

- Loss of Material

Aging Management Programs

The aging effects for components in the Condenser Circulating Water Discharge Pipe are managed by the following AMPs:

- Inspection of Water-Control Structures Associated with Nuclear Power Plants (B2.1.34)

3.5.2.1.20 Health Physics Office Building

Materials

Components in the Health Physics Office Building are constructed of the following materials:

- Aluminum
- Concrete
- Elastomer, Rubber and Other Similar Materials
- Steel

Environments

Components in the Health Physics Office Building are exposed to the following environments:

- Air – Indoor Uncontrolled
- Air – Outdoor
- Groundwater/Soil
- Soil
- Water – Flowing

Aging Effects Requiring Management

Components in the Health Physics Office Building require aging management to address the following aging effects:

- Cracking
- Cracking, Distortion
- Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
- Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
- Increase in Porosity and Permeability, Loss of Strength
- Loss of Material
- Loss of Material (Spalling, Scaling), Cracking

* Loss of Preload
* Loss of Sealing

Aging Management Programs

The aging effects for components in the Health Physics Office Building are managed by the following AMPs:

* Structures Monitoring (B2.1.33)

3.5.2.1.21 Administration Building

Materials

Components in the Administration Building are constructed of the following materials:

* Concrete
* Concrete Block

Environments

Components in the Administration Building are exposed to the following environments:

* Air – Indoor Uncontrolled
* Air – Outdoor
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Administration Building require aging management to address the following aging effects:

* Cracking
* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material (Spalling, Scaling), Cracking

Aging Management Programs

The aging effects for components in the Administration Building are managed by the following AMPs:

* Masonry Walls (B2.1.32)
* Structures Monitoring (B2.1.33)

3.5.2.1.22 Component Supports

Materials

Components in the Component Supports are constructed of the following materials:

* Aluminum
* High-Strength Steel
* Lubrite; Fluorogold; Lubrofluor
* PVC
* Stainless Steel
* Steel

Environments

Components in the Component Supports are exposed to the following environments:

* Air
* Air – Indoor Uncontrolled
* Air – Outdoor
* Air with Borated Water Leakage
* Concrete
* Treated Borated Water

Aging Effects Requiring Management

Components in the Component Supports require aging management to address the following aging effects:

* Cracking
* Cumulative Fatigue Damage (Only if CLB fatigue analysis exists)
* Loss of Material
* Loss of Mechanical Function
* Loss of Preload

Aging Management Programs

The aging effects for components in the Component Supports are managed by the following AMPs:

* ASME Section XI, Subsection IWF (B2.1.30)
* Boric Acid Corrosion (B2.1.4)
* Structures Monitoring (B2.1.33)
* TLAA
* Water Chemistry (B2.1.2)

3.5.2.1.23 Miscellaneous Structural Commodities

Materials

Components in the Miscellaneous Structural Commodities are constructed of the following materials:

* Cerafiber Bulk, Cerafiber Blanket, Cerafoam, Pyrocrete, Mineral Wool, 3M Putty
* Concrete
* Cork
* Elastomer
* Elastomer, Rubber and Other Similar Materials
* Grout
* Non-Metallic (e.g., Rubber)
* Steel

Environments

Components in the Miscellaneous Structural Commodities are exposed to the following environments:

* Air
* Air – Indoor Uncontrolled
* Air – Outdoor
* Air with Borated Water Leakage
* Groundwater/Soil
* Soil
* Water – Flowing

Aging Effects Requiring Management

Components in the Miscellaneous Structural Commodities require aging management to address the following aging effects:

* Cracking

* Cracking, Distortion
* Cracking, Loss of Bond, Loss of Material (Spalling, Scaling)
* Hardening, loss of strength, or shrinkage
* Increase in Porosity and Permeability, Cracking, Loss of Material (Spalling, Scaling)
* Increase in Porosity and Permeability, Loss of Strength
* Loss of Material
* Loss of Material (Spalling, Scaling), Cracking
* Loss of Material, Cracking/Delamination, Change in Material Properties, Separation
* Loss of Sealing
* Reduction in Concrete Anchor Capacity
* Reduction or Loss of Isolation Function

Aging Management Programs

The aging effects for components in the Miscellaneous Structural Commodities are managed by the following AMPs:

* Boric Acid Corrosion (B2.1.4)
* Fire Protection (B2.1.15)
* Structures Monitoring (B2.1.33)

3.5.2.2 Further Evaluation of Aging Management as Recommended by NUREG-2192

NUREG-2192 provides the bases for identifying those programs that warrant further evaluation by the reviewer in the SLRA. For the containment, structures and component supports those evaluations are addressed in the following sections.

3.5.2.2.1 Pressurized Water Reactor and Boiling Water Reactor Containments

3.5.2.2.1.1 Cracking and Distortion Due to Increased Stress Levels from Settlement; Reduction of Foundation Strength, and Cracking Due to Differential Settlement and Erosion of Porous Concrete Subfoundations

NUREG-2192

Cracking and distortion due to increased stress levels from settlement could occur in PWR and BWR concrete and steel containments. The existing program relies on ASME Code Section XI, Subsection IWL to manage these aging effects. Also, reduction of foundation strength and cracking, due to differential settlement and erosion of porous concrete subfoundations could occur in all types of PWR and BWR containments. The existing program relies on the structures monitoring program to manage these aging effects. However, some plants may rely on a dewatering system to lower the site groundwater level. If the plant's current licensing basis (CLB) credits a dewatering system to control settlement, further evaluation is recommended to verify the continued functionality of the dewatering system during the subsequent period of extended operation.

Evaluation

[3.5.1-001], [3.5.1-002] – ONS does not use a dewatering system to lower site groundwater level in the vicinity of the reactor containments. The *Structures Monitoring* (B2.1.33) program is relied upon to manage reduction of foundation strength and cracking due to differential settlement. ONS did not use high-alumina cement in reactor containments; therefore, erosion of porous concrete subfoundations is not applicable.

3.5.2.2.1.2 Reduction of Strength and Modulus Due to Elevated Temperature

NUREG-2192

Reduction of strength and modulus of concrete due to elevated temperatures could occur in PWR and BWR concrete and steel containments. The implementation of 10 CFR 50.55a and ASME Code Section XI, Subsection IWL would not be able to identify the reduction of strength and modulus of concrete due to elevated temperature. Subsection CC-3440 of ASME Code Section III, Division 2, specifies the concrete temperature limits for normal operation or any other long-term period. Further evaluation is recommended to determine the need for a plant-specific AMP or plant-specific enhancements to ASME Code Section XI Subsection IWL and/or Structures Monitoring AMPs, to manage these aging effects for portion of the concrete *containment components that exceed specified temperature limits {i.e., general area temperature greater than 66 °C (Celsius) [150 °F (Fahrenheit)] and local area temperature greater than 93 °C (200 °F)}. Higher temperatures may be allowed if tests and/or calculations are provided to evaluate the reduction in strength and modulus of elasticity and these reductions are applied to the design calculations. Acceptance criteria are described in Branch Technical Position (BTP) RLSB (License Renewal and Standardization Branch)-1, "Aging Management Review – Generic, July 2017" (Appendix A.1 of this SRP-SLR.*

Evaluation

[3.5.1-003] – Most open areas in the reactor building have a maximum temperature of 140°F. These values are below the thresholds for localized and general area temperatures specified in this item.

The only high temperature piping penetrating the reactor building shell are the main steam lines and feedwater lines. These main steam penetrations (shown in UFSAR Figure 3-20) are designed with cooling fans and stacks. A review of ONS OE reflects that localized concrete temperatures at the main steam penetrations have marginally exceeded 200°F areas around the penetrations due to limitations of air movement. Exposure to localized, high temperatures can cause immediate cracking of concrete due to restraint of expansion caused by the increased temperatures and is not a potential long term aging effect and mechanism, such as degradation due to radiation exposure where there is a buildup of the aging effect over time before it becomes apparent.

The concrete aggregate used at ONS is a crushed, Gaffney marble obtained from Blacksburg, South Carolina, which produces an excellent, high strength, dense, sound concrete. The design strength was 5000 psi at 28 days for the containment shell. Marble is a calcareous aggregate, which is less susceptible to lower strength (by percentage) at high temperature than siliceous aggregates in concrete as described in NUREG/CR-6900, "The Effect of Elevated Temperature on Concrete Materials and Structures - A Literature Review", in Section 2.2.1. As a result, it is not expected that there would be a reduction in strength for the concrete at ONS due to relatively small, elevated temperatures noted at the main steam line penetrations. Volumetric non-destructive concrete testing was performed to address the exposure to elevated temperature concern, which determined that there was no adverse impact to the concrete strength due to the marginally higher temperatures in these areas. (More detail is provided in OE discussion in the *ASME Section XI – Subsection IWL* (B2.1.29) program)

Therefore, change in material properties due to elevated temperature is not an aging effect and mechanism combination requiring management for ONS concrete structures. For the main steam pipe penetration, the *ASME Section XI – Subsection IWL* (B2.1.29) program is adequate to manage the concrete in these areas. The visual examinations of the containment by the *ASME Section XI – Subsection IWL* (B2.1.29) program are adequate to monitor the exposed concrete surface of the containment structure. Acceptance criteria include the absence of spalling, cracking, and other physical damage, consistent with the parameters identified in American Concrete Institute (ACI) 349.3R-02 for concrete degradation due to thermal exposure. Failure to meet the acceptance criteria is cause for documenting the condition in the ONS corrective action program for further evaluation, which may include other examinations.

3.5.2.2.1.3 Loss of Material Due to General, Pitting and Crevice Corrosion

NUREG-2192

1. *Loss of material due to general, pitting, and crevice corrosion could occur in steel elements of inaccessible areas for all types of PWR and BWR containments. The existing program relies on ASME Code Section XI, Subsection IWE, and 10 CFR Part 50, Appendix J AMPs, to manage this aging effect. Further evaluation is recommended of plant-specific programs to manage this aging effect if corrosion is indicated from the IWE examinations Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).*

2. *Loss of material due to general, pitting, and crevice corrosion could occur in steel torus shell of Mark I containments. The existing program relies on ASME Code Section XI, Subsection IWE, and 10 CFR Part 50, Appendix J, to manage this aging effect. If corrosion is significant, recoating of the torus is recommended. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).*

3. *Loss of material due to general, pitting, and crevice corrosion could occur in steel torus ring girders and downcomers of Mark I containments, downcomers of Mark II containments, and interior surface of suppression chamber shell of Mark III containments. The existing program relies on ADME Code Section XI, Subsection IWE to manage this aging effect. Further evaluation is recommended of plant-specific programs to manage this aging effect if corrosion is significant. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).*

Evaluation

[3.5.1-005], [3.5.1-035] –The *ASME Section XI, Subsection IWE* (B2.1.28) program manages aging of the steel liner of the concrete containment building. The *10 CFR Part 50, Appendix J* (B2.1.31) program manages loss of leak tightness, loss of sealing, and leakage through containment to assure that allowable leakage rate limits specified in the technical specifications are not exceeded. An evaluation of the acceptability of the inaccessible areas is completed whenever conditions are detected in accessible areas that could indicate the presence of, or result in, degradation to such inaccessible areas. OE associated with accessible areas from the *ASME Section XI, Subsection IWE* (B2.1.28) program has identified only minor indications of corrosion, which have been evaluated for continued service or otherwise addressed by the corrective action program.

ONS containment concrete components were designed in accordance with ACI 318-63, “Building Code Requirements for Reinforced Concrete”, and constructed in accordance with ACI 301, using ingredients conforming to ACI and ASTM standards which provide a dense, low permeability concrete to protect against corrosion. Crack control was achieved through proper sizing, spacing, and distribution of reinforcing steel in accordance with ACI 318-63. Procedural controls ensured quality throughout the batching, mixing, and placement processes. The *ASME Section XI, Subsection IWL* (B2.1.29) program identifies and manages cracks in the containment concrete that could potentially provide a pathway for water to reach inaccessible portions of the steel containment liner. Therefore, a plant-specific aging management program to manage the effects of general, pitting and crevice corrosion is not required.

[3.5-1-004] Not applicable - BWR only.

[3.5-1-006] Not applicable - BWR only.

[3.5-1-007] Not applicable - BWR only.

3.5.2.2.1.4 Loss of Prestress Due to Relaxation, Shrinkage, Creep, and Elevated Temperature

NUREG-2192

Loss of prestress forces due to relaxation, shrinkage, creep, and elevated temperature for PWR prestressed concrete containments and BWR Mark II prestressed concrete containments is a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). The evaluation of this TLAA is addressed in Section 4.5, "Concrete Containment Unbonded Tendon Pre-stress Analysis," and/or Section 4.7 "Other Plant-Specific Time-Limited Aging Analyses," of this SRP-SLR.

Evaluation

[3.5.1-008] – Containment tendon loss of prestress is a TLAA, as defined in 10 CFR 54.3. Loss of prestress forces due to relaxation, shrinkage, creep, and elevated temperature for the containment structures is addressed in Section 4.5, "Concrete Containment Tendon Prestress Analysis", and is managed by the *ASME Section XI, Subsection IWL* (B2.1.29) program and the *Concrete Containment Unbonded Tendon Prestress* (B3.4) program. The *Concrete Containment Unbonded Tendon Prestress* (B3.4) program takes exceptions to NUREG-2191. The exceptions are related to the exclusion of certain historical data since the historical results do not truly represent the tendon forces in the group as common tendons and can result in misleading trend lines if included, due to the wire removal and retensioning of the tendons. As the exceptions pertain to historical data, there are no impacts to aging management activities associated with the program for the SPEO.

Loss of prestress of secondary shield wall tendons is managed by the plant specific *Secondary Shield Wall Tendon Surveillance* (B4.1) program. This program performs periodic inspections of tendons and associated hardware, as well as liftoff testing to verify tendon prestress is maintained above established acceptance criteria.

3.5.2.2.1.5 Cumulative Fatigue Damage

NUREG-2192

Evaluations involving time-dependent fatigue, cyclical loading, or cyclical displacement of metal liner, metal plates, suppression pool steel shells (including welded joints) and penetrations (including personnel airlock, equipment hatch, control rod drive (CRD) hatch, penetration sleeves, dissimilar metal welds, and penetration bellows) for all types of PWR and BWR containments and BWR vent header, vent line bellows, and downcomers may be TLAAs as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c)(1). The evaluation of this TLAA is addressed in Section 4.6, "Containment Liner Plates, Metal Containments, and Penetrations Fatigue Analysis," and for cases of plant-specific components, in Section 4.7 "Other Plant-Specific Time-Limited Aging Analyses," of this SRP-SLR. For plant-specific cumulative usage factor calculations, the method used is appropriately defined and discussed in the applicable TLAAs.

For the above-stated containment pressure-retaining components (corresponding to Table 3.5-1, Items 027 and 040) subject to cyclic loading for which no CLB fatigue analysis exists at the time of an SLRA submittal, a plant-specific further evaluation may be performed to demonstrate that cracking due to cyclic loading is an aging effect that does not require aging management for the component. As one acceptable approach, the aging effect does not require aging management actions if the further evaluation demonstrates that the six criteria for cyclic loading in paragraph NE-3222.4(d) (NE-3221.5(d) in 1980 and later code editions), "Analysis for Cyclic Operation, Vessels Not Requiring Analysis for Cyclic Service," of ASME Code, Section III, Division 1 (1974 edition or later edition incorporated by reference in 10 CFR 50.55a(a)(i)), that provide for a waiver from detailed fatigue analysis are satisfied for applicable component materials through the end of the subsequent period of extended operation. The option to perform a fatigue waiver analysis to address the aging effect of cracking due to cyclic loading, for specific containment metallic components, is in lieu of performing supplemental surface examinations or performing or crediting an appropriate 10 CFR Part 50, Appendix J, leak-rate test discussed in GALL-SLR Report AMP XI.S1, "ASME Section XI, Subsection IWE."

Evaluation

[3.5.1-009] – Containment Liner, Main Feedwater and Main Steam Containment Penetration/ Fatigue Cracking is a TLAA, as defined in 10 CFR 54.3. The evaluation of this TLAA is addressed in Section 4.6, "Containment Liner Plate, Metal Containments and Penetration Fatigue Analysis".

3.5.2.2.1.6 Cracking Due to Stress Corrosion Cracking

NUREG-2192

Stress corrosion cracking (SCC) of stainless steel (SS) penetration sleeves, penetration bellows, vent line bellows, suppression chamber shell (interior surface), and dissimilar metal welds could *occur in PWR and/or BWR containments. The existing program relies on ASME Code Section XI, Subsection IWE and10 CFR Part 50, Appendix J, to manage this aging effect. Further evaluation, including consideration of SCC susceptibility and applicable operating experience (OE) related to detection, is recommended of additional appropriate examinations/evaluations implemented to detect this aging effect for these SS components and dissimilar metal welds.*

Evaluation

[3.5.1-010] – ONS containment does not have stainless steel penetration sleeves, penetration bellows, vent line bellows, or suppression chamber shell (interior surface) as part of the containment pressure boundary. Stainless steel high energy pipes that penetrate the containment are connected to carbon steel penetration sleeves with dissimilar metal welds. Review of plant OE has not identified stress corrosion cracking associated with these welds. The *ASME Section XI, Subsection IWE* (B2.1.28) program, and *10 CFR Part 50, Appendix J* (B2.1.31) program manages the aging of these dissimilar metal welds.

3.5.2.2.1.7 Loss of Material (Scaling, Spalling) and Cracking Due to Freeze-Thaw

NUREG-2192

Loss of material (scaling, spalling) and cracking due to freeze-thaw could occur in inaccessible areas of PWR and BWR concrete containments. Further evaluation is recommended of this aging effect to determine the need for a plant-specific AMP or plant-specific enhancements to ASME Code Section XI, Subsection IWL, and/or Structures Monitoring AMPs, to manage these aging effects for plants located in moderate to severe weathering conditions. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).

Evaluation

[3.5.1-011] – ONS is located in a moderate weathering region, as defined in ASTM C-33. ONS containment concrete components were designed in accordance with ACI 318-63 and constructed in accordance with ACI 301, using ingredients conforming to ACI and ASTM standards which provide a dense, low permeability concrete to protect against corrosion. Procedural controls ensured quality throughout the batching, mixing, and placement processes. Review of plant OE has not identified aging effects related to freeze-thaw in accessible areas and the *Structures Monitoring* (B2.1.33) program and the *ASME Section XI, Subsection IWL* (B2.1.29) program confirm the absence of aging effects by examining normally inaccessible structural components when scheduled maintenance work and planned plant modifications permit access. Therefore, a plant-specific AMP or plant-specific enhancements to the *Structures Monitoring* (B2.1.33) program and the *ASME Section XI, Subsection IWL* (B2.1.29) program for inaccessible areas to manage the aging effects of loss of material (scaling, spalling) and cracking due to freeze-thaw are not required.

3.5.2.2.1.8 Cracking Due to Expansion From Reaction with Aggregates

NUREG-2192

Cracking due to expansion from reaction with aggregates could occur in inaccessible areas of concrete elements of PWR and BWR concrete and steel containments. The GALL-SLR Report recommends further evaluation to determine the need for a plant-specific AMP or plant-specific enhancements to ASME Code Section XI, Subsection IWL, and/or Structures Monitoring AMPs to manage this aging effect. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).

Evaluation

[3.5.1-012] – Inspection for Alkali-Silica Reaction has been incorporated into the *ASME Section XI, Subsection IWL* (B2.1.29) program. Augmented inspections for the *ASME Section XI, Subsection IWL* (B2.1.29) program include examination for pattern cracking with darkened crack edges, water ingress, and misalignment inspections. Alkali-Silica Reaction inspection results are evaluated by the responsible engineer each inspection cycle to identify changes that could be indicative of Alkali-Silica Reaction development. Such indications will be entered into the corrective action program. Review of plant OE has not identified evidence of Alkali-Silica Reaction in ONS containments.

3.5.2.2.1.9 Increase in Porosity and Permeability Due to Leaching of Calcium Hydroxide and Carbonation

NUREG-2192

Increase in porosity and permeability due to leaching of calcium hydroxide and carbonation could occur in inaccessible areas of concrete elements of PWR and BWR concrete and steel containments. Further evaluation is recommended to determine the need for a plant-specific AMP or plant-specific enhancements to ASME Code Section XI, Subsection IWL and/or Structures Monitoring AMPs, to manage these aging effects if leaching is observed in accessible areas that impact intended functions. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).

Evaluation

[3.5.1-014] – Reinforced concrete structures at ONS were designed, constructed, and inspected in accordance with ACI and ASTM standards, which provide for a good quality, dense, well-cured, and low permeability concrete. Procedural controls ensured quality throughout the batching, mixing, and placement processes. The *ASME Section XI, Subsection IWL* (B2.1.29) program and the *Structures Monitoring* (B2.1.33) program identify and manage cracks in the containment concrete. Review of plant OE has not identified aging effects related to increase in porosity and permeability due to leaching of calcium hydroxide and carbonation. The *Structures Monitoring* (B2.1.33) program and the *ASME Section XI, Subsection IWL* (B2.1.29) program confirm the absence of aging effects related to leaching of calcium hydroxide and carbonation. Therefore, a plant-specific AMP or plant-specific enhancements to the *Structures Monitoring* (B2.1.33) program and the *ASME Section XI, Subsection IWL* (B2.1.29) program for inaccessible areas to manage the aging effects of increase in porosity and permeability due to leaching of calcium hydroxide and carbonation are not required.

3.5.2.2.2 Safety Related and Other Structures and Component Supports

3.5.2.2.2.1 Aging Management of Inaccessible Areas

NUREG-2192

1. *Loss of material (spalling, scaling) and cracking due to freeze-thaw could occur in below-grade inaccessible concrete areas of Groups 1–3, 5 and 7–9 structures. Further evaluation is recommended of inaccessible areas of these Groups of structures for plants located in moderate to severe weathering conditions to determine the need for a plant-specific AMP or plant-specific enhancements to Structures Monitoring AMP, to manage these aging effects. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).*

2. *Cracking due to expansion and reaction with aggregates could occur in inaccessible concrete areas for Groups 1–5 and 7–9 structures. Further evaluation is recommended of inaccessible areas of these Groups of structures to determine the need for a plant-specific AMP or plant-specific enhancements to Structures Monitoring AMP, to manage this aging effect. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).*

3. *Cracking and distortion due to increased stress levels from settlement could occur in below-grade inaccessible concrete areas of structures for all Groups, and reduction in foundation strength, and cracking due to differential settlement and erosion of porous concrete subfoundations could occur in below-grade inaccessible concrete areas of Groups 1–3, 5–9 structures. The existing program relies on structure monitoring programs to manage these aging effects. Some plants may rely on a dewatering system to lower the site groundwater level. If the plant's CLB credits a dewatering system, verification is recommended of the continued functionality of the dewatering system during the subsequent period of extended operation. No further evaluation is recommended if this activity is included in the scope of the applicant's structures monitoring program.*

4. *Increase in porosity and permeability, and loss of strength due to leaching of calcium hydroxide and carbonation could occur in below-grade inaccessible concrete areas of Groups 1–5 and 7–9 structures. Further evaluation is recommended to determine the need for a plant-specific AMP or plant-specific enhancements to Structures Monitoring AMP, to manage these aging effects if leaching is observed in accessible areas that*

impact intended functions. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).

Evaluation

[3.5.1-042] – ONS is located in a moderate weathering region, as defined in ASTM C-33. Reinforced concrete structures at ONS were designed, constructed, and inspected in accordance with ACI and ASTM standards, which provide for a good quality, dense, well-cured, and low permeability concrete. Procedural controls ensured quality throughout the batching, mixing, and placement processes. Review of plant OE has not identified aging effects related to freeze-thaw in accessible areas and the *Structures Monitoring* (B2.1.33) program confirms the absence of aging effects by examining normally inaccessible structural components when scheduled maintenance work and planned plant modifications permit access. Therefore, a plant-specific AMP or plant-specific enhancements to the *Structures Monitoring* (B2.1.33) program for inaccessible areas to manage the aging effects of loss of material (scaling, spalling) and cracking due to freeze-thaw are not required

[3.5.1-043] – Inspection for Alkali-Silica Reaction has been incorporated into the *Structures Monitoring* (B2.1.33) program. Structures Monitoring Inspections include examination for pattern cracking with darkened crack edges, water ingress, and misalignment inspections. Alkali-Silica Reaction inspection results are evaluated by the responsible engineer to identify changes that could be indicative of Alkali-Silica Reaction development. Such indications will be entered into the corrective action program. Review of plant OE has not identified evidence of Alkali-Silica Reaction in below-grade inaccessible concrete areas of ONS groups 1–5 and 7–9 structures.

[3.5.1-044], [3.5.1-046] – ONS does not rely on a dewatering system to lower site groundwater level. The *Structures Monitoring* (B2.1.33) program is relied upon to detect cracking and distortion due to increased stress levels from settlement, as well as reduction of foundation strength and cracking, due to differential settlement. FERC Inspections of the Keowee hydro station have been substituted and will be used to manage cracking and distortion due to increased stress levels from settlement for the Keowee hydro station concrete exposed to soil environments for the penstock, power tunnels, spillway and intake. Oconee did not use high-alumina cement in reactor containments; therefore, erosion of porous concrete subfoundations is not applicable.

[3.5.1-047] – Reinforced concrete structures at ONS were designed, constructed, and inspected in accordance with ACI and ASTM standards, which provide for a good quality, dense, well-cured, and low permeability concrete. Procedural controls ensured quality throughout the batching, mixing, and placement processes. Review of plant OE has not identified aging effects related to increase in porosity and permeability due to leaching of calcium hydroxide and carbonation. The *Structures Monitoring* (B2.1.33) program confirms the absence of aging effects related to leaching of calcium hydroxide and carbonation. Therefore, a plant-specific AMP or plant-specific enhancements to the *Structures Monitoring* (B2.1.33) program for inaccessible areas to manage the aging effects of increase in porosity and permeability due to leaching of calcium hydroxide and carbonation are not required in below-grade inaccessible concrete areas of ONS groups 1–5 and 7–9 structures.

3.5.2.2.2.2 Reduction of Strength and Modulus Due to Elevated Temperature

NUREG-2192

Reduction of strength and modulus of concrete due to elevated temperatures could occur in PWR and BWR Group 1–5 concrete structures. For any concrete elements that exceed specified temperature limits, further evaluations are recommended. Appendix A of American Concrete Institute (ACI) 349-85, "Code Requirements for Nuclear Safety-Related Concrete Structures," specifies the concrete temperature limits for normal operation or any other long-term period. The temperatures shall not exceed 66 °C (150 °F) except for local areas, which are allowed to have increased temperatures not to exceed 93 °C (200°F). Further evaluation is recommended to determine the need for a plant-specific AMP or plant-specific enhancements to Structures Monitoring AMP, to manage these aging effects if any portion of the safety-related and other concrete structures exceeds specified temperature limits [i.e., general area temperature greater than 66 °C (150 °F) and local area temperature greater than 93 °C (200 °F)]. Higher temperatures may be allowed if tests and/or calculations are provided to evaluate the reduction in strength and modulus of elasticity and these reductions are applied to the design calculations. The acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).

Evaluation

[3.5.1-048] – UFSAR Section 9.1.3 states that the ONS spent fuel pool cooling systems are designed to maintain the pool bulk water temperature below 150 for normal heat loads. The spent fuel pools have an actual operating limit of 205°F (abnormal case). Analyses have been performed to ensure that seismic and structural integrity of the pool liner, supporting concrete, and fuel racks are not compromised at this temperature limit.

General area air temperature in other Class I Structures is maintained at values less than where degradation would be expected to occur. Review of operating experience has identified no issues related to elevated temperatures affecting concrete structures. Additionally, analysis performed to determine the maximum concrete temperature of the primary shield wall illustrates that the concrete will not exceed 200 °F for local loads. Therefore, a plant-specific aging management program to manage the effects of reduction of strength and modulus due to elevated temperature is not required.

3.5.2.2.2.3 Aging Management of Inaccessible Areas for Group 6 Structures

NUREG-2192

Further evaluation is recommended for inaccessible areas of certain Group 6 structure/aging effect combinations as identified below, whether or not they are covered by inspections in accordance with the GALL-SLR Report, AMP XI.S7, "Inspection of Water-Control Structures Associated with Nuclear Power Plants," or Federal Energy Regulatory Commission (FERC)/U.S. Army Corp of Engineers dam inspection and maintenance procedures.

1. *Loss of material (spalling, scaling) and cracking due to freeze-thaw could occur in below-grade inaccessible concrete areas of Group 6 structures. Further evaluation is recommended of this aging effect to determine the need for a plant-specific AMP or plant-specific enhancements to Structures Monitoring AMP, to manage these aging effects for inaccessible areas for plants located in moderate to severe weathering conditions. Acceptance criteria are described in BTP RLSB-1 (Appendix A1 of this SRP-SLR).*

2. *Cracking due to expansion and reaction with aggregates could occur in inaccessible concrete areas of Group 6 structures. Further evaluation is recommended to determine the need for a plant-specific AMP or plant-specific enhancements to Structures Monitoring AMP, to manage this aging effect. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).*

3. *Increase in porosity and permeability and loss of strength due to leaching of calcium hydroxide and carbonation could occur in inaccessible areas of concrete elements of Group 6 structures. Further evaluation is recommended to determine the need for a plant-specific AMP or plant-specific enhancements to Structures Monitoring AMP, to manage these aging effects if leaching is observed in accessible areas that impact intended functions. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).*

<u>Evaluation</u>

[3.5.1-049] – ONS is located in a moderate weathering region, as defined in ASTM C-33. Reinforced concrete structures at ONS were designed, constructed, and inspected in accordance with ACI and ASTM standards, which provide for a good quality, dense, well-cured, and low permeability concrete. Procedural controls ensured quality throughout the batching, mixing, and placement processes. Review of plant OE has not identified any aging effects related to freeze-thaw in accessible areas. The *Structures Monitoring* (B2.1.33) program confirms the absence of aging effects by examining normally inaccessible structural components when scheduled maintenance work and planned plant modifications permit access. Therefore, a plant-specific AMP or plant-specific enhancements to the *Structures Monitoring* (B2.1.33) program for inaccessible areas to manage the aging effects of loss of material (scaling, spalling) and cracking due to freeze-thaw are not required.

[3.5.1-050] – Plant operating experience has not identified any indications of Alkali-Silica Reaction for the concrete structures at ONS, except for at the Keowee dam spillway. During 2001 and 2003, gate binding problems were experienced at Gates 4 and 1, respectively. The binding was resolved by recessing the guide plates into the piers to increase the clearances. A threshold of 0.75 inches of additional spillway end wall movement was established as part of the Potential Failure Modes Analysis, which is performed during each FERC Part 12D inspection. In 2008, the movement threshold on the spillway abutment walls was exceeded. The concrete was then evaluated through drilling, sampling, borehole imaging, compression testing, petrographic testing, in-situ stress testing, biaxial modulus testing, and stress calculation. The investigations found that no significant deterioration of the spillway concrete had occurred. As there are no reliable methods to stop or retard the Alkali-Silica Reaction process, the most viable solution was determined to be monitor and adjust the gates as needed to maintain sufficient operating clearance.

The information obtained from the Alkali-Silica Reaction evaluations has provided anticipated rates of progression that is used in conjunction with visual inspections to guide the implementation schedule for the plant modification of the gates. This is surveyed and monitored by the Dam Safety Surveillance and Monitoring Plan (DSSMP), which is utilized to meet the guidelines of FERC and is evaluated as part of the FERC Part 12D inspection. As stated in NUREG-2191 XI.S7, for dam inspection and maintenance, programs under the regulatory jurisdiction of the FERC or the U.S. Army Corps of Engineers (USACE), continued through the SPEO, are adequate for the purpose of aging management.

Inspection for Alkali-Silica Reaction has been incorporated into the *Structures Monitoring* (B2.1.33) program. Changes that could be indicative of Alkali-Silica Reaction development will be entered into the corrective action program. Therefore, a plant-specific aging management for inaccessible areas is not required to manage cracking due to expansion from reaction with aggregates.

ONS Alkali-Silica Reaction operating experience is limited to the Keowee dam spillway and is not indicative of the potential for Alkali-Silica Reaction in other concrete structures at ONS. Therefore, a plant-specific AMP or plant-specific enhancements to *Structures Monitoring* (B2.1.33) AMP for inaccessible areas are not required to manage cracking due to expansion from reaction with aggregates.

[3.5.1-051] – Reinforced concrete structures at ONS were designed, constructed, and inspected in accordance with ACI and ASTM standards, which provide for a good quality, dense, well-cured, and low permeability concrete. Procedural controls ensured quality throughout the batching, mixing, and placement processes. The *Structures Monitoring* (B2.1.33) program, which includes Group 6 structures, identifies and manages cracks in the concrete structures. Review of plant OE has not identified aging effects related to increase in porosity and permeability due to leaching of calcium hydroxide and carbonation. Therefore, a plant-specific AMP or plant-specific enhancements to the *Structures Monitoring* (B2.1.33) program for inaccessible areas to manage the aging effects of increase in porosity and permeability due to leaching of calcium hydroxide and carbonation are not required in Group 6 structures.

3.5.2.2.2.4 Cracking Due to Stress Corrosion Cracking, and Loss of Material Due to Pitting and Crevice Corrosion

NUREG-2192

Cracking due to SSC and loss of material due to pitting and crevice corrosion could occur in (a) Group 7 and 8 SS tank liners exposed to standing water; and (b) SS and aluminum alloy support members; welds; bolted connections; or support anchorage to building structure exposed to air or condensation (see SRP-SLR Sections 3.2.2.2.2, 3.2.2.2.4, 3.2.2.2.8, and 3.2.2.2.10 for background information).

For Group 7 and 8 SS tank liners exposed to standing water, further evaluation is recommended of plant-specific programs to manage these aging effects. The acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).

For SS and aluminum alloy support members; welds; bolted connections; support anchorage to building structure exposed to air or condensation, the plant-specific OE and condition of the SS and aluminum alloy components are evaluated to determine if the plant-specific air or condensation environments are aggressive enough to result in loss of material or cracking after prolonged exposure. The aging effects of loss of material and cracking in SS and aluminum alloy components is not applicable and does not require management if (a) the plant-specific OE does not reveal a history of pitting or crevice corrosion or cracking and (b) a one-time inspection demonstrates that the aging effects are not occurring or that an aging effect is occurring so slowly that it will not affect the intended function of the components during the subsequent period of extended operation. The applicant documents the results of the plant-specific OE review in the SLRA. Visual inspections conducted in accordance with GALL-SLR Report AMP XI.M32, "One-Time Inspection," are an acceptable method to demonstrate that the aging effects are not occurring at a rate that affects the intended function of the components. One-time inspections are conducted between the 50th and 60th year of operation, as recommended by the "detection of aging effects" program element in AMP XI.M32. If loss of material or cracking has occurred and is sufficient to potentially affect the intended function of SS or aluminum alloy support members; welds; bolted connections; or support anchorage to building structure, either: (a) enhancing the applicable AMP (i.e., GALL-SLR Report AMP XI.S3, "ASME Section XI, Subsection IWF," or AMP XI.S6, "Structures Monitoring"); (b) conducting a representative sample inspection consistent with GALL-SLR Report AMP XI.M36, "External Surfaces Monitoring of Mechanical Components;" or (c) developing a plant-specific AMP are acceptable programs to manage loss of material or cracking (as applicable). Tempers have been specifically developed to improve the SCC resistance for some aluminum alloys. Aluminum alloy and temper combinations which are not susceptible to SCC when used in structural support applications include 1xxx series, 3xxx series, 6061-T6x, and 5454-x. For these alloys and tempers, the susceptibility of cracking due to SCC is not applicable. If these alloys or tempers have been used, the SLRA states the specific alloy or temper used for the applicable in-scope components.

Evaluation

[3.5.1-052] – There are no stainless steel tank liners in the scope of SLR for ONS.

[3.5.1-099], [3.5.1-100] – A review of ONS OE has not identified pitting or crevice corrosion or cracking for stainless steel or aluminum structural components exposed to air or condensation. The *ASME Section XI, Subsection IWF* (B2.1.30) program or *Structures Monitoring* (B2.1.33) program will manage the aging of stainless steel and aluminum component supports to ensure that these components continue to perform their intended functions during the SPEO, except as follows: (1) Stainless steel components of the trash rack filter at the intake structure will be managed by the *Inspection of Water-Control Structures Associated with Nuclear Power Plants* (B2.1.34) program. (2) Stainless steel structural elements and bolting of the penstock, power tunnels, and spillway will be managed by the FERC Inspections of the Keowee hydro station.

3.5.2.2.2.5 Cumulative Fatigue Damage

NUREG-2192

Evaluations involving time-dependent fatigue, cyclical loading, or cyclical displacement of component support members, anchor bolts, and welds for Groups B1.1, B1.2, and B1.3 component supports are TLAAs as defined in 10 CFR 54.3 only if a CLB fatigue analysis exists. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). The evaluation of this TLAA is addressed in Section 4.3, "Metal Fatigue Analysis," and/or Section 4.7, "Other Plant-Specific Time-Limited Aging Analyses," of this SRP-SLR. For plant-specific cumulative usage factor calculations, the method used is appropriately defined and discussed in the applicable TLAAs.

Evaluation

[3.5.1-053] – The evaluation of fatigue for component support members, anchor bolts, and welds for Groups B1.1, B1.2, and B1.3 component supports are TLAAs as defined in 10 CFR 54.3, and is addressed in SLRA Section 4.3, "Metal Fatigue".

3.5.2.2.2.6 Reduction of Strength and Mechanical Properties of Concrete Due to Irradiation

NUREG-2192

Reduction of strength, loss of mechanical properties, and cracking due to irradiation could occur in PWR and BWR Group 4 concrete structures that are exposed to high levels of neutron and gamma radiation. These structures include the reactor (primary/biological) shield wall, the sacrificial shield wall, and the reactor vessel support/pedestal structure. Data related to the effects and significance of neutron and gamma radiation on concrete mechanical and physical properties is limited, especially for conditions (dose, temperature, etc.) representative of light-water reactor (LWR) plants. However, based on literature review of existing research, radiation fluence limits of 1×10^{19} neutrons/cm^2 neutron radiation and 1×10^8 Gy (1×10^{10} rad) gamma dose are considered conservative radiation exposure levels beyond which concrete material properties may begin to degrade markedly.

Further evaluation is recommended to determine the need for a plant-specific AMP or plant-specific enhancements to selected existing AMPs to manage the aging effects of irradiation if the estimated (calculated) fluence levels or irradiation dose received by any portion of the concrete from neutron (fluence cutoff energy E > 0.1 MeV) or gamma radiation exceeds the respective threshold level during the subsequent period of extended operation that could affect intended functions. Higher fluence or dose levels may be allowed in the concrete if tests and/or calculations are provided to evaluate the reduction in strength and/or loss of mechanical properties of concrete from those fluence levels, at or above the operating temperature experienced by the concrete, and the effects are applied to the design calculations. Supporting calculations/analyses, test data, and other technical basis are provided to estimate and evaluate *fluence levels and the plant-specific program. The acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).*

Evaluation

[3.5.1-097] – The following information describes the general configuration of the steel reactor vessel support skirt and support embedment and the adjacent reinforced concrete primary shield wall and reactor vessel pedestal, the analytical methods used to determine the neutron and gamma radiation environment, and the analytical results of the radiation impact to the reactor vessel steel supports and concrete structures.

Reactor Vessel Support Skirt and Reactor Cavity Configuration

The reactor vessel is located within the reactor cavity (also known as the primary shield wall). The reactor vessel head and control rod drives extend into the fuel transfer canal. Openings are provided in the lower part of the shield wall to provide vent area. Piping carrying high pressure injection water are routed outside the reactor cavity and two steam generator cavities entering only when connecting to the loop. The steam generator cavities (or secondary shield walls) house the steam generators, coolant pumps, associated piping and the pressurizer.

The reactor cavity serves as a biological shield wall. The reactor cavity is also designed to contain core flooding water up to the level of the reactor nozzle. The reactor consists of reinforced concrete surrounding the reactor vessel and extends upward from the reactor building floor to form the walls of the fuel transfer canal. The thickness is 5 ft. up to the height of the reactor vessel flange, where the thickness is reduced to 4.5 ft.

The reactor cavity does not provide a support function for the reactor coolant system. The reactor coolant piping is self-supporting with respect to deadweight, seismic, and thermal loading. The reactor coolant pumps are partially supported by rod hangers which are designed to support the dead weight of the pump motor, with the remainder of the dead weight of the pump being supported by the piping. A reactor vessel support skirt provides support for the reactor vessel during seismic events or to transfer lateral and vertical loads to the reinforced reactor vessel foundation. The reactor vessel support skirt is welded to the reactor vessel transition forging (i.e. dutchman). The support skirt flange is bolted to reactor vessel support embedment which transfers loads to the pedestal concrete. The transition forging and anchoring bolts are low alloy steel and the reactor vessel skirt is carbon steel.

Analytical Methodology

To determine the potential impact of neutron and gamma radiation to the reactor cavity wall, Duke Energy utilized an analytical model developed by Framatome to estimate fluence and gamma dose analysis at the inside surface of the reactor cavity wall, reactor vessel support skirt, and reactor vessel support embedment to support operation to 80 years. The methodology used is consistent with BAW-2241PA using DORT 2-D methodology for the beltline region.

The analytical model utilized a bounding source term to determine neutron flux and fluence, as well as the gamma dose at the inside surface of the reactor cavity. The bounding source term is based a conservative core design bounding all potential future fuel cycle design. DORT is used to determine the neutron flux and fluence in the air cavity above the reactor vessel skirt support weld and reactor vessel support embedment to determine a bounding fluence value for these locations. DORT is also used to determine the peak neutron fluence and gamma dose in the concrete bio-shield. Since the Oconee DORT model does not include the reactor vessel skirt weld and support embedment, an extrapolation was performed using a curve fit to flux profiles at the outer surface of the reactor vessel to obtain results for these locations. The extrapolations were terminated below the DORT model near the top of the reactor vessel skirt weld.

The neutron and gamma fluxes were calculated at the cavity locations of interest by generating by synthesis of DORT model calculations to provide neutron and gamma flux values at the chosen locations for fluence and dose projections to 72 EFPY. A bounding estimated cumulative fluence through Cycle 24 for all three Oconee units was added to the fluence determined by DORT from the beginning of Cycle 25 to 72 EFPY.

Reactor Cavity Wall Concrete Evaluation

Neutron fluence and gamma dose at the inside surface of the reactor cavity wall were obtained by extending the DORT model into the wall at the height where the maximum neutron flux (E > 0.1 MeV) and gamma heating occurs. The inside surface of reactor vessel cavity is 353 cm from the core's centerline. The maximum value is axially adjacent to the core region.

- The maximum neutron fluence at 72 EFPY for the inside surface of the reactor cavity walls is 9.36E18 n/cm2 (E > 0.1 MeV). This value is below the SRP-SLR threshold limit of 1E19 n/cm2 for fast neutron fluence (E > 0.1 MeV). The location of the maximum neutron fluence is 3 cm above core midplane.
- The maximum gamma dose at 72 EFPY for the inside surface of the reactor cavity wall is 5.87E+09 rads. This value is below the SRP-SLR threshold limit of 1E10 rads gamma dose. The location of maximum gamma heating is 3 cm below the core midplane.

Reactor Vessel Embedment Pedestal Concrete Evaluation

The bottom of the DORT model extends out to and including the reactor vessel transition forging to lower shell forging weld. However, the reactor vessel support embedment, which is more than 5 feet below reactor vessel transition forging to lower shell forging weld, is not part of the DORT model. Thus, to estimate neutron fluence and gamma dose at the reactor vessel support embedment, flux and gamma heating rate profiles were generated on the outer reactor vessel surface in the air cavity region and extrapolated below the DORT model out to the reactor vessel support skirt weld to ensure conservatism in the analyses of the pedestal concrete due to the change in the shape of the cavity at the reactor vessel support embedment.

- The maximum neutron fluence at 72 EFPY for the reactor vessel support skirt weld is 1.63E+18 n/cm2 n/cm2 (E > 0.1 MeV). This value is below the SRP-SLR threshold limit of 1E19 n/cm2 for fast neutron fluence (E > 0.1 MeV). The support skirt weld is located 71 cm above the reactor vessel support embedment and provides a bounding fluence projection for the embedment pedestal concrete.

- The maximum gamma dose for the reactor vessel support skirt weld is 1.75E09 rads. This value is below the SRP-SLR threshold limit of 1E10 rads gamma dose and provides a bounding gamma dose projection for the embedment pedestal concrete.

Reactor Vessel Support Steel Evaluation

The reactor vessel support assembly and embedment consist of a support skirt, a support flange, anchor bolts and associated washers and hex nuts, sole plate, vertical bearing plate and associated nelson studs, grout, and reinforced concrete pedestal that contains the embedded anchor bolts. The reactor vessel support assembly is defined as the reactor vessel support skirt and the reactor vessel support flange, which were attached to the reactor vessel during fabrication of the reactor vessel. The reactor vessel embedment includes the anchor bolts and associated washers and hex nuts, sole plate, vertical bearing plate and associated nelson studs, grout, and reinforced concrete pedestal that contain the embedded anchor bolts.

Based on configuration of the reactor vessel support assembly and embedment detail, the following items were determined to directly support the reactor vessel support intended function (i.e., provide structural support for the reactor vessel):

- RPV support skirt (SA-516 Grade 70)
- RPV support flange (SA-515 Grade 70)
- Anchor bolts (A490)
- Anchor bolt jamb nuts, hex nuts, and washers

These structural steel components performing an intended function were subject to evaluation for susceptibility to irradiation embrittlement using the process documented in NUREG-1509. Details of that evaluation may be found in Framatome document ANP-3898P.

The evaluation of reactor vessel support steel determined that the reactor vessel support flange (all three ONS units) and the ONS Unit 1 and Unit 2 reactor vessel support flange welds connecting the 90 degree segments together to form a circular support plate are potentially susceptible to reduction of fracture toughness by irradiation embrittlement at 72 EFPY of operation. All remaining reactor vessel support assembly and embedment items that support the vessel support intended function were determined to not be susceptible to irradiation embrittlement. The evaluation concluded that the potential for irradiation embrittlement of the support flange is acceptable considering: (1) configuration of the reactor vessel support skirt welded to the flange plate and the numerous bolts connecting the flange plate to the concrete, and (2) stresses in the flange plate are bounded by the stresses in the RPV support skirt, which is considered the most vulnerable part of the fracture-critical member. Since the RPV support skirt is the critical location of the reactor vessel support assembly and is not susceptible to irradiation embrittlement based on the NDT evaluation reported above, the reactor vessel support intended function will be maintained consistent with the CLB during the SPEO when considering damage due to irradiation.

3.5.2.2.3 Quality Assurance for Aging Management of Non-Safety Related Components

NUREG-2192

Acceptance criteria are described in BTP IQMB-1 (Appendix A.2 of this SRP-SLR).

Evaluation

Quality Assurance provisions applicable to SLR are discussed in Appendix B1.3, Quality Assurance Program and Administrative Controls.

3.5.2.2.4 Ongoing Review of Operating Experience

NUREG-2192

Acceptance criteria are described in Appendix A.4, "Operating Experience for Aging Management Programs."

Evaluation

The operating experience process and acceptance criteria are described in Appendix B1.4, Operating Experience.

Results Tables: Containments, Structures, And Component Supports

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-001	Concrete: dome; wall; basemat; ring girders; buttresses, concrete elements, all	Cracking and distortion due to increased stress levels from settlement	AMP XI.S2, "ASME Section XI, Subsection IWL," and/or AMP XI.S6, "Structures Monitoring"	Yes (SRP-SLR Section 3.5.2.2.1.1)	Consistent with NUREG-2191. The *Structures Monitoring* (B2.1.33) program is relied upon to detect cracking and distortion due to increased stress levels from settlement. See further evaluation in Section 3.5.2.2.1.1.
3.5.1-002	Concrete: foundation; subfoundation	Reduction of foundation strength and cracking due to differential settlement and erosion of porous concrete subfoundation	AMP XI.S6, "Structures Monitoring"	Yes (SRP-SLR Section 3.5.2.2.1.1)	Consistent with NUREG-2191. See further evaluation in Section 3.5.2.2.1.1.
3.5.1-003	Concrete: dome; wall; basemat; ring girders; buttresses, concrete: containment; wall; basemat, concrete: basemat, concrete fill-in annulus	Reduction of strength and modulus of elasticity due to elevated temperature (>150°F general; >200°F local)	Plant-specific aging management program, or AMP XI.S2, "ASME Section XI, Subsection IWL," and/or AMP XI.S6, "Structures Monitoring" enhanced as necessary	Yes (SRP-SLR Section 3.5.2.2.1.2)	Not applicable. The associated NUREG-2191 aging items are not used. See further evaluation in Section 3.5.2.2.1.2.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-004	Steel elements (inaccessible areas): drywell shell; drywell head	Loss of material due to general, pitting, crevice corrosion	AMP XI.S1, “ASME Section XI, Subsection IWE,” and AMP XI.S4, “10 CFR Part 50, Appendix J”	Yes (SRP-SLR Section 3.5.2.2.1.3.1)	Not applicable. BWR only.
3.5.1-005	Steel elements (inaccessible areas): liner; liner anchors; integral attachments, steel elements (inaccessible areas): suppression chamber; drywell; drywell head; embedded shell; region shielded by diaphragm floor (as applicable)	Loss of material due to general, pitting, crevice corrosion	AMP XI.S1, “ASME Section XI, Subsection IWE,” and AMP XI.S4, “10 CFR Part 50, Appendix J”	Yes (SRP-SLR Section 3.5.2.2.1.3.1)	Consistent with NUREG-2191. See further evaluation in Section 3.5.2.2.1.3.
3.5.1-006	Steel elements: torus shell	Loss of material due to general, pitting, crevice corrosion	AMP XI.S1, “ASME Section XI, Subsection IWE,” and AMP XI.S4, “10 CFR Part 50, Appendix J”	Yes (SRP-SLR Section 3.5.2.2.1.3.2)	Not applicable. BWR only.
3.5.1-007	Steel elements: torus ring girders; downcomers;, Steel elements: suppression chamber shell (interior surface)	Loss of material due to general, pitting, crevice corrosion	AMP XI.S1, “ASME Section XI, Subsection IWE”	Yes (SRP-SLR Section 3.5.2.2.1.3.3)	Not applicable. BWR only.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-008	Prestressing system: tendons	Loss of prestress due to relaxation; shrinkage; creep; elevated temperature	TLAA, SRP-SLR Section 4.5, "Concrete Containment Tendon Prestress," and/or SRP-SLR Section 4.7, "Other Plant-Specific Time-Limited Aging Analyses"	Yes (SRP-SLR Section 3.5.2.2.1.4)	Consistent with NUREG-2191. Containment tendon loss of preload is a TLAA, as defined in 10 CFR 54.3. The evaluation of this TLAA is addressed in Section 4.5. Containment tendon loss of preload is managed under the *ASME Section XI, Subsection IWL* (B2.1.29) program and *Concrete Containment Unbonded Tendon Prestress* (B3.4) program. The *Concrete Containment Unbonded Tendon Prestress* (B3.4) program takes some exceptions to NUREG-2191. The secondary shield wall tendons have also been aligned to this item. Loss of prestress of secondary shield wall tendons is managed by the plant specific *Secondary Shield Wall Tendon Surveillance* (B4.1) program. See further evaluation in Section 3.5.2.2.1.4.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-009	Metal liner, metal plate, personnel airlock, equipment hatch, CRD hatch, penetration sleeves; penetration bellows, steel elements: torus; vent line; vent header; vent line bellows; downcomers, suppression pool shell; unbraced downcomers, steel elements: vent header; downcomers	Cumulative fatigue damage due to cyclic loading (Only if CLB fatigue analysis exists)	TLAA, SRP-SLR Section 4.6, “Containment Liner Plate and Penetration Fatigue Analysis”	Yes (SRP-SLR Section 3.5.2.2.1.5)	Consistent with NUREG-2191. Containment Liner and containment penetration fatigue cracking is a time-limited aging analysis (TLAA), as defined in 10 CFR 54.3. The evaluation of this TLAA is addressed in Section 4.6. See further evaluation in Section 3.5.2.2.1.5.
3.5.1-010	Penetration sleeves; penetration bellows	Cracking due to SCC	AMP XI.S1, “ASME Section XI, Subsection IWE,” and AMP XI.S4, “10 CFR Part 50, Appendix J”	Yes (SRP-SLR Section 3.5.2.2.1.6)	Not applicable. ONS containment does not have stainless steel (SS) penetration sleeves, penetration bellows, vent line bellows, or suppression chamber shell (interior surface) as part of the Containment pressure boundary. See further evaluation in Section 3.5.2.2.1.6. The associated NUREG-2191 aging items are not used.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-011	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Plant-specific aging management program, or AMP XI.S2, "ASME Section XI, Subsection IWL," and/or AMP XI.S6, "Structures Monitoring" enhanced as necessary	Yes (SRP-SLR Section 3.5.2.2.1.7)	Consistent with NUREG-2191. See further evaluation in Section 3.5.2.2.1.7.
3.5.1-012	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses, containment, concrete fill-in annulus	Cracking due to expansion from reaction with aggregates	Plant-specific aging management program, or AMP XI.S2, "ASME Section XI, Subsection IWL," and/or AMP XI.S6, "Structures Monitoring" enhanced as necessary	Yes (SRP-SLR Section 3.5.2.2.1.8)	Consistent with NUREG-2191. See further evaluation in Section 3.5.2.2.1.8.
3.5.1-014	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses, containment	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Plant-specific aging management program, or AMP XI.S2, "ASME Section XI, Subsection IWL," and/or AMP XI.S6, "Structures Monitoring" enhanced as necessary	Yes (SRP-SLR Section 3.5.2.2.1.9)	Consistent with NUREG-2191. See further evaluation in Section 3.5.2.2.1.9.
3.5.1-016	Concrete (inaccessible areas): basemat, concrete: containment; wall	Increase in porosity and permeability; cracking; loss of material (spalling, scaling) due to aggressive chemical attack	AMP XI.S2, "ASME Section XI, Subsection IWL," and/or AMP-XI.S6, "Structures Monitoring"	No	Consistent with NUREG-2191.

3.5.1-037	Steel elements: suppression chamber (torus) liner (interior surface)	Loss of material due to general (steel only), pitting, crevice corrosion	AMP XI.S1, "ASME Section XI, Subsection IWE," and AMP XI.S4, "10 CFR Part 50, Appendix J"	No	Not applicable. BWR only.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-038	Steel elements: suppression chamber shell (interior surface)	Cracking due to SCC	AMP XI.S1, “ASME Section XI, Subsection IWE,” and AMP XI.S4, “10 CFR Part 50, Appendix J”	Yes (SRP-SLR Section 3.5.2.2.1.6)	Not applicable. BWR only.
3.5.1-039	Steel elements: vent line bellows	Cracking due to SCC	AMP XI.S1, “ASME Section XI, Subsection IWE,” and AMP XI.S4, “10 CFR Part 50, Appendix J”	Yes (SRP-SLR Section 3.5.2.2.1.6)	Not applicable. BWR only.
3.5.1-040	Unbraced downcomers, steel elements: vent header; downcomers	Cracking due to cyclic loading (CLB fatigue analysis does not exist)	AMP XI.S1, “ASME Section XI, Subsection IWE”	Yes (SRP-SLR Section 3.5.2.2.1.5)	Not applicable. BWR only.
3.5.1-041	Steel elements: drywell support skirt, steel elements (inaccessible areas): support skirt	None	None	No	Not applicable. BWR only.
3.5.1-042	Groups 1-3, 5, 7-9: concrete (inaccessible areas): foundation	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Plant-specific aging management program, or AMP XI.S6, “Structures Monitoring” enhanced as necessary	Yes (SRP-SLR Section 3.5.2.2.2.1.1)	Consistent with NUREG-2191. See further evaluation in Section 3.5.2.2.2.1.
3.5.1-043	All Groups except Group 6: concrete (inaccessible areas): all	Cracking due to expansion from reaction with aggregates	Plant-specific aging management program, or AMP XI.S6, “Structures Monitoring” enhanced as necessary	Yes (SRP-SLR Section 3.5.2.2.2.1.2)	Consistent with NUREG-2191. See further evaluation in Section 3.5.2.2.2.1.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-044	All Groups: concrete: all	Cracking and distortion due to increased stress levels from settlement	AMP XI.S6, "Structures Monitoring"	Yes (SRP-SLR Section 3.5.2.2.2.1.3)	Consistent with NUREG-2191, except that a different program is used for concrete elements of the Keowee Hydro Station Penstock, Power Tunnels, and Spillway. FERC Inspections of the Keowee Hydro Station is credited for aging management of these components. See further evaluation in Section 3.5.2.2.2.1.
3.5.1-046	Groups 1-3, 5, 7-9: concrete: foundation; subfoundation	Reduction of foundation strength and cracking due to differential settlement and erosion of porous concrete subfoundation	AMP XI.S6, "Structures Monitoring"	Yes (SRP-SLR 3.5.2.2.2.1.3)	Consistent with NUREG-2191. See further evaluation in Section 3.5.2.2.2.1.
3.5.1-047	Groups 1-5, 7-9: concrete (inaccessible areas): exterior above - and below-grade; foundation	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Plant-specific aging management program, or AMP XI.S6, "Structures Monitoring" enhanced as necessary	Yes (SRP-SLR 3.5.2.2.2.1.4)	Consistent with NUREG-2191. The *Structures Monitoring* program (B2.1.33) confirms the absence of aging effects related to leaching of calcium hydroxide and carbonation. See further evaluation in Section 3.5.2.2.2.1.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-048	Groups 1-5: concrete: all	Reduction of strength and modulus due to elevated temperature (>150°F general; >200°F local)	Plant-specific aging management program, or AMP XI.S6, "Structures Monitoring" enhanced as necessary	Yes (SRP-SLR 3.5.2.2.2.2)	Not applicable. See further evaluation in Section 3.5.2.2.2.2. The associated NUREG-2191 aging items are not used.
3.5.1-049	Group 6 - concrete (inaccessible areas): exterior above- and below-grade; foundation; interior slab	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Plant-specific aging management program, or AMP XI.S6, "Structures Monitoring" enhanced as necessary	Yes (SRP-SLR 3.5.2.2.2.3.1)	Consistent with NUREG-2191. See further evaluation in Section 3.5.2.2.2.3.
3.5.1-050	Groups 6: concrete (inaccessible areas): all	Cracking due to expansion from reaction with aggregates	Plant-specific aging management program, or AMP XI.S6, "Structures Monitoring" enhanced as necessary	Yes (SRP-SLR 3.5.2.2.2.3.2)	Consistent with NUREG-2191. ASR progression at the Keowee Dam spillway is monitored by the Dam Safety Surveillance and Monitoring Plan, which is implemented to meet the guidelines of FERC and is evaluated as part of the FERC Part 12D inspection. See further evaluation in Section 3.5.2.2.2.3.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-051	Groups 6: concrete (inaccessible areas): exterior above- and below-grade; foundation; interior slab	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Plant-specific aging management program, or AMP XI.S6, “Structures Monitoring” enhanced as necessary	Yes (SRP-SLR 3.5.2.2.2.3.3)	Consistent with NUREG-2191. See further evaluation in Section 3.5.2.2.2.3.
3.5.1-052	Groups 7, 8 - steel components: tank liner	Cracking due to SCC; Loss of material due to pitting and crevice corrosion	Plant-specific AMP	Yes (SRP-SLR 3.5.2.2.2.4)	Not applicable. ONS has no stainless steel tank liners in the scope of subsequent license renewal. The associated NUREG-2191 aging items are not used.
3.5.1-053	Support members; welds; bolted connections; support anchorage to building structure	Cumulative fatigue damage due to cyclic loading (Only if CLB fatigue analysis exists)	TLAA, SRP-SLR Section 4.3 “Metal Fatigue,” and/or Section 4.7 “Other Plant-Specific Time-Limited Aging Analyses”	Yes (SRP-SLR Section 3.5.2.2.2.5)	Consistent with NUREG-2191. The evaluation of fatigue for component support members, anchor bolts, and welds for Groups B1.1, B1.2, and B1.3 component supports is a TLAA as defined in 10 CFR 54.3, and is addressed in SLRA Section 4.3. See further evaluation in Section 3.5.2.2.2.5.
3.5.1-054	All groups except 6: concrete (accessible areas): all	Cracking due to expansion from reaction with aggregates	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-055	Building concrete at locations of expansion and grouted anchors; grout pads for support base plates	Reduction in concrete anchor capacity due to local concrete degradation/service-induced cracking or other concrete aging mechanisms	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191.
3.5.1-056	Concrete: exterior above- and below- grade; foundation; interior slab	Loss of material due to abrasion; cavitation	AMP XI.S7, “Inspection of Water-Control Structures Associated with Nuclear Power Plants” or the FERC/ US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-2191.
3.5.1-057	Constant and variable load spring hangers; guides; stops	Loss of mechanical function due to corrosion, distortion, dirt or debris accumulation, overload, wear	AMP XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-2191.
3.5.1-058	Earthen water-control structures: dams; embankments; reservoirs; channels; canals and ponds	Loss of material; loss of form due to erosion, settlement, sedimentation, frost action, waves, currents, surface runoff, seepage	AMP XI.S7, “Inspection of Water-Control Structures Associated with Nuclear Power Plants” or the FERC/ US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-059	Group 6: concrete (accessible areas): all	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	AMP XI.S7, "Inspection of Water-Control Structures Associated with Nuclear Power Plants" or the FERC/ US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-2191.
3.5.1-060	Group 6: concrete (accessible areas): exterior above- and below-grade; foundation	Loss of material (spalling, scaling) and cracking due to freeze-thaw	AMP XI.S7, "Inspection of Water-Control Structures Associated with Nuclear Power Plants" or the FERC/ US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-2191.
3.5.1-061	Group 6: concrete (accessible areas): exterior above- and below-grade; foundation; interior slab	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	AMP XI.S7, "Inspection of Water-Control Structures Associated with Nuclear Power Plants" or the FERC/ US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-062	Group 6: Wooden Piles; sheeting	Loss of material: change in material properties due to weathering, chemical degradation, and insect infestation repeated wetting and drying, fungal decay	AMP XI.S7, "Inspection of Water-Control Structures Associated with Nuclear Power Plants" or the FERC/ US Army Corp of Engineers dam inspections and maintenance programs.	No	Not applicable. ONS has no wooden piles; sheeting in the scope of subsequent license renewal. The associated NUREG-2191 aging items are not used.
3.5.1-063	Groups 1-3, 5, 7-9: concrete (accessible areas): exterior above- and below-grade; foundation	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	AMP XI.S6, "Structures Monitoring"	No	Consistent with NUREG-2191.
3.5.1-064	Groups 1-3, 5, 7-9: concrete (accessible areas): exterior above- and below-grade; foundation	Loss of material (spalling, scaling) and cracking due to freeze-thaw	AMP XI.S6, "Structures Monitoring"	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-065	Groups 1-3, 5, 7-9: concrete (inaccessible areas): below-grade exterior; foundation, Groups 1-3, 5, 7-9: concrete (accessible areas): below-grade exterior; foundation, Groups 6: concrete (inaccessible areas): all	Cracking; loss of bond; and loss of material (spaling, scaling) due to corrosion of embedded steel	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191, except that a different program is used for concrete (inaccessible areas) of the Keowee Hydro Station Penstock, Power Tunnels, and Spillway. FERC Inspections of the Keowee Hydro Station is credited for aging management of these components.
3.5.1-066	Groups 1-5, 7, 9: concrete (accessible areas): interior and above-grade exterior	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191.
3.5.1-067	Groups 1-5, 7, 9: Concrete: interior; above-grade exterior, Groups 1-3, 5, 7-9 - concrete (inaccessible areas): below-grade exterior; foundation, Group 6: concrete (inaccessible areas): all	Increase in porosity and permeability; cracking; loss of material (spalling, scaling) due to aggressive chemical attack	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191, except that a different program is used for concrete (inaccessible areas) of the Keowee Hydro Station Penstock, Power Tunnels, and Spillway. FERC Inspections of the Keowee Hydro Station is credited for aging management of these components.
3.5.1-068	High-strength steel structural bolting	Cracking due to SCC	AMP XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-070	Masonry walls: all	Cracking due to restraint shrinkage, creep, aggressive environment	AMP XI.S5, “Masonry Walls”	No	Consistent with NUREG-2191.
3.5.1-071	Masonry walls: all	Loss of material (spalling, scaling) and cracking due to freeze-thaw	AMP XI.S5, “Masonry Walls”	No	Not applicable. ONS has no masonry walls in an outdoor environment in the scope of Subsequent License Renewal.
3.5.1-072	Seals; gasket; moisture barriers (caulking, flashing, and other sealants)	Loss of sealing due to wear, damage, erosion, tear, surface cracks, other defects	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191.
3.5.1-073	Service Level I coatings	Loss of coating or lining integrity due to blistering, cracking, flaking, peeling, delamination, rusting, or physical damage	AMP XI.S8, “Protective Coating Monitoring and Maintenance”	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-074	Sliding support bearings; sliding support surfaces	Loss of mechanical function due to corrosion, distortion, dirt or debris accumulation, overload, wear	AMP XI.S6, “Structures Monitoring”	No	Not applicable. ONS has no sliding support surfaces in the scope of subsequent license renewal outside of the scope of the *ASME Section XI, Subsection IWF* (B2.1.30) program. The associated NUREG-2191 aging items are not used.
3.5.1-075	Sliding Surfaces	Loss of mechanical function due to corrosion, distortion, dirt or debris accumulation, overload, wear	AMP XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-2191.
3.5.1-076	Sliding surfaces: radial beam seats in BWR drywell	Loss of mechanical function due to corrosion, distortion, dirt or debris accumulation, overload, wear	AMP XI.S6, “Structures Monitoring”	No	Not applicable. BWR only.
3.5.1-077	Steel components: all structural steel	Loss of material due to corrosion	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191.
3.5.1-078	Stainless steel fuel pool liner	Cracking due to SCC; Loss of material due to pitting and crevice corrosion	AMP XI.M2, “Water Chemistry,” and monitoring of the spent fuel pool water level and leakage from the leak chase channels.	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-079	Steel components: piles	Loss of material due to corrosion	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191.
3.5.1-080	Structural bolting	Loss of material due to general, pitting, crevice corrosion	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191.
3.5.1-081	Structural bolting	Loss of material due to general, pitting, crevice corrosion	AMP XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-2191.
3.5.1-082	Structural bolting	Loss of material due to general, pitting, crevice corrosion	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191.
3.5.1-083	Structural bolting	Loss of material due to general, pitting, crevice corrosion	AMP XI.S7, "Inspection of Water-Control Structures Associated with Nuclear Power Plants” or the FERC/ US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-2191.
3.5.1-085	Structural bolting	Loss of material due to pitting, crevice corrosion	AMP XI.M2, “Water Chemistry” and AMP XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-086	Structural bolting	Loss of material due to general, pitting, crevice corrosion	AMP XI.S3, “ASME Section XI, Subsection IWF”	No	Not applicable. ONS has no in-scope stainless steel structural bolting exposed to air-outdoor that is managed by the *ASME Section XI, Subsection IWF* (B2.1.30) program in Containments, Structures, and Component Supports. The associated NUREG-2191 aging items are not used.
3.5.1-087	Structural bolting	Loss of preload due to self-loosening	AMP XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-088	Structural bolting	Loss of preload due to self-loosening	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191, except that a different program is used as follows: (1) The *Inspection of Water-Control Structures Associated with Nuclear Power Plants* (B2.1.34) program will be used to manage loss of preload due to self-loosening for submerged bolting at the Keowee Hydro Station and the Intake Structure. (2) FERC Inspections of the Keowee Hydro Station are crediting with aging management of structural bolting of the Keowee Hydro Station Penstock, Power Tunnels and Spillway.
3.5.1-089	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to boric acid corrosion	AMP XI.M10, “Boric Acid Corrosion”	No	Consistent with NUREG-2191.
3.5.1-090	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to general (steel only), pitting, crevice corrosion	AMP XI.M2, “Water Chemistry,” and AMP XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-091	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to general, pitting corrosion	AMP XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-2191.
3.5.1-092	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to general, pitting corrosion	AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191, except that a different program is used for steel support members of the Trash Rack Filter. The *Inspection of Water-Control Structures Associated with Nuclear Power Plants* (B2.1.34) program will be used to manage loss of material due to general and pitting corrosion of these components.
3.5.1-093	Galvanized steel support members; welds; bolted connections; support anchorage to building structure	Loss of material due to pitting, crevice corrosion	AMP XI.S6, “Structures Monitoring”	No	Not applicable. Galvanized steel components are evaluated using NUREG-2191 items for Steel. The associated NUREG-2191 aging items are not used.
3.5.1-094	Vibration isolation elements	Reduction or loss of isolation function due to radiation hardening, temperature, humidity, sustained vibratory loading	AMP XI.S3, “ASME Section XI, Subsection IWF,” and/or AMP XI.S6, “Structures Monitoring?	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-095	Galvanized steel support members; welds; bolted connections; support anchorage to building structure	None	None	No	Not applicable. Galvanized steel components are evaluated using NUREG-2191 items for Steel. The associated NUREG-2191 aging items are not used.
3.5.1-096	Group 6: concrete (accessible areas): all	Cracking due to expansion from reaction with aggregates	AMP XI.S7, "Inspection of Water-Control Structures Associated with Nuclear Power Plants"	No	Consistent with NUREG-2191, except that a different program is used for concrete (accessible areas) of the Keowee Hydro Station Penstock, Power Tunnels, and Spillway. FERC Inspections of the Keowee Hydro Station is credited for aging management of these components.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-097	Group 4: Concrete (reactor cavity area proximate to the reactor vessel): reactor (primary/biological) shield wall; sacrificial shield wall; reactor vessel support/ pedestal structure	Reduction of strength; loss of mechanical properties due to irradiation (i.e., radiation interactions with material and radiation-induced heating)	Plant-specific aging management program or other selected AMPs or plant-specific enhancements to selected AMPs	Yes (SRP-SLR Section 3.5.2.2.2.6)	Not applicable. The evaluation of fluence/ irradiation of the shield wall determined that fluence values through 80 years of operation remain below threshold values at which aging effects might be expected. See further evaluation in Section 3.5.2.2.2.6. The associated NUREG-2191 aging items are not used.
3.5.1-098	Stainless steel, aluminum alloy support members; welds; bolted connections; support anchorage to building structure	None	None	No	Consistent with NUREG-2191.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-099	Aluminum, stainless steel support members; welds; bolted connections; support anchorage to building structure	Loss of material due to pitting and crevice corrosion, cracking due to SCC	AMP XI.M32, "One-Time Inspection," AMP XI.S3, "ASME Section XI, Subsection IWF," or AMP XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes (SRP-SLR Section 3.5.2.2.2.4)	Consistent with NUREG-2191. The *ASME Section XI, Subsection IWF* program (B2.1.30) will manage the aging of stainless steel and aluminum component supports to ensure that these components continue to perform their intended functions during the subsequent period of extended operation. See further evaluation in Section 3.5.2.2.2.4.

Table 3.5.1 Summary of Aging Management Programs for Containments, Structures and Component Supports Evaluated in Chapters II and III of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.5.1-100	Aluminum, stainless steel support members; welds; bolted connections; support anchorage to building structure	Loss of material due to pitting and crevice corrosion, cracking due to SCC	AMP XI.M32, "One-Time Inspection," AMP XI.S6, "Structures Monitoring," or AMP XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes (SRP-SLR Section 3.5.2.2.2.4)	Consistent with NUREG-2191 except that a different program is used as follows: (1) Stainless steel components of the trash rack filter at the intake structure will be managed by the *Inspection of Water-Control Structures Associated with Nuclear Power Plants* (B2.1.34) program. (2) Stainless steel structural elements and bolting of the Keowee Hydro Station Penstock, Power Tunnels, and Spillway will be managed by the FERC Inspections of the Keowee Hydro Station. See further evaluation in Section 3.5.2.2.2.4.

Component Type	Intended Function	Material	Environment	Aging Effect	Aging Management Program	NUREG-2191 Item	NUREG-2192 Table 1	Notes

Plant Specific Notes:

1. Concrete Elements include beams, columns, walls, slabs, curbs, foundations and pads.
2. Steel elements include beams, columns, baseplates, bracing, stairs, platforms, grating, decking, ladders and embedded steel.
3. Stainless steel elements include fall restraint system.
4. None.
5. Sump includes the concrete sump and the stainless steel lined concrete cover for the low and high activity tanks.
6. The Masonry Walls are internal to the building structure and are not subject to air - outdoor aging effects.
7. The Structures Monitoring AMP is credited for monitoring the leak chase channels for liner leakage.

Component Type	Intended Function	Material	Environment	Aging Effect	Aging Management Program	NUREG-2191 Item	NUREG-2192 Table 1	Notes

Plant Specific Notes:

1. This line item is associated with inaccessible areas.
2. This line item is associated with accessible areas.
3. Subject component is the fuel transfer canal annulus seal plate.
4. Subject component is the fuel transfer canal liner plate.
5. The outside main steam line penetrations for Units 1, 2, and 3 are subject concrete temperature > 200°F for local areas. Non-destructive testing has determined no significant reduction in concrete strength due to elevated temperature. Cooling fans maintain concrete on the inside of the penetration within limits. See Further Evaluation 3.5.2.2.1.2.
6. Concrete Elements include beams, columns, walls, slabs, curbs, foundations and pads within the interior or above-grade exterior of the Reactor Building.
7. Subject component is the floor slab over the containment liner plate.
8. CLB fatigue analysis exists only for the main feedwater and main steam line penetration.
9. Subject component are the secondary shield wall tendons.
10. The concrete for the primary shield wall and reactor vessel support skirt embedment is not subject to reduction of strength and mechanical properties due to irradiation. See Further Evaluation 3.5.2.2.2.6.
11. The concrete for the primary shield wall and reactor vessel support skirt embedment is not subject to reduction of strength and modulus due to elevated temperatures. See Further Evaluation 3.5.2.2.2.2.
12. The tendon wire loss of prestress due to relaxation; shrinkage; creep; elevated temperature is addressed by the TLAA consistent with NUREG-2191. This aging effect is managed by ASME Section XI, Subsection IWL AMP and Concrete Containment Unbonded Tendon Prestress AMP, which takes some exceptions to NUREG-2191. See Further Evaluation 3.5.2.2.1.4.

Component Type	Intended Function	Material	Environment	Aging Effect	Aging Management Program	NUREG-2191 Item	NUREG-2192 Table 1	Notes

Plant Specific Notes:

1. Concrete Elements include beams, columns, walls, slabs, curbs, sumps, foundations and pads.
2. Steel elements include beams, columns, metal siding, baseplates, bracing, stairs, platforms, grating, decking and ladders.
3. The Penstock, Power Tunnel, Spillway and Intake Steel Elements include beams, columns, tunnel steel liner and taintor gates.
4. Trash Rack Filter includes the structural members and structural bolting.
5. The Penstock, Power Tunnel, Spillway and Intake Stainless Steel Elements include beams, columns, framing and miscellaneous stainless steel members.
6. The FERC Inspections of the Keowee Hydro Station (Dam) are the aging management program credited for the Penstock, Power Tunnels, Spillway and Intake portions of the Keowee Hydro Station (Dam). Keowee is licensed by the Federal Energy Regulatory Commission (FERC). Screening and aging management review of the Penstock, Power Tunnels, Spillway and Intake portions of the Keowee Hydro Station (Dam) were performed for the second period of extended operation based on current licensing basis established for Oconee in NUREG-1723, Safety Evaluation Report Related to the License Renewal of Oconee Nuclear Station, Units 1,2, and 3. The staff concluded as stated in paragraph 3.8.3.2.2 “Aging Management Program”, “Therefore, for earthen embankments, dams, and related structures identified as being subject to an AMR, the staff concludes that continued compliance with requirements of FERC into the license renewal period, by virtue of that agency's authority and responsibility for ensuring that its regulated projects are constructed, operated, and maintained to protect life, health, and property, will constitute an acceptable dam AMP for the purposes of license renewal.” ONS will continue to comply with these FERC requirements during the second period of extended operation.
7. The Underwater Inspection and Penstock Inspection performed under the Inspection of Water-Control Structures Associated With Nuclear Power Plants program are credited for the material, environment and aging effect combination.
8. The Underwater Inspection performed under the Inspection of Water-Control Structures Associated With Nuclear Power Plants program are credited for the material, environment and aging effect combination.

Component Type	Intended Function	Material	Environment	Aging Effect	Aging Management Program	NUREG-2191 Item	NUREG-2192 Table 1	Notes

Plant Specific Notes:

1. Concrete Elements include Yard Structure Foundations, Valve Pits and Transformer Epuipment Pads.
2. Sheet piles are aligned to III.A3.TP-219, since metal piles do not appear in GALL Tables for Group 6 Structures.
3. Piles include the foundation dowels, pipe piles and piles.
4. Penetration sleeves includes louvers.
5. Air with Borated Water Leakage Environment is for components in the Auxiliary Building, Reactor Building and Borated Water Storage Tank Superstructure.

Tables 3.5.2-1 through 3.5.2-23 Industry Standard Notes:

A. Consistent with NUREG-2191 item for component, material, environment, and aging effect. AMP is consistent with NUREG-2191 AMP.

B. Consistent with NUREG-2191 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-2191 AMP.

C. Component is different, but consistent with NUREG-2191 item for material, environment, and aging effect. AMP is consistent with NUREG-2191 AMP.

D. Component is different, but consistent with NUREG-2191 item for material, environment, and aging effect. AMP takes some exceptions to the NUREG-2191 AMP.

E. Consistent with NUREG-2191 item for material, environment, and aging effect, but a different AMP is credited or NUREG-2191 identifies a plant-specific AMP.

F. Material not in NUREG-2191 for this component.

G. Environment not in NUREG-2191 for this component and material.

H. Aging effect not in NUREG-2191 for this component, material, and environment combination.

I. Aging effect in NUREG-2191 for this component, material, and environment combination is not applicable.

J. Neither the component nor the material and environment combination are evaluated in NUREG-2191.

3.6 AGING MANAGEMENT OF ELECTRICAL AND INSTRUMENTATION AND CONTROLS

3.6.1 INTRODUCTION

This section provides the results of the AMR for components and commodities identified in Section 2.5.1, Electrical and Instrumentation and Control Component Commodity Groups as being subject to AMR. Components and commodities addressed in this section are described in the indicated sections.

- Cable and Connections (Section 2.5.1.1)
- Fuse Holders (Not Part of Active Equipment) (Section 2.5.1.2)
- Metal Enclosed Bus (Section 2.5.1.3)
- Switchyard Bus and Connections (Section 2.5.1.4)
- Transmission Conductors and Connections (Section 2.5.1.5)
- High Voltage Insulators (Section 2.5.1.6)

3.6.2 RESULTS

- Table 3.6.2-1, Electrical and Instrumentation and Controls - Electrical and Instrumentation and Controls Commodities - Aging Management Evaluation

3.6.2.1 Materials, Environments, Aging Effects Requiring Management and Aging Management Programs

3.6.2.1.1 Cables Connections (Metallic Parts)

Materials

Components in the cables connections (metallic parts) are constructed of the following materials:

- Various Metals Used for Electrical Contacts

Environments

Components in the cables connections (metallic parts) are exposed to the following environments:

- Air - Indoor, Controlled
- Air - Indoor Uncontrolled
- Air - Outdoor

Aging Effects Requiring Management

Components in cables connections (metallic parts) require aging management to address the following aging effects:

- Increased Electrical Resistance of Connection

Aging Management Programs

The aging effects for components in cables connections (metallic parts) are managed by the following AMPs:

- Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements (B2.1.43)

3.6.2.1.2 Connector Contacts for Electrical Connections Exposed to Borated Water

Materials

Components in the connector contacts for electrical connections exposed to borated water are constructed of the following materials:

- Various Metals Used for Electrical Contacts

Environments

Components in the connector contacts for electrical connections exposed to borated water are exposed to the following environments:

- Air with Borated Water Leakage

Aging Effects Requiring Management

Components in connector contacts for electrical connections exposed to borated water require aging management to address the following aging effects:

- Increased Electrical Resistance of Connection Due to Corrosion of Connector Contact Surfaces Caused by Intrusion of Borated Water

Aging Management Programs

The aging effects for components in connector contacts for electrical connections exposed to borated water are managed by the following AMPs:

- Boric Acid Corrosion (B2.1.4)

3.6.2.1.3 Insulation for Electrical Cables and Connections

Materials

The insulation for electrical cables and connections are constructed of the following materials:

- Various Organic Polymers

Environments

The insulation for electrical cables and connections are exposed to the following environments:

- Adverse Localized Environment
- Adverse Localized Environment Caused by Significant Moisture

Aging Effects Requiring Management

The insulation for electrical cables and connections require aging management to address the following aging effects:

- Degraded Dielectric Strength
- Reduced Electrical Insulation Resistance

Aging Management Programs

The aging effects for insulation for electrical cables and connections are managed by the following AMPs:

- Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements (B2.1.36)
- Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements Used in Instrumentation Circuits (B2.1.37)
- Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements (B2.1.39)
- Electrical Insulation for Inaccessible Low Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements (B2.1.40)

- Electrical Insulation for Inaccessible Medium Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements (B2.1.38)

3.6.2.1.4 Fuse Holders (Not Part of Active Equipment): Insulation Material

Materials

Components in the fuse holders (not part of active equipment) insulation material are constructed of the following materials:

- Bakelite
- Ceramic
- Molded Polycarbonate
- Other Organic Polymers
- Phenolic Melamine

Environments

Components in the fuse holders (not part of active equipment) insulation material are exposed to the following environments:

- Air - Indoor Controlled
- Air - Indoor Uncontrolled

Aging Effects Requiring Management

Components in fuse holders (not part of active equipment) insulation material require aging management to address the following aging effects:

- Reduced Electrical Insulation Resistance

Aging Management Programs

The aging effects for components in fuse holders (not part of active equipment) insulation material are managed by the following AMPs:

- Fuse Holders (B2.1.42)

3.6.2.1.5 Fuse Holders (Not Part of Active Equipment): Metallic Clamps

Materials

Components in the fuse holders (not part of active equipment) metallic clamps are constructed of the following materials:

- Various Metals Used for Electrical Connections

Environments

Components in the fuse holders (not part of active equipment) metallic clamps are exposed to the following environments:

- Air - Indoor Controlled
- Air - Indoor Uncontrolled

Aging Effects Requiring Management

Components in fuse holders (not part of active equipment) metallic clamps require aging management to address the following aging effects:

- Increased Electrical Resistance of Connection

Aging Management Programs

The aging effects for components in fuse holders (not part of active equipment) are managed by the following AMPs:

- Fuse Holders (B2.1.42)

3.6.2.1.6 Metal Enclosed Bus

Materials

Components in the metal enclosed bus are constructed of the following materials:

- Galvanized Steel, Aluminum
- Porcelain
- Various Metals Used for Electrical Bus and Connections
- Various Organic Polymers

Environments

Components in the metal enclosed bus are exposed to the following environments:

- Air - Indoor Controlled
- Air - Indoor Uncontrolled
- Air - Outdoor

Aging Effects Requiring Management

Components in metal enclosed bus require aging management to address the following aging effects:

- Elastomer Hardening or Loss of Strength
- Increased Electrical Resistance of Connection
- Loss of Material
- Reduced Electrical Insulation Resistance

Aging Management Programs

The aging effects for components in metal enclosed bus are managed by the following AMPs:

- Metal Enclosed Bus (B2.1.41)
- Structures Monitoring (B2.1.33)

3.6.2.1.7 Switchyard Bus and Connections

Materials

Components in the switchyard bus and connections are constructed of the following materials:

- Aluminum
- Bronze
- Copper
- Galvanized Steel
- Stainless Steel

Environments

Components in the switchyard bus and connections are exposed to the following environments:

- Air - Outdoor

Aging Effects Requiring Management

Components in switchyard bus and connections have no aging effects requiring aging management.

Aging Management Programs

Because there are no aging effects requiring aging management, no AMPs are required for switchyard bus and connections.

3.6.2.1.8 Transmission Conductors and Connections

Materials

Components in the transmission conductors and connections are constructed of the following materials:

- Aluminum
- Aluminum, Steel

Environments

Components in the transmission conductors and connections are exposed to the following environments:

- Air - Outdoor

Aging Effects Requiring Management

Components in transmission conductors and connections have no aging effects requiring aging management.

Aging Management Programs

Because there are no aging effects requiring aging management, no AMPs are required for transmission conductors and connections.

3.6.2.1.9 High Voltage Insulators

Materials

Components in the high voltage insulators are constructed of the following materials:

- Aluminum
- Cement
- Galvanized Steel
- Malleable Iron
- Porcelain

Environments

Components in the high voltage insulators are exposed to the following environments:

- Air - Outdoor

Aging Effects Requiring Management

Components in high voltage insulators have no aging effects requiring aging management.

Aging Management Programs

Because there are no aging effects requiring aging management, no AMPs are required for high voltage insulators.

3.6.2.2 Further Evaluation of Aging Management as Recommended by NUREG-2192

NUREG-2192 provides the bases for identifying those programs that warrant further evaluation by the reviewer in the SLRA. For electrical and I&C, those evaluations are addressed in the following sections.

3.6.2.2.1 Electrical Equipment Subject to Environmental Qualification

NUREG-2192

Environmental qualification is a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c)(1). The evaluation of this TLAA is addressed separately in Section 4.4, "Environmental Qualification (EQ) of Electrical Equipment," of this SRP-SLR.

Evaluation

[3.6.1-001] - Environmental qualification is a TLAA as defined in 10 CFR 54.3. The evaluation of this TLAA is addressed in Section 4.4, "Environmental Qualification of Electric Equipment".

3.6.2.2.2 Reduced Insulation Resistance Due to Age Degradation of Cable Bus Arrangements Caused by Intrusion of Moisture, Dust, Industrial Pollution, Rain, Ice, Photolysis, Ohmic Heating and Loss of Strength of Support Structures and Louvers of Cable Bus Arrangements Due to General Corrosion and Exposure to Air Outdoor

NUREG-2192

Reduced insulation resistance due to age degradation of cable bus caused by intrusion of moisture, dust, industrial pollution, rain, ice, photolysis (for ultraviolet sensitive material only), ohmic heating and loss of strength of support structures, covers or louvers of cable bus arrangements due to general corrosion or exposure to air outdoor could occur in cable bus assemblies. Cable bus is a variation of metal enclosed bus (MEB) which is similar in construction to an MEB, but instead of segregated or nonsegregated electrical buses, cable bus is comprised of a fully enclosed metal enclosure that utilizes three-phase insulated power cables installed on insulated support blocks. Cable bus may omit the top cover or use a louvered top cover and enclosure. Both the cable bus and enclosures are not sealed against intrusion of dust, industrial pollution, moisture, rain, and ice and therefore may introduce debris into the internal cable bus assembly.

Consequently, cable bus construction and arrangements are such that it may not readily fall under a specific GALL-SLR Report AMP (e.g., GALL-SLR Report AMP XI.E1 and AMP XI.E4). GALL-SLR Report AMP XI.E1 calls for a visual inspection of accessible insulated cables and connections subject to an adverse localized environment which may not be applicable to cable bus due to inaccessibility or applicability of the aging mechanisms and effects. GALL-SLR Report

AMP XI.E4 includes tests and inspections of the internal and external portions of the MEB. The MEB internal and external inspections and tests may not be applicable to cable bus aging mechanisms and effects. Therefore, the GALL-SLR Report recommends cable bus aging mechanisms and effects be evaluated as a plant-specific further evaluation. The evaluation includes associated AMPs: AMP XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components," and AMP XI.S6, "Structures Monitoring." Acceptance criteria are described in Branch Technical Position (BTP) RLSB-1 (Appendix A.1 of this SRP-SLR).

Evaluation

[3.6.1-029], [3.6.1-030], [3.6.1-031] - UFSAR Section 8.3.1.4 identifies cable bus as being installed by the protected service water project, the 13.8 kV protected service water Keowee power feeder switchgear line side cable bus. Power cable bus is a manufacturer-designed engineered system that consists of single-conductor cables installed in a metallic enclosure with conductor spacing devices that are integral to the cable bus. These conductor spacing devices physically separate and electrically isolate each cable using insulated support blocks. The Keowee power feeder switchgear line side cable bus is not true power cable bus, but rather an enclosed cable tray design with three phase conductors braced together by cleats in a triangular configuration. The safety-function of the cleats is to eliminate the hazard of cable whip during a fault downstream of the transition junction boxes. These cable cleats are constructed of stainless steel, with a Low-Smoke/Low-Fume cushioning pad that is used to protect the cables prior to closing the cable cleat locking tang. This Low-Smoke/Low-Fume pad has no electrical function and failure of the Low-Smoke/Low-Fume pad after installation will not prevent the cable cleat from bracing the cable. The cleat to tray hardware and cleat locking tang are secured with stainless-steel hardware using good bolting practices that includes locking nuts. There is therefore no aging management required for the cable cleat.

Aging management of the cables is implemented under the *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements Aging Management* program (B2.1.36), whereas aging management of the cable tray and associated hardware is accomplished using the *Structures Monitoring* program (B2.1.33). These aging management programs provide reasonable assurance that aging effects of the 13.8 kV protected service water Keowee power feeder switchgear line side cable bus are adequately managed, such that no plant specific program is required.

3.6.2.2.3 Loss of Material Due to Wind-Induced Abrasion, Loss of Conductor Strength Due to Corrosion, and Increased Resistance of Connection Due to Oxidation or Loss of Preload for Transmission Conductors, Switchyard Bus, and Connections

NUREG-2192

Loss of material due to wind-induced abrasion, loss of conductor strength due to corrosion, and increased resistance of connection due to oxidation or loss of preload could occur in transmission conductors and connections, and in switchyard bus and connections. The GALL-SLR Report recommends further evaluation of a plant-specific AMP to demonstrate that this *aging effect is adequately managed. Acceptance criteria are described in BTP RLSB-1 (Appendix A.1 of this SRP-SLR).*

Evaluation

The transmission conductors, transmission connectors, and switchyard bus and connections evaluated for ONS are those that are part of the circuits which supply power from the electric utility transmission system to plant buses, including connecting the alternate ac source in the event of a station blackout. These circuits provide power to in-scope license renewal components used for coping during and recovery from a station blackout event and during post fire safe shutdown, when offsite power is credited.

The in-scope commodities in the circuits for offsite power sources and the station blackout alternate ac source include 230 kV and 100 kV transmission conductors and connections; which include aluminum conductor, steel reinforced transmission conductors and drop lines connected to the station startup transformers.

Wind-Induced Abrasion and Fatigue – Transmission Conductors

[3.6.1-007] – Aluminum Conductor Steel Reinforced and Aluminum Transmission Conductors: Transmission conductor vibration or sway could be caused by wind loading. Industry experience has shown that the transmission conductors do not normally swing significantly, and when they do swing due to a substantial wind, they do not continue to swing for very long once the wind has subsided. For most ONS transmission conductors, wind loading that can cause a transmission line to vibrate or sway is adequately addressed in design and installation, such that abrasion/ fatigue that could result from wind-induced transmission conductor vibration or sway is not applicable and would not cause a loss of intended function for transmission conductors for the SPEO.

ONS operating experience includes the failure of aluminum conductor steel reinforced transformer conductors/terminations to startup transformer CT3. The ONS startup transformer lines consist of 4/0 aluminum conductor steel reinforced cable with a 0.556 inch diameter, which is substantially smaller than the cable size typical of today's standards for 230 kV operation. While this smaller cable is capable of carrying the required ampacity of the startup transformer, the causal evaluation for this failure determined wind-induced (aeolian) vibrations of these smaller conductors can produce damage that will negatively impact the reliability of these lines. The causal evaluation further determined that vulnerability to this aging mechanism at ONS is limited to the overhead transmission conductors and drop lines to startup transformers CT1, CT2, and CT3. The corrective action arising from this failure resulted in a preventive maintenance activity to replace the aluminum conductor steel reinforced transmission conductors and drop lines to all three startup transformers on a 10 year frequency. Given that these conductors are now replaced on a specified frequency, they are considered short-lived, such that no further aging management is required.

Corrosion – Transmission Conductors

[3.6.1-004] - All transmission conductors under the scope of 10 CFR 54.4 at ONS are aluminum conductor steel reinforced, or all aluminum conductor. The aluminum conductor steel reinforced conductor size ranges from 4/0 to 2156 MCM, and the all aluminum conductor size is 2000 MCM. The most prevalent mechanism contributing to loss of conductor strength of an aluminum conductor steel reinforced transmission conductor is corrosion, which includes corrosion of the steel core and aluminum strand pitting. For aluminum conductor steel reinforced conductors, degradation begins as a loss of zinc from the galvanized steel core wires. Corrosion rates depend largely on air quality, which includes suspended particles chemistry, SO_2 concentration in air, precipitation, fog chemistry and meteorological conditions. Tests performed by Ontario Hydroelectric showed a 30% loss of composite conductor strength of an 80 year old aluminum conductor steel reinforced conductor due to corrosion.

There is set percentage of composite conductor strength established at which a transmission conductor is replaced. As illustrated below, there is ample strength margin to maintain the transmission conductor intended function through the SPEO.

The National Electrical Safety Code requires that tension on installed conductors be a maximum of 60% of the ultimate conductor strength. The National Electrical Safety Code also sets the maximum tension a conductor must be designed to withstand under heavy load requirements, which includes consideration of ice, wind and temperature. These requirements are reviewed concerning the specific conductors included in the AMR. The conductors with the smallest ultimate strength margin are 4/0 aluminum conductor steel reinforced and will be used as an illustration.

The ultimate strength and the National Electrical Safety Code heavy load tension requirements of 4/0 aluminum conductor steel reinforced are 8350 lbs. and 2761 lbs. respectively. The margin between the National Electrical Safety Code heavy load and the ultimate strength is 5589 lb.; i.e., there is a 67% of ultimate strength margin. The Ontario Hydroelectric study showed a 30% loss of composite conductor strength in an 80 year old conductor. In the case of the 4/0 aluminum conductor steel reinforced transmission conductors, a 30% loss of ultimate strength would mean that there would still be a 37% ultimate strength margin between what is required by the National Electrical Safety Code and the actual conductor strength.

The 4/0 aluminum conductor steel reinforced conductors have the lowest initial design margin of transmission conductors included in the AMR. Corrosion of aluminum conductor steel reinforced conductors is a very slow acting aging effect that is even slower for rural areas, such as ONS, with generally less suspended particles and SO_2 concentrations in the air than urban areas. Therefore the environmental impact to the ONS transmission conductors (which are located in a rural area) are bounded by the Ontario Hydroelectric conductors (which were located in polluted and urban environments). This illustrates with reasonable assurance the aluminum conductor steel reinforced transmission conductors will have ample strength through the SPEO.

All aluminum conductors are not subject to the aging effect of loss of conductor strength due to corrosion. Therefore, the all aluminum conductors transmission conductors that are within the scope of 10 CFR 54.4 do not require aging management for loss of conductor strength due to corrosion.

In conclusion, the in-scope ONS aluminum conductor steel reinforced transmission conductors that must be reviewed for susceptibility to loss of conductor strength due to corrosion are bounded by the Ontario Hydroelectric study by test methodology, design and construction, and environment. In-scope all aluminum conductors do not experience loss of conductor strength due to corrosion per NUREG-2191. The above evaluations demonstrate with reasonable assurance that transmission conductors will have ample strength margin through the SPEO. Therefore, based on ONS design and confirmed by their OE, the loss of transmission conductor strength does not require aging management activities for the SPEO.

Oxidation or Loss of Preload – Transmission Connectors

[3.6.1-005] - Transmission Connectors: Transmission connectors employ good bolting practices. The connections are treated with corrosion inhibitors to avoid connection oxidation and torqued at the time of installation to avoid loss of preload. The transmission connectors are designed and installed using stainless steel lock washers that provide vibration absorption and prevent loss of preload. Therefore, based on ONS design and confirmed by operating experience, oxidation and loss of preload are not applicable aging mechanisms for ONS transmission connectors.

Wind-Induced Abrasion and Fatigue – Switchyard Bus

[3.6.1-006] – Switchyard Bus and Connections: Switchyard buses are connected to flexible conductors that do not normally vibrate and are supported by insulators and ultimately by static, structural components, such as concrete footings and structural steel. Switchyard bus is rigidly mounted and is therefore not subject to abrasion induced by wind loading. Therefore, based on ONS design and confirmed by operating experience, wind-induced abrasion and fatigue are not applicable aging mechanisms for ONS switchyard bus.

Oxidation or Loss of Pre-Load – Switchyard Bus Connections

[3.6.1-006] – Switchyard bus is used to provide an electrically common connection point for disconnect switches and flexible conductors. Since the connections to disconnect switches are maintained as part of the switch, switchyard bus connections to disconnect switches are considered part of the disconnect switch. Bolted flexible connections to the switchyard bus are part of the transmission connectors [3.6.1-005]. All rigid switchyard bus connections are welded connections. Therefore, based on ONS design and confirmed by operating experience, oxidation and loss of preload are not applicable aging mechanisms for ONS switchyard bus connections.

Conclusion

Aging management activities for ONS transmission conductors and transmission connections, switchyard bus and connections are not required for the SPEO. Overhead aluminum conductor steel reinforced transmission conductors and drop lines to startup transformers CT1, CT2, and CT3 are periodically replaced, and therefore short lived.

3.6.2.2.4 Quality Assurance for Aging Management of Non-Safety Related Components

NUREG-2192

Acceptance criteria are described in BTP IQMB-1 (Appendix A.2 of this SRP-SLR).

Evaluation

Quality Assurance provisions applicable to SLR are discussed in Appendix B1.3, Quality Assurance Program and Administrative Controls.

3.6.2.2.5 Ongoing Review of Operating Experience

NUREG-2192

Acceptance criteria are described in Appendix A.4, "Operating Experience for Aging Management Programs."

Evaluation

The OE process and acceptance criteria are described in Appendix B1.4, Operating Experience.

3.6.2.3 Aging Management Review Results Not Consistent With or Not Addressed in the Generic Aging Lessons Learned for Subsequent License Renewal Report

3.6.2.3.1 High Voltage Electrical Insulators

The high voltage electrical insulators included in the scope of SLR are associated with the QA-1 onsite and non-QA offsite power source circuits and the alternate AC power sources required to cope with SBO or SBO recovery path.

The overhead QA-1 onsite power path provides emergency power from Keowee hydro to the 230 kV switchyard yellow bus.

Per NUREG-2192 Section 2.5.2.1.1, *Components Within the Scope of SBO (10 CFR 50.63)*, the SBO recovery path is defined as:

> *The plant system portion of the offsite power system that is used to connect the plant to the offsite power source meeting the requirements under 10 CFR 54.4(a)(3). The electrical distribution equipment out to the first circuit breaker with the offsite distribution system (i.e., equipment in the switchyard). This path typically includes the circuit breakers*

that connect to the offsite system power transformers (startup transformers), the transformers themselves, the intervening overhead or underground circuits between circuit breaker and transformer and transformer and onsite electrical distribution system, and the associated control circuits and structures. However, the NRC staff's review is based on the plant-specific CLB, regulatory requirements, and offsite power design configurations.

The ONS primary transmission system consists of 230 kV and 525 kV loop networks with corresponding onsite 230 kV (Unit 1 and 2) and 525 kV (Unit 3) switchyards.

When there is inadequate power from the generating units, the 230 kV switchyard and the Keowee hydro units, power is available to the plant standby power buses either directly from the 100 kV Central Tie substation or from Lee Steam Station via a 100 kV transmission line connected to 100/4 kV transformer CT5 located at ONS. If an emergency occurs that would require the use of the 100 kV transmission system, this line can either be isolated from the balance of the transmission system to supply emergency power directly to ONS from Lee Steam Station, or emergency power can be supplied directly from the 100 kV system from the Central Tie Substation to ONS.

Each ONS unit has a startup circuit that connects the 230 kV switchyard yellow bus to 4 kV main feeder buses 1 and 2 through unit startup transformers CT1, CT2 and CT3. The 230 kV startup circuits each include a breaker-and-a-half design consisting of three power circuit breakers. The startup transformers have 4 kV and 7 kV secondary windings. The 4 kV windings are connected to main feeder buses via switchgear breakers. The 7 kV windings power reactor coolant pumps and thus are not associated with the SBO recovery path.

In addition, the main feeder buses for each unit can also be energized from a 100 kV offsite circuit to onsite transformer CT5 which provides 4 kV power via insulated cable to the standby buses which can be aligned to power the main feeder buses. CT5 is fed from 100 kV oil circuit breaker OCB-101.

The in-scope high voltage insulators associated with the QA-1 onsite overhead power path are:

- 230 kV post and strain insulators from Keowee hydro via the overhead power path to PCB-9
- 230 kV post and strain insulators associated with PCBs-8, 12, 15, 17, 21, 24, 26, 28, and 33. These PCBs are required to trip and/or close to isolate the switchyard and align the overhead path from Keowee hydro to the 230 kV switchyard yellow bus.
- 230 kV post and strain insulators associated with the 230 kV switchyard yellow bus.

The in-scope high voltage insulators associated with the offsite SBO recovery paths are:

- 230 kV post and strain insulators from PCB-17 and PCB-18 to start-up transformer CT1
- 230 kV post and strain insulators from PCB-26 and PCB-27 to start-up transformer CT2

- 230 kV post and strain insulators from PCB-28 and PCB-30 to start-up transformer CT3
- 100 kV and 4.16 kV post and strain insulators from OCB-101 to transformer CT5

The in-scope high voltage insulators provide electrical insulation for switchyard bus, transmission conductors, switchyard active components, and associated connections that are part of the circuits that supply power from the offsite power distribution system electric utility transmission system to plant buses, including connecting the alternate AC source in the event of an SBO. These circuits provide power to in-scope SLR components used for coping during and recovery from an SBO event and during post fire safe shutdown when offsite power is credited.

Airborne Contamination

Various airborne materials such as salt, dust, fog, cooling tower plume, foreign debris, or industrial effluents can contaminate insulator surfaces. An excessive buildup of surface contamination enables the conductor voltage to track along the insulator surface more easily and can lead to insulator flashover. The buildup of surface contamination is gradual and typically such contamination is washed away by normal rain action aided by the glazed insulator surface.

Excessive surface contamination can be a problem in areas where there are greater concentrations of airborne particles such as near the seacoast where salt spray is prevalent, dust, near industrial facilities that discharge airborne pollutants, or at sites where the cooling tower plume may deposit contaminants on switchyard components and transmission lines.

At ONS, the in-scope 230 kV and 4.16 kV post and strain insulators were evaluated for susceptibility to airborne surface contamination from salt, dust, fog, cooling tower plume, foreign debris, and industrial effluents. ONS is not situated in an environment conducive to accelerated aging.

ONS is located in the upstate of South Carolina in a predominantly rural wooded area where salt and dust contamination, and wind-driven particles are not high voltage insulator aging factors. Fog alone is not considered a high voltage insulator contaminant since it eventually evaporates as temperatures rise above the dewpoint for fog formation. ONS has no cooling towers and uses freshwater Lake Keowee for cooling and ultimate heat sink and thus cooling tower plumes are not present. There are no nearby heavy industries, mining, factories, agriculture or other facilities emitting significant foreign debris or industrial effluent that could promote high voltage insulator aging effects. There are no past or existing preventive measures that perform routine insulator cleaning.

A ten-year review of operating experience for in-scope high voltage insulators was performed. Accumulation of high voltage insulator contamination or insulator flashover has not been experienced at ONS. Existing maintenance procedures include inspections for insulator contamination, corrosion and other forms of degradation or damage.

A review was performed with respect to applicability to ONS of the draft Interim Staff Guidance SLR-ISG-Electrical -2021-04 Electrical Appendix D (Proposed Revisions to AMP XI.E7, “High-

Voltage Insulators”). As part of the review, walkdowns and discussions were conducted with personnel responsible for the switchyards to determine if there were any in-scope polymer or toughened-glass type insulators, past history of excessive insulator contamination or flashover, or other high voltage insulator age-related issues. These walkdowns confirmed that there are no in-scope polymer or toughened-glass type insulators, past history of excessive insulator contamination, flashover, or other high voltage insulator aging issues. Additionally, high voltage insulator cleaning due to contamination has never been determined to be necessary at ONS.

Based on the location of ONS, lack of substantial airborne contaminants, corroborating operating experience, excessive high voltage insulator surface contamination is not expected to occur. Therefore, aging effects of surface contamination from salt, dust, fog, cooling tower plume, foreign debris, and industrial effluents are not applicable to ONS for the SPEO. No aging management activity is required for the in-scope high voltage insulators due to airborne contamination.

In addition, an evaluation was performed for high voltage insulator porcelain cracking. Porcelain cracking or breaking is commonly caused by an object striking the high voltage insulator or cement growth. Porcelain cracking due to external forces is not in the scope of high voltage insulator aging management. Cement growth occurs due to improper manufacturing that results in excessive expansion of the cement binding the insulator components. This expansion makes the cement more susceptible to moisture intrusion. ONS OE indicates that cement growth induced porcelain cracking has not occurred. Therefore, high voltage insulator porcelain cracking caused by physical damage is not an aging effect, is not subject to an AMR, and does not require aging management.

Loss of Material – Mechanical Wear or Corrosion

High voltage insulator loss of material can occur due to the oscillating movement of transmission conductors due to significant and sustained winds. These wind conditions can result in mechanical wear of metallic parts. Surface corrosion of high voltage insulator metallic parts can also occur due to environmental contamination or if galvanized or other protective coatings are worn from significant wind induced movement of transmission conductors.

Mechanical wear is an aging effect for strain insulators when they are subject to excessive movement. Movement can be caused by wind blowing the supported transmission conductor causing swinging. If this swinging is frequent and severe enough, wear could be caused on the metal contact points of the insulator string.

Although transmission conductor swing is possible, ONS experience has shown that swinging is atypical. When persistent and substantial wind conditions induce conductor swing, after the winds subside the swing ceases. Mechanical wear of high voltage insulator strain insulator metallic components has not been identified during routine inspections at ONS or plant specific OE review.

Loss of material due to high voltage insulator corrosion can also occur due to airborne contamination. A large buildup of contamination could result in corrosion of the high voltage insulator metallic parts, which if significant, could eventually impact the structural intended function. However, as previously stated, based on the ONS location, lack of airborne contaminants including salt or industrial effluent and corroborating operating experience, high voltage insulator metallic parts are not subject to a significant buildup of contamination from airborne contaminants.

High voltage insulator mechanical wear due to wind induced transmission conductor movement and corrosion is not a significant aging effect at ONS and does not require aging management for the SPEO.

Conclusion:

Airborne contamination (including wind-driven particles) and loss of material due to mechanical wear and corrosion are not significant aging affects at ONS. Aging management activities for high voltage insulators are not required. Therefore, the GALL-SLR report XI.E7 High Voltage Insulators AMP is not required.

The electrical commodities that are subject to AMR have been identified in accordance with the requirements of 10 CFR 54.4. The AMPs selected to manage aging effects for the electrical commodities are identified in the summaries in Section 3.6.2.1 above. A description of the AMPs is provided in Appendix B, along with the demonstration that the identified aging effects will be managed for the SPEO. Based on the conclusions provided in Appendix B, the effects of aging associated with the electrical commodities will be adequately managed so that there is reasonable assurance that the intended functions are maintained consistent with the CLB during the SPEO.

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.6.1-010	Electrical conductor insulation for inaccessible power, instrumentation, and control cables (e.g., installed in duct bank, buried conduit or direct buried) composed of various organic polymers such as EPR, SR, EPDM, XLPE, butyl rubber, and combined thermoplastic jacket/ insulation shield exposed to an adverse localized environment caused by significant moisture	Reduced electrical insulation resistance or degraded dielectric strength due to significant moisture	AMP XI.E3A, “Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject To 10 CFR 50.49 Environmental Qualification Requirements,” AMP XI.E3B, “Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject To 10 CFR 50.49 Environmental Qualification Requirements,” or AMP XI.E3C, “Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject To 10 CFR 50.49 Environmental Qualification Requirements”	No	Consistent with NUREG-2191. The *Electrical Insulation for Inaccessible Medium Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* (B2.1.38) program, *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* (B2.1.39) program, and *Electrical Insulation for Inaccessible Low Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* (B2.1.40) program will be used to manage reduced electrical insulation resistance or degraded dielectric strength of the various organic polymers in electrical conductor insulation for inaccessible medium voltage (>2 kV to 35 kV) power, instrumentation and control and low voltage

Table 3.6.1 Summary of Aging Management Programs for the Electrical Components Evaluated in Chapters VI of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
					(typically < 1 kV but no greater than 2 kV) cables exposed to adverse localized environments caused by significant moisture.
3.6.1-011	Metal enclosed bus: enclosure assemblies composed of elastomers exposed to air – indoor controlled or uncontrolled, air – outdoor	Surface cracking, crazing, scuffing, dimensional change (e.g. “ballooning” and “necking”), shrinkage, discoloration, hardening or loss of strength due to elastomer degradation	AMP XI.E4, “Metal Enclosed Bus,” or AMP XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Consistent with NUREG-2191. The *Metal Enclosed Bus* (B2.1.41) program will manage surface cracking, crazing, scuffing, dimensional change (e.g. “ballooning” and “necking”), shrinkage, discoloration, hardening or loss of strength of metal enclosed bus enclosure assemblies composed of elastomers exposed to an air-indoor controlled, air-indoor uncontrolled, or air-outdoor environment.
3.6.1-012	Metal enclosed bus: bus/ connections composed of various metals used for electrical bus and connections exposed to air – indoor controlled or uncontrolled, air –outdoor	Increased electrical resistance of connection due to the loosening of bolts caused by thermal cycling and ohmic heating	AMP XI.E4, “Metal Enclosed Bus”	No	Consistent with NUREG-2191.

Table 3.6.1 Summary of Aging Management Programs for the Electrical Components Evaluated in Chapters VI of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.6.1-013	Metal enclosed bus: electrical insulation; insulators composed of porcelain; xenoy; thermo-plastic organic polymers exposed to air – indoor controlled or uncontrolled, air – outdoor	Reduced electrical insulation resistance due to thermal/ thermoxidative degradation of organics/ thermoplastics, radiation-induced oxidation, moisture/debris intrusion, and ohmic heating	AMP XI.E4, “Metal Enclosed Bus”	No	Consistent with NUREG-2191.
3.6.1-014	Metal enclosed bus: external surface of enclosure assemblies composed of steel exposed to air – indoor uncontrolled, air – outdoor	Loss of material due to general, pitting, crevice corrosion	AMP XI.E4, “Metal Enclosed Bus,” or AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191. The *Metal Enclosed Bus* (B2.1.41) program will manage loss of material due to general, pitting, or crevice corrosion of metal enclosed bus enclosure assemblies composed of steel exposed to an air-indoor uncontrolled environment.

Table 3.6.1 Summary of Aging Management Programs for the Electrical Components Evaluated in Chapters VI of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.6.1-015	Metal enclosed bus: external surface of enclosure assemblies composed of galvanized steel; aluminum exposed to air - outdoor	Loss of material due to pitting, crevice corrosion	AMP XI.E4, “Metal Enclosed Bus,” or AMP XI.S6, “Structures Monitoring”	No	Consistent with NUREG-2191. The *Metal Enclosed Bus* (B2.1.41) program will manage loss of material due to general, pitting, or crevice corrosion of metal enclosed bus enclosure assemblies composed of aluminum exposed to an air-outdoor environment.
3.6.1-016	Fuse holders (not part of active equipment): metallic clamps composed of various metals used for electrical connections exposed to air – indoor uncontrolled	Increased electrical resistance of connection due to chemical contamination, corrosion, and oxidation (in an air, indoor controlled environment, increased resistance of connection due to chemical contamination, corrosion and oxidation do not apply)	AMP XI.E5, “Fuse Holders” - No AMP is required for those applicants who can demonstrate these fuse holders are located in an environment that does not subject them to environmental aging mechanisms and effects due to chemical contamination, corrosion, and oxidation.	No	Consistent with NUREG-2191.

Table 3.6.1 Summary of Aging Management Programs for the Electrical Components Evaluated in Chapters VI of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.6.1-017	Fuse holders (not part of active equipment): metallic clamps composed of various metals used for electrical connections exposed to air-indoor controlled or uncontrolled	Increased electrical resistance of connection due to fatigue from ohmic heating, thermal cycling, electrical transients.	AMP XI.E5, “Fuse Holders” - No AMP is required for those applicants who can demonstrate these fuse holders are not subject to fatigue due to ohmic heating, thermal cycling, electrical transients.	No	Consistent with NUREG-2191.
3.6.1-018	Fuse holders (not part of active equipment): metallic clamps composed of various metals used for electrical connections exposed to air-indoor controlled or uncontrolled	Increased electrical resistance of connection due to fatigue caused by frequent fuse removal/ manipulation or vibration	AMP XI.E5, “Fuse Holders” - No AMP is required for those applicants who can demonstrate these fuse holders are not subject to fatigue caused by frequent fuse removal/manipulation or vibration.	No	Consistent with NUREG-2191.
3.6.1-019	Cable connections (metallic parts) composed of various metals used for electrical contacts exposed to air – indoor controlled or uncontrolled, air – outdoor	Increased electrical resistance of connection due to thermal cycling, ohmic heating, electrical transients, vibration, chemical contamination, corrosion, and oxidation	AMP XI.E6, “Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements”	No	Consistent with NUREG-2191.

Table 3.6.1 Summary of Aging Management Programs for the Electrical Components Evaluated in Chapters VI of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.6.1-020	Electrical connector contacts for electrical connectors composed of various metals used for electrical contacts exposed to air with borated water leakage	Increased electrical resistance of connection due to corrosion of connector contact surfaces caused by intrusion of borated water	AMP XI.M10, “Boric Acid Corrosion”	No	Consistent with NUREG-2191.
3.6.1-021	Transmission conductors composed of aluminum exposed to air – outdoor	Loss of conductor strength due to corrosion	None - for ACAR and All Aluminum Conductor (AAC)	No	Consistent with NUREG-2191.
3.6.1-022	Fuse holders (not part of active equipment): insulation material composed of electrical insulation material: bakelite; phenolic melamine or ceramic; molded polycarbonate, and other, exposed to air – indoor controlled or uncontrolled	Reduced electrical insulation resistance due to thermal/ thermoxidative degradation of organics, radiolysis, and photolysis (UV sensitive materials only) of organics; radiation-induced oxidation; moisture intrusion	AMP XI.E5, “Fuse Holders” - No AMP is required for those applicants who can demonstrate these fuse holders are located in an environment that does not subject them to environmental aging mechanisms	No	Consistent with NUREG-2191.
3.6.1-023	Metal enclosed bus: external surface of enclosure assemblies. Galvanized steel; aluminum. air - indoor controlled or uncontrolled	None	None	No	Consistent with NUREG-2191.

Table 3.6.1 Summary of Aging Management Programs for the Electrical Components Evaluated in Chapters VI of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.6.1-024	Metal enclosed bus: external surface of enclosure assemblies. Steel air – indoor controlled	None	None	No	Consistent with NUREG-2191.
3.6.1-027	Cable bus: external surface of enclosure assemblies galvanized steel; aluminum; air – indoor controlled or uncontrolled	None	None	No	Not applicable. ONS has no galvanized steel or aluminum cable bus, external surfaces of enclosure assemblies, exposed to air - indoor, controlled or uncontrolled environments in Electrical Commodities. See further evaluation in Section 3.6.2.2.2. The associated NUREG-2191 aging items are not used.
3.6.1-029	Cable bus: electrical insulation; insulators – exposed to air – indoor controlled or uncontrolled, air – outdoor	Reduced electrical insulation resistance due to degradation caused thermal/ thermoxidative degradation of organics and photolysis (UV sensitive materials only) of organics, moisture/debris intrusion and ohmic heating	A plant-specific AMP is to be evaluated	Yes (SRP-SLR Section 3.6.2.2.2)	Not applicable. ONS has no cable bus, electrical insulation and insulators, exposed to air - indoor, controlled or uncontrolled, or air - outdoor in Electrical Commodities. See further evaluation in Section 3.6.2.2.2. The associated NUREG-2191 aging items are not used.

Table 3.6.1 Summary of Aging Management Programs for the Electrical Components Evaluated in Chapters VI of the GALL-SLR Report

Item Number	Component	Aging Effect/ Mechanism	Aging Management Program	Further Evaluation Recommended	Discussion
3.6.1-030	Cable bus: external surface of enclosure assemblies composed of steel exposed to air – indoor uncontrolled or air – outdoor	Loss of material due to general, pitting, crevice corrosion	A plant-specific AMP is to be evaluated	Yes (SRP-SLR Section 3.6.2.2.2)	Not applicable. ONS has no cable bus, external surface of enclosure assemblies, composed of steel, exposed to air - indoor, controlled or uncontrolled, or air - outdoor in Electrical Commodities. See further evaluation in Section 3.6.2.2.2. The associated NUREG-2191 aging items are not used.
3.6.1-031	Cable bus external surface of enclosure assemblies composed of galvanized steel; aluminum exposed to air – outdoor	Loss of material due to general, pitting, crevice corrosion	A plant-specific AMP is to be evaluated	Yes (SRP-SLR Section 3.6.2.2.2)	Not applicable. ONS has no cable bus, external surface of enclosure assemblies, composed of galvanized steel or aluminum, exposed to air - outdoor in Electrical Commodities. See further evaluation in Section 3.6.2.2.2. The associated NUREG-2191 aging items are not used.

Table 3.6.2-1 Plant-Specific Notes:

1. Based on ONS design and OE, loss of material is not an applicable aging effect for ONS high voltage electrical insulators. In scope high voltage electrical insulator comprised of porcelain, malleable iron, aluminum, galvanized steel, and cement in an air - outdoor environment are not subject to mechanical wear or corrosion caused by wind blowing on transmission conductors. For more information, see Section 3.6.2.3.1.

2. Based on ONS design and OE, reduced insulation resistance is not an applicable aging effect for ONS high voltage electrical insulators. In scope high voltage electrical insulators comprised of porcelain, malleable iron, aluminum, galvanized steel, and cement in an air - outdoor environment are not subject to reduced electrical insulation resistance due to presence of cracks, foreign debris, salt, dust, cooling tower plume, or industrial effluent contamination. For more information, see Section 3.6.2.3.1.

3. Based on ONS design and OE, loss of material and increased resistance of connection are not applicable aging effects for ONS switchyard bus and connections. In scope switchyard bus and connections comprised of aluminum and stainless steel in an air - outdoor environment are not subject to wind induced abrasion nor oxidation of loss of preload. For more information, see Section 3.6.2.2.3.

4. Based on ONS design and operating experience, loss of material is not an applicable aging effect for ONS aluminum conductor steel reinforced transmission conductors. In scope ONS transmission conductors comprised of aluminum and steel in an air – outdoor environment are not subject to wind induced abrasion. For more information see Section 3.6.2.2.3.

5. Based on ONS design and operating experience, loss of conductor strength is not an applicable aging effect for ONS ACSR transmission conductors. In scope ONS transmission conductors comprised of aluminum and steel in an air – outdoor environment are not subject to corrosion. For more information see Section 3.6.2.2.3.

6. Based on ONS design and operating experience, increased resistance of connection is not an applicable aging effect for ONS transmission connectors. In scope ONS transmission connectors utilize good bolting practices, are treated with inhibitors to avoid connection oxidation and torqued at the time of installation to avoid the loss of preload. Transmission connectors are designed in installed utilizing stainless steel lock washers that provide vibration absorption and prevent loss of preload. Therefore, based on ONS design and confirmed by operating experience, oxidation and loss of preload are not applicable aging mechanisms for ONS transmission connectors. For more information see Section 3.6.2.2.3.

Table 3.6.2-1 Industry Standard Notes:

A. Consistent with NUREG-2191 item for component, material, environment, and aging effect. AMP is consistent with NUREG-2191 AMP.

B. Consistent with NUREG-2191 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-2191 AMP.

C. Component is different, but consistent with NUREG-2191 item for material, environment, and aging effect. AMP is consistent with NUREG-2191 AMP.

D. Component is different, but consistent with NUREG-2191 item for material, environment, and aging effect. AMP takes some exceptions to the NUREG-2191 AMP.

E. Consistent with NUREG-2191 item for material, environment, and aging effect, but a different AMP is credited or NUREG-2191 identifies a plant-specific AMP.

F. Material not in NUREG-2191 for this component.

G. Environment not in NUREG-2191 for this component and material.

H. Aging effect not in NUREG-2191 for this component, material and environment combination.

I. Aging effect in NUREG-2191 for this component, material and environment combination is not applicable.

J. Neither the component nor the material and environment combination is evaluated in NUREG-2191.

4.0 TIME-LIMITED AGING ANALYSES

Time limited aging analyses (TLAA) are described in 10 CFR 54, *"Requirements for Renewal of Operating Licenses for Nuclear Power Plants."* Section 4.0 presents the description of the TLAA for Oconee 1, 2 and 3 in accordance with 10 CFR 54.3(a) and 10 CFR 54.21(c). Section 4.0 is divided into Sections 4.1 through 4.7.

Section 4.1 provides the regulatory definitions and standards required to demonstrate TLAA acceptability through the subsequent period of extended operation. The process used for identifying and evaluating TLAA and exemptions are also summarized there along with a summary of the overall results.

The specific results of evaluations of TLAA and any exemptions that are based on TLAA in accordance with 10 CFR 54.21(c) are provided in subsequent sections, as follows:

- Reactor Vessel Neutron Embrittlement Analysis (Section 4.2)
- Metal Fatigue (Section 4.3)
- Environmental Qualification of Electric Equipment (Section 4.4)
- Concrete Containment Tendon Prestress (Section 4.5)
- Containment Liner Plate, Metal Containments, and Penetrations Fatigue (Section 4.6)
- Other Plant-Specific Time-Limited Aging Analyses (Section 4.7)

4.1 IDENTIFICATION OF TIME-LIMITED AGING ANALYSES

TLAA are defined in 10 CFR 54.3(a) as those licensee calculations and analyses that meets all six of the following specific criteria:

1. Involves systems, structures, and components within the scope of license renewal, as delineated in 10 CFR 54.4(a);

2. Considers the effects of aging;

3. Involves time-limited assumptions defined by the current operating term, for example, 40 years,

4. Was determined to be relevant by the licensee in making a safety determination;

5. Involves conclusions or provides the basis for conclusions related to the capability of the system, structure, and component to perform its intended functions, as delineated in 54.4(b); and

6. Is contained or incorporated by reference in the CLB.

4.1.1 TIME-LIMITED AGING ANALYSES IDENTIFICATION PROCESS

The process used to identify the ONS-specific time limited aging analyses is consistent with the guidance provided in NEI 17-01, "Industry Guideline for Implementing the Requirements of 10 CFR Part 54 for Subsequent License Renewal," NUREG-2191, "Generic Aging Lessons Learned for Subsequent License Renewal (GALL-SLR) Report" and NUREG-2192, "Standard Review Plan for Review of Subsequent License Renewal Applications for Nuclear Power Plants."

The identification of the ONS TLAA began with the development of a list of potential TLAA identified from documentation that describes the ONS CLB. This list of potential TLAA was also compared to other industry documents that list TLAA to ensure completeness of the identification of the potential ONS TLAA.

Keyword searches of the documentation that describes the ONS CLB included the following documents:

- UFSAR
- Facility Operating Licenses
- Quality Assurance Program
- Inservice Inspection and Inservice Testing Program Documents
- Offsite Dose Calculation Manual
- Technical Specifications and Bases
- Docketed Licensing Correspondence
- Design Specifications, Calculations and Reports incorporated by reference in CLB
- Exemptions granted pursuant to 10 CFR 50.12

Industry documents to which the potential ONS TLAA were compared included:

- NUREG-2191, "Generic Aging Lessons Learned for Subsequent License Renewal (GALL-SLR) Report" [Reference 1.7.3]
- NUREG-2192, "Standard Review Plan for Review of Subsequent License Renewal Applications for Nuclear Power Plants" [Reference 1.7.2]
- NEI 17-01, "Industry Guideline for Implementing the Requirements of 10 CFR Part 54 for Subsequent License Renewal" [Reference 1.7.6]
- Sampling of recent License Renewal Applications or associated SER for B&W PWR designs and PWR plants which utilize B&W fabricated reactor vessels
- Sampling of recent License Renewal Applications or associated SER for other PWR designs

Finally, the Oconee SER [Reference 4.1-9] for initial license renewal was also reviewed to ensure all TLAAs from the initial license renewal period were either included or otherwise justified as no longer applicable for SLR.

The list of potential Oconee TLAA was then reviewed against the TLAA definition in 10 CFR 54.3(a). Potential TLAAs that met all six elements of the 10 CFR 54.3(a) definition were identified as ONS TLAA that required evaluation for the SPEO. For each TLAA from the initial license renewal there is a corresponding TLAA for the SPEO.

4.1.2 EVALUATION OF TIME-LIMITED AGING ANALYSIS

For each TLAA identified, 10 CFR 54.21(c)(1) requires that the applicant shall demonstrate that

(i) The analyses remain valid for the PEO;
(ii) The analyses have been projected to the end of the PEO; or
(iii) The effects of aging on the intended function(s) will be adequately managed for the PEO.

In subsequent sections, the following details are captured for each Oconee TLAA and serve as the demonstration prescribed in 10 CFR 54.21(c)(1).

<u>TLAA Description:</u>

A description of the analysis that has been identified as a TLAA, including a description of the associated aging effect and the time-limited assumption used in the analysis.

<u>TLAA Evaluation:</u>

The evaluation of the TLAA for the SPEO. This section provides the information associated with 80 years of operation for comparison with the information used in the related TLAA that considered the previous license term of operation. This evaluation provides the basis for the disposition, which will be one of the three options specified in 10 CFR 54.21(c)(1).

<u>TLAA Disposition:</u>

Each TLAA is demonstrated acceptable in accordance with one of the three options from 10 CFR 54.21(c)(1).

4.1.3 IDENTIFICATION AND EVALUATION OF EXEMPTIONS

10 CFR 54.21(c)(2) requires a list of plant-specific exemptions granted pursuant to 10 CFR 50.12 and in effect that are based on time-limited aging analyses as defined in 10 CFR 54.3. For exemptions that have such a time dependency, the applicant shall provide an evaluation that justifies the continuation of these exemptions for the period of extended operation.

A review of the Oconee CLB was performed, and the results of this review confirmed that no exemptions to 10 CFR 50.12 have been granted based on a TLAA as defined in 10 CFR 54.3.

4.1.4 SUMMARY OF RESULTS

Sections 4.2 through Section 4.7 of this chapter describe the evaluations of six general categories of TLAA. The TLAA categories and associated analysis are listed in Table 4.1.4-1, *Time-Limited Aging Analyses Categories and Dispositions*. The TLAA categories are presented in the order in which they appear in Sections 4.2 through Section 4.7 of NUREG-2192**.** The table entries also indicate the disposition method used in evaluating the TLAA and include a reference to the applicable SLRA section where the TLAA is evaluated for the SPEO.

As an aid to the reviewer, two additional summary tables, Table 4.1.4-2 and Table 4.1.4-3, have been provided. Both Table 4.1.4-2, *Review of TLAA Listed in NUREG-2192, Table 4.1-2* and Table 4.1.4-3, *Review of TLAA Listed in NUREG-2192, Table 4.7-1* list the example TLAA provided in NUREG-2192 and specify whether they have been identified as TLAA for ONS. The sections where the applicable TLAA are evaluated are identified. Those items with a “Yes” entry apply. Those items with a “No” entry do not apply. These latter TLAA were found not to apply either because they are associated with design features not employed or because no analysis was identified that meets all six elements of the TLAA definition in 10 CFR 54.3(a).

Table 4.1.4-1: Oconee Time-Limited Aging Analyses Categories and Dispositions

TLAA CATEGORY	ANALYSIS	DISPOSITION (Note 1)	SECTION
REACTOR VESSEL NEUTRON EMBRITTLEMENT	Neutron Fluence Projections	(ii)	4.2.1

Note 1:
(i) Validation: The analyses remain valid for the SPEO.
(ii) Projection: The analyses have been projected to the end of the SPEO.
(iii) Aging Management: The effects of aging on the intended function(s) will be adequately managed for the SPEO.

Table 4.1.4-2: Review of Time-Limited Aging Analyses Listed in NUREG-2192, Table 4.1-2

NUREG-2192, Table 4.1-2 - Generic Time-Limited Aging Analyses	Applies to ONS	SLRA Section
REACTOR VESSEL NEUTRON EMBRITTLEMENT		
Neutron Fluence	Yes	4.2.1
Pressurized Thermal Shock (PWRs Only)	Yes	4.2.3
Upper-Shelf Energy (PWRs and BWRs)	Yes	4.2.2
Pressure-Temperature Limits (PWRs and BWRs)	Yes	4.2.4
Low Temperature Overpressure Protection System Setpoints (PWRs Only)	Yes	4.2.5
Ductility Reduction Evaluation for Reactor Internals (B&W designed PWRs only)	Yes	4.7.1.1
Reactor Vessel Circumferential Weld Relief - Probability of Failure and Mean Adjusted Reference Temperature Analysis for the RV Circumferential Welds (BWRs only)	No	NA
Reactor Vessel Axial Weld Probability of Failure and Mean Adjusted Reference Temperature Analysis (BWRs only)	No	NA
METAL FATIGUE		
Metal Fatigue of Class 1 Components	Yes	4.3.2
Metal Fatigue of Non-Class 1 Components	Yes	4.3.3
Environmentally Assisted Fatigue	Yes	4.3.4
High Energy Line Break Analyses	No (Note 1)	NA

Table 4.1.4-2: Review of Time-Limited Aging Analyses Listed in NUREG-2192, Table 4.1-2

NUREG-2192, Table 4.1-2 - Generic Time-Limited Aging Analyses	Applies to ONS	SLRA Section
Cycle-Dependent Fracture Mechanics or Flaw Evaluations	Yes	4.3.5
Cycle-Dependent Fatigue Waivers	Yes	4.3.2.9
Environmental Qualification of Electric Equipment	Yes	4.4
Concrete Containment Tendon Prestress	Yes	4.5
Containment Liner Plate, Metal Containments, and Penetrations Fatigue	Yes	4.6

Note 1: A review of the ONS CLB was performed, which included HELB postulation for low pressure injection/ decay heat removal piping. For Units 1, 2, and 3, thermal aging was addressed through the lower-bound, unaged J-R curve for submerged arc welds and gas-tungsten arc welds from NUREG/CR-6428. It was also found that an explicit fatigue analysis was not necessary since the stresses at the critical locations are too low to justify a need for a quantitative fatigue crack growth analysis. Therefore, the leak before break analyses for the Units 1, 2, and 3 low pressure injection/decay heat removal piping are not TLAA.

Table 4.1.4-3: Review of Generic Time-Limited Aging Analyses Listed in NUREG-2192, Table 4.7-1

NUREG-2192, Table 4.7-1 - Examples of Potential Plant Specific TLAA Topics	Applies to ONS	SLRA Section
Reactor Pressure Vessel Underclad Cracking	Yes	4.7.2
Leak Before Break	Yes	4.7.4
Reactor Coolant Pump Flywheel Fatigue Crack Growth	Yes	4.7.3
Response to NRC Bulletin 88-11, Pressurizer Surge Line Thermal Stratification	Yes	4.3.2.8
Response to NRC Bulletin 88-08, Thermal Stresses in Piping Connected to Reactor Cooling Systems	No (Note 1)	NA
Fatigue of Cranes (Crane Cycle Limits)	Yes	4.7.5
Fatigue of the Spent Fuel Pool Liner	No (Note 2)	NA
Corrosion Allowance Calculations	No (Note 2)	NA
Flaw Growth Due to Stress Corrosion Cracking	No (Note 2)	NA
Predicted Lower Limit	No (Note 2)	NA

Note 1: No ASME Code, Section III cumulative usage factor analyses were generated in response to NRC Bulletin 88-08. Ultrasonic inspections were performed in response to NRC Bulletin 88-08.

Note 2: Not a TLAA for Oconee

4.2 REACTOR VESSEL NEUTRON EMBRITTLEMENT ANALYSES

10 CFR 50.60, *“Acceptance Criteria for Fracture Prevention Measures for Lightwater Nuclear Reactors for Normal Operation,”* requires that all light water reactors meet the fracture toughness, Pressure-Temperature limits, and materials surveillance program requirements for the reactor coolant pressure boundary as set forth in 10 CFR 50, Appendices G and H. 10 CFR 50.61 requires that all light water reactors meet the fracture toughness requirements for protection against pressurized thermal shock events. The ONS *Reactor Vessel Material Surveillance* AMP (B2.1.19, GALL-SLR XI.M31), which is an integrated surveillance program as defined by 10 CFR 50 Appendix H, in combination with the ONS *Neutron Fluence Monitoring* AMP (B3.2, GALL-SLR X.M2) will ensure that the TLAA requirements of 10 CFR 50 Appendix G and 10 CFR 50.61 reported herein remain valid through the SPEO.

The ferritic materials of the reactor vessel are subject to embrittlement due to high energy (E > 1.0 MeV) neutron exposure. Embrittlement means the material has lower toughness (i.e., will absorb less strain energy during crack propagation or rupture), thus allowing a crack to propagate more easily under thermal and pressure loading. Neutron embrittlement analyses account for the reduction in fracture toughness associated with the cumulative neutron fluence. Because these neutron embrittlement analyses are evaluated for the plant's service lifetime (10 CFR 50 Appendix G, IV., Fracture Toughness Requirements, Item 1) or end-of-life (10 CFR 50.61(a)(6)), they are identified as TLAA.

<u>Current Licensing Basis</u>

Compliance with the requirements of 10 CFR 50 Appendix G and 10 CFR 50.61 by Duke Energy for 60 years of operation is in accordance with the following.

1. Letter from Duke Energy Corporation forwarding application for renewal of operating licenses for the Oconee Nuclear Station, Units 1, 2, and 3, U. S. Nuclear Regulatory Commission, July 6, 1998 [Reference 4.2-1].

2. The ONS LRA references BAW-2251A [Reference 4.2-2] relative to evaluation of reactor vessel TLAA for 60 years. All TLAA evaluations were reported at 48 EFPY.

3. NUREG-1723, Safety Evaluation Report Related to the License Renewal of Oconee Nuclear Station, Units 1, 2, and 3 [Reference 4.2-3].

4. Oconee Nuclear Station, Units 1, 2, and 3, issuance of amendments regarding revised pressure-temperature limits, ADAMS Accession No. ML14041A093 [Reference 4.2-4]

    - NRC approval of Oconee pressure-temperature limits to 54 EFPY and reconciliation of upper-shelf energy from 48 EFPY to 54 EFPY.

5. Oconee Nuclear Station, Units 1, 2, and 3 license amendment request for measurement uncertainty recapture power uprate, February 19, 2020, ADAMS Accession Number ML20050D379 and SER for measurement uncertainty recapture power uprate, January

26, 2021, ADAMS Accession Number ML20335A001 [Reference 4.2-5 and 4.2-33, respectively].

- Reduces the applicability for the reactor coolant system heatup and cooldown limit curves from 54 EFPY to 44.6 EFPY for Unit 1, to 45.3 EFPY for Unit 2, and to 43.8 EFPY for Unit 3 based on updated reactor vessel material evaluations discussed in Section IV.1 of the measurement uncertainty recapture submittal.

- Maintains RT_{PTS} and underclad cracking at 48 EFPY and upper-shelf energy at 54 EFPY for all three units.

6. All TLAA for subsequent license renewal reported in this Chapter consider the revised operating conditions (i.e, 1.64% increase in power) associated with measurement uncertainty recapture as reported in References 4.2-5 and 4.2-33. Measurement uncertainty recapture is assumed at the beginning of Cycle 30 for ONS Unit 1, Cycle 29 for ONS Unit 2, and Cycle 29 for ONS Unit 3. At present, measurement uncertainty recapture has not been implemented. Each unit is currently operating in Cycles 32, 30, and 31, respectively. The effects of the measurement uncertainty recapture were considered and found to have no impact on SLR.

<u>Subsequent License Renewal</u>

Reactor vessel beltline items must comply with the requirements of 10 CFR 50, Appendices G and H, and 10 CFR 50.61 for SLR. The reactor vessel beltline is defined by 10 CFR 50 Appendix G, II., F, and 10 CFR 50.61(a)(3) in accordance with the following definition: *"the region of the reactor vessel (shell material, including welds, heat-affected zones, and plate or forgings) that directly surrounds the effective height of the active core and the adjacent regions of the reactor vessel that are predicted to experience sufficient neutron irradiation damage to be considered in the selection of the most limiting material with regard to radiation damage during the licensed period."*

For SLR, the NRC staff has directed applicants to consider additional reactor vessel items (i.e., extended beltline) that may be subject to reduction of fracture toughness as defined in RIS 2014-11 [Reference 4.2-6]. Specifically, extended beltline means the region of the reactor vessel (shell material, including welds, heat-affected zones, and plate or forgings) adjacent to the traditional beltline region that will have associated fluence values projected to exceed 1.0E+17 n/cm^2 (E > 1.0 MeV) at end of license to experience sufficient neutron damage to be included in the beltline. In accordance with RG 1.99, Revision 2 [Reference 4.2-12], Figure 1, the fluence threshold of 1.0E+17 n/cm^2 (E > 1.0 MeV) reported in RIS-2014-11 is assumed to be at the inside wetted surface of the reactor vessel. The 72 EFPY fluence projections used to establish ONS reactor vessel beltline and extended beltline locations are discussed in Section 4.2.1.

Based on accrued EFPY through Cycles 31, 29 and 30 for Oconee Units 1 through 3 and assuming breaker-to-breaker operation and no outages per cycle (Capacity Factor = 1), the bounding projected EFPY for 80 years for each Oconee unit is less than 72 EFPY. Therefore, for Oconee, TLAA evaluations are completed to 80 years. A measurement uncertainty capture uprate is conservatively factored in at 2% for all TLAA evaluations that utilize neutron fluence as an input.

Adjusted Reference Temperatures

Adjusted reference temperatures, as defined by Regulatory Guide 1.99, Revision 2, Position 1.1, and 2.1, are utilized in the calculation of upper-shelf energy/equivalent margins (Section 4.2.2), pressurized thermal shock (Section 4.2.3), pressure-temperature limits (Section 4.2.4), low temperature overpressure (Section 4.2.5), and underclad cracking (Section 4.7.2). As such, adjusted reference temperatures are discussed in the applicable SLRA sections.

Description of Reactor Vessels: Oconee Units 1, 2, and 3

A schematic of the reactor vessel shell and closure head that applies to all 3 ONS units is provided in Figure 4.2-1. The reactor vessel shells for all three units are shown in Figure 4.2-2 for Unit 1, Figure 4.2-3 for Unit 2, and Figure 4.2-4 for Unit 3. Extended beltline items are identified with a (superscript 1) and include the reactor vessel inlet/outlet nozzles and associated welds, and the transition forging (dutchman forging) for all three units; material properties for these items have not been previously reviewed and accepted by the NRC. The remaining reactor vessel items are all considered traditional beltline items, have been reviewed previously by the NRC, and are available through the 60-year reactor vessel integrity TLAA evaluations cited above. Material properties that are required for reactor vessel integrity TLAA evaluations (beltline and extended beltline) required by 10 CFR 50 Appendix G and 10 CFR 50.61 for SLR are reported in Section 4.2.2, Upper Shelf Energy, Section 4.2.3, Pressurized Thermal Shock, and Section 4.2.4, Pressure-Temperature limits.

ONS Unit 1 Beltline and Extended Beltline Reactor Vessel Items (Figure 4.2-2)

1. Forgings are ASTM A 508 Class 2

   - Reactor vessel outlet nozzles (2) and reactor vessel inlet nozzles (4)[1]
   - Lower nozzle belt forging (AHR 54: ZV 2861)
   - Transition forging (122S347VA1)[1]

2. Plates are ASTM A 302B, Modified

   - Intermediate shell (C2197-2)
   - Upper shell (C3265-1 and C3278-1)
   - Lower shell (C2800-1 and C2800-2)

3. Linde 80 Welds

   - Reactor vessel inlet and outlet nozzle to nozzle belt forging welds[1]
   - Lower nozzle belt forging to intermediate shell circumferential weld (SA-1135)
   - Intermediate shell axial welds (SA-1073)

- Intermediate shell to upper shell circumferential weld (SA-1229, 61% ID; WF 25, 39% OD)
- Upper shell axial welds (SA-1493)
- Upper Shell-to-lower shell circumferential weld (SA-1585)
- Lower shell axial welds (SA-1430 and SA-1426)
- Lower shell forging to transition forging circumferential weld (WF-9)

ONS Unit 2 Beltline and Extended Beltline Reactor Vessel Items (Figure 4.2-3)

1. Forgings are all ASTM A 508 Class 2

- Reactor vessel outlet nozzles (2) and reactor vessel inlet nozzles (4)[1]
- Lower nozzle belt forging (AMX 77: 123T382)
- Upper shell forging (AAW 163:3P2359)
- Lower shell forging (AWG 164: 4P1885)
- Transition forging (122T293VA1)[1]

2. Linde 80 Welds

- Reactor vessel inlet and outlet nozzle to nozzle belt forging welds[1]
- Lower nozzle belt forging to upper shell forging circumferential weld (WF-154)
- Upper shell forging to lower shell forging circumferential weld (WF-25)
- Lower shell forging to transition forging circumferential weld (WF-112)

ONS Unit 3 Beltline and Extended Beltline Reactor Vessel Items (Figure 4.2-4)

1. Forgings are all ASTM A 508 Class 2

- Reactor vessel outlet nozzles (2) and reactor vessel inlet nozzles (4)[1]
- Lower nozzle belt forging (4680)
- Upper shell forging (AWS 192: 522314)
- Lower shell forging (ANK 191:522194)
- Transition forging (417543-1)[1]

2. Linde 80 Welds

- Reactor vessel inlet and outlet nozzle to nozzle belt forging welds[1]
- Lower nozzle belt forging to upper shell forging circumferential weld (WF-200)
- Upper shell forging to lower shell forging circumferential weld (WF-67, 75% ID; WF-70, 25% OD)
- Lower shell forging to transition forging circumferential weld (WF-169-1)

Note 1: Extended beltline items

The evaluations of TLAA related to neutron embrittlement for the reactor vessel items listed above are described in the following subsections.

1. Neutron Fluence Projections (Section 4.2.1)

2. Upper-Shelf Energy (Section 4.2.2)

3. Pressurized Thermal Shock (Section 4.2.3)

4. Pressure-Temperature Limits (Section 4.2.4)

5. Low Temperature Overpressure Protection (Section 4.2.5)

Figure 4.2-1: Reactor Vessel Shell and Closure Head (Longitudinal Section)

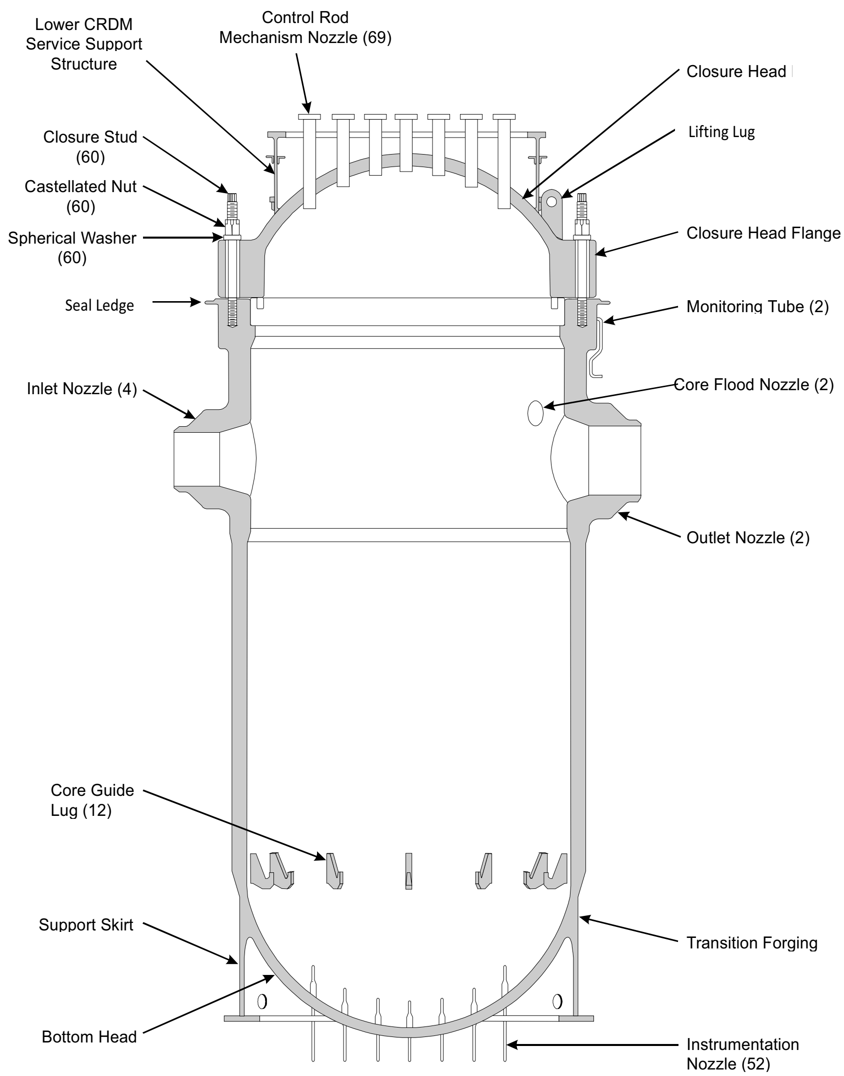

Figure 4.2-2: ONS Unit 1 Reactor Vessel Shell

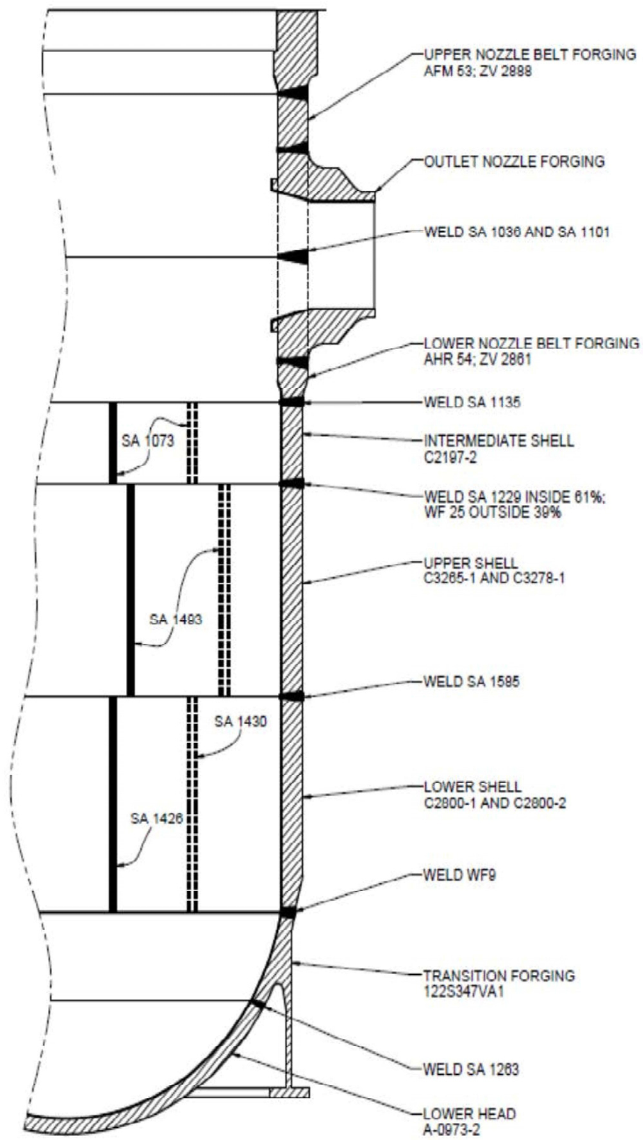

Figure 4.2-3: ONS Unit 2 Reactor Vessel Shell

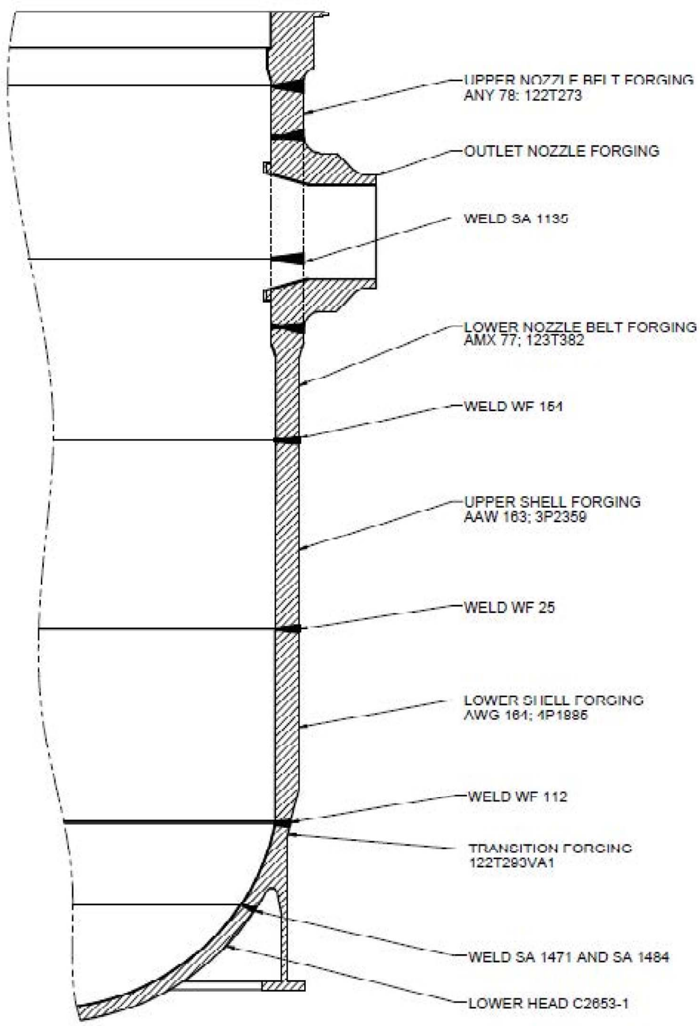

Figure 4.2-4: ONS Unit 3 Reactor Vessel Shell

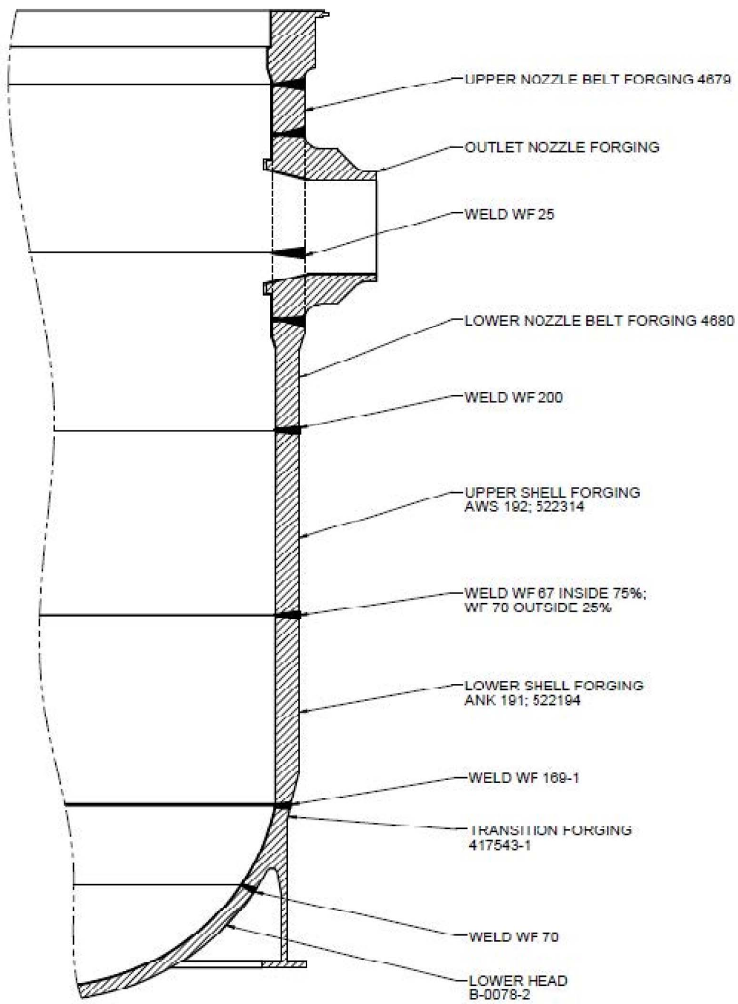

4.2.1 NEUTRON FLUENCE PROJECTIONS

TLAA Description:

Neutron fluence is defined as the time integral of the neutron flux density, expressed as number of particles (neutrons) per cm^2. Neutron fluence is used as an input to quantify the change in material properties of the reactor vessel (beltline and extended beltline) regions, as required by 10 CFR 50 Appendix G and 10 CFR 50.61, over the life of the plant. Because these neutron embrittlement analyses are evaluated for the plant's service lifetime (10 CFR 50 Appendix G, IV.A.1) or end-of-life (10 CFR 50.61(a)(6)), they are identified as TLAA.

TLAA Evaluation:

The calculation based fluence analysis methodology contained in BAW-2241P-A, Revision 2 [Reference 4.2-7] is used to predict the 80-year fluence at reactor vessel shell locations. As discussed in the Oconee UFSAR, Section 18.3.19, only the ONS Unit 2 reactor vessel has installed cavity dosimetry. However, the ONS Unit 1 and ONS Unit 3 reactor vessel fluence uncertainty values are based on ONS Unit 2 cavity dosimetry results due to similar design, fabrication, operation, and fuel loading patterns. The use of the ONS Unit 2 cavity dosimetry for Oconee Unit 1 and Oconee Unit 3 was approved by the NRC in a letter to Duke Power Company dated December 5, 1988 [ADAMS Accession Number ML16152A761]. The BAW-2241P-A, Revision 2 fluence analysis methodology was developed through a full-scale benchmark experiment that was performed at the Davis Besse reactor. Results of the benchmark experiment demonstrated the accuracy of a fluence analysis that employs the methodology reported in BAW-2241P-A, Revision 2 is unbiased and has a precision within the RG 1.190, March 2001 [Reference 4.2-8] suggested one standard deviation (σ) limit of 20% for locations in the reactor vessel beltline (i.e., traditional beltline locations). Uncertainty for extended beltline locations has not been quantified in BAW-2241P-A, Revision 2.

For the Oconee Nuclear Station, neutron transport calculations, using the methodology from BAW-2241P-A, Revision 2, were completed for Cycles 27-29 for ONS Unit 1, Cycles 25-28 for ONS Unit 2, and Cycles 26-28 for ONS Unit 3, and used to project fast neutron fluence at the reactor vessel shell (i.e., beltline and extended beltline locations) to 72 EFPY. A measurement uncertainty capture uprate is conservatively factored in at 2% and is assumed at the beginning of Cycle 30 for Oconee Unit 1, Cycle 29 for Oconee Unit 2, and Cycle 29 for Oconee Unit 3.

In addition to calculation of fluence at reactor vessel shell locations, the BAW-2241P-A, Revision 2, methodology is used to calculate the fast neutron fluence (E > 1.0 MeV) exposure to the cavity dosimetry holder. The energy-dependent fast fluence rate (E > 1.0 MeV) flux exposure to the cavity dosimetry is used to determine the calculated activity of each dosimeter. Geometric detail is selected to explicitly represent the dosimeter holder and the reactor vessels. The calculated activities are adjusted for known biases (photofission, short half-life, U-235 impurity, non-leakage and non-saturation) and directly compared to measured activities. Cavity dosimetry measurements are not used in any way to determine the magnitude of the flux or the fluence. Instead, the measurements are used only to show that the calculation results are reasonable and to show that the results are consistent with the benchmark database of uncertainties relative to reactor vessel locations adjacent to the effective height of the active core also known as the traditional reactor vessel beltline.

As cavity dosimetry is exchanged, neutron transport calculations are performed for all 3 units using the methodology as described in BAW-2241P-A, Revision 2. Typical process steps are as follows.

- After cavity dosimetry is removed and exchanged, dosimetry is sent to a laboratory for testing and activation evaluation.

- Reactor vessel fluence from the prior analyzed cycles are obtained from the latest transport analyses for each unit (i.e., Cycle 26 for ONS Unit 1, Cycle 24 for ONS Unit 2, and Cycle 25 for ONS Unit 3).

- Transport calculations are performed for the reactor vessel shell for all three Oconee units and for the cavity dosimetry. The transport calculation methodology synthesizes the results of two 2-dimensional radial (RT or Rθ) and axial (RZ) discrete ordinates transport cases which use the BUGLE cross-section library. The synthesis produces a 3-dimensional flux result from the two 2-dimensional discrete ordinate transport at all reactor vessel shell locations of interest and at the cavity dosimetry locations.

- Incremental fluence is determined by multiplying the 3D synthesized fluence rate from each operating cycle by the length of each cycle (i.e., Cycles 27-29 for ONS Unit 1, Cycles 25-28 for ONS Unit 2, and Cycles 26-28 for ONS Unit 3).

- Cumulative fluence is determined by summation of incremental fluence for each cycle. Reactor vessel fluence is projected to longer time periods (e.g., 72 EFPY) to estimate the total fluence at locations of interest. This projection is performed by assuming that the average fluence at the location of interest for the projected time is at equilibrium at the average fluence rate (flux) of the last cycle analyzed for a given location of interest. This assumption is acceptable as long as future core configurations are equivalent to the core design of the last cycle analyzed. The ONS *Neutron Fluence Monitoring* AMP (B3.2, GALL-SLR X.M2) will ensure that any future core configurations are assessed relative to applicable impacts to TLAA for SLR. The end of life (72 EFPY) fluence values are determined by taking the cumulative fluence and then projecting forward by utilizing the fluence rate (flux) of the last cycle analyzed for a given location of interest.

- The weighted mean values of the ratio of calculated cavity dosimeter activities to measurements have been statistically evaluated. The standard deviation was computed, and the deviation indicates that the benchmark comparisons are consistent with the BAW-2241P-A, Revision 2 database. The consistency to the BAW-2241P-A, Revision 2 database indicates that the ONS fluence calculations have no discernible bias in the greater than 1.0 MeV fluence values. In addition, the consistency indicates that the fluence values can be represented by the BAW-2241P-A, Revision 2 reference set and the applicable standard deviation.

As the lifetime of the reactor vessel for each Oconee unit is extended to 80 years, reactor vessel regions that may be susceptible to reduction of fracture toughness may extend beyond traditional beltline locations to areas such as the reactor vessel nozzle and transition regions. As such, estimation of the fluence in reactor vessel regions adjacent to those that surround the effective height of the active core (traditional beltline) is required and the (accepted) fluence threshold for irradiation damage of reactor vessel materials, relative to the monitoring of limiting materials, is 1.0E+17 n/cm^2 (E > 1.0 MeV) [Reference 4.2-6]. For locations of interest beyond the reactor vessel regions that surround the effective height of the active core, the model developed using the methodology from BAW-2241P-A, Revision 2 is extended to provide estimates of the fluence rates, and calculated fluence at 72 EFPY, in the reactor vessel nozzle and transition regions.

For extended beltline locations, an adjustment of the method is employed to obtain best estimate cumulative (E > 1.0 MeV) fluence values. Specifically, a displacement per atom adjustment is used wherein a ratio of the discrete ordinate transport calculated displacement per atom at the extended beltline location of interest (e.g., reactor vessel nozzle) to the discrete ordinate transport calculated displacement per atom at the circumferential weld that connects the upper shell to the lower shell (SA-1585 for Unit 1, WF-25 for Unit 2, and WF-67 for Unit 3), is multiplied by the fluence at the circumferential weld to obtain the fluence at the extended beltline location of interest (e.g., reactor vessel nozzle). This adjustment factor method is shown to be conservative for extended beltline relative to recent 3-D Monte Carlo N-Particle calculations reported in Section 2.0 of Proprietary Report ANP-3898P, Revision 0 and in Section 2.0 of Non-Proprietary Report ANP-3898NP, Revision 0 [References 4.2-18 and 4.2-20, respectively] for inside surface fluence and attenuated fluence through the nozzle regions. Section 2.0 of Proprietary Report ANP-3898P, Revision 0 and in Section 2.0 of Non-Proprietary Report ANP-3898NP, Revision 0 illustrates that use of a displacement per atom at the inner surface in the nozzle region to obtain attenuated fluence, which accounts for the full neutron energy spectrum, produces significantly less attenuation at the ¼ T and ¾ T locations when compared to the Regulatory Guide 1.99 Revision 2 fluence attenuation formulation.

Based on the above discussion, neutron fluence projections at 72 EFPY are provided for Oconee Units 1, 2 and 3 in Table 4.2.1-1, Table 4.2.1-2 and Table 4.2.1-3, respectively. Inside wetted surface fluence at 72 EFPY is reported for all reactor vessel shell locations that exceed 1.0E +17 n/cm^2 (E > 1.0 MeV). Fluence is attenuated through the thickness of the shell by taking the ratio of displacement per atom at the depth in question to the displacement per atom at the inner surface, as permitted by RG 1.99, Revision 2, Section 1.1. Displacements per atom at the inner surface and at the depth in question were obtained from the discrete ordinate transport analyses described above. With regard to reactor pressure vessel embrittlement evaluation reported in subsequent SLRA sections, the following is implemented relative to extended beltline fluence.

Upper Shelf Energy

- Upper shelf energy reduction per RG 1.99, Revision 2, Positions 1.2 and 2.2 are reported in Section 4.2.2. The reactor pressure vessel inlet nozzle and outlet nozzle fluence values at the bottom of the respective nozzle to nozzle belt forging Linde 80 welds are assumed to apply to the forgings. Fluence at the ¼T location for the reactor pressure vessel nozzle forgings is determined using the conservative displacement per atom adjustment method discussed above.

- The equivalent margins analysis of the Linde 80 reactor pressure vessel nozzle welds reported in BAW-2192, Revision 0, Supplement 1P-A, Revision 0 [Reference 4.2-13] and BAW-2178, Revision 0, Supplement 1P-A, Revision 0 [Reference 4.2-14]) utilized an inside wetted surface fluence of 1.5E+18 n/cm^2. This is significantly higher than the 72 EFPY inside wetted surface fluence values for the reactor pressure vessel nozzle welds reported inTable 4.2.1-1, Table 4.2.1-2, and Table 4.2.1-3 (highest at 3.50E+17 n/cm^2). The 72 EFPY values reported herein were obtained using a conservative displacement per atom adjustment method as reported above.

- The equivalent margins analysis of the Unit 3 nozzle and transition forgings is reported in Section 4.2.2. A conservative fluence of 1.0E+18 n/cm^2 at the inside wetted surface was assumed at the reactor vessel nozzles and transition forging, with no attenuation, and the 72 EFPY upper shelf energy values at the reactor pressure vessel nozzles and transition forging were calculated using RG 1.99, Revision 2, Position 1.2 and fluence of 1.0E+18 n/cm^2. That is, no attenuation was assumed.

Pressurized Thermal Shock

- RT_{PTS} per RG 1.99, Revision 2, Positions 1.1 and 2.1 and the supplemental PTS evaluation of reactor pressure vessel nozzles are reported in Section 4.2.3. Neutron fluence at extended beltline locations (clad/base metal interface) was conservatively obtained using the displacement per atom adjustment method described above. The reactor pressure vessel inlet nozzle and outlet nozzle fluence values at the bottom of the nozzle to nozzle belt forging Linde 80 welds are assumed to apply to the forgings.

Pressure-Temperature Limits and Low Temperature Overpressure Protection

- Inside wetted surface fluence at the postulated flaw corner flaws (inside radius) of the reactor pressure vessel inlet and outlet nozzles was used. No attenuation was assumed, and inside wetted surface fluence at the flaw locations are determined using the conservative displacement per atom adjustment method discussed above.

Margins to embrittlement limits for PTS (10 CFR 50.61 using RG 1.99, Revision 2) and upper shelf energy (10 CFR 50.60 using RG 1.99, Revision 2) for extended beltline locations are much greater than traditional beltline locations and are reported in Sections 4.2.2 and 4.2.3.

TLAA Disposition: 10 CFR 54.21(c)(1)(ii):

The fluence analyses have been projected to the end of the subsequent period of extended operation. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(ii). The results are to be used as inputs in the reactor vessel neutron embrittlement TLAA evaluations in Sections 4.2.2 through 4.2.5.

4.2.2 UPPER-SHELF ENERGY

TLAA Description:

Appendix G of 10 CFR 50.60, [Reference 4.2-11], requires that reactor vessel beltline materials *"must have Charpy upper-shelf energy in the transverse direction for base metal and along the weld for weld material according to the ASME Code, of no less than 75 ft-lb (102 J) initially and must maintain Charpy upper-shelf energy throughout the life of the vessel of no less than 50 ft-lb (68 J) unless it is demonstrated in a manner approved by the Director, Office of Nuclear Reactor Regulation or Director, Office of New Reactors, as appropriate, that the lower values of Charpy upper-shelf energy will provide margins of safety against fracture equivalent to those required by Appendix G of Section XI of the ASME Code."* The CLB upper-shelf energy calculations were prepared for the Oconee reactor vessel beltline materials for 54 EFPY as discussed in Section 4.2. Since upper-shelf energy reduction is a function of the 54 EFPY fluence, which is associated with the 60-year licensed operating period, the upper-shelf energy calculations meet the criteria of 10 CFR 54.3(a) and have been identified as TLAA requiring evaluation for 80 years.

TLAA Evaluation:

For SLR, the upper-shelf energy values for the traditional beltline and extended beltline materials were determined for the ONS reactor vessel beltline and extended beltline items using methods consistent with RG 1.99, Revision 2 [Reference 4.2-12]. Two methods may be used to predict the decrease in upper-shelf energy with irradiation, depending on the availability of credible surveillance capsule data as defined in RG 1.99, Revision 2. For vessel beltline materials that are not in the surveillance program or for locations with non-credible data, the Charpy upper-shelf energy is assumed to decrease as a function of fluence and copper content, as indicated in RG 1.99, Revision 2 (Position 1.2). When two or more credible surveillance data sets are available from the reactor, they may be used to determine the Charpy upper-shelf energy of the surveillance material. The surveillance data are then used in conjunction with the regulatory guide to predict the change in upper-shelf energy of the reactor vessel material due to irradiation (Position 2.2).

Copper content and initial upper shelf energy for extended beltline locations have not previously been reported to the NRC and are derived in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0. Material properties for traditional beltline locations are in general consistent with the 60-year current licensing basis neutron embrittlement evaluations that comply with 10 CFR 50 Appendix G; however, differences that result in increased margins to embrittlement limits (e.g., decrease in Copper wt% or increase in initial upper-shelf energy) are derived in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0.

The 72 EFPY RG 1.99, Revision 2 (Position 1.2) upper-shelf energy values of the vessel materials are predicted using the corresponding ¼T fluence projection, copper content of the materials provided in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0 and Figure 2 in RG 1.99, Revision 2. The predicted Position 2.2 upper-shelf energy values are determined for the reactor vessel materials that are contained in the surveillance program by using surveillance data along with the corresponding ¼T fluence projection.

The ¼T fluence projections are ¼T displacement per atom adjusted values for Oconee are reported in Table 3-6 for Unit 1, Table 3-7 for Unit 2 and Table 3-8 for Unit 3 within Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0 unless the attenuation of fluence from the inside wetted surface using RG 1.99, Revision 2, Equation (3), $f = f_{surf}\ (e^{-0.24\ x})$ exceeds the ¼T displacement per atom adjusted values. The projected upper-shelf energy values were calculated to determine if the Oconee Units 1, 2, and 3 beltline and extended beltline materials remain above the 50 ft-lb limit at 72 EFPY.

All ONS Unit 1 reactor vessel beltline and extended beltline plate and forging materials maintain an upper-shelf energy value greater than 50 ft-lbs at 72 EFPY (Table 3-6 of Proprietary Report ANP-3898P, Revision 0 and Table 3-6 of Non-Proprietary Report ANP-3898NP, Revision 0). All ONS Unit 1 reactor vessel beltline and extended beltline Linde 80 welds have upper-shelf energy values less than 50 ft-lbs at 72 EFPY and require an equivalent margins analysis to demonstrate that lower values of Charpy upper-shelf energy will provide margins of safety against fracture equivalent to those required by Appendix G of Section XI of the ASME Code.

All ONS Unit 2 reactor vessel beltline and extended beltline forging materials maintain an upper-shelf energy value greater than 50 ft-lbs at 72 EFPY (Table 3-7 of Proprietary Report ANP-3898P, Revision 0 and Table 3-7 of Non-Proprietary Report ANP-3898NP, Revision 0). All ONS Unit 2 reactor vessel beltline and extended beltline Linde 80 welds have upper-shelf energy values less than 50 ft-lbs at 72 EFPY and require an equivalent margins analysis to demonstrate that lower values of Charpy upper-shelf energy will provide margins of safety against fracture equivalent to those required by Appendix G of Section XI of the ASME Code.

All ONS Unit 3 reactor vessel beltline and extended beltline forging materials maintain an upper-shelf energy value greater than 50 ft-lbs at 72 EFPY (Table 3-8 of Proprietary Report ANP-3898P, Revision 0 and Table 3-8 of Non-Proprietary Report ANP-3898NP, Revision 0) with the exception of the reactor vessel inlet and outlet nozzle forgings and the transition forging. All reactor vessel beltline and extended beltline Linde 80 welds have upper-shelf energy values less than 50 ft-lbs at 72 EFPY. The reactor vessel inlet and outlet nozzle forgings, transition forging, and traditional beltline and extended beltline Linde 80 welds require an equivalent margins analysis to demonstrate that lower values of Charpy upper-shelf energy will provide margins of safety against fracture equivalent to those required by Appendix G of Section XI of the ASME Code.

Equivalent Margins Analysis: Linde 80 Welds

The ASME Section XI, acceptance criteria for Levels A through D Service Loadings for Oconee Units 1, 2, and 3 reactor vessel beltline and extended beltline Linde 80 welds are satisfied and are reported in Framatome reports BAW-2192, Revision 0, Supplement 1P-A, Revision 0, *Low Upper-Shelf Toughness Fracture Mechanics Analysis of Reactor Vessels of B&W owners reactor vessel working group for Levels A & B Service Loads* [Reference 4.2-13], and BAW-2178, Revision 0, Supplement 1P-A, Revision 0, *Low Upper-shelf Toughness Fracture Mechanics Analysis Of Reactor Vessels Of B&W Owners Reactor Vessel Working Group For Levels C & D Service Loads* [Reference 4.2-14]. These reports contain equivalent margins analyses for all Oconee Units 1, 2, and 3 Linde 80 welds identified as beltline and extended beltline material for 80 years.

Duke Energy has confirmed that the 80-year inside wetted surface fluence values reported in Table 3-1 of BAW-2178, Supplement 1P-A, and Table 3-1 of BAW-2192, Supplement 1P-A bound the 72 EFPY fluence values reported in Table 3-6, Table 3-7, and Table 3-8 of Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0, with the exception of ONS Unit 1 weld SA-1135, circumferential weld that connects the lower nozzle belt forging to the intermediate shell. Note that the equivalent margins analyses reported in the topical reports conservatively utilized 80-year fluence values of at least an order of magnitude higher than the 72 EFPY nozzle fluence reported in Table 3-6, Table 3-7, and Table 3-8 of Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0. In addition, the weld chemistry data reported in Table 3-1 of BAW-2178, Revision 0, Supplement 1P-A, and Table 3-1 of BAW-2192, Revision 0, Supplement 1P-A, Revision 0 is consistent with weld chemistry copper content reported in Table 3-6 of Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0 for ONS Unit 1; Table 3-7 of Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0 for ONS Unit 2; and Table 3-8 of Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0 for ONS Unit 3.

The level C and D limiting design transients reported in Section 4.3.2 of BAW-2178, Revision 0, Supplement 1P-A, Revision 0 are applicable to Oconee units and are based on a review of the Oconee ASME Section III reactor vessel design specification transients and the UFSAR Chapter 15 events relative to transients that would result in the highest thermal stresses coupled with pressure stresses relative to the equivalent margins analysis satisfies RG 1.161, June 1995 [Reference 4.2-15] with respect to Level C and D transient selection. The materials of construction, reactor vessel geometry, and range of explanatory variables for the J-R model (Section A.5 of BAW-2192, Revision 0, Supplement 1P-A, Revision 0) reported in the topical reports are confirmed to be applicable to Linde 80 beltline and extended beltline welds at Oconee Units 1, 2 and 3.

As such, Duke Energy has confirmed that Oconee Units 1, 2, and 3 are bounded by the topical reports BAW-2178, Revision 0, Supplement 1P-A, Revision 0, and BAW-2192, Revision 0, Supplement 1P-A, Revision 0 relative to fluence (with the exception of Oconee Unit 1 weld SA-1135), weld chemistry, geometry, materials of construction, design transients and the J-R model applicability. The results of the Oconee Units 1, 2, and 3 equivalent margins analysis as reported in BAW-2178, Revision 0, Supplement 1P-A, Revision 0 and BAW-2192, Revision 0, Supplement 1P-A, Revision 0, are summarized below as well as a reconciliation for ONS Unit 1 weld SA-1135.

Levels A & B Service Loadings

Reactor Vessel Shell Welds (Beltline)

The limiting reactor vessel shell weld is Oconee Unit 1 axial weld SA-1073.

- With factors of safety of 1.15 on pressure and 1.0 on thermal loading, the applied J-integral (J_1) is less than the J-integral of the material at a ductile flaw extension of 0.10 in. ($J_{0.1}$). The ratio $J_{0.1}/J_1$ is greater than the required value of 1.0.

- With a factor of safety of 1.25 on pressure and 1.0 on thermal loading, flaw extensions are ductile and stable since the slope of the applied J-integral curve is less than the slope of the lower bound J-R curve at the point where the two curves intersect.

- Oconee Unit 1 weld SA-1135 was evaluated in BAW-2192, Revision 0, Supplement 1P-A, Revision 0, at a fluence of 1.90 $x10^{18}$ n/cm^2 yet the fluence for weld SA-1135 is reported in Table 4.2.1-1 as $2.91x10^{18}$ n/cm^2. Therefore, an equivalent margins analysis reconciliation was performed for this weld at a fluence of $2.91x10^{18}$ n/cm^2. The ratio $J_{0.1}/J_1$ for weld SA-1135 decreased slightly, is greater than the required value of 1.0, and flaw extensions remain ductile and stable. The limiting weld remains Oconee Unit 1 axial weld SA-1073 as reported in BAW-2192, Revision 0, Supplement 1P-A, Revision 0.

<u>Reactor Vessel Transition Welds and Reactor Vessel Nozzle Welds (Extended Beltline)</u>

The limiting weld for ONS Units 1, 2, and 3 considering reactor vessel transition welds (upper and lower) and the reactor vessel inlet and outlet nozzle-to-shell welds is the reactor vessel outlet nozzle to nozzle belt forging weld.

- With factors of safety of 1.15 on pressure and 1.0 on thermal loading, the applied J-integral (J_1) is less than the J-integral of the material at a ductile flaw extension of 0.10 in. ($J_{0.1}$). The ratio $J_{0.1}/J_1$ is greater than the required value of 1.0.

- With a factor of safety of 1.25 on pressure and 1.0 on thermal loading, flaw extensions are ductile and stable since the slope of the applied J-integral curve is less than the slope of the lower bound J-R curve at the point where the two curves intersect.

<u>Levels C & D Service Loadings</u>

<u>Reactor Vessel Shell Welds (Beltline)</u>

The limiting weld among the Oconee reactor vessel shell welds is Oconee Unit 1 longitudinal weld SA-1073. The limiting transient for Level C & D service Loads is the hot leg LOCA.

- With a factor of safety of 1.0 on loading, the applied J-integral (J_1) for the limiting reactor vessel shell weld (Oconee Unit 1, SA-1073) is less than the lower bound J-integral of the material at a ductile flaw extension of 0.10 inch ($J_{0.1}$) with a ratio $J_{0.1}/J_1$ that is greater than the required value of 1.0.

- With a factor of safety of 1.0 on loading, flaw extensions are ductile and stable for the limiting reactor vessel shell weld (SA-1073) since the slope of the applied J-integral curve is less than the slopes of both the lower bound and mean J-R curves at the points of intersection.

- For weld SA-1073 it was demonstrated that flaw growth is stable at much less than 75% of the vessel wall thickness. It has also been shown that the remaining ligament is sufficient to preclude tensile instability.

Reactor Vessel Transition Welds and Reactor Vessel Nozzle Welds (Extended Beltline)

The reactor vessel inlet and outlet nozzle-to-shell welds were evaluated for Levels C and D Service Loadings. The limiting transient for Level C & D service loads is the hot leg LOCA. ONS Unit 1 upper transition weld SA-1135 along with the lower transition welds in each of the Oconee units reactor vessels are bounded by the limiting Unit 1 reactor vessel shell weld SA-1073. This conclusion remains valid considering the higher fluence associated with ONS Unit 1 weld SA-1135 reported in Section 4.2.1. As such, only the reactor vessel nozzle-to-shell welds are addressed herein.

- With a factor of safety of 1.0 on loading, the applied J-integral (J_1) for the reactor vessel nozzle-to-shell welds is less than the lower bound J-integral of the material at a ductile flaw extension of 0.10 inch ($J_{0.1}$). All ratios are greater than 1.0.

- With a factor of safety of 1.0 on loading, flaw extensions are ductile and stable for the reactor vessel nozzle-to-shell welds.

- For the reactor vessel nozzle-to-shell welds it was demonstrated that flaw growth is stable at much less than 75% of the vessel wall thickness. It has also been shown that the remaining ligament is sufficient to preclude tensile instability.

Equivalent Margins Analysis: ONS Unit 3 Reactor Vessel Outlet Nozzles and Transition Forging

As reported in Proprietary Report ANP-3898P, Revision 0, Table 3-8 and in Non-Proprietary Report ANP-3898NP, Revision 0, Table 3-8, the Oconee Unit 3 reactor vessel outlet nozzle forgings and Oconee Unit 3 transition forging have predicted 72 EFPY upper-shelf energy values that are either not defined (i.e., reactor vessel outlet nozzles) or are below 50 ft-lbs at 80 years (i.e., transition forging); all remaining beltline and extended beltline plate and forging materials for Units 1, 2, and 3 are above 50 ft-lbs at 72 EFPY. The Oconee Unit 3 reactor vessel outlet nozzle forgings (2) and the transition forging (1) were procured from Klockner-Werke, are extended beltline materials for SLR, and Charpy V-Notch (CVN) testing on the upper shelf was not required by the construction code for these forgings. Therefore, 72 EFPY equivalent margins analyses are required for the ONS Unit 3 reactor vessel outlet nozzle forgings and Oconee Unit 3 transition forging to demonstrate compliance with 10 CFR 50, Appendix G, for subsequent license renewal.

The analytical procedure used for the 72 EFPY equivalent margins analyses of the Oconee Unit 3 reactor vessel outlet nozzle forgings and transition forging are in accordance with ASME Section XI, Appendix K, 2017 Edition, with selection of design transients based on the guidance in RG 1.161 [Reference 4.2-15]. Selection of design transients and the methodology for calculation of applied J-integrals for the reactor vessel outlet nozzles and transition forging are consistent with the methodology used to calculate applied J-integrals for Linde 80 welds [Reference 4.2-13, Reference 4.2-14]. Both axial and circumferential flaws are postulated in the reactor vessel outlet nozzle and transition forgings as required by ASME Section XI. The J-integral resistance model is from NUREG/CR-5729 [Reference 4.2-16], i.e., reactor vessel J_d base metal models reported in Table 11, Charpy Model and CVN_P model. The J-integral resistance models (Charpy Model or CVN_P) that provides the most conservative J-integral resistance at a crack extension of 0.10 inches was selected for each evaluation. In order to utilize the NUREG/CR-5729 base metal J_d Charpy and CVN_P models, initial unirradiated upper shelf energy must be established for these extended beltline forgings procured from Klockner-Werke.

Unirradiated Upper Shelf Energy-Transition Forging and Reactor Vessel Nozzles

By letter dated February 27, 2014, NRC issued new Technical Specification pressure-temperature limits applicable to 54 EFPY for ONS [Reference 4.2-4]. As part of the review of the technical basis for proposed pressure-temperature curves, the Oconee Unit 3 transition forging unirradiated upper-shelf energy was established. As discussed in the SER, additional information (ADAMS Accession number ML13350A098) was provided to the NRC wherein the unirradiated upper-shelf energy of 59.2 ft-lbs in the weak direction is reported for the Oconee Unit 3 transition forging. This value is not a measured upper shelf energy but was obtained as follows.

Data taken from the actual reactor vessel certified material test report where limited CVN test data were performed at a single test temperature (+10 °F) to confirm that at least 30 ft-lbs was obtained for the material. CVN test data does not represent the impact energy upper-shelf (i.e., >95% shear), but is a mean value of 91.1 ft-lbs in the strong direction taken at a reduced percent shear fracture and is a conservative estimate of the upper-shelf energy in that the impact energy will increase as the percent shear fracture increases. This test report data was conservatively considered to be in the strong direction and the mean value of the reported CVN data at +10 °F was multiplied by 65% to obtain 59.2 ft-lbs in the weak direction.

Unirradiated upper-shelf energy for the Oconee reactor vessel outlet nozzle forgings procured from Klockner-Werke is not available from the certified material test report and was conservatively estimated at 78 ft-lbs in the strong direction and 52 ft-lbs in the weak direction based on the data reported in PWROG-17090-NP-A, Revision 0, *Generic Rotterdam Forging and Weld Initial Upper-Shelf Energy Determination* [Reference 4.2-17]. The mean minus 2 standard deviations upper-shelf energy, in the strong and weak directions, for Fried-Krupp Huttenwerke AG Forgings reported in Table 6 were conservatively assumed to apply to the Klockner-Werke forgings. This assumption is justified based on review of PWROG-17090-NP-A, Revision 0, Table 7, wherein use of actual Klockner-Werke measured data and statistical mean in the strong direction minus 2 standard deviations would result in an unirradiated upper-shelf energy greater than 78 ft-lbs.

The NUREG/CR-5729 reactor vessel J_d base metal Charpy model requires upper shelf energy at 72 EFPY as input. As such, a conservative fluence of 1.0E+18 n/cm^2 at the inside wetted surface was assumed at the reactor vessel nozzles and transition forging, with no attenuation, and the 72 EFPY upper-shelf energy values at the reactor vessel nozzles and transition forging were calculated using RG 1.99, Position 2.1. The NUREG/CR-5729 reactor vessel J_d CVN_p model requires unirradiated upper shelf energy, discussed above, and fluence (assumed at 1.0E+18 n/cm^2) as inputs. The estimate of 72 EFPY fluence of 1.0E+18 n/cm^2 is conservative relative to that reported in Table 4.2.1-3 for the Oconee reactor vessel outlet nozzles and the transition forging. The copper content of the Oconee Unit 3 reactor vessel nozzles and transition forging are reported in Reference 4.2-18.

Applicability of NUREG/CR-5729 J-Integral Resistance Models

The explanatory variables used to develop the reactor vessel J_d base metal models (Charpy and CVN_p) are reported in NUREG/CR-5729, Table 2. The ONS Unit 3 reactor vessel nozzle and transition forgings have material properties (unirradiated and at 72 EFPY - i.e., fluence, temperature, and CVN) within the range of these explanatory variables [Reference 4.2-18]. Therefore, NUREG/CR-5729 reactor vessel J_d base metal Charpy Model and CVN_p J-integral resistance models may be applied to the ONS Unit 3 reactor vessel nozzle and transition forgings for SLR.

Results of the equivalent margins analysis for the ONS Unit 3 reactor vessel outlet nozzles and transition forging are reported in [Reference 4.2-18] and are summarized below.

Levels A & B Service Loads

- The applied J-integral values for the assumed ¼-thickness inside-surface circumferential and axial flaws in the reactor vessel outlet nozzles (with the exception that a 3-inch flaw is postulated at the nozzle inside radius, which is substantially greater than the allowable planar flaw per the inservice inspection standards given in Table IWB-3512-1) and in the transition forging with a structural factor of 1.15 on pressure loading is within the material fracture toughness J-resistance at 0.1 inch crack extension. The ratio $J_{0.1}/J_1$ is greater than the required value of 1.0 for both the axial and circumferential postulated flaws in both the reactor vessel outlet nozzle and transition forging. The limiting flaw is an axial flaw in the reactor vessel outlet nozzle, since this location reports the limiting (lowest) $J_{0.1}/J_1$ ratio.

- With a structural factor of 1.25 on pressure and 1.0 on thermal loading, flaw extensions are ductile and stable since the slope of the applied J-integral curve is less than the slope of the lower bound J-R curve for crack extensions less than or equal to 0.10 inches.

Levels C & D Service Loads

Consistent with BAW-2178, Revision 0, Supplement 1P-A, Revision 0, only the limiting location (i.e., reactor vessel outlet nozzle forging), considering Levels A & B service loads, is evaluated for Levels C & D Service Loads.

- With a structural factor of 1.0 on loading, the applied J-integral (J_1) for the reactor vessel outlet nozzle forging postulated axial and circumferential flaws are less than the lower bound J-integral of the material at a ductile flaw extension of 0.10 inch ($J_{0.1}$) with a ratio $J_{0.1}/J_1$ is greater than the required value of 1.0.

- With a structural factor of 1.0 on loading, flaw extensions are ductile and stable for the reactor vessel outlet nozzle forging postulated circumferential and axial flaws since the slopes of the applied J-integral curves are less than the slopes of the lower bound J-R curves for crack extensions less than or equal to 0.10 inches.

- For the postulated reactor vessel outlet nozzle forging circumferential and axial flaws, flaw growth is stable at much less than 75% of the vessel wall thickness. Also, the remaining ligament is sufficient to preclude tensile instability by a large margin.

TLAA Disposition: 10 CFR 54.21(c)(1)(ii):

The Oconee Units 1, 2, and 3 upper-shelf energy analyses have been projected to the end of the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(ii).

4.2.3 PRESSURIZED THERMAL SHOCK

TLAA Description:

10 CFR 50.61(b)(1) [Reference 4.2-19] provides rules for protection against pressurized thermal shock events for pressurized water reactors. Licensees are required to perform an assessment of the projected values of reference temperature whenever a significant change occurs in projected values of RT_{PTS} or upon request for a change in the expiration date for the operation of the facility. For SLR, RT_{PTS} values are calculated at 72 EFPY for Oconee Units 1, 2, and 3.

TLAA Evaluation:

10 CFR 50.61(c) provides two methods for determining RT_{PTS}. These methods are also described in Section 1.1 (i.e., Position 1.1) and Section 2.1 (i.e., Position 2.1) of Regulatory Guide 1.99, Revision 2 [Reference 4.2-12]. Position 1.1 applies for material without credible surveillance data available and Position 2.1 is used for material with two or more credible surveillance data sets available. The RT_{PTS} values are calculated for both Positions 1.1 (all 3 units) and 2.1 (ONS Unit 3 only) by following the guidance in RG 1.99, Revision 2, using the copper and nickel content of the Units 1, 2, and 3 reactor vessel materials, and subsequent period of extended operation fluence projections at 72 EFPY.

Copper content, nickel content, and initial RT_{NDT}, including standard deviation for initial RT_{NDT}, for extended beltline locations have not previously been reported to the NRC and are derived in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0. Material properties for traditional beltline locations are in general consistent with the 60-year current licensing basis neutron embrittlement evaluations that comply with 10 CFR 50.61; however, differences that result in increased margins to embrittlement limits (e.g., decrease in Copper weight%) are derived in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0.

The 10 CFR 50.61(c) accepted methods and the material properties reported in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0 were used with the base metal/clad interface fluence values reported in Tables 4.2.1-1 through 4.2.1-3 above to calculate the following RT_{PTS} values for Oconee Units 1, 2, and 3 reactor vessel materials at 72 EFPY. The subsequent period of extended operation RT_{PTS} calculations are summarized in Table 5-10, Table 5-11, and Table 5-12 that are provided in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0 for Oconee Units 1, 2, and 3, respectively.

10 CFR 50.61(b)(2) establishes screening criteria for RT_{PTS} as 270°F for plates, forgings, and longitudinal welds and 300°F for circumferential welds. All of the ONS Units 1, 2, and 3 reactor vessel materials are below the RT_{PTS} screening criteria values of 270°F for base metal and longitudinal welds, and 300°F for circumferentially oriented welds through the subsequent period of extended operation. For Unit 1, the limiting materials are axial welds SA-1426 and SA-1430 with a projected value of RT_{PTS} at 72 EFPY of 207.2°F (screening criterion of 270°F). For Unit 2, the limiting material is circumferential weld WF-25 with a projected value of RT_{PTS} at 72 EFPY of

245.1°F (screening criterion of 300°F). For Unit 3, the limiting material is circumferential weld WF-67 with a projected value of RT_{PTS} at 72 EFPY of 240.2°F (screening criterion of 300°F).

The Oconee Units 1, 2, and 3 reactor pressure vessel materials remain below the 10 CFR 50.61 screening criteria at 72 EFPY.

TLAA Disposition: 10 CFR 54.21(c)(1)(ii):

The Oconee Units 1, 2, and 3 PTS analyses, utilizing 10 CFR 50.61 for traditional and extended beltline locations have been projected to the end of the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(ii).

4.2.4 PRESSURE-TEMPERATURE LIMITS

TLAA Description:

10 CFR 50 Appendix G requires that the reactor vessel be maintained within established pressure-temperature limits, including heatup and cooldown operations. These limits specify the maximum allowable pressure as a function of reactor coolant temperature. As the reactor vessel is exposed to increased neutron irradiation, its fracture toughness is reduced. The pressure-temperature limits must account for the anticipated reactor vessel fluence. The current ONS 54 EFPY pressure-temperature limits are based upon fluence projections for 60 years of plant operation [Reference 4.2-4]. Because they were based upon a fluence assumption of 60 years of operation, the pressure-temperature limits analyses meet the definition of 10 CFR 54.3(a) and have been identified as TLAA.

TLAA Evaluation:

Heatup and cooldown limit curves are calculated using the most limiting value of RT_{NDT} corresponding to the limiting material in the beltline region of the reactor vessel. The most limiting RT_{NDT} of the material in the beltline of the reactor vessel is determined by using the unirradiated reactor vessel material fracture toughness properties and estimating the irradiation induced shift (ΔRT_{NDT}). RT_{NDT} increases as the material is exposed to fast neutron irradiation; therefore, to find the most limiting RT_{NDT} at any time, ΔRT_{NDT} due to neutron radiation exposure associated with that time, plus a margin term, must be added to the original unirradiated RT_{NDT}. The resulting value, called the adjusted reference temperature, is used to determine pressure-temperature limit curves in accordance with the requirements of 10 CFR Part 50, Appendix G.

Pressure-temperature limits (54 EFPY) for the ONS units reactor vessels were developed in accordance with the requirements of 10 CFR Part 50, Appendix G, utilizing the analytical methods and flaw acceptance criteria of topical report BAW-10046A, Revision 2 [Reference 4.2-23], and ASME Code Section XI, Appendix G (1998 Edition with Addenda through 2000, which permits use of K_{Ic}). As reported in the ONS measurement uncertainty recapture SER [Reference 4.2-33], the EFPY applicability of the ONS 54 EFPY pressure-temperature limits was reduced as follows: ONS Unit 1 to 44.6 EFPY, ONS Unit 2 to 45.3 EFPY, and ONS Unit 3 to 43.8 EFPY. The approximate 10 EFPY reduction in the applicability of the pressure-temperature limit curves is not due solely to the small increase in fluence from measurement uncertainty recapture, but is primarily due to consideration of NRC RIS 2014-11, *"Information on Licensing Applications for Fracture Toughness Requirements for Ferritic Reactor Coolant Pressure Boundary Components,"* and the need to consider extended beltline materials [Reference 4.2-6]. As such, the EFPY applicability was reduced until the reactor vessel nozzle fluence reached 1.0E+17 n/cm^2 (E > 1.0 MeV).

In accordance with NUREG-2192 [Reference 4.2-26], Section 4.2.2.1.4, the P-T limits for the SPEO need not be submitted as part of the SLRA since the pressure-temperature limits are required to be updated through the 10 CFR 50.90 licensing process when necessary for pressure-temperature limits that are located in the Technical Specifications. The CLB will ensure that the pressure-temperature limits for the SPEO will be updated prior to exceeding the EFPY for which they remain valid.

Consistent with the Oconee 60-year license renewal application, NUREG-1723 [Reference 4.2-3], Section 4.2.4.3.1, Duke Energy prepared 72 EFPY (equivalent to 80 years of operation) pressure-temperature limits to demonstrate that the predicted operating window is sufficient to conduct heatups and cooldowns. The 72 EFPY pressure-temperature limits were developed with consideration of traditional and extended beltline materials (i.e., locations where reactor vessel neutron fluence > 1.0E+17 n/cm^2, E > 1 MeV) using the analytical methods and flaw acceptance criteria of topical report BAW-10046A, Revision 2 and ASME Code Section XI, Appendix G (2013 Edition, which permits use of K_{Ic}).

Copper content, nickel content, and initial RT_{NDT}, including standard deviation for initial RT_{NDT}, for extended beltline locations have not previously been reported to the NRC and are derived in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0. Material properties for traditional beltline locations are in general consistent with the 60-year current licensing basis neutron embrittlement evaluations that comply with 10 CFR 50 Appendix G; however, differences that result in increased margins to embrittlement limits (e.g., decrease in Copper weight %, decrease in initial RT_{NDT}, or decrease in margin) are derived in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0. The full set of adjusted reference temperatures for traditional and extended beltline locations are reported in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0.

Geometric discontinuities at the lower shell to lower transition forging and the nozzle belt forging to intermediate/upper shell (i.e., taper transition regions) were not explicitly modeled for the development of the ONS 72 EFPY pressure-temperature limits. However, to support 60-year pressure-temperature limits for a B&W designed plant, detailed 2-D ANSYS finite element models were prepared to evaluate the impact of taper transition on pressure-temperature limits. The taper transition region pressure-temperature limits were compared to the existing uncorrected 60-year pressure-temperature limits and the existing limits were found to be more restrictive.

Limiting materials relative to adjusted reference temperatures at 54 EFPY (measurement uncertainty recapture submittal maintained the 54 EFPY pressure-temperature limit curves and reduced their EFPY applicability) and 72 EFPY are reported in Table 4.2.4-1 for Oconee Unit 1, Table 4.2.4-2 for Oconee Unit 2, and Table 4.2.4-3 for Oconee Unit 3. The 72 EFPY adjusted reference temperatures are higher than the 54 EFPY adjusted reference temperatures, with the exception of the lower shell to transition forging, at all locations for Oconee Unit 1. The 72 EFPY adjusted reference temperatures are higher than the 54 EFPY adjusted reference temperatures at all locations for Oconee Unit 2 with the exception of the lower shell to transition forging weld and nozzle belt forging AMX-77; the reduction in adjusted reference temperature for AMX-77 is attributed to a reduction in the chemistry factor owing to an updated and revised copper content of forging AMX-77. The 72 EFPY adjusted reference temperatures are higher than the 54 EFPY adjusted reference temperatures at all locations for Oconee Unit 3 with the exception of the lower shell to transition forging weld and nozzle belt forging 4680. Reduction in adjusted reference temperature at 72 EFPY for nozzle belt forging 4680 is attributed to testing that was completed on a lower nozzle belt forging nozzle cutout thus significantly reducing the initial RT_{NDT} and margin term relative to what was reported for 54 EFPY. The 54 EFPY adjusted reference temperature reported for the lower shell to transition forging weld of <115°F conservatively includes consideration of the lower shell to transition forging weld, transition forging, and lower head.

As discussed in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898NP, Revision 0, it was confirmed that all three Oconee units will have sufficient operating windows to conduct heatups and cooldowns at 72 EFPY. In general, the ONS-1 and ONS-2, 72 EFPY pressure-temperature limits are slightly more restrictive than the 54 EFPY pressure-temperature limits over the entire reactor coolant system temperature range. For ONS-3, the 72 EFPY pressure-temperature limits are more restrictive than the 54 EFPY pressure-temperature limits between reactor coolant system temperatures of 60°F and approximately 170°F; above approximately 170°F the 54 EFPY pressure-temperature limits are more restrictive than the 72 EFPY pressure-temperature limits since the adjusted reference temperature for the controlling nozzle belt forging (4680) was lowered at 72 EFPY relative to 54 EFPY.

The peak inside surface fluence at the postulated inlet and outlet nozzle flaw location at 72 EFPY, considering all three Oconee units, is below 2.25E+17 n/cm^2, which is well below the screening criterion of 4.28E+17 n/cm^2 reported in PWROG-15109-NP-A [Reference 4.2-28]. However, the 72 EFPY pressure-temperature limits reported herein considered a shift in RT_{NDT} (ΔRT_{NDT}) for the reactor vessel outlet nozzle materials for all three units using RG 1.99 Revision 2 even though the projected shift in RT_{NDT} exceeded 25°F only for the ONS-3 outlet nozzles. The ONS-3 reactor vessel outlet nozzles were found to be limiting for a narrow temperature range (60°F to less than approximately 170°F) of the heatup and cooldown curves, and margin for ONS-3 may be regained by removing conservatisms in the 72 EFPY analysis (e.g., revision of heat transfer coefficients to be consistent with reactor coolant system flow during 1 and 2 pump operation at low reactor coolant system temperatures, reducing the heatup/cooldown rates at low reactor coolant system temperatures, and utilizing isothermal conditions to establish low temperature overpressure pressure-temperature limits) or utilizing provisions permitted by GL 88-11 [Reference 4.2-29], *"NRC Position on Radiation Embrittlement of Reactor Vessel Materials and its Impact on Plant Operations."*

> *"As plants age, it is expected that the operating window will continue to narrow and startup operations will become more difficult. [Regulatory Guide 1.99] Revision 2 accelerates this narrowing of the operating window. Licensees are encouraged to review system hardware and operating procedures to determine what changes could be made to reduce the likelihood of LTOP challenges. If changes can be implemented to demonstrate that the frequency of an LTOP event that would exceed [10 CFR 50] Appendix G limits is expected to be much less than one per reactor lifetime, then the staff would consider alternatives to Appendix G LTOP set points with appropriate justification of adequate safety from the standpoint of fracture prevention."*

<u>TLAA Disposition: 10 CFR 54.21(c)(1)(iii):</u>

Since the pressure-temperature limits will be updated through the 10 CFR 50.90 process at a later, more appropriate date, the effects of aging on the intended function(s) of the reactor vessels will be adequately managed for the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii). The ONS *Reactor Vessel Material Surveillance* AMP (B2.1.9, GALL-SLR XI.M31), ONS *Neutron Fluence Monitoring* AMP (B3.2, GALL-SLR X.M2), and plant Technical Specifications will ensure that updated pressure-temperature limits based upon updated adjusted reference temperature values will be submitted to the NRC for approval prior to exceeding the period of applicability for Units 1, 2, and 3.

Table 4.2.4-1: Limiting Adjusted Reference Temperature Values for ONS-1 Reactor Vessel

Vessel Item	Wall Location	Limiting RT_{NDT} (^oF) at 54 EFPY	Limiting RT_{NDT} (^oF) at 72 EFPY
Beltline Base Metal/ Axial Weld	1/4T	171.0 (SA-1493)	188.1 (SA-1426/1430)
	3/4T	132.9 (C2197-2)	139.8 (C2197-2)
Beltline Circ. Weld	1/4T	164.2 (SA-1229)	182.6 (SA-1229)
	3/4T	132.1 (WF-25)	151.1 (WF-25)
Nozzle Belt (at 12-inch Wall Thickness)	1/4T	111.9 (AHR-54)	122.1 (AHR-54)
	3/4T	83.5 (AHR-54)	104.9 (AHR-54)
Outlet Nozzle (Postulated Corner Flaw	(1)	(2)	81.6
Lower Shell to Transition Forging Weld	1/4T	< 115 (3)	72.4 (WF-9)
	3/4T	< 115 (3)	69.6 (WF-9)

Note (1): Inside wetted surface

Note (2): No shift assumed; initial RT_{NDT} at 60°F per BAW-10046A, Revision 2, and Table 3-1. Fluence at 54 EFPY < 1.0E+17 n/cm^2 (E > 1.0 MeV)

Note (3): ANP-3127Q1NP-- Response to NRC Request for Additional Information Regarding License Amendment Request to Update Pressure-Temperature Limit Curves for Oconee Units 1, 2, and 3, (ADAMS Accession Number ML13259A120)

Beltline Circ. Weld	1/4T	195.6 (WF-67)	219.9 (WF-67)
	3/4T	162.1 (WF-70)	183.4 (WF-70)
Nozzle Belt (at 12-inch Wall Thickness)	1/4T	106.3 (4680)	106.0 (4680)
	3/4T	88.8 (4680	87.0 (4680)
Outlet Nozzle (Postulated Corner Flaw)	(1)	(2)	118.4
Lower Shell to Transition Forging Weld	1/4T	< 115 (3)	68.1 (WF-169-1)
	3/4T	< 115 (3)	65.8 (WF-169-1)

Note (1): Inside wetted surface

Note (2): No shift assumed; initial RTNDT at 60°F per BAW-10046A, Revision 2, Table 3-1. Fluence at 54 EFPY < 1.0 E+17 n/cm^2 (E > 1.0 MeV)

Note (3): ANP-3127Q1NP-- Response to NRC Request for Additional Information Regarding License Amendment Request to Update Pressure-Temperature Limit Curves for Oconee Units 1, 2, and 3, (ADAMS Accession Number ML13259A120). Includes consideration of lower shell to Transition forging weld, transition forging, and lower head.

4.2.5 LOW TEMPERATURE OVERPRESSURE PROTECTION

TLAA Description:

Low temperature overpressure protection systems at Oconee Units 1, 2, and 3 are required by Technical Specification Limited Condition for Operation 3.4.12 [Reference 4.2-30]. A pressurizer power operated relief valve provides the automatic relief capability during the design basis mass input and the design basis heat input transients to automatically prevent the reactor coolant system pressure from exceeding the pressure-temperature limit curves based on 10 CFR 50, Appendix G. Low temperature overpressure system setpoints and low temperature overpressure pressure-temperature limits are based on the pressure-temperature limit calculation which is a TLAA.

TLAA Evaluation:

The low temperature overpressure enable temperature has been determined for 72 EFPY in accordance with the requirements of ASME Section XI, Appendix G and is 269.2°F for ONS-1, and 307°F for Units 2 and 3, which are below the current Technical Specification requirement of 325°F. In MODE 3 with reactor coolant system cold leg temperatures less than 325°F, Technical Specification Limiting Condition of Operation 3.4.12 requires an operable power operated relief valve with a lift setpoint of < 535 psig for each unit. Calculation of a revised power operated relief valve setpoint and low temperature overpressure pressure-temperature limits will be performed at a later time and shall be consistent with ASME Section XI, Appendix G (2013 Edition or later), G-2215, as supplemented by consideration of applicable low temperature overpressure events and low temperature overpressure methodology as described in Duke Energy's license amendment requests for 33 EFPY pressure-temperature limits [Reference 4.2-31 and 4.2-32].

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

Since the low temperature overpressure enable temperature, power operated relief valve setpoint, and low temperature overpressure pressure-temperature limits will be updated through the 10 CFR 50.90 process at a later, appropriate date, the effects of aging on the intended function(s) of the ONS reactor vessels will be adequately managed for the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii) The ONS *Reactor Vessel Material Surveillance* AMP (B2.1.19, GALL-SLR XI.M31) and plant Technical Specifications will ensure that updated low temperature overpressure enable temperature, power operated relief valve setpoint, and low temperature overpressure pressure-temperature limits, and pressure-temperature limits, based upon updated fluence and adjusted reference temperature values, will be submitted to the NRC for approval prior to exceeding the period of applicability for Units 1, 2, and 3.

4.3 METAL FATIGUE

Fatigue analyses are required on components designed to ASME, Section III, Class 1 and USAS (ANSI) B31.7. In addition, certain other codes such as ASME Section III, Class 2 and 3, USAS (ANSI) B31.1, and ASME Section VIII Division 2, may require a fatigue analysis or assume a stated number of full-range thermal and displacement transient cycles. NUREG-2192 also provides examples of components that are likely to have fatigue TLAAs within the CLB that would require evaluation for the SPEO. Searches were performed to identify these and any other potential fatigue TLAAs within the CLB for Oconee Units 1, 2 and 3. Each of the potential TLAAs were evaluated against the six TLAA screening criteria specified in 10 CFR 54.3. The TLAA evaluated were determined to meet the criteria of 10 CFR 54.21 and are within the scope of SLR. Those that were identified as fatigue TLAAs are evaluated using 80-year transient cycle and cumulative usage projections, described is Section 4.3.1, and summarized in the following subsections:

- Transient Cycle Projections for 80 Years (Section 4.3.1)
- Class 1 Fatigue Analyses (including fatigue waivers) (Section 4.3.2)
- Non-Class 1 Fatigue Analyses (Section 4.3.3)
- Environmentally-Assisted Fatigue (Section 4.3.4)
- Analytical Evaluation of Flaws (Section 4.3.5)
- Weld Overlay Fatigue Analyses (Section 4.3.6)

4.3.1 TRANSIENT CYCLE PROJECTIONS FOR 80 YEARS

Transient cycle projections for 80 years are not themselves time-limited aging analysis for Oconee. Transient cycle projections do form what is considered to be the time-limited aspect of various fatigue analysis. Fatigue analyses are based upon numbers and amplitudes of thermal and pressure transients. UFSAR Tables 5-2, “Transient Cycles for RCS Components Except Pressurizer Surge Line” and UFSAR Table 5-23, “Operating Design Transient Cycles for Pressurizer Surge Line” [Reference 4.3-1] list the design transients and associated design cycles. The intent of the design basis transient definitions is to bound a wide range of possible events with the varying ranges of severity in temperature and pressure. CLB fatigue analyses are based upon the original number of design cycles (40 years) and are postulated to bound 60 years of service. Since the fatigue analyses are based upon the number of cycles postulated to bound 60 years of service, these fatigue analyses are considered TLAAs and require disposition for the SPEO.

A review of *Fatigue Monitoring* program data was performed to identify the number of cumulative cycles for each transient type that occurred at Units 1, 2, and 3 up to May 6, 2019. Baseline cycle counts were projected to an 80-year operating life based on the actual accumulation history since December 2011 (December 2011 through May 6, 2019). They do not represent a revision of the design basis. These transient cycles and projections are documented in Table 4.3.1-1, *“80-year*

Transient Cycle Projections." As shown in industry operating experience for most nuclear power plants, accumulation of transients have decreased over time. Therefore, transient projections based on operating experience provide an appropriate basis for future projections. Each monitored design transient was evaluated to determine the maximum rate of accumulation of the individual transients per unit. The maximum rate of accumulation was used to extrapolate the projected number of future occurrences beginning May 6, 2019 and ending at 60 years of operation. The 60-year projections are scaled by the maximum rate of accumulation determined for each of the design transients for twenty additional years of operation (80 years). The end of 80-year life is February 2053 for Unit 1, October 2053 for Unit 2, and July 2054 for Unit 3.

Three components at Oconee have a reduced set of analyzed operating cycles for 60 years of operation that will remain valid for 80 years of operation. These components are the pressurizer surge line elbow, the main steam penetrations, and the main feedwater penetrations. The pressurizer surge line elbow is addressed in Section 4.3.4 of the application. The main steam and main feedwater penetrations are addressed in Section 4.6.3 of the application. As part of subsequent license renewal these components were re-analyzed and the 80-year projections are bounded by the refined allowable transient cycles for these components. The *Fatigue Monitoring* aging management program will track the governing transients for these penetrations, using the refined, current operating period cycle count and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

As shown in Table 4.3.1-1, the projected cycles for 80 years of plant operation are less than the 40-year design cycles, or CLB cycles, used in the fatigue analyses. Therefore, the design cycles originally projected for 40-year operation bound the 80-year projected operating cycles. The basis for assessing and projecting design transient cycles to the end of the subsequent period of operation is not a TLAA because the basis does not involve assessment of an applicable aging effect and does not meet criterion 2 for defining TLAAs in 10 CFR 54.3(a). The evaluation of fatigue is a TLAA for those major components and piping exposed to reactor coolant in the reactor coolant system pressure boundary, including the reactor vessel and the reactor vessel internals, as well as fatigue related to the containment pressure boundary.

Two major plant changes have occurred since initial license renewal - reactor vessel closure head replacements and once-through steam generator replacements:

- The design of the reactor vessel closure head replacements, installed in 2003 and 2004, were based upon the projected 60-year design cycles which are bounded by the 40-year design cycles.
- The design of the replacement once-through steam generators, also installed in 2003 and 2004, were based upon the projected 60-year design cycles which are bounded by the 40-year design cycles.

For each instance described in the following sections where the values in Table 4.3.1-1 are used in the disposition of the TLAA, in order to ensure the design cycles remain bounding in the component fatigue analyses, the *Fatigue Monitoring* AMP will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits. A condition report will be initiated based upon an administrative limit of 80% of the fatigue cycles or if the minimum time for any transient event total occurrence projection to reach the allowable is less than three years.

Table 4.3.1-1: 80-Year Transient Cycle Projections

Transient Description	Observed Transient Cycles (5/6/19)			Projected Cycles for 80 years	Percent of Design Cycles	CLB cycles (40 year design cycles)
	Unit 1	Unit 2	Unit 3			
Heatup (1A)	124	125	100	189	52.8	360(1)
Cooldown (1B)	125	131	98	197	54.8	360(1)
Stratification Reactor Coolant Pump > 120 (1AP4)	31	25	24	88	39.9	220
Stratification Reactor Coolant Pump < 120 (1AP5)	4	5	5	11	25	43
Stratification Hot Leg: Pressurizer dT > 250F (1BP1)	24	14	15	70	41.2	170
Stratification Hot Leg: Pressurizer dT < 250F (1BP2)	10	16	14	34	18	190
0 – 15% Power (2A)	234	194	178	335	23.2	1440
15 – 0% Power (2B)	149	113	109	220	15.3	1440
Step Up (7A) (Turbine Trip)	6	5	2	8	5	160
Step Down (7B) (Load Rejection)	21	18	10	27	18	150

Table 4.3.1-1: 80-Year Transient Cycle Projections

Transient Description	Observed Transient Cycles (5/6/19)			Projected Cycles for 80 years	Percent of Design Cycles	CLB cycles (40 year design cycles)
	Unit 1	Unit 2	Unit 3			
Reactor Trip with Loss Reactor Coolant Flow (8A)	4	1	0	7	17	40(1)
Reactor Trip with Turbine Trip, no runback (8B)	28	17	15	48	29.7	160(1)
Reactor Trip w/ Loss of Main FW Flow (8C)	29	19	13	47	52	90(1)
Other Reactor Trips (8D)	61	49	59	102	83.5	122(1)
Manual High Pressure Injection Actuation (8E)	20	19	12	29	26.5	70
Rapid De-pressurization (9)	0	0	2	27	67	40(1)
Reactor Coolant Flow Changes, Loss Reactor Coolant Pumps (10)	11	3	5	12	3	412
Rod Withdrawal (11)	0	0	0	0	0	40
Rod Drop (14)	16	19	10	28	46.5	60
Loss of Power (15)	1	2	1	3	7	40

Table 4.3.1-1: 80-Year Transient Cycle Projections

Transient Description	Observed Transient Cycles (5/6/19)			Projected Cycles for 80 years	Percent of Design Cycles	CLB cycles (40 year design cycles)
	Unit 1	Unit 2	Unit 3			
Steam Line Failure (16)	0	0	0	0	0	1
Loss of Feedwater to one A Once Through Steam Generators (17A)	12	3	3	16	52	30
Loss of Feedwater to one B Once Through Steam Generators (17B)	0	0	1	1	13	10
Loss of Coolant (Faulted) (21)	0	0	0	0	0	1
High Pressure Injection System Test (performed <200F) (22A)	4	2	8	11	27	40

Note 1: These transients have a reduced set of analyzed transient cycles for 60 years for the pressurizer surge line, main steam penetrations and main feedwater penetrations. The pressurizer surge line elbow is addressed in Section 4.3.4 and the main steam and main feedwater penetrations are addressed in Section 4.6.3.

4.3.2 CLASS 1 COMPONENT FATIGUE EVALUATIONS

Class 1 fatigue analyses were originally performed in accordance with the ASME Code, Section III for reactor coolant system vessels supplied by B&W, USAS B31.7, Class I for B&W supplied piping, and USAS B31.7, Class II for Bechtel supplied piping in ancillary systems attached to B&W supplied components and extending to the first outboard isolation valve. In accordance with the ONS UFSAR, Section 3.2.2.2, reactor coolant system Class 1 piping (USAS B31.7 Class I and II) was redesigned to the 1983 ASME Section III Code during the steam generator replacement project. The reactor coolant pump casings were designed, fabricated, inspected and tested to meet the intent of the ASME Boiler and Pressure Vessel Code, Section III, for Class A vessels, but are not code stamped. The specific ONS reactor coolant system component design codes are reported in the Oconee UFSAR, Table 5-4. Each Class 1 fatigue analysis must demonstrate that the CUF for the component will not exceed the code design limit of 1.0 when the component is exposed to all postulated normal and upset design transients.

During the initial license renewal period, several changes occurred that potentially impact the TLAA evaluation for the reactor coolant system Class 1 components. These changes are listed here and discussed within the appropriate sections that follow:

- Reactor vessel closure head replacement in 2003-2004 (Units 1, 2, and 3)
- Steam generator replacement 2003-2004 (Units 1, 2, and 3)
- Alloy 600 primary water stress corrosion cracking mitigation including nozzle repair and/or full structural weld overlay for pressurizer nozzles, pressurizer spray, and pressurizer safety/relief nozzles, both surge line nozzles, and the reactor coolant system branch attached piping.
- Measurement uncertainty recapture (ONS 1, 2, and 3) [References 4.3-3 and 4.3-26].

The following subsections characterize the fatigue TLAA evaluation results for the safety class 1 components:

- Reactor vessel (Section 4.3.2.1)
- Reactor vessel internals (Section 4.3.2.2)
- Once through steam generators (Section 4.3.2.3)
- Reactor coolant pumps (Section 4.3.2.4)
- Pressurizer (Section 4.3.2.5)
- Control rod drive mechanism housing (Section 4.3.2.6)

- Reactor coolant system piping and connected lines (Section 4.3.2.7)
- Pressurizer surge line (Section 4.3.2.8)

In addition, a detailed fatigue evaluation is not required if components conform to the waiver of fatigue requirements per ASME Code, Section III. These fatigue waivers depend on the numbers of anticipated transients over the life of the plant and therefore constitute TLAAs. Fatigue waivers are discussed separately in Section 4.3.2.9.

4.3.2.1 Reactor Vessel

TLAA Description:

Reactor vessel fatigue evaluations were performed to the requirements of ASME Code, Section III, Class A, 1965 Edition through Summer 1967 Addenda (Oconee Units 1, 2, and 3) for the vessel shell and lower head for all three Oconee units. The original reactor vessel closure heads were replaced at all three Oconee units utilizing the ASME Code, Section III, 1989 Edition with no addenda [Reference 4.3-11]. Fatigue analyses that consider transient cycles that occur over the life of the plant constitute TLAA that must be evaluated for subsequent license renewal.

TLAA Evaluation:

The transient cycles for the reactor vessel were projected for 80 years of operation as discussed in Section 4.3.1 and the count found to be adequate for the SPEO. As reported in Table 4.3.1-1, the 40-year design cycles (CLB cycles) are postulated to bound 80 years of plant operation. The *Fatigue Monitoring* AMP (B3.1) will continue to monitor all design transients. The program will assure that appropriate actions are taken to ensure that the design CUF values remain less than unity during the SPEO.

During the initial LR period, several changes occurred that potentially impact the TLAA evaluation for the reactor coolant system class 1 components. The reactor vessel was involved in two of these changes. The first change was the reactor vessel closure head replacement in 2003 and 2004. The replacement closure heads were designed and fabricated by B&W Canada. The sizing calculations and the stress and fatigue analysis were performed to ASME Code, Section III, Class 1, 1989 Edition with no Addenda. These analyses utilize the original 40-year design transient cycles to calculate a fatigue CUF. A second change is the ongoing pursuit of a measurement uncertainty recapture power uprate. The revised operating conditions associated with the uprate were reviewed for impacts to the existing design basis analyses for the reactor vessel, specifically the reactor vessel shells, lower head and replacement closure heads [Reference 4.3-3]. No impacts were found. No changes in the reactor coolant system functional design or operating pressures are included in the design of the uprate. The effects of operating temperature changes (T_{hot}/T_{cold}) are within design limits. The measurement uncertainty recapture power uprate conditions are bounded by the design conditions. The *Fatigue Monitoring* program (B3.1) will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The effects of fatigue on the intended functions of the reactor vessels will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) for the SPEO.

4.3.2.2 Reactor Vessel Internals

TLAA Description:

As described in BAW-2248A [Reference 4.3-4], Sections 2.0 and 4.5.1, the reactor vessel internals were designed and constructed prior to the development of ASME Code requirements for core support structures. Because of the lack of specific ASME design rules for core support structures at the time of design and construction of the Oconee reactor vessel internals, Section III of the ASME code was used as a guideline for the design criteria for the reactor vessel internals. Qualification of the internals was accomplished by both analytical and test methods. The only specific fatigue analyses performed in the original design were those that addressed flow-induced vibration reported in BAW-10051, Revision 1 [Reference 4.3-7], Section 4.7.1.2, *Reactor Vessel Internals Flow Induced Vibration Endurance Limits*, herein, addresses this Oconee reactor internals TLAA issue.

After operations began, Inservice Inspection (ISI) at the three Oconee nuclear plants during 1981 and 1982 revealed failed bolts in the joint fastening the lower end of the reactor vessel thermal shield to the lower grid assembly. These bolts were made of A-286 material. The failed bolts were replaced with X-750 bolting and fatigue analyses were performed for the replacement bolts as reported in BAW-1843PA [Reference 4.3-5]. This topical report summarize fatigue analyses performed to the ASME code (Section III, Subsection NG) including both high cycle fatigue (flow-induced vibration) and low cycle fatigue (design transients). The ASME Section III fatigue evaluations for internal replacement bolting were evaluated in BAW-2248A [Reference 4.3-4] for 60-years and are addressed here for SLR. The low cycle fatigue (design transients) of the replacement bolting is the only reactor internals component discussed in this section.

TLAA Evaluation:

The transient cycles for the reactor internals replacement bolting were projected for 80 years of operation as discussed in Section 4.3.1 and the count found to be adequate for the SPEO. As reported in Table 4.3.1-1, the 40-year design cycles (CLB cycles) are postulated to bound 80 years of plant operation. The *Fatigue Monitoring* AMP (B3.1) will continue to monitor all design transients. The program will assure that appropriate actions are taken to ensure that the design CUF values remain less than unity during the SPEO.

The contribution of flow-induced vibration to the total CUF for replacement bolting, as first reported in BAW-1843PA, was extended to 80-years consistent with the methodology used for the 60-year evaluation using Crandall’s method, and is reported in Proprietary Report ANP-3899P, Revision 0 and in Non-Proprietary Report ANP-3899NP, Revision 0 [References 4.3-6 and 4.3-7 respectively]. With consideration of contributions from thermal fatigue and flow-induced vibration the total CUF of reactor vessel internals replacement bolting remains less than unity during the SPEO.

Therefore, the fatigue analyses for the reactor internals replacement bolting are projected to have adequate margin in order to remain valid for the SPEO. In order to ensure the design cycles remain bounding for the reactor internals replacement bolting, the *Fatigue Monitoring* AMP (B3.1) will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The effects of fatigue on the intended functions of the reactor vessel internals bolting have been projected to the end of the SPEO and adequate margin exists. The *Fatigue Monitoring* AMP (B3.1) will continue to monitor reactor coolant system design transients for the SPEO. Therefore, This TLAA is dispositioned in accordance with 10 CFR 54.21(c)(iii).

4.3.2.3 Once Through Steam Generators

TLAA Description:

The original steam generators at Oconee have been replaced with new steam generators. The original Unit 1 steam generators were replaced in 2003 during the 1EOC21 refueling outage. Units 2 and 3 original steam generators were replaced in 2004 during the 2EOC20 and 3EOC21 refueling outages. The replacement once though steam generators were fabricated by BWC, Limited. The materials used in the construction of the replacement once though steam generators were equivalent or superior to the original once though steam generators design with regard to fabricability, thermal expansion differentials, and corrosion resistance. The replacement steam generators are designed and fabricated in accordance with the 1989 edition, no addenda of the ASME Boiler and Pressure Vessel Code Section III [Reference 4.3-11]. The fatigue evaluations of the steam generators were performed to the requirements of ASME Code, Section III. These analyses utilize the 40-year design transient cycles to obtain usage factors.

TLAA Evaluation:

The transient cycles for the replacement once though steam generators were projected for 80 years of operation as discussed in Section 4.3.1 and the count found to be adequate for the SPEO. As reported in Table 4.3.1-1, the 40-year design cycles (CLB cycles) are postulated to bound 80 years of plant operation. Therefore, the fatigue analyses for the steam generator components are projected to have adequate margin in order to remain valid for the SPEO. In order to ensure the design cycles remain bounding in the steam generator component fatigue analyses, the *Fatigue Monitoring* AMP (B3.1) will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The effects of fatigue on the intended functions of the steam generator components will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) for the SPEO. Therefore, this TLAA is dispositioned in with 10 CFR 54.21(c)(1)(iii).

4.3.2.4 Reactor Coolant Pumps

TLAA Description:

The reactor coolant pumps for Unit 1 are Westinghouse Type 93A and Units 2 and 3 are Bingham-Willamette Pumps. The reactor coolant pump casings were designed to ASME Code, Section III, Class A, 1965 Edition, 1967 Addendum, but are not Code stamped [Reference 4.3-11]. Fatigue evaluations of the reactor coolant pumps were performed to various editions of the ASME Code, Section III.

TLAA Evaluation:

The transient cycles for the reactor coolant pumps were projected for 80 years of operation as discussed in Section 4.3.1 and the count found to be adequate for the SPEO. As reported in Table 4.3.1-1, the 40-year design cycles (CLB cycles) are postulated to bound 80 years of plant operation. Therefore, the fatigue analyses for the reactor coolant pumps are projected to have adequate margin in order to remain valid for the SPEO. In order to ensure the design cycles remain bounding in the reactor coolant pump fatigue analyses, the *Fatigue Monitoring* AMP (B3.1) will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The effects of fatigue on the intended functions of the reactor coolant pump components will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) for the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

4.3.2.5 Pressurizer

TLAA Description:

Units 1, 2, and 3 each have a 1,500 ft^3 cylindrical pressurizer. The fatigue evaluations of the pressurizer were performed to the requirements of ASME Code, Section III, Class A, Summer 67 Addendum [Reference 4.3-11]. The fatigue analyses associated with the pressurizer utilize 40-year design cycles as inputs to obtain usage factors.

Additionally, at the time of steam generator replacement, code reconciliation and reanalysis to ASME Section III, Subsection NB, 1983, no addenda was performed for the pressurizer relief valve nozzles.

TLAA Evaluation:

The transient cycles for the pressurizer components were projected for 80 years of operation as discussed in Section 4.3.1 and the count found to be adequate for the SPEO. As reported in Table 4.3.1-1, the 40-year design cycles (CLB cycles) are postulated to bound 80 years of plant operation. Therefore, the fatigue analyses for the pressurizer components are projected to have adequate margin in order to remain valid for the SPEO. In order to ensure the design cycles remain bounding in the pressurizer component fatigue analyses, the *Fatigue Monitoring* AMP (B3.1) will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The effects of fatigue on the intended functions of the pressurizer components will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) for the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

4.3.2.6 Control Rod Drive Mechanism Housing

TLAA Description:

The control rod drive mechanisms at all three Oconee units were replaced with Type C drives with the reactor vessel closure head replacements. The design of the control rod drive mechanism pressure boundary has been shown to satisfy all of the applicable design criteria for the replacement control drive mechanisms and the requirements of the ASME Boiler and Pressure Vessel Code, 1968 Edition with Addenda through the Summer of 1970 for all of the pressure boundary items except for the “Quick Vent” and “Hydraulic Closure.” The “Quick Vent” meets the requirements of its design code; the ASME Boiler and Pressure Vessel Code, Section III, 1974 with no Addenda. The “Hydraulic Closure” meets the requirements of its design code; the ASME Boiler and Pressure Vessel Code, Section III, 1980 with Addenda through Summer of 1982.

The replacement control rod drive mechanisms were spare control rod drive mechanisms in Framatome’s inventory that were available from plants that were not completed. These replacement control rod drive mechanisms were structurally assessed against the original design reports and were shown to be acceptable for fatigue by meeting exemption from fatigue analysis requirements per paragraph N-415.1 of the ASME Code Section III – 1968 edition with Summer 1970 Addenda. Exemption from fatigue analyses that consider design transient cycles that occur over the life of the plant constitute TLAA that must be evaluated for SLR.

TLAA Evaluation:

The transient cycles for the control rod drive mechanism housings were projected for 80 years of operation as discussed in Section 4.3.1 and the count found to be adequate for the SPEO. As reported in Table 4.3.1-1, the 40-year design cycles (CLB cycles) are postulated to bound 80 years of plant operation. Therefore, the exemption from fatigue analyses for the control rod drive mechanism housings are projected to have adequate margin in order to remain valid for the SPEO. In order to ensure the design cycles remain bounding in the control rod drive mechanism housing fatigue analyses, the *Fatigue Monitoring* AMP (B3.1) will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

<u>TLAA Disposition: 10 CFR 54.21(c)(1)(iii):</u>

The effects of fatigue on the intended function(s) of the ONS Type C control rod drive mechanisms will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) for the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

4.3.2.7 Reactor Coolant System Piping and Connected Lines

<u>TLAA Description:</u>

The design cycles originally projected for a 40 year operating life for the reactor coolant system piping and connected lines is the focus of this TLAA. Reactor coolant system piping, excluding the pressurizer surge line and spray line, was originally designed to USAS (ANSI) B31.7, 1968 with Errata through June 1968. The pressurizer surge line was originally analyzed to ASME Code, Section III, 1977 Edition through Summer 1979 Addenda and then reanalyzed to ASME Section III, 1986 Edition in response to NRC Bulletin 88-11 [Reference 4.3-8]. The pressurizer surge line is addressed in Section 4.3.2.8. The original pressurizer spray line was redesigned and evaluated to ASME Section III, 1986 Edition. The redesign eliminated the welded attachments on the piping by relocating some of the pipe supports. A new bypass valve and isolation valve were also added as well as replacement of the auxiliary spray to main spray tee, which was a high fatigue location. The replacement of the steam generators necessitated the reanalysis of the main reactor coolant piping. For the reactor coolant system piping, a design code change was reconciled and the main reactor coolant system piping analysis was updated to ASME Section III, Subsection NB, 1983, no addenda from ANSI B31.7, Class 1, 1968 with Errata through June 1968.

Additionally at the time of steam generator replacement, code reconciliation and reanalysis to ASME Section III, Subsection NB, 1983, no addenda was done for the following reactor coolant system piping branch lines that were reanalyzed up to the first isolation valve from the main reactor coolant system piping.

1. High Pressure Injection (Emergency Injection)
2. High Pressure Injection (Normal Injection)
3. High Pressure Injection (Letdown)
4. Low Pressure Injection (Decay Heat Removal Drop-line)
5. Low Pressure Injection (Core Flood)
6. Reactor Coolant Drains

<u>TLAA Evaluation:</u>

The transient cycles for the reanalyzed reactor coolant system piping components, including various branch lines, were projected for 80 years of operation as discussed in Section 4.3.1 and the count found to be adequate for the SPEO. As reported in Table 4.3.1-1, the 40-year design cycles (CLB cycles) are postulated to bound 80 years of plant operation. Therefore, the fatigue analyses for the reactor coolant system piping components, including various branch lines, are projected to have adequate margin in order to remain valid for the SPEO. In order to ensure the design cycles remain bounding in the reactor coolant system piping components and connected lines pressurizer component fatigue analyses, the *Fatigue Monitoring* AMP (B3.1) will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The effects of fatigue on the intended functions of the reactor coolant system piping and connected lines will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) for the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

4.3.2.8 Pressurizer Surge Line

TLAA Description:

Specific industry issues associated with fatigue due to thermal stratification were identified for the pressurizer surge line in NRC Bulletin 88-11 [Reference 4.3-8], *Pressurizer Surge Line Thermal Stratification.* Original design analyses of the surge line did not include stratified flow loading conditions. An assessment of stratification effects on the pressurizer surge line was necessary to ensure piping integrity and code compliance. NRC Bulletin 88-11, issued in December 1988, requested utilities to establish and implement a program to confirm the integrity of the pressurizer surge line. The program required both visual inspection of the surge line and demonstration that the design requirements of the surge line are satisfied, including the consideration of stratification effects. The demonstration was an ASME Code, Section III fatigue analysis to account for thermal stratification. The analysis uses time-limited assumptions such as thermal and pressure transients and operating cycles for the licensed life of the plant. In addition to the focus on this piping related to the Bulletin, the surge line is also identified as a fatigue sentinel location for environmentally assisted fatigue which is discussed in SLR-ONS-TLAA-0306P/NP, Revision 0 (Enclosure 5, Attachment 3 for the Proprietary version and Enclosure 4, Attachment 3 for the Non-Proprietary version).

TLAA Evaluation:

The transient cycles for the reanalyzed pressurizer surge line were projected for 80 years of operation as discussed in Section 4.3.1 and the count found to be adequate for the SPEO. As reported in Table 4.3.1-1, the 40-year design cycles (CLB cycles) are postulated to bound 80 years of plant operation. Therefore, the fatigue analyses for the pressurizer surge line is projected to have adequate margin in order to remain valid for the SPEO. In order to ensure the design cycles remain bounding in the pressurizer surge line fatigue analyses, the *Fatigue Monitoring* AMP (B3.1) will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The effects of fatigue on the intended function(s) of the pressurizer surge line as established as a result of reanalysis for I E Bulletin 88-11 will be adequately managed by the *Fatigue Monitoring* aging management program (B3.1) for the subsequent period of extended operation. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

4.3.2.9 Class 1 Component Fatigue Waiver Evaluations

TLAA Description:

The 1983 ASME Section III, Subsection NB-3630 allows for Class 1 piping to be exempt from Class 1 analysis requirements if the piping meets all the conditions specified in subparagraph NB-3630(d)(2)(a) through (e) [Reference 4.3-11]. A detailed fatigue evaluation is not required if components conform to specific waiver of fatigue requirements. The 40-year design cycles are utilized to classify piping to be exempt from Class 1 analysis. ASME Code Section III, Class 1 component fatigue waivers are discussed in this section.

The following reactor coolant system piping components, reanalyzed to ASME Section III as discussed in Section 4.3.2.7, contain fatigue waivers.

1. Oconee Units 1, 2 and 3 pressurizer spray nozzles
2. Oconee Units 1, 2 and 3 letdown lines
3. Oconee Units 1, 2 and 3 decay heat line
4. Oconee Units 1, 2 and 3 loop drain piping and nozzles
5. Portion of Oconee Units 1, 2 and 3 core flood piping

In addition to these components, preemptive repairs were designed for the hot leg and cold leg resistance temperature detector thermowells and pressure tap and flow meter nozzles to eliminate Alloy 600 and Alloy 82/182 materials, which are susceptible to primary water stress corrosion cracking. The following additional component designs involved in these preemptive repairs contain fatigue waivers that are conservatively based on the total number of design cycles even though the first repairs were implemented in 2015, which is after all three Oconee units had been in operation for 40 years.

1. Oconee Units 1 and 2 reactor coolant system small bore nozzle component replacements
2. Oconee Units 1, 2 and 3 reactor coolant system abandoned thermowell mitigation

The 1983 ASME Code, under sub article NB-3630, Section III, Division 1 allows for Class 1 piping to be exempt from Class 1 analysis requirements if the piping meets all the conditions specified in subparagraph NB-3630(d)(2)(a) through (e).

TLAA Evaluation:

The transient cycles utilized in the fatigue waivers were projected for 80 years of operation as discussed in Section 4.3.1 and the count found to be adequate for the SPEO. As reported in Table 4.3.1-1, the 40-year design cycles (CLB cycles) are postulated to bound 80 years of plant operation. Therefore, the fatigue waivers are projected to remain valid for the SPEO. In order to ensure the design cycles remain bounding for the fatigue waivers, the *Fatigue Monitoring* AMP (B3.1) will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The ASME Code, Section III Class 1 component fatigue waivers will be managed by the *Fatigue Monitoring* AMP (B3.1) through the SPEO. The *Fatigue Monitoring* program will monitor the transient cycles in Table 4.3.1-1 which are the inputs to the fatigue waiver analyses and require action prior to exceeding design limits that would invalidate the fatigue waivers. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

4.3.3 NON-CLASS 1 PIPING FATIGUE ANALYSES

TLAA Description:

For all the Oconee non-class 1 mechanical systems within the scope of SLR, only the piping components have been explicitly designed to consider thermal transient cycle count assumptions that must be revalidated for the extended period of operation. These piping systems are designed to ANSI B31.7 Class II and Class III and ANSI B31.1 requirements. Piping systems designed to these codes are not required to have an explicit analysis of cumulative fatigue usage, but rather cyclic loading is considered in a simplified manner in the design process. A stress range reduction factor is required to be used based on the number of expected thermal cycles during the period of plant operation. If the total number of expected thermal cycles for a piping system is less than 7,000, then a stress range reduction factor of 1.0 is applied. If the total number of expected thermal cycles for a piping system is greater than 7,000, a stress range reduction factor less than 1.0 is applied to reduce the alternating stress range to demonstrate the likelihood of piping failure is low. The stress range reduction factors for piping design requirements are shown in Table 4.3.3-1. The evaluation for required stress range reduction factors performed as part of the piping design are implicit fatigue analyses since they are based upon the number of fatigue cycles expected for the life of the piping, therefore they are TLAAs that require evaluation for subsequent license renewal. In addition, there are no components within the systems managed by this TLAA, that are designed in accordance with ASME Code, Section VIII, Division 2 requirements.

Table 4.3.3-1: Stress Range Reduction Factors for Piping Designed per ANSI B31.1

Number of Equivalent Full Temperature Cycles	Stress Range Reduction Factor
7,000 and less	1.0
7,000 - 14,000	0.9
14,000 - 22,000	0.8
22,000 - 45,000	0.7
45,000 - 100,000	0.6
100,000 and over	0.5

TLAA Evaluation:

Non-class 1 piping systems are often subject to continuous steady state operation such that operating temperatures only vary during operational transients. Included in these transients are reactor trips, heatups, cooldowns, and system actuations. Each of these transients can affect systems differently (for example, a reactor trip could cause a thermal transient for high pressure turbine exhaust, low pressure turbine extraction, condensate and feedwater, but not main steam lines); therefore, it is important to separate these events out as described below.

Data from the life of the plant, along with system knowledge, was used to project the various types of plant transients that could cause a thermal cycle in any portion of non-class 1 mechanical piping systems. Conservatism was built into these projections to further demonstrate the adequacy of the current stress range reduction factors that are applied to the piping systems. The estimated 80-year thermal cycles for in scope systems were found to be less than 7,000 cycles in all locations, expect for one portion of the chemical addition system. The pressurizer sample line is expected to experience 29,200 cycles due to daily sampling. This location was identified during initial license renewal, and a stress range reduction factor of 0.7 has been applied to this section of piping to allow for a total of 45,000 thermal cycles to occur.

Portions of the following piping systems are in scope for subsequent license renewal, were designed in accordance with ANSI B31.7 or ANSI B31.1 requirements, and are operated in a manner that subjects the piping to thermal cycles: auxiliary steam, chemical addition, component cooling water, condensate, condenser circulating water, coolant storage, feedwater, gaseous waste disposal, heater drain, heater vent, high pressure injection, high pressure turbine exhaust, instrument air, low pressure injection, low pressure service water, low pressure turbine extraction, main steam, plant heating, reactor coolant, standby shutdown facility air intake and exhaust, standby shutdown facility diesel lube oil, steam drain, steam seal, and vacuum.

Table 4.3.3-2 provides a summary description of which systems will experience thermal cycles during various modes of operation, along with the 80-year projected number of cycles that will occur. There are no portions of non-class 1 piping in scope for SLR that exceed the allowable number of thermal cycles; therefore, the stress range reduction factors applied to the piping systems remain valid in all locations.

Table 4.3.3-2: 80-Year Thermal Cycle Projections for Non-Class 1 Piping Designed to ANSI B31.1 Code Requirements

Piping System	Description of System Locations	Conservative Assumption of Cycles	Projected Cycles for 80 Years
Auxiliary Steam	Swapping steam source between units	Monthly	<1,000
	Steam to feedwater pump turbines	2 per heatup, 1 per reactor trip	<1,000
	Steam to plant drinking water heater	1 per cooldown, 1 per heatup	<1,000
	Steam to various loads associated with power operation	1 per cooldown, 1 per heatup	<1,000
Chemical Addition	Pressurizer sample line[(1)]	Daily	<30,000
	Steam generator sample line	1 per cooldown, 1 per heatup	<1,000
	Moisture separator reheater and feedwater sample lines	1 per cooldown, 1 per heatup, 1 per reactor trip	<1,000
Component Cooling	Reactor coolant letdown cooler	1 per cooldown, 1 per heatup	<1,000

Table 4.3.3-2: 80-Year Thermal Cycle Projections for Non-Class 1 Piping Designed to ANSI B31.1 Code Requirements

Piping System	Description of System Locations	Conservative Assumption of Cycles	Projected Cycles for 80 Years
Condensate	Hotwell to feedwater pumps	1 per cooldown, 1 per heatup	<1,000
	Recirculation cleanup lines	1 per cooldown, 1 per heatup	<1,000
Condenser Circulating Water	Service water discharge from residual heat removal coolers	1 per cooldown, 2 per heatup	<1,500
Coolant Storage	Steam generator and pressurizer vent lines to the quench tank	1 per cooldown, 1 per heatup	<1,000
Feedwater	Feedwater pumps to steam generators	1 per reactor trip, 1 per heatup, 1 per cooldown	<1,000
	Feedwater pump minimum recirculation lines	2 per cooldown, 2 per heatup, 1 per reactor trip	<1,500
	Feedwater start up control valve lines	2 per cooldown, 2 per heatup	<1,500
	Final emergency feedwater lines to steam generator	1 per cooldown, 1 per emergency feedwater actuation, 1 per heatup	<2,500
	Recirculation cleanup lines	1 per cooldown, 1 per heatup	<1,000
Gaseous Waste Disposal	Quench tank vent lines to gaseous waste disposal vent header	1 per cooldown, 1 per heatup	<1,000

Table 4.3.3-2: 80-Year Thermal Cycle Projections for Non-Class 1 Piping Designed to ANSI B31.1 Code Requirements

Piping System	Description of System Locations	Conservative Assumption of Cycles	Projected Cycles for 80 Years
Heater Drain	Drain piping from heaters	1 per cooldown, 1 per heatup, 1 per reactor trip	<1,000
	Lines from flash tanks to the condenser	1 per cooldown, 1 per heatup, 1 monthly	<1,500
Heater Vents	Vent piping	1 per cooldown, 1 per heatup, 1 per reactor trip	<1,000
High Pressure Injection	Reactor coolant letdown and makeup lines	1 per cooldown, 1 per heatup, 1 per reactor trip	<1,000
	Reactor coolant pump seal return	1 per cooldown, 1 per heatup,	<1,000
High Pressure Turbine Exhaust	Extraction steam to high pressure feedwater heaters and condenser bypasses	1 per cooldown, 1 per heatup, 1 per reactor trip	<1,000
	First stage reheater heating steam supply and condensate drain	1 per cooldown, 1 per heatup, 1 per reactor trip	<1,000
	Moisture separator reheater steam supply and condensate drains	1 per cooldown, 1 per heatup, 1 per reactor trip	<1,000
Instrument Air	Backup instrument air compressor discharge lines to the aftercooler	Quarterly, 48 per year	<4,500

Table 4.3.3-2: 80-Year Thermal Cycle Projections for Non-Class 1 Piping Designed to ANSI B31.1 Code Requirements

Piping System	Description of System Locations	Conservative Assumption of Cycles	Projected Cycles for 80 Years
Low Pressure Injection	Reactor coolant drop line through the system back to the reactor vessel	2 per cooldown, 2 per heatup	<1,500
Low Pressure Service Water	Residual heat removal cooler discharge	2 per cooldown, 2 per heatup	<1,500
Low Pressure Turbine Extraction	Extraction steam to low pressure feedwater heaters and condenser drains	1 per cooldown, 1 per heatup, 1 per reactor trip	<1,000
Main Steam	Main steam lines	1 per cooldown, 1 per heatup	<1,000
	Second stage reheater steam supply and condensate drain	1 per cooldown, 1 per heatup, 1 per reactor trip	<1,000
	Shared steam startup headers	Monthly	<1,000
	Steam lines to feedwater pumps	1 per cooldown, 1 per heatup, 1 per reactor trip, 1 per EFW actuation	<3,000
	Steam to emergency feedwater pump turbine	1 per emergency feedwater actuation, Quarterly	<2,500
	Turbine bypass and condensate steam air ejector lines	1 per cooldown, 1 per heatup	<1,000

Table 4.3.3-2: 80-Year Thermal Cycle Projections for Non-Class 1 Piping Designed to ANSI B31.1 Code Requirements

Piping System	Description of System Locations	Conservative Assumption of Cycles	Projected Cycles for 80 Years
Plant Heating	Lines with steam for environment heating	1 per cooldown, 1 per heatup	<1,000
Reactor Coolant	Non-Class 1 vents and drains	1 per cooldown, 1 per heatup	<1,000
	Reactor coolant pump oil lift system	1 per cooldown, 1 per heatup	<1,000
Standby Shutdown Facility Air Intake and Exhaust	Diesel exhaust discharge lines	36 per year	<3,000
Standby Shutdown Facility Diesel Lube Oil	Diesel Lubricating oil lines	Monthly	<1,000
Steam Drain	General station steam line drains	1 per cooldown, 1 per heatup, 1 per reactor trip	<1,000
Steam Seals	Steam seal system	1 per cooldown, 1 per heatup	<1,000
Vacuum	Steam lines going into the condensate steam air ejectors	1 per cooldown, 1 per heatup	<1,000

Note 1: The pressurizer sample piping stress range reduction factor has been reduced from 1.0 to 0.7 to allow for a total of 45,000 thermal cycles.

TLAA Disposition: 10 CFR 54.21(c)(1)(ii):

There are no portions of non-class 1 piping in scope for SLR that exceed the allowable number of thermal cycles; therefore, the stress range reduction factors applied to the piping systems remain valid in all locations. The plant analyses has been projected to the end of the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(ii).

4.3.4 ENVIRONMENTALLY-ASSISTED FATIGUE

Fatigue occurs in a metal component when it is subjected to fluctuating loads. The analysis must consider the effects of reactor water environment on fatigue. The Environmental-Assisted Fatigue discussion for Oconee is provided in Proprietary Report SLR-ONS-TLAA-0306P [Reference 4.3-12] and in the Non-Proprietary Report SLR-ONS-TLAA-0306NP [Reference 4.3-13]. The proprietary information is owned by both Duke Energy and Framatome and is annotated as such.

4.3.5 ANALYTICAL EVALUATION OF FLAWS

TLAA Description:

The ASME Section XI ISI requirements are contained in Subsection IWB for Class 1 pressure retaining components, Subsection IWC for Class 2 pressure-retaining components, and Subsection IWD for Class 3 pressure retaining components. ISI at Oconee has, in a number of instances, lead to the identification of crack-like indications (primarily in welds). For indications detected during ISI that exceed acceptance standards in IWB, IWC, and IWD (1) repairs may be made, (2) affected portions of the component may be replaced, or (3) the flaw may be shown to be acceptable through analytical evaluation.

Acceptance through analytical evaluation requires a prediction of crack growth through the end of service life of the component. The crack growth analysis is based on fracture mechanics techniques and helps determine the course of action required in the management of these flaws. Indications that are determined not to grow beyond an acceptable limit during the projected lifetime of the component are justified for continued operation. These crack growth analyses involve the same design thermal transient cycle assumptions considered in the original design. Because the crack growth rate determined by these analyses may further limit the design life of the components, a review of the transient cycle assumptions considered in these analyses is required in order to justify 80 years of operation.

TLAA Evaluation:

For initial license renewal, Duke identified several fracture mechanics analyses that were performed to the end of the service of the component at Oconee and then re-evaluated these analyses for applicability to the period of extended operation (60-years). The acceptable cycle count basis for several of these analyses required management under the current thermal fatigue management program. For SLR, Duke Energy again reviewed the status of those analyses and found that only some of those are still applicable to the current plant configuration. Additionally, Duke reviewed ISI records that included the third, fourth, and part of the fifth inspection intervals, the period since initial license renewal, to identify any new flaws that require evaluation for the subsequent period of extended operation.

The results of the SLR review of those still-applicable flaw growth analyses identified for initial LR found that all flaws where reduced numbers of acceptable cycles did require management under the thermal fatigue management program have either since been re-evaluated or the component containing the flaw has been replaced. Those reanalyzed flaws are now acceptable for their full controlling design basis transient cycles as discussed in Section 4.3.1.

The ISI record review to support SLR identified only one additional indication in an HPI piping weld in Oconee Unit 1. This flaw evaluation determined that the flaw would be acceptable for the full controlling design basis transient cycles as discussed in Section 4.3.1.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

Since the analytical evaluation of these flaws are acceptable for their full controlling design transient cycles, the effects of fatigue on the intended functions of the components containing these flaws will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) for the subsequent period of operation. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

4.3.6 WELD OVERLAY FATIGUE ANALYSIS

TLAA Description:

Structural weld overlays were installed on the pressurizer spray, pressurizer surge, reactor coolant system hot leg surge, reactor coolant system letdown, hot leg decay heat and safety and relief nozzles to eliminate concerns with stress corrosion cracking of Alloy 600. Analyses of the weld overlays for these locations includes both fatigue analyses and postulated flaw growth analyses.

Analysis of these locations also includes postulated flaw growth analyses. The flaw growth analyses are used to justify the service life of the weld overlays should one be needed. A review of the fatigue flaw growth analyses for the following weld overlays indicates no need to establish service limits when considering the thermal transients originally established for 40 years when projected to 80 years of operation.

- pressurizer spray nozzle weld overlay (all units)
- pressurizer safety relief valve nozzle weld overlay (all units)
- reactor coolant system hot leg surge nozzle weld overlay (Unit 1)

A review of the fatigue flaw growth analyses for the following weld overlays indicated the established service life limits. These service limits establish the required time frame for inspection of the associated weld overlays. Specifically, a 25% sample population of the weld overlays are inspected during each ASME Section XI, Inservice Inspection interval in accordance with the rules outlined Code Case N-770-5, Item F-1. This inspection is currently part of the Oconee Inservice Inspection Program. After a location is inspected and no flaw is detected the service life for these weld overlays resets. The following weld overlays contain a specified service life:

- pressurizer surge nozzle weld overlay (all units)
- reactor coolant system hot leg surge nozzle weld overlay (Units 2 and 3)
- hot leg decay heat nozzle weld overlay (all units)
- reactor coolant system letdown nozzle weld overlay (all units)

TLAA Evaluation:

The transient cycles considered in the weld overlays were projected for 80 years of operation as discussed in Section 4.3.1 and were found to be adequate for the subsequent period of extended operation. As reported in Table 4.3.1-1, the 40-year design cycles (CLB cycles) are postulated to bound 80 years of plant operation. Therefore, the fatigue analyses for the weld overlays have adequate margin in order to remain valid for the subsequent period of extended operation. In order to ensure the design cycles remain bounding for the weld overlays, the *Fatigue Monitoring* AMP (B3.1) will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

A 25% sample population of the weld overlays will be inspected for cracking during the subsequent period of operation. The examinations will be performed in accordance with the rules outlined in Code Case N-770-5, Item F-1. The sample population for each unit will include the two most limiting overlays for each unit. These inspections will be managed by the *ASME Section XI Inservice Inspection, Subsection IWB, IWC, and IWD* AMP (B2.1.1).

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The effects of fatigue on the intended function(s) of the weld overlays will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) and the *ASME Section XI Inservice Inspection, Subsection IWB, IWC, and IWD* AMP (B2.1.1) through the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

4.4 ENVIRONMENTAL QUALIFICATIONS OF ELECTRICAL EQUIPMENT

TLAA Description:

Thermal, radiation, and cyclical aging analyses of plant electrical and instrumentation components, developed to meet 10 CFR 50.49 requirements, have been identified as TLAAs. The NRC nuclear station EQ requirements in 10 CFR 50.49 require that an EQ program be established to demonstrate that certain electrical equipment located in harsh plant environments is qualified to perform applicable safety functions in those harsh environments after the effects of inservice aging. Harsh environments are defined as those areas of the plant that could be subject to the harsh environmental effects of a LOCA, HELB, and post-LOCA radiation. 10 CFR 50.49 requires that the effects of significant aging mechanisms be addressed as part of EQ.

Environmental Qualification Program Background:

10 CFR 50.49 requires that an EQ program be established to demonstrate that certain electrical components located in harsh plant environments are qualified to perform their safety function in those respective harsh environments after the effects of inservice (operational) aging. 10 CFR 50.49 requires that the effects of significant aging mechanisms be addressed as part of EQ. Those components with a qualified life equal or greater than the duration of the current plant operating term are covered by TLAA analyses.

The EQ program was evaluated against the Division of Operating Reactors (DOR), “Guidelines for Evaluating Qualification of Class 1E Electrical Equipment in Operating Reactors”, Inspection and Enforcement Bulletin (IEB) 79-01B, “Environmental Qualification of Class 1E Equipment”, and IEEE Standard 323-1974, “IEEE Standard for Qualifying Class 1E Equipment for Nuclear Power Generating Stations,” as codified by 10 CFR 50.49. IEEE 323-1974 provides the criteria for safety related equipment (electrical “Class 1E” equipment) and the basis for categorizing equipment important to safety, and defines environmental service conditions (Reference 4.4-3). Therefore, the EQ program includes and identifies electrical equipment that is important to safety and that could be exposed to harsh environment accident conditions, consistent with 10 CFR 50.49. The Oconee EQ program was inspected in 1985 by the NRC and found to comply with the requirement of 10 CFR 50.49 (Reference 4.4-4). Ongoing self-assessments, such as the 2018 EQ readiness self-assessment, and NRC inspection ensures that the EQ program continues to comply with the requirement of 10 CFR 50.49.

As required by 10 CFR 50.49, EQ equipment not qualified for the current license term is refurbished or replaced, or has its qualified life extended through reanalysis or ongoing qualification prior to reaching the designated life aging limits established in the evaluation. Aging evaluations for EQ equipment that specify a qualified life of at least 60 years are TLAA for SLR.

Reanalysis of an aging evaluation to extend the qualified life of equipment qualified under the program requirements of 10 CFR 50.49(e) is performed as part of the EQ program. Important attributes for the reanalysis of an aging evaluation include analytical methods, data collection and reduction methods, underlying assumptions, acceptance criteria, and corrective actions (if acceptance criteria are not met).

TLAA Evaluation:

Environmental Qualification Reanalysis:

Reanalysis evaluates the original attributes, assumptions and conservatisms for environmental conditions and other factors of an aging evaluation to demonstrate that equipment qualified life can be extended. Reanalysis of equipment qualified under the program requirements of 10 CFR 50.49(e) is performed as part of an EQ program. Important attributes for the reanalysis of an aging evaluation include analytical methods, data collection and reduction methods, underlying assumptions, acceptance criteria, and corrective actions. These attributes are discussed in the "Environmental Qualification Equipment Reanalysis Attributes" section below.

Environmental Qualification Equipment Reanalysis Attributes:

The reanalysis of an existing aging evaluation is normally performed to extend the qualified life by reevaluating original attributes, assumptions and conservatisms in environmental conditions and other factors to identify excess conservatisms incorporated in the prior evaluation. Reanalysis of an aging evaluation to extend the qualified life of electrical equipment is performed pursuant to 10 CFR 50.49(e) as part of an EQ program. While an electrical equipment life limiting condition may be due to thermal, radiation, or cyclical aging, the majority of electrical equipment aging limits are based on thermal conditions. Conservatism may exist in aging evaluation parameters, such as the assumed service conditions or unrealistically low activation energy. The reanalysis of an aging evaluation is performed according to the station's quality assurance (QA) program requirements, which requires the verification of assumptions and conclusions including the maintenance of required margins.

As already noted, important attributes of a reanalysis include analytical methods, data collection and reduction methods, underlying assumptions, acceptance criteria, and corrective actions. These attributes are discussed below.

Analytical Methods:

The analytical models used in the reanalysis of an aging evaluation are the same as those previously applied during the prior evaluation. The Arrhenius methodology is an acceptable thermal model for performing a thermal aging evaluation. The analytical method used for a radiation aging evaluation is to demonstrate qualification for the total integrated dose that includes normal radiation dose for the projected installed life plus accident radiation dose. For SLR, one acceptable method of establishing the 80-year normal radiation dose is to multiply the initial 40-year normal radiation dose by two. The result is added to the accident radiation dose to obtain the total integrated dose for the component. For cyclical aging, a similar approach may be used. Other models may be justified on a case-by-case basis.

Data Collection and Reduction Methods:

The identification of excess conservatism in electrical equipment service conditions used in the prior aging evaluation is the chief method used for a reanalysis. For example, temperature data, associated margins, and uncertainties used in an equipment EQ evaluation may be based on anticipated plant design temperatures found to be conservative when compared to actual plant temperature data. When used, plant environmental data may be obtained from monitors used for technical specification compliance; other installed monitors, measurements made by plant operators during rounds, dedicated monitors for EQ equipment or combinations of the above. The environmental data gathering and analysis method can be used to identify conservatism in the original qualification and justify additional qualified life for the EQ equipment. Any changes to material activation energy values included as part of a reanalysis are justified by the applicant on a component-specific basis.

Underlying Assumptions:

EQ equipment aging evaluations account for environmental changes occurring due to plant modifications, seasonal changes, and events. A reanalysis demonstrates that adequate margin is maintained consistent with the original analysis in accordance with 10 CFR 50.49. 10 CFR 50.49 requires further consideration of certain margins and accounting for unquantified uncertainties such as diffusion limited oxidation, activation energy, synergistic effects, inverse temperature, and dose rate effects. Reanalysis that utilizes initial qualification conservatisms and/or inservice environmental conditions (e.g., actual temperature and radiation conditions) are part of an EQ program.

Acceptance Criteria and Corrective Actions:

Reanalysis of an aging evaluation is used to extend the qualified life of the component. If the qualified life cannot be extended by reanalysis, the equipment is refurbished, replaced, or requalified prior to exceeding the current qualified life. A reanalysis is performed in a timely manner to ensure sufficient time is available to refurbish, replace, or requalify the equipment if the result is unfavorable.

A modification to qualified life by reanalysis must demonstrate that adequate margin is maintained consistent with the original analysis including unquantified uncertainties established in the original EQ equipment aging evaluation.

Environmental Qualification Ongoing Qualification:

Ongoing qualification, for the purposes of this document is defined as the process of requalifying a component through activities similar to the original qualification which may include testing, type testing, or a monitoring program. When assessed, if margins, conservatisms, or assumptions do not support extending qualified life, the following methods may be used:

- The retention and continued aging of a test sample from the original EQ test program with demonstration that the qualified life is bounding for the SPEO.
- Removal and type testing of additional EQ equipment installed in identical service conditions with a greater period of operational aging.
- Monitoring Program - Requires that EQ equipment characteristics subject to aging degradation be monitored at specific intervals and compared to specified acceptance criteria. The acceptance criteria are based on the capability of post aging characteristics for the EQ equipment to retain functional properties during and after

enduring design bases environment, as applicable. Condition monitoring intervals are established to prevent age degradation beyond the acceptance criteria prior to corrective action.

The above methods are considered ongoing qualification. Other methods or approaches may be acceptable. A modification to extend qualified life must be justified including program documentation and auditable evidence that adequate margin is maintained consistent with the original analysis including unquantified uncertainties established in the original EQ equipment aging evaluation.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The implementation of the enhanced EQ AMP (B3.3) provides reasonable assurance that thermal, radiation, and cyclical aging effects will be adequately managed so that the intended functions of components within the scope of license renewal will be maintained during the SPEO.

4.5 CONCRETE CONTAINMENT UNBONDED TENDON PRESTRESS ANALYSIS

TLAA Description

The Oconee containment buildings are post-tensioned, reinforced concrete structures composed of vertical cylinder walls and a shallow dome, supported on a conventional reinforced concrete base slab. The cylinder wall is prestressed by 176 vertical tendons anchored at the top surface of the upper ring girder at the top of the concrete cylinder and at the bottom of the foundation slab and six groups of 105 hoop tendons plus two additional tendons enclosing 120° of arc for a total of 632 tendons anchored at the six vertical buttresses. The dome is prestressed by three groups of 54 tendons oriented at 120° to each other for a total of 162 tendons anchored at the vertical face of the upper ring girder. Each tendon consists of 90 wires bundled together.

Over time, the containment prestressing forces decrease due to relaxation of the steel tendons and due to creep and shrinkage of the concrete. The containment tendon prestressing forces were calculated during the original design considering the magnitude of the tendon relaxation and concrete creep and shrinkage over the 40-year life of the plant. The *Concrete Containment Unbonded Tendon Prestress* AMP (B3.4) perform periodic surveillances of individual tendon prestressing values. Predicted lower limit force values are calculated for each tendon prior to the surveillances to estimate the magnitude of the tendon relaxation and concrete creep and shrinkage for the given surveillance period. The prestressing forces are measured and plotted, and trend lines are developed, to ensure the average tendon group prestressing values remain above the respective minimum required values until the next scheduled surveillance. The predicted lower limit force values and regression analyses, utilizing actual measured tendon forces, are used to evaluate the acceptability of the containment structure to perform its intended function over the current 60-year life of the plant, and therefore, are TLAAs requiring evaluation for the SPEO.

TLAA Evaluation

The prestress of containment tendons decreases over time as a result of elastic shortening of concrete, creep of concrete, shrinkage of concrete, relaxation of prestressing steel, and friction losses. At the time of initial licensing, the magnitude of the prestress losses throughout the life of the plant was predicted and the estimated final effective preload at the end of 40 years was calculated for each tendon type. The final effective preload was then compared with the minimum required preload to confirm the adequacy of the design. The estimated final effective prestressing force at the end of plant life was projected to 60 years during the original license renewal process. Described below is the summary of the evaluation for 80 years.

Predicted Lower Limit

The containment tendon prestressing force values were calculated during the original design of the containment structure to determine the initial prestressing force required for each tendon group such that the prestressing force would remain above the respective minimum required values over the 40-year life of the plant. The initial tendon prestressing force was calculated for each tendon type to compensate for the steel tendon relaxation and friction losses as well as concrete elasticity, creep, and shrinkage so that the estimated final effective tendon prestressing force at the end of the 40 years would be higher than the minimum required values. The estimated final effective prestressing force was extended to 60 years during the original license renewal process. As part of the *ASME Section XI, Subsection IWL* (B2.1.29) AMP inspections related to tendon examinations, a predicted lower limit force value is calculated for each tendon group scheduled for examination, for the given surveillance year. The predicted lower limit force values are developed consistent with the guidance presented in Regulatory Guide 1.35, considering the average values for the tendon groups. Actual measured values for each tendon are compared to their respective predicted lower limit values, with acceptance criteria consistent with *ASME Section XI, Subsection IWL* (B2.1.29) requirements.

Regression Analysis

A regression analysis is developed for each of the three tendon groups to determine the trend over time in prestressing values of individual tendons within each tendon group. The regression analysis consists of a trend line utilizing actual, representative individual tendon prestressing forces measured during successive *ASME Section XI, Subsection IWL* (B2.1.29) surveillances, consistent with NRC Information Notice 99-10, Attachment 3. The trend lines are periodically updated with new tendon prestressing force data following each surveillance. The trend lines are used to demonstrate that the average group prestressing forces will remain above the group minimum required value until the next scheduled surveillance, and potentially for the life of the plant.

The original ONS tendon surveillance requirements were not in accordance with *ASME Section XI, Subsection IWL*. The examined tendons were preselected and a fixed population, so that as a result the same tendons were inspected by lift-off tests for all surveillances. The surveillance program consisted of periodic inspections of nine predesignated tendons; three horizontal, three vertical, and three dome tendons on each unit. One of the three tendons in each group was detensioned and retensioned for wire sample removal on a rotational basis. As a result of repeated detensioning and retensioning, tendons were damaged to the extent that they were precluded from future lift-off tests. It was concluded that the repeated lift-off testing of the fixed sample of tendons could not be used to truly represent the tendon forces in the group as common tendons. The results of the sixth tendon inspection for Unit 3 showed low tendon forces, which were attributed mostly to the repeated testing of the same tendons. As a result, ONS submitted and had approved in 1997 a Technical Specification change [Reference 4.5-11] so that instead of using nine fixed tendons (i.e., three from each group), 11 representative tendons (five hoop, three vertical, and three dome) would be selected randomly with one in each group to be kept unchanged for the subsequent inspection. The original ONS tendon prestressing force examination results are not included in the current trend lines, except for the test results from the first year, since the results do not truly represent the tendon forces in the group as common tendons and can result in misleading trend lines if included, due to the wire removal and retensioning of the tendons.

The tendon prestressing force examination results for those hoop and vertical tendons that were retensioned or replaced as part of the steam generator replacement project have not been included in the development of trend lines for the hoop and vertical tendons. These tendons constitute a subgroup of hoop and vertical tendons due to the different maintenance history. There are too few examination results for these tendons to create a trend line for these subgroups and the measured tendon prestress values are significantly higher than the original tendons so that if included, the trend line would become unconservative. The examination results for these subgroups currently exceed the minimum required value and predicted lower limit.

Evaluation

The regression analyses associated with the tendons have been reanalyzed to extend the trend lines from 60 years to 80 years. The extended trend lines have been calculated using individual tendon prestressing force values based on data incorporating the latest surveillances for Oconee. In all cases, the regression analyses predict the prestressing forces will remain above the respective group minimum required values through the SPEO.

Figures 4.5-1 through 4.5-9 contain the reanalyzed regression analyses of the original tendons for each tendon group at Oconee. Extended trend lines have been developed for all tendons within the respective group, including the control tendons, and plotted with the minimum required values and predicted lower limits over the 80 year period.

Figures 4.5-10 through 4.5-15 contain the data plots of the tendons that were retensioned or replaced as part of the steam generator replacement project. There are too few examination results for these tendons to create a trend line for these subgroups and the measured tendon prestress values are significantly higher than the original tendons. The examination results for these subgroups currently exceed the minimum required value and predicted lower limit and are expected to remain so during the SPEO.

The *Concrete Containment Unbonded Tendon Prestress* AMP (B3.4) will monitor and manage the TLAA and the associated loss of tendon prestressing forces during the SPEO. The regression analyses are periodically updated following successive surveillances to ensure that estimated values remain above the minimum required values until the next scheduled surveillance, and potentially for the life of the plant. Individual measured tendon prestressing forces will be compared to predicted lower limit values and trend lines developed for the SPEO.

Predicted lower limit lines and trend lines of measured prestressing forces have been established for applicable tendon groups through the SPEO as part of the *Concrete Containment Unbonded Tendon Prestress* (B3.4) AMP. The predicted final effective preload at the end of 80 years exceeds the minimum required preload for all containment tendons. Consequently, the post-tensioning system will continue to perform its intended function throughout the SPEO.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The *Concrete Containment Unbonded Tendon Prestress* (B3.4) AMP and *ASME Section XI, Subsection IWL* (B2.1.29) AMP will manage the effects of aging related to prestress forces on the containment tendon prestressing system so that the intended function will be adequately managed for the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

4.6 CONTAINMENT LINER PLATE, METAL CONTAINMENTS AND PENETRATION FATIGUE ANALYSIS

4.6.1 CONTAINMENT LINER PLATE

TLAA Description:

The interior surface of the containments for Oconee Units 1, 2, and 3 are lined with a ¼” thick welded steel plate to provide an essentially leak-tight barrier. At all penetrations, the liner plate is thickened to reduce stress concentrations. The following fatigue loads were considered in the design of the liner plate, as described in USFAR Section 3.8.1.5.3, and are considered to be time-limited aging analyses for the purpose of license renewal:

(a) Thermal cycling due to annual outdoor temperature variations. The number of cycles for this loading is 40 cycles for the plant life of 40 years. The Oconee liners plates are positioned on the interior of the Containment and are shielded from the outdoor environments by an approximately 3-3/4 ft wall of concrete. The change in temperature from the outer surface of the concrete to the inner surface would be insignificant from a thermal fatigue impact. Furthermore, increasing the 40 cycles to 80 cycles for 80 years of operation would be considered insignificant in comparison to the assumed 500 thermal cycles due to variations of containment interior temperature during heatup and cooldown of the reactor coolant system.

(b) The combined loading of thermal cycling due to reactor building interior temperature varying during the startup and shutdown of the reactor coolant system and Type A integrated leak rate tests required by 10 CFR 50, Appendix J, including any Type A tests that may be performed if major modifications or repairs are made to the containment pressure boundary. The number of cycles for this loading is assumed to be 500 cycles. This loading is the governing design aspect that is the focus to be evaluated for the SPEO.

(c) Thermal cycling due to the LOCA will be assumed to be one cycle. This is not a time-limited design parameter.

(d) Thermal load cycles in the piping system are somewhat isolated from the liner plate penetrations by concentric sleeves between the pipe and the liner plate. The attachment sleeve is designed in accordance with ASME Section III considerations. All penetrations are reviewed for a conservative number of cycles to be expected during the plant life in Section 4.6.3.

TLAA Evaluation:

The associated temperature and pressure changes from reactor coolant system heatups and cooldowns and Type A integrated leak rate test are the main contributors to fatigue of the containment liner plate. The design of the containment liner relied on a cumulative number of 500 cycles for these transients, which control the other design parameters of the liner plate.

The ONS UFSAR, Table 5-2, provides the 40-year design transient number of 360 heatup and cooldown cycles for the reactor coolant system. The projected number of cycles for each ONS unit through 80 years of operation has been determined to be less that the original 360 cycle design limits as shown in Table 4.3.1-1. Periodic Type A integrated leak rate tests are additional major sources of load changes. These Type A loads are considered within the set of design loads whose cumulative total was assumed to be 500 cycles. For license renewal it was projected that there would be a total of 11 Type A tests performed per unit, with 7 being documented for each unit in 1998. This would result in approximately 25 Type A tests per each unit to the end of the SPEO.

Combining the total number of cycles for outdoor temperature variations, the total number of Type A tests, and the projected heatups and cooldowns from Table 4.3.1-1 would result in a transient cycle count less than 500 cycles. Therefore, it is concluded that thermal fatigue of the containment liner would be acceptable for the SPEO. The *Fatigue Monitoring* AMP will track cycles for significant fatigue transients listed in Table 4.3.1-1 and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii)

The effects of fatigue on the intended function(s) of the containment liner plate will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) for the SPEO.

As described in UFSAR Section 3.8.1.5.3, the only portions of the liner plate that contain fatigue analysis are those thickened portions at the penetrations. The containment penetration fatigue analysis is contained in Section 4.6.3 and validates these sections of the liner plate. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

4.6.2 METAL CONTAINMENT

Each unit has a concrete containment with a metal liner. Therefore, the topic of metal containment fatigue analysis is not applicable.

4.6.3 CONTAINMENT PENETRATIONS FATIGUE ANALYSIS

TLAA Description:

The interior surface of the containment is lined with welded steel plate to provide an essentially leak tight barrier. At all penetrations, the liner plate is thickened to reduce stress concentrations of the liner plate. Oconee Units 1, 2 and 3 process lines that penetrate the primary containment and experience significant thermal expansion and contraction are solidly anchored to the containment wall. These high temperature lines penetrating the containment wall and liner plate are the main steam and main feedwater lines.

The primary containment penetrations were originally designed to ASME Section III [Reference 4.6-1]. The original design was to the 1965 Code Edition, which was revised for the main steam and main feedwater penetrations to ASME Section III, Subsection NE and NC, 1992 Edition with 1992 Addenda. Fatigue loads were considered in the current analysis of the main steam and main feedwater piping penetrations. The main steam and main feedwater penetrations are reviewed for a conservative number of cycles to be expected during plant life which are less than the 40-year design cycles.

TLAA Evaluation:

The transient cycles count assumptions related to the main steam and main feedwater penetrations analyses begins with information updated since initial design and applicable for the current operating period. The controlling transients for the penetrations are a specific subset of governing transients listed in Table 4.3.1-1. The cycle count assumptions associated with these two penetration sets have been refined from the original design and new values established for the current operating period. These refined cycle count assumptions are the basis for the SLR evaluation. Specifically, the main steam penetrations have refined cyclic limits associated with heatups, cooldowns, and reactor trips. The main feedwater penetrations have refined cyclic limits associated with heatups, cooldowns, and seismic loads.

Using the refined transient cycle count values, the main steam and main feedwater cycle counts were projected for 80 years as shown in Table 4.6.3-1 and the projected values bound the SPEO. In order to ensure the refined, current operating period cycles remain bounding for the main steam and main feedwater penetrations, the *Fatigue Monitoring* AMP will track the governing transients for these penetrations, using the refined, current operating period cycle count and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The effects of fatigue on the intended functions of the containment penetrations piping will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) for the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

Table 4.6.3-1: ONS Main Steam and Main Feedwater Containment Penetrations

Name	Governing Transient	40-Year Design Allowable Cycles	Refined Allowable Cycles	Current Count[2]	Projected for 80 years[1]
Main Steam Reactor Building Penetrations	1A Heatup[3]	360	262	125	189
	1B Cooldown[3]	360	262	131	197
	Total Reactor Trips[4]	412	262	135	194
Main Feedwater Reactor Building Penetrations	1A Heatup[3]	360	249	125	189
	1B Cooldown[3]	360	249	131	197

Note 1: The projected 80 year cycles are from Table 4.3.1-1
Note 2: The current count is the maximum accrued cycles from each Oconee unit
Note 3: These governing transients include seismic loads
Note 4: The total number of reactor trips comes from the addition of transients 8A, 8B, 8C, and 8D from Table 4.3.1-1

4.7 OTHER PLANT-SPECIFIC TIME-LIMITED AGING ANALYSES

The following plant-specific safety analysis involve time-limited assumptions and are presented in this section.

- Reactor Vessel Internals - Reduction in Fracture Toughness due to Neutron Embrittlement (Section 4.7.1.1)
- Reactor Vessel Internals - Flow Induced Vibration Endurance Limits (Section 4.7.1.2)
- Reactor Vessel Internals - Irradiation Embrittlement (Section 4.7.1.3)
- Reactor Vessel Underclad Cracking (Section 4.7.2)
- Reactor Coolant Pump Flywheel Fatigue Crack Growth Analyses (Section 4.7.3)
- Leak-Before-Break Analysis for Reactor Coolant System Piping (Section 4.7.4)
- Crane Load Cycle Limits (Section 4.7.5)

4.7.1 REACTOR VESSEL INTERNALS

4.7.1.1 Reduction in Fracture Toughness due to Neutron Embrittlement

TLAA Description:

Framatome Topical Report BAW-10008, Part 1, Revision 1, June 1970 [Reference 4.7-1] documents the acceptability of the reactor vessel internals under LOCA and a combination of LOCA and seismic loadings. The effect of irradiation on the material properties and deformation limits for the internals is presented in Appendix E where it is concluded that at the end of 40 years, the internals will have adequate ductility to absorb local strain at the regions of maximum stress intensity, and that irradiation will not adversely affect deformation limits. Because the conclusion is based on a fluence determination of 40 years of operation, this meets the definition of 10 CFR 54.3(a) and was identified as TLAA.

Framatome Topical Report BAW-2248A [Reference 4.7-2] states that this TLAA will be resolved on a plant-specific basis per 10 CFR 54.21 (c)(1)(iii). Plant-specific analysis is required to demonstrate that, under LOCA and seismic loading and with irradiation accumulated at the expiration of the period of extended operation, the internals have adequate ductility to absorb local strain at the regions of maximum stress intensity and will meet the deformation limits. Subsequently, in a letter to the NRC dated December 17, 1999 [Reference 4.7-3], Duke committed to perform the plant-specific analysis and develop data to demonstrate that the internals will meet the deformation limits at the expiration of the renewal license. In response, the NRC in its SER related to the license renewal of three Oconee units, determined that this program will adequately manage the irradiation aging effect in accordance with 10 CFR 54.21 (c)(1)(iii) [Reference 4.7-4] for the 60-year period.

In a letter to the NRC dated February 20, 2012 [Reference 4.7-5], Duke submitted the plant-specific analysis constituting the updated TLAA for reduction of fracture toughness of the reactor vessel internals for NRC staff review. The NRC reviewed the licensee's basis for the update of the reduction of ductility TLAA for the three Oconee units [Reference 4.7-6] and determined that:

- The licensee has projected the neutron fluence for the reactor vessel internals for the 60-year period using an acceptable methodology consistent with RG 1.190.

- The licensee compiled test data from materials irradiated in operating light-water reactors, plus the Halden test reactor. These materials were irradiated under conditions more similar to the conditions of the ONS, 1, 2, and 3 reactor vessel internals and therefore should more accurately represent the behavior of the Type 304SA (solution annealed) material in the ONS 1, 2 and 3 reactor vessel internals. The newer test data, when plotted on the original graph, confirms the conservatism of the original figure.

- The licensee's evaluation of the deformation limits of BAW-10008, Part 1, Revision 1, considering the change in tensile properties of the Type 304SA material due to irradiation, is correct.

- The licensee appropriately revised Appendix E of BAW-10008, Part 1, Revision 1 to conclude the reactor vessel internals would have adequate ductility at 60 years (54 EFPY) to withstand the postulated LOCA plus seismic event.

- The disposition of the TLAA for loss of fracture toughness was not changed by this analysis. Since the NRC staff-approved disposition of this TLAA is that aging will be adequately managed in accordance with 10 CFR 54.21(c)(1)(iii), the licensee must reevaluate this TLAA if new relevant data on loss of ductility of irradiated stainless steel is generated.

Based on the above, the NRC staff concluded that the licensee's evaluation of the TLAA for reduction of ductility of the reactor vessel internals is acceptable, and the license renewal commitment documented in Section 4.2.5.3 of NUREG-1723 to perform a plant-specific analysis and develop data to demonstrate that the internals will meet the deformation limits at the expiration of the 60-year renewed license, is fulfilled. Therefore, this TLAA must be re-evaluated for subsequent license renewal.

<u>TLAA Evaluation:</u>

Section 3.2 of BAW-10008, Part 1, Revision 1 notes that there are two primary safety considerations that govern the deformation limits of the internals: deformation shall not prevent insertion of control rods, nor shall it prevent adequate post-accident cooling of the core. The resultant faulted condition stresses (Case IV) are provided in Table 1 of BAW-10008, Part 1, Revision 1. Each reactor vessel internals item listed in Table 1 of BAW-10008, Part 1, Revision 1 is assessed in accordance with one of three process steps (i.e., Categories 1-3) for Faulted Conditions to determine if each reactor vessel internals item should be considered potentially susceptible to an unacceptable amount of reduction of ductility at 72 EFPY. This assessment is

similar to that submitted and approved by the NRC for the Davis-Besse Nuclear Power Station, Unit 1 for the period of 60-year license renewal [References 4.7-7 and 4.7-8].

For completeness, stress calculations (developed after the data reported in Table 1 of BAW-10008, Part 1, Revision 1) applicable to the Oconee units were reviewed to ensure that the original design basis calculations reported in Table 1 of BAW-10008, Part 1, Revision 1 capture the limiting reactor internals items for reduction of ductility. Recent stress calculations included asymmetric loading stress calculations for faulted conditions reported in BAW-1621, related to NRC request for additional information, and the Oconee final SER [References 4.7-9, 4.7-10, 4.7-11], and original and replacement high-strength bolting stress calculations. BAW-1621 is not identified as TLAA but is included for completeness since it contains faulted load stress intensities that post-date the stress intensities reported in BAW-10008, Part 1, Revision 1. The three process steps (i.e., Categories 1-3) to determine the impact of reduction of ductility at 72 EFPY on each item (in order of evaluation) are as follows:

1. Determine if the faulted stress intensity for the reactor vessel internals item is less than the unirradiated ASME B&PV Code yield strength at operating temperature (600 ^{o}F) and therefore plasticity will not occur at 72 EFPY. Since the material remains elastic (and neutron embrittlement would increase the yield strength), reduction of ductility is acceptable.

2. Determine if the reactor vessel internals item is already highly irradiated (i.e., only reactor vessel internals items directly adjacent to the fuel assemblies - e.g., baffle plates), such that the Case IV faulted stress intensity remains below the irradiated yield strength (increases as fluence increases) and plasticity will not occur at 72 EFPY. Since the material remains elastic, with large margin to the irradiated yield strength, reduction of ductility is acceptable.

3. Determine if the expected fluence exposure is low enough such that neutron embrittlement is considered negligible, reduction of ductility is minimal or will not occur at 72 EFPY and unirradiated ductility properties are still applicable.

For each process step, further evaluation is required for those items that do not satisfy the screening criterion defined within each process step. For example, items that do not fall below the yield strength criterion in Category 1 are carried forward to Category 2. Category 2 items, developed from the first process step that do meet the irradiated yield strength criterion are carried forward to Category 3. Items that exceed the Category 3 screening criterion require further evaluation to demonstrate that those internals items will have sufficient ductility at 72 EFPY to meet the deformation limits at the expiration of the SPEO. The detailed process step evaluation and results are reported in Proprietary Report ANP-3899P, Revision 0 and in Non-Proprietary Report ANP-3899, Revision 0 [References 4.7-12 and 4.7-16] and are summarized below. Reference to a reactor vessel internals item is equivalent to a part or parts (e.g., plenum cylinder or guide tubes).

BAW-10008, Part 1, Revision 1 Assessment per Criterion Defined by Category 1

For the Category 1 assessment, the faulted stress intensity for each the reactor vessel internals item is compared to the unirradiated ASME B&PV Code yield strength for the applicable material type at operating temperature (i.e., about 550°F to 600°F). For those reactor vessel internals items that have a reported stress intensity value less than the unirradiated ASME B&PV Code yield strength at 600°F, the material should remain elastic (and neutron embrittlement would increase the yield strength), reduction of ductility is acceptable; therefore, no further analysis is required. The unirradiated ASME B&PV Code yield strength (S_y) values at 600°F for the reactor vessel internals items materials of interest are presented in Table 4.7.1-1. Reactor vessel internals items reported in BAW-10008, Part 1, Revision 1, Table 1, that satisfy Category 1 screening criterion are reported in, Table 4.7.1-2 as “Category 1” in the last column. Seven items were carried forward to Process Step 2: lower grid plate, plenum cover, plenum cylinder reinforcing plate, core support shield top flange, core support shield lower flange, baffle plates, and upper core barrel bolts for Oconee Unit 3 only.

Table 4.7.1-1: ASME B&PV Code Yield Strength Values at 600°F

Temperature (ºF)	Yield Strength (psi) of Type 304 (e.g., SA-240)	Yield Strength (psi) of Type 304L (e.g., SA-240)	Yield Strength (psi) of Alloy A-286 (e.g., SA-453 Grade 660	Yield Strength (psi) of Alloy X-750 (SB-637, Grade 688, Type 3)
600	17,300	14,400	81,000	92,500

BAW-10008, Part 1, Revision 1 Assessment per Criterion Defined by Category 2

For the Category 2 assessment, the expected reactor vessel fluence (E > 1.0 MeV) at 72 EFPY of the applicable ONS reactor vessel internals items listed in Table 1 of BAW-10008, Part 1, Revision 1 are reviewed to determine if the item is highly irradiated to the level where saturation of the material’s yield strength has occurred. Only reactor vessel internals items directly adjacent to the fuel assemblies are expected to be highly irradiated. For the case where the item is highly irradiated at 72 EFPY and the Case IV faulted stress intensity is below the irradiated yield strength (which increases as fluence increases), plasticity will not occur at 72 EFPY; therefore, the material remains elastic with large margin to the irradiated yield strength, and the reduction of ductility is acceptable.

Based on the 72 EFPY fluence estimates (see Section 4.7.1.3) for the stress types of the seven items identified in Table 4.7.1-2 where the Case IV faulted stress intensities are greater than the unirradiated yield strengths at 600°F, only the baffle plates are expected to be highly irradiated. The baffle plates Case IV faulted stress intensity in Table 1 of BAW-10008, Part 1, Revision 1, is less than the irradiated saturated yield strength; therefore, the baffle plate material remains elastic with large margin to the irradiated yield strength, and reduction of ductility is acceptable and no further analysis is required.

For the remaining six reactor vessel internals items identified in Table 4.7.1-2 where the Case IV faulted stress intensities are greater than the unirradiated yield strengths at 600°F, further assessment in accordance with criteria defined by Category 3 is performed to determine if the remaining reactor vessel internals items should be considered potentially susceptible to reduction of ductility at 72 EFPY. The six items carried forward to process step 3 include the lower grid plate, plenum cover, plenum cylinder reinforcing plate, core support shield top flange, core support shield lower flange, and upper core barrel bolting for Oconee Unit 3 only.

<u>BAW-10008, Part 1, Revision 1 Assessment per Criterion Defined by Category 3</u>

For the remaining six Oconee reactor vessel internals items not screened out by the Category 1 and 2 assessments above, a review is performed to determine if the expected fluence (E > 1.0 MeV) of the reactor vessel internal item is low enough such that neutron embrittlement is considered negligible at 72 EFPY, thus reduction of ductility is minimal or will not occur at 72 EFPY for the item.

The projected 72 EFPY fluence values for the remaining 6 reactor vessel internals items are reported in Reference 4.7-12 and were developed based on extrapolation of 60-year reactor vessel internals transport calculations that were developed using the Regulatory Guide 1.190 compliant methodology developed for the reactor vessel as described in BAW-2241PA, Revision 2 [Reference 4.7-20]. These are best estimate fluence values and are discussed in Section 4.7.1.3 below. When the projected 72 EFPY fluence values reported in Proprietary Report ANP-3899P, Revision 0 and in Non-Proprietary Report ANP-3899, Revision 0 are applied to Figure E-3 of BAW-10008, Part 1, Revision 1, the uniform elongation for the plenum cover, plenum cylinder reinforcing plate, and core support shield top flange at both 572°F and 752°F (temperatures between which these component items would be expected to experience) is such that the 20 percent uniform elongation of irradiated material credited for 40 years in Appendix E of BAW-10008, Part 1, Revision 1 is met for these materials. Accordingly, these component items will have adequate ductility to absorb local strain at the regions of maximum stress intensity, and irradiation will not adversely affect deformation limits. This is noted by a “Category 3” entry in the last column of Table 4.7.1-2.

For the three remaining reactor vessel internals items (i.e., lower grid plate, core support shield lower flange, and upper core barrel bolts at Oconee Unit 3), further evaluation is required to demonstrate that those internals items will have sufficient ductility at 72 EFPY to meet the deformation limits at the end of the SPEO. As such, a “further evaluation required” entry is noted in the last column of Table 4.7.1-2.

As noted previously, this review included asymmetric loading stress calculations for faulted conditions reported in BAW-1621, Supplement 1 related request for additional information, and NRC SER on *“Asymmetric LOCA Loads, Oconee 1, 2 and 3”* provided by letter dated May 20, 1983 (Reference 4.7-11), and original and replacement high-strength bolting stress calculations. BAW-1621 is not identified as a TLAA but is included for completeness since it contains faulted load stress intensities that post-date the stress intensities reported in BAW-10008, Part 1, Revision 1. The three-step process described above for BAW-10008, Part 1, Revision 1, was repeated for the stress intensities reported in BAW-1621, Supplement 1 and original and replacement high-strength bolting stress calculations, and the results are summarized in Table 4.7.1-3.

Based on the results of the categorization assessments reported in Table 4.7.1-2 and Table 4.7.1-3, the following reactor vessel internals items were determined to be potentially susceptible to reduction of ductility at 72 EFPY and require further evaluation. Duplicate item results between the two evaluations are double underlined.

From Table 4.7.1-2, regarding BAW-10008, Part 1, Revision 1:

1. Lower grid plate (i.e., lower grid rib section)
2. Core support shield lower flange
3. Upper core barrel bolts (ONS-3 only based on stress analysis of the current ONS-3 upper core barrel bolting configuration)

From Table 4.7.1-3, regarding RAI responses to BAW-1621, Supplement 1:

1. Upper core barrel bolts (ONS-3 only based on stress analysis of the current ONS-3 upper core barrel bolting configuration)
2. Core support shield lower flange
3. Lower grid rib section
4. Lower grid rib section/lower grid shell forging joint bolt
5. Support post/support forging joint – weld
6. Upper grid rib section
7. Upper grid pad joint – bolt

To reconcile these reactor vessel internal items for the SPEO, a set of recalculated loads based on smaller break loadings due to LBB of the primary piping were calculated for six of the seven items/welds, excluding the Oconee Unit 3 upper core barrel bolts. Comparison of these recalculated loads showed that, for the six reactor vessel internals items/welds, the recalculated faulted condition stress intensity values are less than the unirradiated ASME Code yield strength at 600°F. Thus, reduction of ductility is acceptable for these six items or welds and no further analysis is required.

For assessment of the Oconee Unit 3 upper core barrel bolts, measured yield strength values at temperatures 600ºF and greater were located during a record search. This data shows that at these elevated temperatures, the measured yield strength values of these tested materials are greater than the calculated stresses for the ONS-3 upper core barrel bolts. Therefore, by comparison, the reduction of ductility is acceptable for the ONS-3 upper core barrel bolts and no further analysis is required.

Therefore, based on the assessments of the effect of irradiation on the mechanical properties and deformation limits of the Oconee reactor vessel internals, reduction of ductility for the reactor vessel internals items listed in Table 1 of BAW-10008, Part 1, Revision 1 is considered acceptable and remains valid for an 72 EFPY lifetime for the reactor vessel internals at all three Oconee units.

TLAA Disposition: 10 CFR 54.21(c)(1)(iii):

The effect of irradiation on the material properties and deformation limits of the reactor vessel internals at all three units at Oconee, as reported in BAW-10008, Part 1, Revision 1, is acceptable for an 72 EFPY lifetime such that the Internals will have adequate ductility to absorb local strain at the regions of maximum stress intensity, and that irradiation will not adversely affect deformation limits under faulted condition loadings. The analyses reported in BAW-10008, Part 1, Revision 1, remain valid for the subsequent period of extended operation and are managed by the PWR Vessel Internals Program (B2.1.7, GALL-SLR XI.M16A), consistent with the current licensing basis [Reference 4.7-6]. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii). The reactor vessel internals 72 EFPY fluence/ displacement per atom values used to disposition the Category 2 and 3 items above are projected to the end of the subsequent period of extended operation in accordance with 54.21(c)(1)(ii) as discussed in Section 4.7.1.3.

		Buckling	N/A

Table 4.7.1-3: Reduction of Ductility Reconciliation of Faulted Component Items from BAW-1621 Supplement 1

Component Item	Material	Stress Type	Category Reconciliation
CRGT Lower Joint – Bolt	Grade B8	P_m	Category 1
CRGT Lower Joint – Dowel	Type 304	Shear	N/A
CRGT/Plenum Cover Joint	Type 308L	P_m	Category 1
Upper Grid Rib Section	Type 304	P_m	Category 1
		$P_m + P_b$	Further Reconciliation Required
Upper Grid Pad Joint – Dowel	Alloy X-750	Dowel	N/A

Note (a): Based on a review of B&W fabrication records, the lowest measured room temperature yield strength was obtained for the barrel to former bolts. Per empirically based correlations between yield strength and temperature for unirradiated stainless steels, it is estimated that the barrel-former bolts measured yield strength at 600^{o}F is above the faulted stress intensity and reduction of ductility is acceptable.

4.7.1.2 Reactor Vessel Internals Flow Induced Vibration Endurance Limits

TLAA Description:

As reported in NUREG-1723 [Reference 4.7-4], SER Related to the LR of Oconee Nuclear Station, Units 1, 2, and 3, Page 4-23, includes the following regarding this TLAA. In Section 5.4.3 of Exhibit A of the ONS LRA [Reference 4.7-13] the applicant states that TLAA applicable to the ONS vessel internals are addressed in topical report BAW-2248A [Reference 4.7-2], *Demonstration of the Management of Aging Effects for the Reactor Vessel Internals*. TLAA identified in the LRA include:

- Flow-induced vibration endurance limit assumptions
- Transient cycle count assumptions for the replacement bolting
- Reduction in fracture toughness

The LRA states that the *Reactor Vessel Internals* program will assure that appropriate action is taken in a timely manner to ensure continued validity of the design of the reactor vessel internals.

The 60-year evaluation of flow-induced vibration endurance limit assumptions is reported in BAW-2248A, Section 4.5.1, flow-induced vibration endurance limit assumptions. NRC acceptance of this TLAA evaluation is contained in the NRC Safety Evaluation to BAW-2248A (NRC SER, Section 3.4.1) and is summarized in NUREG-1723, Pages 4-23 and 4-24. As such, this TLAA must be updated for SLR.

TLAA Evaluation:

The source references that were used to justify the B&W reactor pressure vessel internals flow-induced vibration endurance limit assumptions for 60 years were reviewed and updated for applicability to 80 years. The rationale and methods that are applied to SLR for 80 years are identical to those previously considered for 60 years but augmented with additional justification to conservatively address environmental assisted fatigue affects utilizing the environmental assisted fatigue criteria developed in NUREG/CR-6909, Revision 1 [Reference 4.7-15]. In addition, the more limiting fatigue curves published in the 2013 edition of the ASME Section III code (compared to the 1986 edition used with the ONS LRA for 60 years) are considered with the fatigue evaluation of the B&W reactor vessel internals.

Reference 4.7-16 provides a summary of the flow-induced vibration stress associated with the B&W reactor vessel internals and bolting items. The item with the least margin reported in Reference 4.7-16 has a stress for the thermal shield upper support bolts that is smaller than the allowable cyclic stress. Therefore, a safety factor exists between the maximum flow-induced vibration stress and the allowable cyclic stress from the fatigue curve for this limiting location. Since this stress is below the endurance limit, the maximum fatigue usage factor associated with flow-induced vibration for the reactor vessel internals is below the endurance limit for an 80 year life. These results are in part based upon the original justification of the B&W reactor vessel internals for a 40 year design life, provided in BAW-10051 Revision 1 and BAW-10051 Supplement 1 [Reference 4.7-17 and Reference 4.7-18].

TLAA Disposition: 10 CFR 54.21(c)(1)(ii):

The flow-induced vibration integrity of the ONS reactor vessel internals and bolting is deemed acceptable for SLR for 80 years in accordance with 10 CFR 54.21(c)(1)(ii). The high cycle fatigue affects associated with flow-induced vibration during the SPEO (60 to 80 years) and the concerns associated with the environmental fatigue affects have no impact upon the BAW-10051 analyses and thus have been demonstrated not to be detrimental to the flow-induced vibration performance of the ONS reactor vessel internals and bolting. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(ii).

4.7.1.3 Reactor Vessel Internals Irradiation Embrittlement

TLAA Description:

As described in Section 4.7.1.1, Framatome Topical Report BAW-10008, Part 1, Revision 1, [Reference 4.7-1] documents the acceptability of the reactor vessel internals under LOCA and a combination of LOCA and seismic loadings. Based on the NRC evaluation of this TLAA for 60 years, the staff concluded that the licensee has projected the neutron fluence for the reactor vessel internals using an acceptable methodology consistent with RG 1.190. Therefore, neutron fluence of the reactor vessel internals relative to the evaluation of BAW-10008, Part 1, Revision 1 is a TLAA that must be evaluated for subsequent license renewal. In addition, reactor vessel internals functionality assessment of inaccessible components (MRP-227-A/LAI #6), is identified as a TLAA for SLR.

TLAA Evaluation:

The projected 72 EFPY fluence values developed for the update of BAW-10008, Part 1, Revision 1 (Section 4.7-1) are TLAA and are obtained from Reference 4.7-20. These fluence inputs were developed based on extrapolation of 60-year reactor vessel internals transport calculations that were developed using the RG 1.190 compliant methodology (i.e., deterministic discrete ordinates transport 3-D synthesis methods) developed for the reactor vessel as described in BAW-2241PA, Revision 2, and are consistent with the fluence estimates reported in MRP-189, Revision 3 [Reference 4.7-19]. Since the BAW-2241PA, Revision 2 methodology is mainly concerned with reactor vessel fluence, some specific modeling enhancements were required in order to accurately represent the reactor vessel internals components.

In order to meet the requirements of the GALL-SLR X.M2, a reactor vessel internals fluence analysis described in Proprietary Report ANP-3899P, Revision 0 and in Non-Proprietary Report ANP-3899, Revision 0 was completed for the Oconee Nuclear Station. A single analysis was prepared to represent all three units, since they all have similar design, fabrication, operation, and fuel loading patterns. The calculation methodology included both deterministic (discrete ordinates transport) and Monte Carlo (Monte Carlo N-particle) codes [Reference 4.7-12]. The NRC clearly identified the regions of the reactor internals requiring heterogeneous, Monte Carlo monitoring during a public meeting on reactor internals fluence calculations provided on May 24, 2018 [Reference 4.7-21]. The discrete ordinates transport and Monte Carlo N-Particle results have good agreement at reactor vessel internals items that are above the irradiation degradation criteria values in MRP-175, Revision 1 [Reference 4.7-22]. In accordance with Section 4.7.1.1 above, 72 EFPY fluence/displacement per atom estimates are used to assess susceptibility to irradiation embrittlement relative to the BAW-10008, Part 1, Revision 1 TLAA evaluation for the following items.

- Baffle plates (Category 2 item)
- Plenum cover (Category 3 item)
- Plenum cylinder reinforcing plate (Category 3 item)
- Core support shield top flange (Category 3 item)

Observations of the discrete ordinates transport to Monte Carlo N-Particle comparison are as follows.

1. The discrete ordinates transport geometry is inherently limited by the R-Theta mesh. For example, straight sections in the R-Theta case (i.e., baffle plates) are modeled with a jagged edge.

2. The Monte Carlo N-Particle model of the reactor vessel internals is very detailed in the axial region of interest, with very few components homogenized. In comparison, the discrete ordinates transport model is detailed only in the axial region between the upper and lower grid, and some of those components are homogenized.

3. The Monte Carlo N-Particle model computes true 3D results directly, while the discrete ordinates transport model creates 3D results by synthesizing two 2D models (R-Theta and R-Z), which can lose accuracy outside the beltline region.

4. The Monte Carlo N-Particle model uses a continuous energy cross section set that is not subject to the parameterization of deterministic methods such as discrete ordinates transport. Because of these various limitations, the two codes have good agreement in the beltline region, but diverge in regions away from the beltline. The further from the beltline, the worse the divergence. Because of the greater fidelity of the Monte Carlo N-Particle geometry, the Monte Carlo N-Particle results are expected to be more accurate than the discrete ordinates transport results, especially in the regions far from the beltline where the divergence of the results is greatest.

5. The discrete ordinates transport and Monte Carlo N-Particle analyses used “best-estimate” input parameters. Oconee specific values were used for all of the key inputs, including the power level, axial and radial power distributions, materials, geometry, and operating history.

In addition, reactor vessel internals functionality assessment of inaccessible components (MRP-227-A/LAI #6), is identified as a TLAA for SLR. Duke Energy resolved this issue for 60 years through Framatome report ANP-3477P [Reference 4.7-23]. MRP-227-A/LAI #6 will be addressed for 80 years through the *PWR Vessel Internals* AMP (B2.1.7, GALL-SLR XI.M16A).

TLAA Disposition: 10 CFR 54.21(c)(1)(ii):

The effect of irradiation on the material properties and deformation limits of the reactor vessel internals at all three units at Oconee is acceptable for a 72 EFPY lifetime such that the internals will have adequate ductility to absorb local strain at the regions of maximum stress intensity, and that irradiation will not adversely affect deformation limits under faulted condition loadings and is reported in Section 4.7.1.1. Therefore the neutron fluence input into this TLAA has been projected to the end of the SPEO in accordance with 10 CFR 54.21(c)(1)(ii). Reactor vessel internals fluence shall be monitored for the baffle plates (Category 2 item), plenum cover (Category 3 item), plenum cylinder reinforcing plate (Category 3 item), and core support shield top flange (Category 3 item) in accordance with the ONS *Neutron Fluence Monitoring* Program (B3.2, GALL-SLR X.M2) to ensure that the TLAA reported in Section 4.7.1.1 remains valid during the SPEO.

4.7.2 REACTOR VESSEL UNDERCLAD CRACKING

TLAA Description:

Intergranular separations in the heat-affected zone of reactor vessel low-alloy steel under austenitic stainless steel cladding (i.e., underclad cracking) is a potential TLAA, as indicated in Table 4.7-1 of NUREG-2192 [Reference 4.7-24]. Duke Energy identified and evaluated this TLAA for 60-years in the Oconee LRA [Reference 4.7-13], Section 5.4.2.3, wherein reference is made to BAW-2274, which is contained in BAW-2251-A [Reference 4.7-26] as Appendix C. NRC approval of the application of BAW-2251A, Appendix C, to the ONS 60-year LRA is reported in NUREG-1723 [Reference 4.7-4] Section 4.2.4.4. Underclad cracking was recently evaluated for measurement uncertainty recapture conditions as reported in the ONS License Amendment Request [Reference 4.7-27] Section IV.1.C.vii. The measurement uncertainty recapture evaluation concluded that the generic 48 EFPY evaluation reported in BAW-2251A, Appendix C remained bounding for Oconee when considering measurement uncertainty recapture conditions at 54 EFPY.

TLAA Evaluation:

Underclad cracking refers to intergranular separations in the heat-affected zones of low alloy base metal under austenitic stainless steel cladding in SA-508, Class 2 reactor vessel forgings manufactured to a coarse grain practice, and clad by high-heat-input submerged arc processes. BAW-10013 (Reference 4.7-28) contains a fracture mechanics analysis that demonstrates the critical crack size required to initiate fast fracture is several orders of magnitude greater than the assumed maximum flaw size plus predicted flaw growth due to design fatigue cycles. The flaw growth analysis was performed for a 40-year cyclic loading, and an end-of-life assessment of radiation embrittlement (i.e., fluence at 32 EFPY) was used to determine fracture toughness properties. The report concluded that the intergranular separations found in B&W vessels would not lead to vessel failure. This report was accepted by the Atomic Energy Commission.

In May 1973, the Atomic Energy Commission issued RG 1.43, *"Control of Stainless Steel Weld Cladding of Low-Alloy Steel Components",* Revision 1*,* March 2011 [Reference 4.7-37]. The guide states that intergranular separation *"has been reported only in forgings and plate material of SA-508 Class 2 composition made to coarse grain practice when clad using high-deposition-rate welding processes identified as 'high-heat-input' processes such as the submerged-arc wide-strip and the submerged-arc 6-wire processes. Cracking was not observed in clad SA-508 Class 2 materials clad by 'low-heat-input' processes controlled to minimize heating of the base metal. Further, cracking was not observed in clad SA-533 Grade B Class 1 plate material, which is produced to fine grain practice. Characteristically, the cracking occurs only in the grain-coarsened region of the base-metal heat-affected zone at the weld bead overlap."* The guide also notes that the maximum observed dimensions of these subsurface cracks is 0.5 inch long × 0.165 inch deep.

The methodology used to evaluate intergranular separations for the ONS reactor vessels at 80 years is consistent with the methodology reported in the update of BAW-10013 included as Appendix C of BAW-2251A. An Oconee specific analysis, described in Proprietary Report ANP-3898P, Revision 0 and in Non-Proprietary Report ANP-3898P/NP Revision 0 [References 4.7-40 and 4.7-41 respectively] was performed for 72 EFPY and measurement uncertainty recapture conditions using current fracture toughness information, applied stress intensity factor solutions, fatigue crack growth correlations for SA-508 Class 2 materials, and is evaluated in accordance with the methodology prescribed in ASME Section XI, 2013 Edition, IWB-3612.

The analysis was applied to five regions of the reactor vessel: flange top, nozzle belt, shell taper, shell, and transition forging. Since the closure head for each ONS unit has been replaced, and the replacement closure head is not susceptible to UCC, the closure heads were not reevaluated [Reference 4.7-27 and 4.7-44]. Both axial and circumferential oriented flaws were considered in the evaluation. All significant normal and upset condition transients and emergency and faulted condition transients were evaluated in the analysis. The fatigue crack growth analysis considered all the normal and upset condition transients with associated design cycles (80-year design cycles are equivalent to 40- and 60-year design cycles) for the SPEO.

Semi-elliptical surface flaws (axial and circumferential) with an initial flaw size of 0.353-inch deep (approximately twice that which has been observed) and 2.12-inch long (approximately four times that which has been observed) with a 6:1 aspect ratio was conservatively assumed at each of the two regions. This is contrasted to the observed flaws which are subsurface with a maximum size of 0.165 inch deep by 0.5 inch long.

It was demonstrated that at all the investigated locations, postulated flaws in both the axial and circumferential orientations meet the acceptance criteria of Article IWB-3612 for Level A/B (normal/upset), and Level C/D (emergency/faulted) loading conditions after accounting for plastic zone correction.

The lowest fracture toughness margin for Level A/B (normal/upset) loading conditions is 3.94 and occurs at the flange top location for the axially oriented flaw, which is higher than the minimum required margin of 3.16 ($\sqrt{10}$ = 3.16). The lowest fracture toughness margin for Level C/D (emergency/faulted) loading condition is 1.62 and occurs at the shell taper region due to a circumferentially oriented flaw, which is greater than the minimum required margin of 1.41 ($\sqrt{2}$ =

1.41). Therefore, postulated flaws for the underclad cracking in the reactor vessels for all the three Oconee units remain acceptable at the end of the 72 EFPY service evaluation period.

TLAA Disposition: 10 CFR 54.21(c)(1)(ii):

For the Oconee Units 1, 2, and 3, reactor vessel shells, including the transition forging, nozzle belt and flange, underclad cracking TLAA have been projected to the end of the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(ii).

4.7.3 REACTOR COOLANT PUMP FLYWHEEL FATIGUE ANALYSIS

TLAA Description:

The assessment phase of the ONS SLR Program identified the number of reactor coolant pump motor starts as a potential initiator for fatigue cracking in the reactor coolant pump motor flywheel bore keyway as a TLAA. Hence, this topic is considered a TLAA because the analysis meets all the criteria contained in 10 CFR 54.3.

TLAA Evaluation:

The reactor coolant pump flywheel has been designed for 10,000 loading cycles and has been identified as a TLAA for the ONS initial license renewal application. Utilizing plant data from January 1, 2000 to January 1, 2019 from the station’s operator aid computer, it was determined that, on average each reactor coolant pump is started 3 times per year. The number of reactor coolant pump starts from initial plant startup to January 1, 2000 is unknown, as is the number of future starts which is dependent upon many complex variables such as forced shutdowns, uneven starts between pumps during cooldown/startup, maintenance tests, and uncertainty across the units. To account for these deviations, it will be assumed each reactor coolant pump is started on average double what the data concludes, which yields 6 starts per year. If each flywheel conservatively experiences 6 starts per year, then at the end of the 80 years of operations, each would have roughly 480 loading cycles. Since the flywheel is designed for 10,000 starts, a safety factor of over 20 is maintained before the limitation is met.

TLAA Disposition: 10 CFR 54.21(c)(1)(ii)

The projected number of reactor coolant pump starts after 80 years of operation is 480, which is less than the manufacturers specified limitation of 10,000. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(ii) and the plant analyses has been projected to the end of SPEO.

4.7.4 LEAK BEFORE BREAK ANALYSIS FOR REACTOR COOLANT SYSTEM PIPING

TLAA Description:

The successful application of LBB to the ONS reactor coolant system main coolant piping is described in the BWOG Topical Report titled, *"The B&W Owners Group Leak-Before-Break Evaluation of Margins Against Full Break for reactor coolant system Primary Piping of B&W Designed NSSS,"* BAW-1847, Revision 1, September 1985 [Reference 4.7-29]. Duke Energy demonstrated that the LBB analyses summarized in BAW-1847, Revision 1, remains applicable and bounding to the portions of the main coolant piping that were replaced during SG replacement project. BAW-1847, Revision 1 provides the technical basis for evaluating postulated flaw growth in the main reactor coolant system piping under normal plus faulted loading conditions and was approved by the NRC for the current term of operation. The time-limited aging analyses in BAW-1847, Revision 1 includes a fatigue flaw growth evaluation and a qualitative assessment of thermal aging of cast austenitic stainless steel (CASS) for the reactor coolant inlet and outlet nozzles.

The first aspect of the LBB evaluation involves fatigue flaw growth. It is noted that the fatigue flaw growth evaluations are based on transients defined by the Oconee UFSAR Table 5-2 [Reference 4.7-30], transient cycles for reactor coolant system components except pressurizer surge line. These transients are monitored by the Oconee *Fatigue Monitoring* AMP (B3.1, GALL-SLR X.M1). The Oconee *Fatigue Monitoring* program ensures that the analyzed transient and cycles do not exceed the transients analyzed in BAW-1847, Revision 1 and provides an acceptable method for managing the fatigue flaw growth aspect of the LBB evaluation for the period of extended operation.

The second aspect of the LBB evaluation involves aging of the cast austenitic stainless steel material. Susceptibility of the reactor coolant system items fabricated from cast austenitic stainless steel to thermal aging was qualitatively assessed in BAW-1847, Revision 1. The values of the fracture toughness for aged cast austenitic stainless steel were assumed to be bounded by the ferritic piping and ferritic weldments. However, subsequent data published in NUREG/CR-6177, *"Assessment of Thermal Embrittlement of Cast Stainless Steels"* [Reference 4.7-31] indicate that prolonged exposure of cast austenitic stainless steel to reactor coolant operating temperatures can lead to reduction of fracture toughness by thermal embrittlement. Therefore, a flaw stability analysis using the lower-bound cast austenitic stainless steel fracture toughness curves from NUREG/CR-6177 was used to demonstrate the acceptability of LBB of cast austenitic stainless steel items for the reactor coolant system for the period of extended operation.

In accordance with NUREG-1723 [Reference 4.7-4], SER Related to the LR of Oconee Nuclear Station, Units 1, 2, and 3, Page 4-13, the NRC staff concluded the following.

- The *Fatigue Monitoring* program provides an acceptable method for managing the fatigue flaw growth aspect of the LBB evaluation, and

- The LBB assessment of reactor coolant system cast austenitic stainless steel materials is an acceptable TLAA for the period of extended operation.

TLAA Evaluation:

For the first aspect of the LBB evaluation involving fatigue flaw growth, projected cycles for 80 years of operation are evaluated. The 80 year projected cycles are compared to the original cycles analyzed in BAW-1847, Revision 1 to demonstrate that the original cycles analyzed are bounding and therefore the fatigue flaw growth aspect of the LBB evaluation is acceptable for the SPEO with continued monitoring using the *Fatigue Monitoring* program.

For the second aspect of the LBB evaluation, the flaw stability analysis performed using the lower bound NUREG/CR-6177 fracture toughness curves for the period of extended operation was updated to consider the most recent test data per NUREG/CR-4513, Revision 2 [Reference 4.7-32]. In addition, screening criteria is considered based on EPRI report, TR-106092, *Evaluation of Thermal Aging Embrittlement for Cast Austenitic Stainless Steel Components in LWR Reactor Coolant Systems* [Reference 4.7-33] to screen out reactor coolant pump items that are not susceptible to thermal aging embrittlement. Based on this, all Oconee Unit 1 reactor coolant pump cast austenitic stainless steel items screen out and are not susceptible to thermal aging embrittlement. Selected Oconee Unit 2 and Unit 3 cast austenitic stainless steel reactor coolant pump items screen in as susceptible to thermal embrittlement, and therefore are evaluated utilizing the most limiting heat specific fracture toughness curves per NUREG/CR-4513, Revision 2. Consequently, the flaw stability analysis using the limiting heat specific cast austenitic stainless steel fracture toughness curves per NUREG/CR-4513, Revision 2 demonstrates the acceptability of LBB for the reactor coolant pump cast austenitic stainless steel discharge and suction nozzles for SLR for 80 years of operation.

Fatigue Flaw Growth

The LBB analysis reported in BAW-1847, Revision 1, was performed in accordance with the guidance provided in Section 5.2, Item (d), of NUREG-1061, Volume 3, *"Report of the U.S. Nuclear Regulatory Commission Piping Review Committee, Evaluation of Potential for Pipe Breaks"* [Reference 4.7-34]. Specifically, a surface flaw was postulated at selected locations of the piping system (i.e., highest stress coincident with the lower bound of the material properties for base metal, weldments and safe ends), and a fatigue crack growth analysis for postulated flaws was then performed to demonstrate that the surface flaws are likely to propagate in the through-wall direction and develop leakage before they will propagate circumferentially around the pipe. Fatigue flaw growth calculations are reported in BAW-1847, Revision 1, Section 4.3, Table 4-2, and are based on the stresses and input cycles from Tables 4-3, 4-4, and 4-5 of BAW-1847, Revision 1.

The original transient cycles that were defined for 40 years of operation for reactor coolant system components are compared to the projected cycles for 80 years. The comparison indicates that none of the original 40-year transient cycles are projected to be exceeded for 80 years. Since the *Fatigue Monitoring* program will assure that projected cycles for 80 years will not exceed the original transient cycles that were defined for 40 years, the analysis summarized in BAW-1847, Revision 1 for fatigue flaw growth is still applicable for the SPEO for 80 years of plant operation.

Thermal Aging of Cast Austenitic Stainless Steel Reactor Coolant Pump Suction and Discharge Nozzles

The susceptibility of the reactor coolant system main coolant piping to thermal aging was qualitatively addressed in Section 3.3.4.3 of BAW-1847, Revision 1. As described in BAW-2243A [Reference 4.7-35], there are no reactor coolant system main coolant piping segments fabricated from cast austenitic stainless steel. However, the heat affected zone of the welded joint that connects the wrought austenitic stainless steel 28-inch pump transition piece to the cast austenitic stainless steel reactor coolant pump inlet (suction) and exit (discharge) nozzles may be susceptible to thermal embrittlement. Limited data regarding thermal aging of cast austenitic stainless steel material was available at the time of the preparation of BAW-1847, Revision 1. In the BWOG report, the values of fracture toughness for aged cast austenitic stainless steel were assumed to be bounded by the ferritic piping and ferritic weldments. Since the publication of BAW-1847, Revision 1, a significant amount of data has been obtained regarding thermal aging of cast austenitic stainless steel materials.

Test data obtained by Argonne National Laboratory [O. K. Chopra and W. J. Shack, *"Assessment of Thermal Embrittlement of Cast Stainless Steels,"* NUREG/CR-6177, U.S. Nuclear Regulatory Commission, Washington DC, May 1994 indicated that prolonged exposure of cast austenitic stainless steel to reactor coolant operating temperatures can lead to reduction of fracture toughness by thermal embrittlement. The fracture toughness curves for the ferritic base metal and ferritic weld metals used in the reactor coolant system piping LBB analysis were compared to the lower-bound fracture toughness curves of Oconee Units 1, 2 and 3 reactor coolant pump cast austenitic stainless steel materials (i.e., statically cast CF8M) from the Argonne report. The fracture toughness curve of the lower-bound cast austenitic stainless steel material is below the fracture toughness curves used in the reactor coolant system piping LBB analysis. Therefore, the assumption in BAW-1847, Revision 1, that the fracture toughness of the ferritic piping and ferritic weldments bounds the fracture toughness of cast austenitic stainless steel materials cannot be supported. Therefore, for the PEO for 60 years, a flaw stability analysis was performed using the lower-bound cast austenitic stainless steel fracture toughness curves from NUREG/CR-6177 to show acceptability of LBB.

Subsequent to this in support of SLR for 80 years of operation, the most recent fracture toughness test data from NUREG/CR-4513, Revision 2 was evaluated and determined to be limiting compared to the NUREG/CR-6177 fracture toughness data for the specific reactor coolant pump material heats evaluated. In addition, screening criteria is considered based on NUREG-2191 XI.M12 to screen out any reactor coolant pump items that are deemed not susceptible to thermal aging embrittlement. Based on this, Oconee Unit 1 reactor coolant pump components screen out and are not susceptible to thermal aging embrittlement. Oconee Units 2 and 3 do not screen out, and therefore are evaluated utilizing the most limiting heat specific fracture toughness curves per NUREG/CR-4513, Revision 2 (Reference 4.7-32). Note that the most limiting material and location used in the reactor coolant system piping LBB analysis (i.e., BAW-1847, Revision 1, Reference 4.7-29) was determined to be the base metal material of the straight section of the 28-inch cold leg pipe. Both the suction and discharge nozzles of the reactor coolant pump casings are attached to the 28-inch cold leg pipes and have similar geometry and loading applied to them as the limiting location used for the LBB analysis.

Therefore, the Oconee Units 2 and 3 discharge and suction nozzles of the reactor coolant pump casings were evaluated for LBB using heat specific fracture toughness curves per NUREG/CR-4513, Revision 2 (Reference 4.7-32). The analysis considers a bounding 10 gpm leakage crack size for the reactor coolant pump suction and discharge nozzle, which was determined using a method that is consistent with that reported in BAW-1847, Revision 1. In the revised analysis, the applied loadings were considered using the absolute sum load combination method. Therefore, in accordance with NUREG-0800, Standard Review Plan 3.6.3, Revision 1, a margin of 1.0 on load was used. The leakage crack length (twice the leakage flaw size) for the suction nozzle was determined to be 8.62 inches and the leakage crack length for the discharge nozzle was determined to be 8.86 inches. In addition, a crack extension value of 1.03 inches was considered in the flaw stability analysis for both nozzles. A flaw stability analysis was performed for the reactor coolant pump inlet (suction) and exit (discharge) nozzles. The maximum applied J value for the 10 gpm leakage flaw is 0.223 kips/in for the suction nozzle and 0.222 kips/in for the discharge nozzle. The critical flaw size was determined to be 13.54 inches for the suction nozzle and 13.76 inches for the discharge nozzle. Therefore, the margin on flaw size was determined to be 3.1 for both suction and discharge nozzles. This is greater than the required margin of 2 in accordance with SRP 3.6.3. Based on the results of this analysis, it is concluded that all the required margins for LBB per SRP 3.6.3 are met.

TLAA Disposition: 10 CFR 54.21(c)(1)(i):

The generic LBB analysis for the B&W operating plants reported in BAW-1847, Revision 1, remains valid for the SPEO in accordance with 10 CFR 54.21(c)(1)(i) for the ONS. Reduction of fracture toughness of the reactor coolant pump discharge and suction nozzles was determined to be acceptable for SPEO based on the update to the flaw stability analysis described above. Although the LBB analysis remains valid, the transient cycles will be monitored and management by the *Fatigue Monitoring* AMP (B3.1, GALL-SLR X.M1) provides additional assurance for the SPEO.

4.7.5 CRANE LOAD CYCLE LIMIT

TLAA Description:

A review of design specifications for cranes within the scope of subsequent license renewal was performed to identify those cranes that were designed or otherwise required to meet the intent of Crane Manufacturers Association of America (CMAA) Specification 70-1975, “Specifications for Electric Overhead Traveling Cranes,” and, therefore, have a defined service life as measured in load cycles. The defined service life as measured in load cycles is identified as a TLAA.

TLAA Evaluation:

CMAA Specification 70 presents the bounding combinations of the number of load cycles and mean effective load factors for each service class. These define the acceptable service limits for the TLAA. The plant response to NUREG-0612, as guided by NRC Generic Letter 81-07, *“Control of Heavy Loads,”* indicates that the cranes designed and fabricated in accordance with Electric Overhead Crane Institute (EOCI) Specification 61, “Specifications for Electric Overhead

Traveling Cranes", and compares that design approach to that of CMAA Specification 70, which has superseded EOCI Specification 61. The conclusion reached in the response to NRC Generic Letter 81-07 is that the: 1) reactor building polar cranes: 2) spent fuel pool cranes; 3) spent fuel pool auxiliary cranes; 4) pump aisle crane; 5) turbine aisle crane; 6) turbine aisle auxiliary crane; and 7) heater bay crane satisfy the design intent of CMAA Specification 70. CMAA Specification 70 provides guidance regarding fatigue but EOCI Specification 61 does not explicitly address fatigue failure. The following paragraph describes the method of selecting the service class from CMAA Specification 70 that corresponds to the service class originally specified from EOCI Specification 61. This service class is used with CMAA Specification 70, Table 2.8-1 to identify the applicable number of load cycles for that specific service class. The plant specifications for the cranes identified require design to EOCI Specification 61 Service Class A described as the following:

> *"Standby service: For such use as powerhouse, pump rooms, motor rooms, transformer repair, etc. where the crane is used very infrequently. These cranes must be substantially designed to handle expensive loads."*

The corresponding service class in CMAA Specification 70 is Class A service, which is defined as the following:

> *"Standby or Infrequent service: This service class covers cranes which may be used in installations such as powerhouses, public utilities, turbine rooms, motor rooms and transformer stations where precise handling of equipment at slow speeds with long, idle periods between lifts required. Capacity loads may be handled for initial installation of equipment and for infrequent maintenance."*

Based on the comparison of service classes described in the original design specification (EOCI Specification 61) to CMAA Specification 70, the applicable service class is Class A. CMAA Specification 70 states that a range of load cycles from 20,000 to 100,000 was considered for cranes in Class A (Standby) service thus establishing the envelope for acceptable number of load cycles for this TLAA. The total projected load cycles for the reactor building polar cranes, spent fuel pool cranes, spent fuel pool auxiliary cranes, pump aisle crane, turbine aisle crane, turbine aisle auxiliary crane, and heater bay crane based on past and future use is summarized in Table 4.7-4, Crane Load Cycles.

Table 4.7-4: Crane Load Cycles Summary

Load Handling System	CMAA Service Class	Maximum Number of Load Cycles	Projected Number of Load cycles for 80 Years	Valid for 80 Years
Unit 1 Reactor Building Polar Crane	A	100,000	1,752	Yes
Unit 2 Reactor Building Polar Crane	A	100,000	1,752	Yes
Unit 3 Reactor Building Polar Crane	A	100,000	1,752	Yes
Unit 1/2 Spent Fuel Pool Crane	A	100,000	3,316	Yes
Unit 3 Spent Fuel Pool Crane	A	100,000	2,658	Yes

Heater Bay Crane	A	100,000	3,525	Yes

Reactor Building Polar Crane Evaluation

The 185 ton reactor building polar cranes were designed to meet the intent of Class A (standby) service. The CMAA Specification 70 Class A service design includes consideration of 100,000 load cycles during the life of the crane. Recurring loads associated with the reactor containment polar cranes that are in excess of 5% of crane capacity are presented in Table 4.7-5 together with infrequent loads associated with initial construction and major maintenance. The total projected number of these load cycles is approximately 1,752 for each unit over the 80-year life of the plant. Since the total number of expected load cycles is considerably less than the maximum number of load cycles of 100,000 considered for service Class A in CMA Specification 70, the TLAA for the reactor building polar cranes remains valid.

Table 4.7-5: Evaluation of Containment Polar Crane Operation

Heavy Load Description(1)	Approximate Load Weight (Tons)(1)	Frequency	Number of Refuel Cycles(2)	Number of Lifts Over Plant Life
Shield Block	15	2/refueling cycle	47	94
Reactor Vessel Head	106.4	2/refueling cycle	47	94
Indexing Fixture	30	2/refueling cycle	47	94
Indexing Fixture	25	2/refueling cycle	47	94
Reactor Coolant Pump Motor	50	2/refueling cycle	47	376
Large equipment placement lifts – Initial construction and major equipment replacement	Varible	1,000 over plant life	Not Applicable	1,000
80-year total estimated load lifts per Unit				1,752

Note (1): Load description and weights per Reference 4.7-46.
Note (2): Through the end of 2020, ONS has had 31 refueling cycles on Unit 1, 30 refueling cycles on Unit 2, and 30 refueling cycles on Unit 3. Conservatively used 31 refueling cycles through the end of 2020 and 24 month refuel cycles projected through 80 years.

Spent Fuel Pool Crane and Spent Fuel Auxiliary Crane Evaluation

The 100 ton spent fuel pool crane and 3.5 ton spent fuel auxiliary crane were designed for Class A (standby) service. The CMAA Specification-70 Class A service design includes consideration of 100,000 load cycles during crane operation. Recurring loads associated with the shared Unit 1 and 2 spent fuel pool crane and spent fuel auxiliary crane are presented in Table 4.7-6 and 4.7-7 and include miscellaneous loads and loads identified in NUREG-1723 (only used for spent fuel pool crane). Operation of the Oconee Independent Spent Fuel Storage Installation (ISFSI) results in additional lifts by the spent fuel pool cranes near their rated lifting capacity. Extending this estimate to 80 years of operation results in an estimate that is still well below the allowed number of heavy lifts. The total projected number of these loads cycles for the Spent Fuel Pool cranes are approximately 3,316 and 2,658 respectively for the 80-year operating term of the plant. The load cycles associated with the spent fuel auxiliary cranes are significantly less. Both are significantly less than the maximum number of load cycles of 100,000 considered for service Class A in CMAA Specification-70; therefore, the TLAA for the spent fuel pool crane and the spent fuel auxiliary crane remains valid.

Table 4.7-6: Evaluation of Spent Fuel Pool Crane Operation

Heavy Load Description[(1)]	Approximate Load Weight (tons)[(1)]	Frequency	Number of Refueling Cycles[(2,3)]	Number of Lifts Over Plant Life
Dry Spent Fuel Storage Cask (Units 1 and 2)	> 100	4/refueling cycle	94	376
Miscellaneous (Units 1 and 2)	20	10/refueling cycle	94	940
Dry Spent Fuel Storage Cask (Unit 3)	> 100	4/refueling cycle	94	188
Miscellaneous (Unit 3)	20	10/refueling cycle	47	470
Estimate per NUREG-1723 at 60 years	Variable	2,000 over plant life	Not Applicable	2,000
80-year total estimated load lifts				3,316 (Unit 1/2) 2,658 (Unit 3)

Note (1): Load description and weights per Reference 4.7-46 and Reference 4.7-45 (Dry Spent Fuel Storage Cask).

Note (2): Through the end of 2020, ONS has had 31 refueling cycles on Unit 1, 30 refueling cycles on Unit 2, and 30 refueling cycles on Unit 3. Conservatively used 31 refueling cycles through the end of 2020 and 24 month refuel cycles projected through 80 years.

Note (3): Unit 1 and 2 share a spent fuel pool and crane, while Unit 3 has its own spent fuel pool and crane system.

Table 4.7-7: Evaluation of Spent Fuel Auxiliary Crane Operation

Heavy Load Description[(1)]	Approximate Load Weight (Tons)[(1)]	Frequency	Number of Refueling Cycles[(2,3)]	Number of Lifts Over Plant Life
Miscellaneous (Unit 1 and 2)	3	20/refueling cycle	94	1,880
Miscellaneous (Unit 3)	3	20/refueling cycle	47	940

Table 4.7-7: Evaluation of Spent Fuel Auxiliary Crane Operation

Heavy Load Description[1]	Approximate Load Weight (Tons)[1]	Frequency	Number of Refueling Cycles[2,3]	Number of Lifts Over Plant Life
80-year total estimated load lifts				1,880 (Unit 1/2) 940 (Unit 3)

Note (1): Load description and weights per Reference 4.7-46.

Note (2): Through the end of 2020, ONS has had 31 refueling cycles on Unit 1, 30 refueling cycles on Unit 2, and 30 refueling cycles on Unit 3. Conservatively used 31 refueling cycles through the end of 2020 and 24 month refuel cycles projected through 80 years.

Note (3): Unit 1 and 2 share a spent fuel pool and crane, while Unit 3 has its own spent fuel pool and crane system.

Turbine Building Pump Aisle Crane Evaluation

The 12 ton turbine building pump aisle crane was designed to meet the intent of Class A (standby) service. The CMAA Specification 70 Class A service design includes consideration of 100,000 load cycles during the life of the crane. Recurring loads associated with the pump aisle crane that are in excess of 5% of crane capacity are presented in Table 4.7-8 together with infrequent loads associated with initial construction and major maintenance. The total projected number of these load cycles is approximately 3,820 over the 80-year life of the plant. Since the total number of expected load cycles is considerably less than the maximum number of load cycles of 100,000 considered for Service Class A in CMAA Specification 70, the TLAA for the turbine building pump aisle crane remains valid.

Table 4.7-8: Evaluation of Turbine Building Pump Aisle Crane Operation

Heavy Load Description(1)	Approximate Load Weight (Tons)(1)	Frequency	Number of Refueling Cycles(2,3)	Number of Lifts Over Plant Life
Pump	8	10/refueling cycle	141	1,410
Miscellaneous	10	10/refueling cycle	141	1,410
Large equipment placement lifts – Initial construction and major equipment replacement	Variable	1,000 over plant life	Not Applicable	1,000
80-year total estimated load lifts				3,820

Note (1): Load description and weights per Reference 4.7-46.
Note (2): Through the end of 2020, ONS has had 31 refueling cycles on Unit 1, 30 refueling cycles on Unit 2, and 30 refueling cycles on Unit 3. Conservatively used 31 refueling cycles through the end of 2020 and 24 month refuel cycles projected through 80 years.
Note (3): There is only one Turbine Building pump aisle crane for all 3 ONS Units.

Turbine Aisle Crane Evaluation

The 180 ton turbine aisle crane was designed to meet the intent of Class A (standby) service. The CMAA Specification 70 Class A service design includes consideration of 100,000 load cycles during the life of the crane. Recurring loads associated with the turbine aisle crane that are in excess of 5% of crane capacity are presented in Table 4.7-9 together with infrequent loads associated with initial construction and major maintenance. The total projected number of these load cycles is approximately 6,922 over the 80-year life of the plant. Since the total number of expected load cycles is considerably less than the maximum number of load cycles of 100,000 considered for Service Class A in CMAA Specification 70, the TLAA for the turbine aisle crane remains valid.

Table 4.7-9: Evaluation of Turbine Aisle Crane Operation

Heavy Load Description(1)	Approximate Load Weight (Tons)(1)	Frequency	Number of Refueling Cycles(2,3)	Number of Lifts Over Plant Life
Generator	183	2/refueling cycle	141	282
Low Pressure Rotor	120	8/refueling cycle	141	1,128
Diaphrams	4	8/refueling cycle	141	1,128
3,384Bearings	2	24/refueling cycle	141	3,384
Large equipment placement lifts – Initial construction and major equipment replacement	Variable	1,000 over plant life	Not Applicable	1,000
80-year total estimated load lifts				6,922

Note (1): Load description and weights per Reference 4.7-46.
Note (2): Through the end of 2020, ONS has had 31 refueling cycles on Unit 1, 30 refueling cycles on Unit 2, and 30 refueling cycles on Unit 3. Conservatively used 31 refueling cycles through the end of 2020 and 24 month refuel cycles projected through 80 years.
Note (3): There is only one Turbine aisle crane for all 3 ONS Units.

Turbine Aisle Auxiliary Crane Evaluation

The 25 ton turbine aisle auxiliary crane was designed to meet the intent of Class A (standby) service. The CMAA Specification 70 Class A service design includes consideration of 100,000 load cycles during the life of the crane. Recurring loads associated with the turbine aisle auxiliary crane that are in excess of 5% of crane capacity are presented in Table 4.7-10 together with infrequent loads associated with initial construction and major maintenance. The total projected number of these load cycles is approximately 6,922 over the 80-year life of the plant. Since the total number of expected load cycles is considerably less than the maximum number of load cycles of 100,000 considered for Service Class A in CMAA Specification 70, the TLAA for the turbine aisle auxiliary crane remains valid.

Table 4.7-10: Evaluation of Turbine Aisle Auxiliary Crane Operation

Heavy Load Description[(1)]	Approximate Load Weight (Tons)[(1)]	Frequency	Number of Refueling Cycles[(2,3)]	Number of Lifts Over Plant Life
Diaphrams	4	8/refueling cycle	141	1,128
Bearings	2	24/refueling cycle	141	3,384
Miscellaneous	10	10/refueling cycle	141	1,410
Large equipment placement lifts – Initial construction and major equipment replacement	Variable	1,000 over plant life	Not Applicable	1,000
80-year total estimated load lifts				6,922

Note (1): Load description and weights per Reference 4.7-46.
Note (2): Through the end of 2020, ONS has had 31 refueling cycles on Unit 1, 30 refueling cycles on Unit 2, and 30 refueling cycles on Unit 3. Conservatively used 31 refueling cycles through the end of 2020 and 24 month refuel cycles projected through 80 years.
Note (3): There is only one Turbine aisle auxiliary crane for all 3 ONS Units.

Heater Bay Crane Evaluation:

The 80 ton heater bay crane was designed to meet the intent of Class A (standby) service. The CMAA Specification 70 Class A service design includes consideration of 100,000 load cycles during the life of the crane. Recurring loads associated with the heater bay crane that are in excess of 5% of crane capacity are presented in Table 4.7-11 together with infrequent loads associated with initial construction and major maintenance. The total projected number of these load cycles is approximately 3,525 over the 80-year life of the plant. Since the total number of expected load cycles is considerably less than the maximum number of load cycles of 100,000 considered for Service Class A in CMAA Specification 70, the TLAA for the heater bay crane remains valid.

Table 4.7-11: Evaluation of Heater Bay Crane Operation

Heavy Load Description(1)	Approximate Load Weight (Tons)(1)	Frequency	Number of Refueling Cycles(2,3)	Number of Lifts Over Plant Life
Feedwater Heater Shell	20	10/refueling cycle	141	1,410
Pumps	13	5/refueling cycle	141	705
Miscellaneous	10	10/refueling cycle	141	1,410
80-year total estimated load lifts				3,525

Note (1): Load description and weights per Reference 4.7-46.
Note (2): Through the end of 2020, ONS has had 31 refueling cycles on Unit 1, 30 refueling cycles on Unit 2, and 30 refueling cycles on Unit 3. Conservatively used 31 refueling cycles through the end of 2020 and 24 month refuel cycles projected through 80 years.
Note (3): There is only one heater bay crane for all 3 ONS Units.

TLAA Disposition: 10 CFR 54.21(c)(1)(i):

The load cycle evaluation for the cranes identified in Table 4.7-4 have been demonstrated to remain valid through the subsequent period of extended operation in accordance with the requirements of 10 CFR 54.21(c)(1)(i).

Appendix A

UFSAR Supplement

A1.0 INTRODUCTION

This appendix provides the information to be submitted in a Supplement to the UFSAR as required by 10 CFR 54.21(d) for the ONS, Units 1, 2, and 3, SLRA. Section 4.0 of the SLRA documents the evaluations of TLAAs for the SPEO. Appendix B of the SLRA provides descriptions of the programs and activities that manage the effects of aging for the SPEO. The information in Section 4.0 and Appendix B was used to prepare this appendix.

This appendix, which comprises the UFSAR supplement, includes the following sections:

- Section A2.0 contains summary descriptions of the AMPs used to manage the effects of aging during the SPEO. The AMPs are either consistent with generally accepted industry methods as discussed in NUREG-2191 Chapter XI programs or require enhancements. Commitments for program additions and enhancements are identified in Section A6.0, SLR Commitments.
- Section A3.0 contains summary descriptions of AMPs used for management of TLAAs during the SPEO. The AMPs are either consistent with generally accepted industry methods as discussed in NUREG-2191 Chapter X programs associated with TLAAs or require enhancements. Commitments for program additions and enhancements are identified in Section A6.0, SLR commitments.
- Section A4.0 contains evaluation summaries of TLAAs applicable to the SPEO.
- Section A5.0 contains a summary description of a plant-specific AMP for managing the effects of aging during the SPEO. Commitments for the program additions and enhancements are identified in Section A6.0, SLR commitments
- Section A6.0 contains summary descriptions of SLR commitments. Table A6.0-1, SLR Commitments, includes the commitments for SLR along with an associated schedule indicating when Duke Energy plans to complete each commitment.

Following issuance of the subsequent renewal operating licenses, information in Appendix A will be incorporated in the LR section of the UFSAR, Chapter 18. This is consistent with the requirements of 10 CFR 50.71(e). Upon inclusion in the UFSAR, future changes to the information in UFSAR Chapter 18 will be made under the provisions of 10 CFR 50.59.

The results of the integrated plant assessment and evaluation of TLAAs identified existing and new AMPs necessary to provide reasonable assurance that components within the scope of LR will continue to perform their intended functions consistent with the CLB for the SPEO. The SPEO is defined as 20 years from the current renewed operating license expiration date. In addition, a discussion on quality assurance and OE related to AMPs is provided in this section.

Quality Assurance for Aging Management Programs

The Quality Assurance (QA) Program is described in Topical Report DUKE-QAPD-001-A, “Quality Assurance Program Description, Operating Fleet” which implements the requirements of 10 CFR 50, Appendix B, “Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants.” The QA Program is consistent with the summary in Appendix A.2, “Quality Assurance for AMPs (Branch Technical Position IQMB-1)” of NUREG-2192. The QA Program provides the basis for the corrective actions, confirmation process, and administrative controls elements of AMPs. The scope of the existing QA Program is expanded to include non-safety related structures and components that are subject to an AMR for LR. The QA Program is applicable to the safety related and non-safety related structures, components, and commodity groups that are subject to AMR.

Consideration of Operating Experience in Aging Management Programs

OE from plant-specific and industry sources is captured and systematically reviewed on an ongoing basis in accordance with the QA Program, which meets the requirements of 10 CFR 50, Appendix B, and the OE program, which meets the requirements of NUREG-0737, “Clarification of TMI Action Plan Requirements,” Item I.C.5, “Procedures for Feedback of OE to Plant Staff.”

The Duke Energy OE program interfaces with and relies on active participation in the INPO OE program, as endorsed by the NRC. In accordance with these programs, all incoming OE items are screened to determine whether they may involve age-related degradation or aging management impacts. Research and development is also reviewed. Items so identified are further evaluated and the AMPs are either enhanced or new AMPs are developed, as appropriate, when it is determined through these evaluations that the effects of aging may not be adequately managed. Training on age-related degradation and aging management is provided to those personnel responsible for implementing the AMPs and to those who may submit, screen, assign, evaluate, or otherwise process plant-specific and industry OE. Plant-specific OE associated with aging management and age-related degradation is reported to the industry in accordance with guidelines established in the Duke Energy OE program.

A2.0 SUMMARY DESCRIPTIONS OF AGING MANAGEMENT PROGRAMS

The NUREG-2191 Chapter XI AMPs are described in the following sections. The AMPs are either consistent with generally accepted industry methods as discussed in NUREG-2191 or require enhancements. The following list reflects the status of these programs at the time of the SLRA submittal. Commitments for program additions and enhancements are identified in the Appendix A6.0 Subsequent License Renewal Commitment List.

A2.1 ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD

Program Description

The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP is an existing condition monitoring program that manages the aging effects of cracking, loss of fracture toughness, and loss of material. The program consists of periodic volumetric, surface, and/or visual examinations and leakage tests of ASME Class 1, 2, and 3 pressure retaining components, including welds, pump casings, valve bodies, integral attachments, and pressure retaining bolting. The program includes assessment, identification of signs of degradation and establishment of corrective actions.

The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP is implemented in accordance with 10 CFR 50.55a and ASME Code, Section XI, Subsections IWB, IWC, and IWD. The ASME Code, Section XI, edition and addenda used will be consistent with the provisions of 10 CFR 50.55a during the SPEO. The program includes augmented inservice inspection (ISI) requirements and examinations associated with the ASME Code, Section XI, ISI program. These additional inspections are identified in the ONS Augmented ISI program and are included in the ISI schedule.

Enhancements

The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP will be enhanced to:

1. Revise procedures to require inspections to be performed for components associated with sentinel locations assessed under ASME Code, Section XI, Non-Mandatory Appendix L for the following:

    - Reactor coolant system pressurizer surge line piping (hot leg elbow).
    - High pressure injection piping, stop valve-to-check valve (usage bounds high pressure injection nozzle).

A2.2 Water Chemistry

Program Description

The *Water Chemistry* AMP is an existing program that mitigates aging effects of loss of material due to corrosion, cracking due to stress corrosion cracking, and related mechanisms, and reduction of heat transfer due to fouling in components exposed to a reactor coolant, steam, treated borated water, treated water, or secondary feedwater environment. Chemistry programs are used to control water chemistry for parameters such as conductivity, chloride, fluoride, and sulfate that accelerate corrosion.

The *Water Chemistry* AMP relies on monitoring and control of water chemistry to keep peak levels of various contaminants below the system-specific limits, based on EPRI Report 3002000505, Revision 7, *Pressurized Water Reactor Primary Water Chemistry Guidelines* and EPRI Report 3002010645, Revision 8, *Pressurized Water Reactor Secondary Water Chemistry Guidelines*.

Enhancements

None

A2.3 Reactor Head Closure Stud Bolting

Program Description

The *Reactor Head Closure Stud Bolting* AMP is an existing condition monitoring and preventive program that manages cracking and loss of material for the reactor head closure stud assembly (which includes the closure studs, nuts, and washers) and for the threads in the reactor vessel flange.

The *Reactor Head Closure Stud Bolting* AMP is implemented through station procedures based on the examination requirements specified in the *ASME Code, Section XI, Subsection IWB, Table IWB-2500-1* and preventive measures to mitigate cracking as delineated in RG 1.65, Revision 1, with the exception that existing stud bolting components have a measured yield strength greater than or equal to 150 ksi and an ultimate tensile stress greater than or equal to 170 ksi. In addition, potential replacement stud bolting components in the warehouse may have measured yield strength greater than or equal to 150 ksi.

Enhancements

The *Reactor Head Closure Stud Bolting* AMP will be enhanced to:

1. Revise procurement requirements for reactor head closure stud bolting to incorporate guidance from RG 1.65, Revision 1 and NUREG-2191, Chapter XI.M3, to ensure newly procured bolting material does not exceed the limit for maximum measured yield strength of 150 ksi and ultimate tensile strength of 170 ksi.

A2.4 Boric Acid Corrosion

Program Description

The *Boric Acid Corrosion* AMP is an existing condition monitoring program that manages loss of material due to leaking borated water on structures and components, including electrical equipment/junction boxes. This program relies, in part, on the response to NRC GL 88-05, "*Boric Acid Corrosion of Carbon Steel Reactor Pressure Boundary Components in PWR Plants,*" to identify, evaluate, and correct borated water leaks that could cause corrosion damage to reactor coolant pressure boundary components.

The program also includes inspections, evaluations, and corrective actions for components subject to AMR that may be adversely affected by some form of borated water leakage. This program includes provisions to initiate evaluations and assessments when leakage is discovered by activities not associated with the program. This program further follows the guidance described in Section 7 of WCAP-15988-NP, Revision 2, *Generic Guidance for an Effective Boric Acid Inspection Program for Pressurized Water Reactors*.

Enhancements

None

A2.5 Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid Induced Corrosion in Reactor Coolant Pressure Boundary Components

Program Description

The *Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid Induced Corrosion in Reactor Coolant Pressure Boundary Components* AMP is an existing condition monitoring program that addresses OE of degradation due to primary water stress corrosion cracking for components or welds constructed from Alloy 600/82/182 and exposed to pressurized water reactor primary coolant at elevated temperatures.

The scope of the program includes the following groups of components and materials:

a. Nickel alloy components and welds identified in the industry guidance document "*Materials Reliability Program: Generic Guidance for Alloy 600 Management*" (EPRI MRP-126).

b. Nickel alloy components and welds identified in ASME Code Cases N-770, N-729 and N-722, as incorporated by reference in 10 CFR 50.55a.

c. Alloy 600 full penetration branch connection weld metal buildup for material susceptible to primary water stress corrosion cracking in accordance with ASME Code Case N-853.

d. Components that are susceptible to corrosion by borated water leakage and may be impacted by leakage of borated water from nearby or adjacent nickel alloy components previously described.

Examinations are conducted in accordance with 10 CFR 50.55a and EPRI MRP-126 for nickel-alloy components and welds identified in EPRI MRP-126 and addressed by 10 CFR 50.55a.

The *Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid Induced Corrosion in Reactor Coolant Pressure Boundary Components* AMP is used in conjunction with the *Water Chemistry* AMP (A2.2) because water chemistry can affect the cracking of nickel alloys.

<u>Enhancements</u>

None

A2.6 Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)

<u>Program Description</u>

The *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel* (CASS) AMP is a new condition monitoring program that will provide assurance that specific reactor coolant pressure boundary cast austenitic stainless steel components with the potential for thermal aging embrittlement meet their intended functions. The specific reactor coolant system (Class 1) pressure boundary components consist of those made from CASS with service conditions above 250°C (482°F), including valve bodies and pump casings and covers. Oconee does not have Class 1 piping or fittings fabricated from CASS.

For applicable Class 1 CASS valve bodies, the existing ASME Code, Section XI inspection requirements are adequate to manage thermal aging embrittlement. The Section XI inspection requirements are implemented at Oconee through the ONS *ASME Section XI Inservice Inspection, Subsections IWB, IWC and IWD* AMP.

For Class 1 CASS reactor coolant pump casings and covers with service conditions above 250°C (482°F), a screening for significance is performed as a first step to determine if thermal aging embrittlement is a potentially significant aging effect. This screening considers casting method, molybdenum content, and percent ferrite in each casting.

For reactor coolant pump casings and covers found to be potentially susceptible to thermal aging embrittlement, a bounding flaw tolerance evaluation was performed. The result demonstrates adequate fracture toughness to address thermal aging embrittlement. The successful result also means that no additional inspections or evaluations will be required to address thermal aging embrittlement for the SPEO.

Industry and plant-specific OE will be considered in the development and implementation of this program.

Enhancements

None

A2.7 PWR Vessel Internals

Program Description

The *PWR Vessel Internals* AMP is an existing condition monitoring program that relies on the implementation of the inspection and evaluation guidelines in Electric Power Research Institute (EPRI) Materials Reliability Program (MRP) Report No. 1022863, "Materials Reliability Program: Pressurized Water Reactor (PWR) Internals Inspection and Evaluation Guidelines," MRP-227-A, inspection standard for PWR Internals in MRP-228, and the ONS gap analysis (B2.1.7) that identifies enhancements to the program that are needed to address an 80-year operating period. This program is used to manage: (a) cracking due to stress corrosion cracking, primary water stress corrosion cracking, irradiation-assisted stress corrosion cracking, and cracking due to fatigue/cyclical loading; (b) loss of material due to wear; (c) loss of fracture toughness due to either thermal aging, neutron irradiation embrittlement, or void swelling; (d) dimensional changes due to void swelling or distortion; and (e) loss of preload due to thermal and irradiation-enhanced stress relaxation or creep.

The *PWR Vessel Internals* AMP includes the reactor internals components identified within MRP-227-A for Oconee, and the ONS gap analysis, which is based on MRP-227, Revision 1-A. The completed gap analysis incorporates screening, categorizing, and ranking results from MRP-189, Revision 3, and engineering evaluation and assessment of age-related degradation from MRP-229, to identify revisions and/or additional inspections not listed in MRP-227, Revision 1-A.

The scope of components considered for inspection includes core support structures, those reactor vessel internals components that serve an intended LR safety function pursuant to criteria in 10 CFR 54.4(a)(1), and other reactor vessel internals components whose failure could prevent satisfactory accomplishment of any of the functions identified in 10 CFR 54.4(a)(1)(i), (ii), or (iii). ASME Code, Section XI also includes inspection requirements for PWR removable core support structures in Table IWB-2500-1, Examination Category B-N-3, which are in addition to any inspections that are implemented in accordance with MRP-227, Revision 1-A.

The program establishes acceptance criteria for any visual, volumetric, surface, or physical measurement monitoring methods that are credited for aging management of specific reactor vessel internals components. Any detected conditions that do not satisfy the examination acceptance criteria are required to be dispositioned through the plant corrective action program, which may require repair, replacement, or analytical evaluation for continued service until the next inspection. The disposition will ensure that design basis functions of the reactor internals components will continue to be fulfilled for all licensing basis loads and events. Engineering evaluations used to disposition an examination result that does not meet the examination acceptance criteria will be conducted in accordance with NRC approved evaluation methods.

Enhancements

The following enhancement(s) will be implemented:

1. The *PWR Vessel Internals* AMP will be updated as necessary to provide guidance for implementing the changes to primary and expansion items in MRP-227, Rev 1-A, Tables 4-1, 4-4 (and Table 5-1 for Element 6 only), as modified by the ONS gap analysis reported in Appendix B2.1.7. (Elements 4 and 6)

A2.8 Flow-Accelerated Corrosion

Program Description

The *Flow-Accelerated Corrosion* AMP is an existing condition monitoring program that manages wall thinning caused by flow-accelerated corrosion. The program is based on commitments made in response to NRC GL 89-08, *"Erosion/Corrosion-Induced Pipe Wall Thinning,"* and relies on implementation of the EPRI guidelines in the Nuclear Safety Analysis Center (NSAC)-202L, Revision 4 for an effective flow-accelerated corrosion program.

CHECWORKS™ is used to predict component wear rates and remaining service life in the systems susceptible to flow-accelerated corrosion which provides reasonable assurance that structural integrity will be maintained between inspections. The CHECWORKS™ model is evaluated and updated as required to reflect any significant changes in plant operating parameters such as power uprates to ensure continued accurate modeling and wear rate prediction. This improves the predictive capability of the model to ensure that intended functions are maintained.

The program also manages wall thinning caused by mechanisms other than flow-accelerated corrosion in situations where periodic monitoring is used in lieu of eliminating the cause of various erosion mechanisms.

The program includes: (a) identifying all susceptible piping systems and components; (b) developing flow-accelerated corrosion predictive models to reflect component geometries, materials, and operating parameters; (c) performing analysis of flow-accelerated corrosion models and, with consideration of OE, selecting a sample of components for inspections; (d) inspecting components; (e) evaluating inspection data against acceptance criteria to determine the need for corrective actions including inspection sample expansion, repairs, or replacements, and to schedule future inspections; and (f) incorporating inspection data to refine flow-accelerated corrosion models.

Enhancement

The *Flow-Accelerated Corrosion* AMP will be enhanced to:

1. Reassess infrequently used piping systems excluded from the scope of the program to ensure adequate bases exist to justify this exclusion for the SPEO.

A2.9 Bolting Integrity

Program Description

The *Bolting Integrity* AMP is an existing condition monitoring program. The program manages loss of preload, cracking, and loss of material of safety related and non-safety related closure bolting on pressure-retaining components. The program utilizes recommendations and guidelines delineated in NUREG-1339, EPRI NP-5769, TR-1015336, and TR-1015337 for material selection, use of approved lubricants, proper torqueing, and leakage evaluations which are implemented during plant surveillance and maintenance activities.

The program includes periodic visual inspections of closure bolting on pressure-retaining components for indication of loss of preload, cracking, and loss of material as evidenced by pressure-retaining joint leakage. Closure bolting on pressure-retaining components and mechanical bolting that are submerged or closure bolting on pressure-retaining components located in piping systems that contain air or gas is inspected by alternative means, such as by sample based periodic inspections. The program also includes preventive measures provided in the EPRI guidance documents to preclude or minimize loss of preload and cracking.

High Strength closure bolting greater than 2 inches in diameter (regardless of code classification) with yield strength greater than or equal to 150 ksi (1,034 MPa) will be visually inspected for aging affects and inspected volumetrically in accordance with ASME Code Section XI, Table IWB-2500-1, Examination Category B-G-1.

The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* (A2.1) program includes inspection of safety related closure bolting on pressure-retaining components and supplements this program. Inspection activities for bolting in a buried environment or underground with restricted access are performed in conjunction with buried piping and component inspections performed as part of the *Buried and Underground Piping and Tanks* (A2.26) program.

The *Reactor Head Closure Stud Bolting* (A2.3) program manages the aging effects of the bolting components for the reactor vessel closure head. The *ASME Section XI, Subsection IWE* (A2.28) program, *ASME Section XI, Subsection IWF* (A2.30) program, *Structures Monitoring* (A2.33) program, *Inspection of Water-Control Structures Associated with Nuclear Power Plants* (A2.34) program, and *Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* (A2.13) program manage the aging effects of safety related and non-safety related structural bolting. The *External Surfaces Monitoring of Mechanical Components* (A2.23) program manages the aging effects of safety related and non-safety related bolting associated with ductwork for heating, ventilation, and air conditioning systems.

Enhancements

The *Bolting Integrity* AMP will be enhanced to:

1. Revise applicable procedures and specifications to include reference to EPRI Report 1015336, EPRI Report 1015337, and NUREG-1339, as appropriate.

2. Revise procedures governing the direct visual examination of bolted joints to include inspection parameters such as lighting, distance, and offset.

3. Perform volumetric inspections of non-ASME high strength bolting greater than 2 inches in diameter in accordance with the method described in ASME Code Section XI, Table IWB-2500-1, Examination Category B-G-1.

4. Perform visual inspections of a representative sample of 20 percent of closure bolting where leakage is difficult to detect such as submerged connections or systems containing air/gas or a maximum of 17 bolts for each material and environment population per unit, whichever is less, during each ten year period. If the minimum sample size is not achieved during a ten year period, then alternative inspections may be performed. For submerged bolting, alternative inspections may include (a) diver inspections or (b) remote video inspections. For systems containing air/gas, alternative inspections may include (a) visual inspection for discoloration when leakage from inside the piping system would discolor the external surfaces of the component; (b) monitoring and trending of pressure decay when the bolted connection is located within an isolated boundary; (c) soap bubble testing on the external mating surface of the bolted component; or (d) thermography, when the temperature of the process fluid is higher than ambient conditions around the component.

5. Perform additional inspections of a minimum of 20% of similar bolting or five additional inspections, whichever is less, when sample based inspections do not meet acceptance criteria. If the additional inspections identify bolting that does not meet acceptance criteria, then an extent of condition and extent of cause analysis will be conducted to determine the further extent of inspections. Additional inspections of similar bolting will be performed at all three units and will occur within the same interval in which the original inspection was conducted. The corrective action program will be used to determine if changes to inspection frequency is appropriate if any inspection results indicate that loss of function will occur prior to the next scheduled inspection.

A2.10 Steam Generators

Program Description

The *Steam Generators* AMP is an existing condition monitoring program that manages the aging effects of cracking, loss of material (e.g., wall thinning), and reduction of heat transfer for the steam generators. The scope of the program includes primary-side components (e.g., tubes, plugs, lower/upper heads, tubesheet, etc.), and secondary-side components that are contained within the steam generator. The program performs volumetric inspections for the tubes, and visual inspections for the other primary-side and secondary-side components. The visual inspections of steam generator components in the scope of this AMP are performed in accordance with the degradation assessment that is prepared as each steam generator is scheduled for examination.

Provisions in the *Steam Generators* program address reporting criteria, inspection scope and frequency, assessments, plugging criteria, and water chemistry monitoring to maintain consistency with established requirements. NEI 97-06, *"Steam Generator Program Guidelines,"* and associated EPRI guidelines, provide a generic industry program to implement Oconee technical specifications related to steam generators.

In accordance with technical specification requirements, tubing and primary-side inspections are performed at least every 72 effective full power months or every third refueling outage, whichever results in more frequent inspections. Degradation assessments are performed prior to each in-service inspection, which include a review of applicable industry and plant-specific OE which has occurred since the previous degradation assessment was performed. The degradation assessment review determines the existence of any unaddressed mechanism that could adversely affect steam generator primary-side or secondary-side integrity, as well as the effects of any chemistry excursions or transients that could affect existing degradation mechanisms.

The *Steam Generators* program includes preventive measures to mitigate aging related to corrosion phenomena, and through foreign material exclusion to inhibit tube degradation due to wear. Identification of deposits on the secondary side of the steam generator, and the subsequent removal of sludge deposits help avoid tube degradation.

The Oconee technical specifications require condition monitoring assessments to verify structural and leakage integrity after steam generator inspections have been completed. Operational assessments are also required by NEI 97-06 to ensure tube integrity will be maintained until the next inspection.

<u>Enhancements</u>

None

A2.11 Open-Cycle Cooling Water System

<u>Program Description</u>

The *Open-Cycle Cooling Water System* AMP is an existing preventive, mitigative, condition monitoring, and performance monitoring program based on the implementation of NRC GL 89-13, and includes non-safety related portions of the open-cycle cooling water system. The program includes: (a) surveillance and control to significantly reduce the incidence of flow blockage problems as a result of biofouling, (b) tests to verify heat transfer of heat exchangers, (c) periodic inspection and maintenance so that corrosion, erosion, cracking, fouling, and biofouling cannot degrade the performance of systems serviced by the open-cycle cooling water system. This program includes guidance beyond the requirements contained in NRC GL 89-13, such as inputs from industry reports and documents (e.g., EPRI documents) that address OE such that aging effects are adequately managed. The program also manages loss of coating integrity for certain components that do not perform a pressure boundary intended function and where loss of coating integrity would not impact the intended functions of downstream components.

Enhancements

The *Open-Cycle Cooling Water System* AMP is an existing program that will be enhanced to:

1. Perform periodic inspection, cleaning, and eddy current testing of the ‘A’ and ‘B’ Chiller condensers at least once every five years.

2. Perform a minimum of twenty inspections for recurring internal corrosion in raw water systems every 24 months until the rate of recurring internal corrosion occurrences no longer meets the criteria for recurring internal corrosion as defined in Section 3.3.2.2.7 of NUREG-2192. The selected inspection locations will be periodically reviewed to validate their relevance and usefulness and adjusted as appropriate. Evaluation of the inspection results will include (1) a comparison to the nominal wall thickness or previous wall thickness measurements to determine rate of corrosion degradation; (2) a comparison to the design minimum allowable wall thickness to determine the acceptability of the component for continued use; and (3) a determination of re-inspection interval.

3. Perform periodic internal visual inspections of the visible portion of the supply and return piping to the radwaste equipment cooling system from the condenser circulating water system intake piping in conjunction with the performance of the intake piping internal coating inspections. Visual inspections will be performed to identify direct evidence of internal degradation and indirect evidence of through wall leakage including the presence of backfill material or gravel within the pipe.

4. Provide additional guidance in procedures for inspections of non-ASME Code components for items such as lighting, distance, offset, surface coverage, presence of protective coatings, and cleaning processes.

5. Provide additional guidance for trending of heat exchanger inspection results to evaluate the adequacy of inspection frequencies.

6. If inspections identify wall thickness below the minimum required wall thickness and the cause of the aging effect for each applicable material and environment is not corrected by repair or replacement for all components constructed of the same material and exposed to the same environment, additional inspections will be conducted. The number of increased inspections is determined in accordance with the corrective action program; however, no fewer than five additional inspections will be conducted for each inspection that did not meet acceptance criteria, or 20% of each applicable material, environment, and aging effect combination is inspected, whichever is less. The additional inspections include inspections at all of the units with the same material, environment, and aging effect combination.

7. Incorporate programmatic guidance contained in engineering support documents into controlled plant procedures subject to administrative controls in accordance with the Duke Energy QA program.

A2.12 Closed Treated Water Systems

Program Description

The *Closed Treated Water Systems* AMP is an existing program that manages cracking, loss of material, and reduction of heat transfer for components exposed to a closed treated water environment.

The *Closed Treated Water Systems* program is a mitigation program that also includes condition monitoring activities to monitor the effectiveness of the mitigation activities. The program consists of: (a) water treatment, including use of corrosion inhibitors, to modify the chemical composition of the water such that the effects of corrosion are minimized, (b) chemical testing to ensure water treatment maintains water chemistry within acceptable guidelines, and (c) inspections to determine the presence or extent of degradation. The program includes coupon testing to measure corrosion rates and microbiological testing. The program uses EPRI guidelines for chemistry control of closed cooling water systems.

Enhancements

The *Closed Treated Water Systems* AMP will be enhanced to:

1. Perform condition monitoring using techniques (visual, surface, or volumetric) capable of detecting loss of material, cracking, and fouling as appropriate. Perform visual inspections for loss of material and fouling whenever the system boundaries of the closed treated water systems are opened. Perform surface or volumetric examinations when susceptible materials are inspected for cracking.

2. In each ten year period during the SPEO, perform sufficient number of inspections to ensure that the minimum representative sample of 20% of the population up to 17 inspections per unit is met. A population is defined as components having the same material, water treatment program and aging effect combination. Perform inspections on those components that are more likely to be susceptible to aging based on time in service and severity of operating conditions.

3. Perform additional inspections when inspections do not meet acceptance criteria. Perform at least five additional inspections for every inspection not meeting acceptance criteria or 20% of each applicable material, environment, and aging effect combination, whichever is less.

4. Provide additional guidance in procedures for inspections of non-ASME Code components for items such as lighting, distance, offset, surface coverage, presence of protective coatings, and cleaning processes.

5. Where practical, project the rate of any degradation until the next scheduled inspection or the end of the SPEO (whichever is shorter). Adjust the sampling bases (e.g., selection, size, frequency) as necessary based on the projections.

6. If subsequent inspections identify aging effects, the corrective action program will be used to determine the extent of condition and extent of cause to determine further extent of inspections. Perform additional inspections on all units with the same material, environment, and aging effect combinations and within the interval of the original inspection (e.g., refueling outage interval, 10-year inspection interval).

A2.13 Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems

Program Description

The *Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* AMP is an existing condition monitoring program that manages cracking, loss of material due to corrosion and wear, and loss of preload on bolted connections for cranes and hoists within the scope of SLR. The program includes periodic visual inspections to detect degradation of bridge, rail, and trolley structural components and bolted connections. This program relies on the guidance in NUREG-0612, "*Control of Heavy Loads at Nuclear Power Plants*," ASME B30.2, "*Overhead and Gantry Cranes (Top Running Bridge, Single or Multiple Girder, Top Running Trolley Hoist)*," and other appropriate standards in the ASME/ANSI B30 series to manage aging. These cranes must also comply with the maintenance rule requirements provided in 10 CFR 50.65.

Enhancements

The *Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* AMP will be enhanced to:

1. Provide additional procedural guidance to include visual inspections looking for deformation and cracking of bridges, structural members, and structural components.

2. Provide additional procedural guidance to specify bolted connections are monitored for loss of material, cracking, loose or missing bolts or nuts, and other conditions indicative of loss of preload.

3. Include evaluation of findings according to ASME B30.2 or other applicable ASME B30 series in applicable procedures.

4. Enhance maintenance procedures to ensure repairs are performed in accordance with ASME B30.2 or other applicable ASME B30 series in addition to manufacturers literature as necessary.

A2.14 Compressed Air Monitoring

Program Description

The *Compressed Air Monitoring* AMP is an existing preventive and condition monitoring program that manages loss of material downstream of the instrument air dryers. The program consists of monitoring moisture content, corrosion, and performance of the compressed air system. This includes (a) preventive monitoring of water (moisture) and other potentially corrosive contaminants to keep within the specified limits; and (b) opportunistic inspection of components for indications of loss of material due to corrosion. The program provides reasonable assurance of the integrity of the instrument air system components exposed to a dry air environment.

The *Compressed Air Monitoring* AMP is based on the Oconee responses to NRC GL 88-14, *"Instrument Air Supply Problems"* and INPO SOER 88-01, *"Instrument Air System Failures"*. The program also incorporates the air quality provisions provided in EPRI Compressed Air System Maintenance Guide (Report 1006677) and ANSI/ISA-7.0.01-1996, *"Instrument Society of America Quality Standard for Instrument Air"*. The program is informed by guidance in the American Society of Mechanical Engineers (ASME) operations and maintenance standards and guides (ASME OM-2012, Division 2, Part 28).

Enhancements

The *Compressed Air Monitoring* AMP will be enhanced to:

1. Perform opportunistic visual inspections of select component internal surfaces exposed to a dry air environment for signs of loss of material due to corrosion. Inspections will be performed by station personnel who have been qualified to the task per approved training procedures and programs. Acceptance criteria will ensure that internal surfaces that show signs of corrosion, that could indicate the potential loss of function of the component, are identified. The program will require corrective actions to be taken if loss of material due to corrosion is identified on internal surfaces of components.

A2.15 Fire Protection

Program Description

The *Fire Protection* AMP is an existing condition monitoring and performance monitoring program that includes fire barrier visual inspections and low pressure carbon dioxide system visual inspections and functional testing. The fire barrier inspection program requires periodic visual inspection of fire barrier penetration seals, fire barrier walls, ceilings, floors, fire dampers, and other materials that perform a fire barrier function. Periodic visual inspection and functional testing of the fire rated doors is performed to ensure that their functionality is maintained, and aging effects managed. The program also includes visual inspections and periodic functional tests of the standby shutdown facility CO_2 fire protection system using the NFPA Codes and Standards for guidance.

Enhancements

The *Fire Protection* AMP will be enhanced to:

1. Perform periodic visual inspection every 18 months for identification of corrosion that may lead to loss of material on the external surfaces of the standby shutdown facility CO_2 fire protection system.

A2.16 Fire Water System

Program Description

The *Fire Water System* AMP is an existing condition monitoring program that manages aging effects such as loss of material, cracking, and flow blockage associated with water-based fire protection system components. The program also manages loss of coating integrity of the internal coating of the elevated water storage tank. The program manages these aging effects by conducting periodic visual inspections, flow testing, and flushes using the guidance of the 2011 Edition of NFPA 25. Portions of water-based fire protection systems that have been wetted but are normally dry but periodically subject to flow have been confirmed to drain and are not subjected to augmented testing and inspections in addition to those specified in NFPA 25.

The high pressure service water system is normally maintained at required operating pressure and is monitored such that loss of system pressure is detected. The Keowee fire detection/ protection system is normally charged by static head from Lake Keowee. System flow downstream of the Keowee fire pump is monitored such that leakage from a normally stagnant line would be detected. Monitoring of operating parameters of the high pressure service water system and Keowee fire detection/protection system ensure prompt corrective actions can be initiated if leakage occurs.

Enhancements

The *Fire Water System* AMP will be enhanced to:

1. Perform internal visual inspections of deluge system piping by removing a hydraulically remote nozzle to identify internal corrosion, foreign material, and obstructions to flow. Internal visual inspections will be performed in 50% of the deluge systems within the scope of the *Fire Water System* AMP that are not subject to flow testing every five years. During the subsequent five year inspection period, the alternate systems will be inspected such that piping in 100 percent of the deluge systems within the scope of the program is inspected every ten years. Follow-up volumetric wall thickness examinations will be performed if internal visual inspections detect an unexpected level of degradation due to corrosion and corrosion product deposition.

2. Prior to fifty years in service, sprinkler heads will be submitted for field-service testing by a recognized testing laboratory consistent with NFPA 25, 2011 Edition, Section 5.3.1.

3. Perform a one-time volumetric wall thickness inspection on a representative sample deluge system supply piping that is periodically subjected to flow during functional testing.

4. Perform an obstruction investigation consistent with NFPA 25, 2011 Edition, Section 14.3 if evidence of unacceptable internal flow blockage that could result in failure of system function is identified during internal inspections. When unacceptable internal flow blockage is detected, corrective actions will include removal of the material, an extent of condition determination, review for increased inspections, follow-up examinations, and a flush consistent with NFPA 25 Annex D.5, *Flushing Procedures*.

5. Revise inspection procedures to provide additional inspection guidance regarding age-related degradation and to include inspection parameters for items such as lighting, distance, offset, presence of protective coatings, and cleaning processes.

6. Perform flow testing of at least one hose station in each building every five years to demonstrate the capability to provide the design pressure at required flow. Flow testing will be performed at the hydraulically most remote hose station or, if an alternative hose station is tested, the acceptance criteria for the test will account for the additional head loss that would occur if the hydraulically most remote hose station were tested such that the results of the flow test are representative of the limiting location. If acceptance criteria are not met, at least two additional tests shall be performed within five years. If subsequent tests do not meet acceptance criteria, an extent of condition and extent of cause analysis is conducted to determine the further extent of tests. The additional tests include at least one test at one of the other units with the same material, environment, and aging effect combination.

7. Perform external visual inspections of the elevated water storage tank consistent with Section 9.2.5.5 of NFPA 25, 2011 Edition at least once every two years.

8. Perform flushing of the mainline strainers following system actuation consistent with Section 10.2.7 of NFPA 25, 2011 Edition.

9. Perform main drain testing of the deluge system risers at least once every two years. Main drain testing of deluge systems will be performed consistent with the procedure described in Sections 13.2.5 and A.13.2.5 of NFPA 25, 2011 Edition. When there is a ten percent reduction in full flow pressure when compared to the original acceptance test or previously performed tests, the cause of the reduction shall be identified and corrected if necessary. If acceptance criteria are not met, at least two additional tests shall be performed within two years. If subsequent tests do not meet acceptance criteria, an extent of condition and extent of cause analysis is conducted to determine the further extent of tests. The additional tests include at least one test at one of the other units with the same material, environment, and aging effect combination.

10. Acceptance criteria and corrective actions for internal inspections of the elevated water storage tank will be in accordance with the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers and Tanks* program. Tank wall thickness

measurements will be conducted if interior pitting or general corrosion (beyond minor surface rust) is detected.

A2.17 Outdoor and Large Atmospheric Metallic Storage Tanks

Program Description

The *Outdoor and Large Atmospheric Metallic Storage Tanks* AMP is a new condition monitoring program that manages loss of material on the external surfaces of the Unit 1, 2, and 3 borated water storage tanks and ensures there is no significant degradation of the tank bottom. These are indoor large volume tanks that contain water and are designed with internal pressures approximating atmospheric that are sited on concrete. This program includes preventive measures to mitigate corrosion by protecting the external surfaces of steel components consistent with standard industry practices. The borated water storage tanks are internally coated and protected by missile barriers.

The program manages loss of material by conducting external visual surface inspections. Thickness measurements of the tank bottoms are conducted to ensure that significant degradation is not occurring. *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* (A2.27) AMP will manage the internally coated surfaces of the borated water storage tanks. The *Structures Monitoring* AMP (A2.33) will manage the tank concrete foundations and the borated water storage tank superstructures that serve as missile barriers. Cracking is not a predicted aging effect due to the carbon steel construction.

Inspections not conducted in accordance with ASME Code, Section XI requirements are conducted in accordance with plant-specific procedures that include inspection parameters such as lighting, distance, offset, and surface conditions.

Industry and plant-specific OE will be considered in the development and implementation of this program.

Enhancements

None

A2.18 Fuel Oil Chemistry

Program Description

The Fuel Oil Chemistry program is an existing mitigative and condition monitoring program that relies on a combination of surveillance and maintenance procedures to manage loss of material from tanks, piping and components in a fuel oil environment and to maintain fuel oil quality. Exposure to fuel oil contaminants, such as water and microbiological organisms, is minimized by periodic cleaning/draining of tanks and by verifying the quality of new oil before its introduction into the storage tanks. The fuel oil contained in the standby shutdown facility fuel oil storage tank and the standby shutdown facility fuel oil day tank is maintained in accordance with Technical

Specification 5.5.14, *Standby Shutdown Facility (SSF) Diesel Fuel Oil Testing Program* and Surveillance Requirement 3.10.1.8.

The aging management acceptance criteria for each new fuel and stored fuel testing parameter has been established based on ASTM Standards including ASTM D2709, *Standard Test Method for Water and Sediment in Middle Distillate Fuels by Centrifuge*, ASTM D6217, *Standard Test Method for Particulate Contamination in Middle Distillate Fuels by Laboratory Filtration*, ASTM D4057, *Standard Practice for Manual Sampling of Petroleum and Petroleum Products,* and ASTM D975, *Standard Specification for Diesel Fuel Oils*.

The standby shutdown facility fuel oil storage tank and the standby shutdown facility fuel oil day tank are periodically drained of water and accumulated sediment and then cleaned. The standby shutdown facility fuel oil storage tank is also monitored quarterly for the presence of water by draining oil from the bottom of the tank and water is removed, if found.

Enhancements

The *Fuel Oil Chemistry* AMP will be enhanced to:

1. Monitor the standby shutdown facility fuel oil day tank quarterly for the presence of water by draining oil from the bottom of the tank and remove the water, if found.

2. Monitor the fuel oil stored in the standby shutdown facility fuel oil day tank quarterly for the presence of bacteria and fungus.

3. Perform volumetric wall thickness measurement of the standby shutdown facility fuel oil day tank if evidence of degradation is identified visually during the 10 year internal inspection.

A2.19 Reactor Vessel Material Surveillance

Program Description

The *Reactor Vessel Material Surveillance* AMP is an existing condition monitoring program that manages reduction of fracture toughness due to neutron irradiation embrittlement of the ferritic reactor pressure vessel beltline materials in a reactor coolant and neutron fluence environment. The program uses surveillance capsules containing reactor vessel material specimens that are located near the inside reactor pressure vessel wall in the beltline region so that the specimens duplicate, as closely as possible, the neutron spectrum, temperature history, and maximum neutron fluence experienced at the inner surface of the reactor vessel. As described in RIS 2014-11, beltline materials are those ferritic reactor vessel materials with a projected neutron fluence greater than 1.0E+17 n/cm^2 (E > 1 MeV) at the end of the license period (i.e., the SPEO). Because of the location of the capsules between the reactor core and the reactor vessel wall, the resulting lead factor allows surveillance capsules to achieve a neutron fluence exposure earlier than the inner surface of the reactor pressure vessel.

The program is part of an NRC approved integrated surveillance program that is based on the BWOG reactor vessel integrity program, which consisted of four B&W plant utilities, five Westinghouse plant utilities with B&W fabricated reactor vessels, and Framatome (formally B&W) and is now included within the PWROG. The program meets the requirements of 10 CFR Part 50, Appendix H, which requires the implementation of a reactor vessel material surveillance program when the peak neutron fluence at the end of the design life of the vessel exceeds 1.0E+17 n/cm^2 (E > 1 MeV).

The program provides sufficient material data and dosimetry to (a) monitor irradiation embrittlement to a neutron fluence level that is greater than the projected peak neutron fluence of interest projected to the end of the SPEO, and (b) provide adequate dosimetry monitoring during the SPEO. The *Reactor Vessel Material Surveillance* program is used in conjunction with the *Neutron Fluence Monitoring* program (A3.2) which monitors neutron fluence for reactor vessel components and reactor vessel internal components.

The *Reactor Vessel Material Surveillance* AMP is a condition monitoring program that measures the increase in Charpy V-notch 30 foot-pound (ft-lb) transition temperature and the drop in the upper-shelf energy as a function of neutron fluence and irradiation temperature. The reactor pressure vessel beltline material surveillance capsules are removed at various exposure intervals for monitoring and trending purposes. The reactor pressure vessel beltline material test results from the *Reactor Vessel Material Surveillance* AMP provide reactor vessel material fracture toughness data used to monitor neutron irradiation embrittlement of the reactor vessel and is provided as input to the neutron embrittlement TLAA (e.g., upper-shelf energy and pressure-temperature limits evaluations).

All surveillance capsules, including those previously withdrawn from the reactor vessel, must meet the test procedures and reporting requirements of the applicable ASTM standards referenced in 10 CFR Part 50, Appendix H, to the extent practicable, for the configuration of the specimens in the capsule. Any changes to the surveillance capsule withdrawal schedule must be approved by the NRC prior to implementation, in accordance with 10 CFR Part 50, Appendix H, Paragraph III.B.3.

Enhancements

None

A2.20 One-Time Inspection

Program Description

The *One-Time Inspection* AMP is a new condition monitoring program that will manage loss of material, cracking, and reduction of heat transfer of components exposed to treated borated water, treated water, waste water, raw water, air, condensation, underground, fuel oil, or lubricating oil environments. The program also manages loss of coating integrity for certain components that do not perform a pressure boundary intended function and where loss of coating integrity would not impact the intended functions of downstream components.

The *One-Time Inspection* AMP consists of a one-time inspection of selected components to verify: (a) the system wide effectiveness of an AMP that is designed to prevent or minimize aging to the extent that it will not cause the loss of intended function during the SPEO; (b) the insignificance of an aging effect; and (c) that long-term loss of material will not cause a loss of intended function for steel components exposed to environments that do not include corrosion inhibitors as a preventive action.

The elements of the program will include: (a) determination of the sample size of components to be inspected based on an assessment of materials of fabrication, environment, plausible aging effects, and OE, (b) identification of the inspection locations in the system or component based on the potential for the aging effect to occur, (c) determination of the examination technique, including acceptance criteria that would be effective in managing the aging effect for which the component is examined, and (d) an evaluation of the need for follow-up examinations to monitor the progression of aging if age-related degradation is identified that could jeopardize an intended function before the end of the SPEO.

This program is not used for structures and components with known age-related degradation mechanisms or when the service environment in the SPEO is not expected to be equivalent to that in the prior operating period. Instead, other aging management programs, including programs that rely on periodic inspections, are used to manage age-related degradation of these structures and components. Inspections not conducted in accordance with ASME Code Section XI requirements will be conducted in accordance with plant-specific procedures including inspection parameters such as lighting, distance, offset, and surface conditions..

Industry and plant-specific OE will be considered in the development and implementation of this program.

<u>Enhancements</u>

None

A2.21 Selective Leaching

<u>Program Description</u>

The *Selective Leaching* AMP is a new condition monitoring program that will monitor components constructed of materials which are susceptible to selective leaching. Susceptible materials are gray cast iron, ductile iron, and copper alloys containing greater than 15% zinc or greater than 8% aluminum (aluminum bronze). The *Selective Leaching* program includes a one-time inspection for susceptible components exposed to closed cycle cooling water and treated water environments since plant-specific OE has not revealed evidence of significant selective leaching in these environments, as well as opportunistic and periodic inspections for susceptible components exposed to raw water, waste water, and soil (which may include groundwater) environments.

Visual inspections supplemented by mechanical examination techniques such as chipping or scraping (for ductile and gray cast iron components) will be conducted on a representative sample of susceptible components. In addition, periodic destructive examinations of components for physical properties (i.e., degree of dealloying, depth of dealloying, wall thickness, and chemical composition) will be conducted for components exposed to raw water, waste water, and soil environments. Inspections and tests will be conducted to determine whether loss of material due to selective leaching will affect the ability of the components to perform their intended function for the SPEO. Inspections will be conducted in accordance with plant-specific procedures including inspection parameters such as lighting, distance, offset and surface conditions as appropriate. When the acceptance criteria are not met such that it is determined that the affected component should be replaced prior to the end of the SPEO, additional inspections will be performed.

Industry and plant-specific OE will be considered in the development and implementation of this program.

Enhancements

None

A2.22 ASME Code Class 1 Small-Bore Piping

Program Description

The *ASME Code Class 1 Small-Bore Piping* AMP is a new condition monitoring program that will manage cracking in ASME Code Class 1 small-bore piping that is defined as greater than or equal to one-inch nominal pipe size (NPS) diameter and less than four inches NPS. The program augments the existing ASME Code, Section XI requirements and provides for examination of a sample of full penetration (butt) welds and partial penetration (socket) welds in Class 1 piping to manage cracking due to stress corrosion cracking or thermal or vibratory fatigue loading. Volumetric or destructive examinations will be employed to augment inspections performed by the *ASME Code, Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* (A2.1) AMP. This program provides for volumetric examination of a sample of full penetration (butt) welds and partial penetration (socket) welds in Class 1 piping to manage cracking due to stress corrosion cracking or thermal or vibratory fatigue loading.

Volumetric examinations will employ techniques that have been demonstrated to be capable of detecting flaws and discontinuities in the examination volume of interest. Destructive examination methods may be used in lieu of volumetric examination. The extent and schedule for volumetric examination in this program is based on plant-specific OE and whether actions have been implemented that effectively mitigate the cause(s) of any past cracking. One-time inspections and periodic inspections will determine the presence of cracking for locations within the scope of the *ASME Code Class 1 Small-Bore Piping* program. The program includes one-time inspections for a sample of the population of welds that have not experienced cracking and periodic inspections for a sample of the population of welds that have experienced cracking and have not implemented corrective actions to fully mitigate the cause(s) of the cracking for all similar welds (i.e., for all butt welds or all socket welds).

Age-related cracking has been experienced in ONS Class 1 small-bore piping butt weld populations and, therefore, the program will perform periodic examinations to monitor for cracking of butt welds within the scope of the *ASME Code Class 1 Small-Bore Piping* program. Periodic examinations of ten percent of the butt welds within the scope of this program will be performed every ten years, up to a maximum of 25 welds per unit. Since age-related cracking has not been identified in Class 1 small bore socket welded piping for ONS Units 1, 2 or 3, one-time examinations of these welds will be performed. One-time examinations of three percent of the socket welds within the scope of this program, up to a maximum of ten welds per unit, will be performed. If evidence of cracking is identified during the one-time inspections, periodic examinations of ten percent of the socket welds within the scope of this program will be performed every ten years.

Industry and plant-specific OE will be considered in the development and implementation of this program.

Enhancements

None

A2.23 External Surfaces Monitoring of Mechanical Components

Program Description

The *External Surfaces Monitoring of Mechanical Components* AMP is a new condition monitoring program that will manage the following aging effects:

- Loss of material, cracking, and reduction of heat transfer of metallic components;
- Hardening or loss of strength, loss of material, and cracking or blistering of polymeric components;
- Hardening or loss of strength, and loss of material of elastomeric components;
- Loss of material, cracking, and loss of preload for heating, ventilation, and air conditioning closure bolting; and
- Reduced thermal insulation resistance

Periodic visual inspections, not to exceed a refueling outage interval, of accessible surfaces of metallic, polymeric, and elastomeric components, and insulation metallic jacketing (or protective outer layer if metal jacketing is not used) will be conducted. For certain materials, such as flexible polymers and elastomers, physical manipulation or pressurization to detect hardening or loss of strength will be used to augment the visual examinations conducted under this program.

Surface examinations or ASME Code, Section XI, visual examinations (VT-1) will be conducted to detect cracking of copper alloy (>15% zinc or >8% aluminum) components.

A sample of outdoor component surfaces that are insulated and a sample of indoor insulated components exposed to condensation (due to the in scope component being operated below the dew point) will be periodically inspected every ten years during the SPEO.

Inspections not conducted in accordance with ASME Code Section XI requirements will be conducted in accordance with plant-specific procedures which include inspection parameters such as lighting, distance, offset, and surface conditions.

Acceptance criteria are such that the component will meet its intended function until the next inspection or the end of the SPEO. For qualitative evaluations, applicable parameters such as change in hardness, flexibility, or surface condition will be used to reasonably ensure that a consistent determination is made based on the observed conditions.

Industry and plant-specific OE will be considered in the development and implementation of this program.

Enhancements

None

A2.24 Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components

Program Description

The *Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components* AMP is a new condition monitoring program that will manage loss of material and cracking of metallic components, as well as loss of material, cracking, blistering, hardening, and loss of strength of polymeric and elastomeric materials. The program also manages loss of coating integrity for certain components that do not perform a pressure boundary intended function and where loss of coating integrity would not impact the intended functions of downstream components. Reduction of heat transfer and flow blockage will also be managed. This program will consist of visual inspections of internal surfaces of piping, piping components, ducting, heat exchanger components, polymeric and elastomeric components, and other mechanical components. Applicable environments include air, condensation, closed cycle cooling water, diesel exhaust, fuel oil, gas, lubricating oil, raw water, treated water, and waste water. Periodic visual (VT-1) or surface examinations will be performed to detect cracking of stainless steel components exposed to a diesel exhaust, potable raw water, and waste water and in copper alloys exposed to waste water. Visual inspections may be conducted in lieu of VT-1 or surface examinations where it has been analytically demonstrated that surface cracks can be detected by leakage prior to a crack challenging the structural integrity or intended function of the component. Except for hardening and loss of strength of elastomers, aging effects associated with components within the scope of the *Open Cycle Cooling Water System* (A2.11) AMP, *Closed Treated Water Systems* (A2.12) AMP, and *Fire Water System* (A2.16) AMP will not be managed by this program. The *Inspections* *of Internal Surfaces of Miscellaneous Piping and Ducting Components* is not relied on to manage recurring internal corrosion.

Internal inspections will be performed during the periodic system and component surveillances or during the performance of maintenance activities when the surfaces are made accessible for visual inspection. At a minimum, in each ten year period during the SPEO, a representative sample of twenty percent of the population (defined as components having the same combination of material, environment, and aging effect) or a maximum of 17 components per population per unit, where the sample size is not based on percentage of the population, will be inspected. Sample selection will consider component susceptibility to aging due to factors such as time in service and severity of operating conditions. Opportunistic inspections will continue in each period despite meeting the sampling limit. For certain materials, such as flexible polymers, physical manipulation to detect hardening or loss of strength will be used to augment the visual examinations conducted under this program.

Inspections not conducted in accordance with ASME Code Section XI requirements will be conducted in accordance with plant-specific procedures which include inspection parameters such as lighting, distance, offset, and surface conditions. Acceptance criteria will ensure that the component will meet its intended function until the next inspection or the end of the SPEO. Qualitative acceptance criteria are clear enough to reasonably assure a singular decision is derived based on observed conditions.

Industry and plant-specific OE will be considered in the development and implementation of this program.

Enhancements

None

A2.25 Lubricating Oil Analysis

Program Description

The *Lubricating Oil Analysis* AMP is an established program intended to avoid the loss of material and reduction of heat transfer to in-scope components by maintaining the quality of the lubricating oil and hydraulic oil. The program provides reasonable assurance that contaminants (particularly water and particulates) are maintained within acceptable limits. Testing activities include sampling and analysis of lubricating oil and hydraulic oil using manufacturer, industry and ASTM guidelines.

Enhancements

The *Lubricating Oil Analysis* AMP will be enhanced to:

1. Update the *Lubricating Oil Analysis* program procedures to specify that in all cases, phase-separated water in any amount is not acceptable.

A2.26 Buried and Underground Piping and Tanks

Program Description

The *Buried and Underground Piping and Tanks* AMP is an existing condition monitoring program that manages the aging effects associated with the external surfaces of buried and underground piping and tanks including loss of material and cracking of components in soil or underground environments within the scope of SLR. The program addresses piping and tanks of any material, including carbon steel, ductile iron, gray cast iron, stainless steel and copper alloys. There are no buried or underground cementitious or polymeric piping or tanks within the scope of SLR at Oconee. Condition monitoring of the buried and underground piping and tanks relies on inspections conducted by qualified individuals.

The program also manages aging through preventive and mitigative actions (i.e., coatings, backfill quality, and cathodic protection). The number of inspections is based on the effectiveness of the preventive and mitigative actions. Annual cathodic protection surveys are conducted. The acceptance criteria for cathodic protection system effectiveness is -850 mV relative to copper/copper sulfate reference electrode.

Enhancements

The *Buried and Underground Piping and Tanks* AMP will be enhanced to:

1. Install a cathodic protection system in accordance with NACE SP0169-2007 for buried carbon steel piping within the scope of this program.

2. Complete a modification to abandon the buried copper alloy instrument air system piping within the scope of this program.

3. Annual cathodic protection system monitoring will be performed with a maximum grace period of two months. The system will be monitored at least once during each calendar year.

4. Utilize an inspection method that has been demonstrated to be capable of detecting cracking for uncoated stainless steel piping and when visual inspections of coated stainless steel piping detect coating degradation or damage which could potentially result in stress corrosion cracking of the base material. Indications of cracking will be evaluated in accordance with applicable codes and plant-specific design criteria.

5. Perform wall thickness measurement if visual inspections identify evidence of corrosion beyond minor surface rusting for both coated and uncoated metallic piping or tanks. The results of the wall thickness measurement will be used to calculate a corrosion rate and project wall thickness through the end of the SPEO. If the depth or extent of degradation of the base metal could have resulted in a loss of pressure boundary function when the loss of material is extrapolated to the end of the SPEO, then additional inspections will be performed as follows: When measured pipe wall thickness, projected to the end of the SPEO, does not meet the minimum pipe wall thickness requirements due to external

corrosion, the number of inspections within the affected piping category will be doubled or increased by five, whichever is smaller. If adverse indications are found in the expanded sample, an extent of condition and extent of cause analysis to determine the further extent of inspections. Timing of any additional inspections will be based on the severity of the identified degradation and the consequences of leakage or loss of function. Any additional inspections will be performed within the same 10-year inspection interval in which the original degradation was identified, or within four years after the end of the 10-year interval if the degradation was identified in the latter half of the 10-year interval. Expansion of sample size may be limited by the extent of piping subject to the observed degradation mechanism or if the piping system or portion of the system is replaced or otherwise mitigated within the same 10-year inspection interval in which the original degradation was identified or within four years after the end of the 10-year interval, if the degradation was identified in the latter half of the 10-year interval.

6. Perform inspections of buried steel condenser circulating water system piping at least once every ten years. The minimum number of inspections will be determined based on the effectiveness of preventive actions in accordance with NUREG-2191, Table XI.M41-2. Ten linear feet of piping will be exposed for each inspection. Inspections of the large diameter condenser circulating water system intake piping will expose a quadrant (i.e., 9 to 12 o'clock or 12 to 3 o'clock) of the piping. External inspections of the large diameter condenser circulating water system intake piping will be supplemented by low frequency electromagnetic testing performed from the internal surface of the same section of piping that is externally inspected with follow-up ultrasonic wall thickness measurements performed of areas identified as low points during low frequency electromagnetic testing.

7. Perform visual inspections of at least two ten-linear foot sections of buried uncoated stainless steel piping at least once every ten years. Piping inspection locations will be selected based on risk (i.e., susceptibility to degradation and consequences of failure).

8. Perform visual inspections of at least four ten linear foot sections of underground coated steel piping at least once every ten years. Piping inspection locations will be selected based on risk (i.e., susceptibility to degradation and consequences of failure).

9. Internal volumetric inspections of the standby shutdown facility diesel engine fuel oil tank will cover at least 25% of the surface area of the tank and include at least some of both the top and bottom of the tank.

10. Personnel performing inspections of buried coated piping and tanks will either: 1) possess an Association for Materials Protection and Performance coating inspector program level 2 or level 3 inspector qualification, 2) complete the EPRI *Comprehensive Coatings Course* and complete the EPRI *Buried Pipe Condition Assessment and Repair Training Computed Based Training Course*, or 3) be qualified as a coatings specialist in accordance with ASTM D7108.

11. If significant coating damage is identified during visual inspections, then perform an evaluation to determine if the coating damage was caused by nonconforming backfill. If it is determined that the coating damage was caused by nonconforming backfill, then

conduct an extent of condition evaluation to determine the extent of degraded backfill in the vicinity of the observed damage.

A2.27 Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers and Tanks

Program Description

The *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* AMP is a new condition monitoring program that manages degradation of internal coatings/linings exposed to raw water, treated water, treated borated water, or lubricating oil that can lead to loss of base metal material or downstream effects such as reduction in flow, pressure, or heat transfer when coatings/linings become debris. There are no internally coated or lined piping, piping components, heat exchangers, or tanks exposed to closed-cycle cooling water, waste water, fuel oil, air or condensation within the scope of this program and the program is not used to manage loss of coating integrity of external coatings.

This program manages these aging effects for internal coatings by conducting periodic visual inspections of all coatings/linings applied to the internal surfaces of in scope components where loss of coating or lining integrity could impact the component's or downstream component's CLB intended functions.

For tanks and heat exchangers, all accessible surfaces are inspected. Piping inspections are sampling based. The training and qualification of individuals involved in coating/lining inspections of non-cementitious coatings/linings are conducted in accordance with ASTM International Standards endorsed in RG 1.54, *"Service Level I, II and II Protective Coatings Applied to Nuclear Power Plants,"* including the NRC guidance contained in RG 1.54 associated with a particular standard. For cementitious coatings, training and qualifications are based on an appropriate combination of education and experience related to inspecting concrete surfaces. Peeling and delamination is not acceptable. Blisters are evaluated by a coatings specialist, and should be limited to a few intact small blisters that are completely surrounded by sound material, and with size and frequency not increasing. Minor cracks in cementitious coatings are acceptable provided there is no evidence of debonding. All other degraded conditions are evaluated by a coatings specialist. For coated/lined surfaces determined to not meet the acceptance criteria, physical testing is performed where physically possible (i.e., sufficient room to conduct testing) in conjunction with repair or replacement of the coating/lining.

Aging of the internal coating for the elevated water storage tank will be managed as described in the *Fire Water System* (A2.16) program.

Industry and plant-specific OE will be considered in the development and implementation of this program.

Enhancements

None

A2.28 ASME XI, Subsection IWE

Program Description

The *ASME Section XI, Subsection IWE* AMP is an existing condition monitoring program that manages cracking, loss of material, loss of sealing, loss of preload, and loss of leak tightness. This program is in accordance with ASME Section XI, Subsection IWE, consistent with 10 CFR 50.55a *"Codes and Standards*," with supplemental recommendations. The *ASME Section XI, Subsection IWE* program includes periodic visual, surface, and volumetric examinations, where applicable, of the metallic pressure-retaining components of the concrete containment for signs of degradation, damage, irregularities including discernible liner plate bulges, and for coated areas, distress that might be indicative of degradation of the underlying metal shell or liner, and corrective actions. Acceptability of inaccessible areas of the concrete containment steel liner is evaluated when conditions found in accessible areas, indicate the presence of, or could result in, flaws or degradation in inaccessible areas.

The program includes supplemental surface or enhanced examinations to detect cracking for specific pressure-retaining components. Containment liners and penetrations were analyzed for cyclic fatigue and do not require surface examinations in addition to visual examinations to detect cracking in stainless steel and dissimilar metal welds of penetration sleeves and components that are subject to cyclic loading. A one-time volumetric examination of metal liner surfaces that are inaccessible from one side will be performed if triggered by plant-specific OE. This supplemental volumetric examination consists of a sample of one-foot square locations that include both randomly selected and focused areas most likely to experience degradation based on operating experience and/or relevant considerations such as environment. Inspection results will be compared with prior recorded results in acceptance of components for continued service.

In conformance with 10 CFR 50.55a(g)(4)(ii), the *Containment Inservice Inspection* AMP will be updated during each successive 120 month inspection interval to comply with the requirements of the latest edition and addenda of the Code specified 12 months before the start of the inspection interval.

Enhancements

The *ASME Section XI, Subsection IWE* AMP will be enhanced to:

1. Specify that for "high strength" structural bolting consisting of ASTM A325, ASTM F1852, and/or ASTM A490 bolts, the preventive actions for storage, lubrication, and stress corrosion cracking potential discussed in Section 2.0 of RCSC (Research Council for Structural Connections) publication *"Specification for Structural Joints Using ASTM A325 or ASTM A490 Bolts,"* will be used.

2. Include inspection attributes for the aging mechanisms listed in NUREG-2191. For non-coated surfaces this includes evidence of cracking, discoloration, wear, pitting, excessive corrosion, arc strikes, gouges, surface discontinuities, dents, and other signs of surface irregularities including discernible liner plate bulges. For painted or coated surfaces this includes evidence of flaking, blistering, peeling, discoloration, and other signs of potential distress of the underlying metal shell or liner system, including discernible liner plate bulges.

3. Specify a one-time volumetric examination of metal liner surfaces that are inaccessible from one side if triggered by plant-specific OE. The trigger for this supplemental examination is plant-specific occurrence or recurrence of measurable metal liner corrosion (base metal material loss exceeding 10% of nominal plate thickness) initiated on the inaccessible side or areas, identified since the date of issuance of the first renewed license. This supplemental volumetric examination consists of a sample of one-foot square locations that include both randomly-selected and focused areas most likely to experience degradation based on operating experience and/or other relevant considerations such as environment. The supplemental volumetric examinations for each unit will occur within two refueling outages after identifying the trigger for the examination. Any identified degradation is addressed in accordance with the applicable provisions of the ASME Section XI, Subsection IWE program. The sample size, locations, and any needed scope expansion (based on findings) for this one-time set of volumetric examinations should be determined on a plant-specific basis to demonstrate statistically with 95% confidence that 95% of the accessible portion of the containment liner is not experiencing corrosion degradation with greater than 10% loss of nominal thickness.

A2.29 ASME XI, Subsection IWL

Program Description

The *ASME Section XI, Subsection IWL* AMP is an existing condition monitoring program that manages the following effects for containment concrete and post-tensioning system: cracking, loss of material, loss of material (spalling, scaling), distortion, loss of bond, and increase in porosity and permeability. The program is in accordance with ASME Section XI, Subsection IWL, and consistent with 10 CFR 50.55a, *"Codes and Standards."* In conformance with 10 CFR 50.55a(g)(4)(ii), the Containment Inservice Inspection program will be updated during each successive 120 month inspection interval to comply with the requirements of the latest edition and addenda of the code specified 12 months before the start of the inspection interval.

This AMP includes inspection of tendon and anchorage hardware surfaces and measurement of tendon force and elongation. The program also includes inspection of containment reinforced concrete above ground for evidence of concrete degradation. The ASME Section XI, Subsection IWL AMP consists of (a) periodic visual inspection of accessible concrete surfaces for the reinforced and prestressed concrete containments, (b) periodic visual inspection and sample tendon-testing of unbonded post-tensioning system components for signs of degradation, assessment of damage, and corrective actions, and (c) testing of the tendon corrosion protection medium and free water.

Measured tendon lift-off forces in select sample tendons are compared to predicted tendon group forces calculated using the guidance presented in NRC RG 1.35.1, *"Determining Prestressing Forces for Inspection of Prestressed Concrete Containments."* The Subsection IWL requirements are supplemented to include quantitative acceptance criteria for the evaluation of concrete surfaces based on the "*Evaluation Criteria"* provided in Chapter 5 of American Concrete Institute (ACI) 349.3R, *"Evaluation of Existing Nuclear Safety-Related Concrete Structures."* Inspection results are compared with prior recorded results in acceptance of components for continued service.

<u>Enhancements</u>

The *ASME Section XI, Subsection IWL* AMP will be enhanced to:

1. Incorporate monitoring for changes in material properties of increase in porosity and permeability, and loss of strength and pattern cracking with darkened edges.

2. Specify that inspection results are documented and compared to previous results to identify changes from prior inspections.

A2.30 ASME XI, Subsection IWF

<u>Program Description</u>

The *ASME Section XI, Subsection IWF* AMP is an existing condition monitoring program that manages loss of material, cracking, loss of preload, and loss of mechanical function for supports of Class 1, 2, and 3 components. This program consists of periodic visual examinations of piping and component supports for signs of degradation, evaluation, and corrective actions. Supports for Class 1, 2, and 3 piping and component supports are selected for examination per the requirements of ASME Code, Section XI, Subsection IWF. Acceptance standards are specified in ASME Code, Section XI, Subsection IWF, Article IWF-3400. If a component support does not meet the acceptance standards of IWF-3400 but is electively repaired to as new condition, the sample is increased or modified to include another support that is representative of the remaining population of supports that were not repaired. The scope of the inspection for supports is based on class and total population as defined in Table IWF-2500-1. Inspections that reveal indications or relevant conditions that are unacceptable are entered in the corrective actions program.

This program recommends additional inspections beyond the inspections required by the 10 CFR 50.55a *ASME Section XI, Subsection IWF* AMP. This includes a one-time inspection within five years prior to entering the SPEO of an additional 5% of the sample populations of Class 1, 2, and 3 piping supports. The additional supports will be selected from the remaining population of IWF piping supports and will include components that are most susceptible to age-related degradation. For high strength bolting with an actual yield strength equal to or greater than 150 ksi in sizes greater than one inch nominal diameter, volumetric examination comparable to that of ASME Code Section XI, Table IWB-2500-1, Examination Category B-G-1 will be performed to detect cracking in addition to the VT-3 examination. Examinations that reveal indications are evaluated. Evaluations that find relevancy is substantiated and the condition is unacceptable then a corrective action is generated.

<u>Enhancements</u>

The *ASME Section XI, Subsection IWF* AMP will be enhanced to:

1. Perform periodic evaluations of the acceptability of inaccessible areas of supports (e.g., portions of supports encased in concrete, buried underground, or encapsulated by guard pipe), when conditions exist in accessible areas that could indicate the presence of, or result in, degradation to inaccessible areas of supports. Perform these evaluations once every ten years during the SPEO.

2. Procedures will be revised to specify that for structural bolting consisting of ASTM A325, ASTMF1852, and/or ASTM A490, the preventative actions for storage, lubricants, and stress corrosion cracking potential discussed in Section 2 of RCSC (Research Council for Structural Connections) publication, "*Specification for Structural Joints Using ASTM A325 or A490 Bolts*," will be used.

3. Procedures will be revised to specify that whenever replacement of bolting is required, bolting material, installation torque or tension, and use of lubricants and sealants will be in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339.

4. Perform a one-time inspection within five years prior to entering the SPEO of an additional 5% of the sample populations for Class 1, 2, and 3 piping supports. The additional supports will be selected from the remaining population of IWF piping supports and will include components that are most susceptible to age-related degradation.

5. Procedures will be revised to specify that, for NSSS component supports, high strength bolting greater than one-inch nominal diameter, volumetric examination comparable to that of ASME Code, Section XI, Table IWB-2500-1, Examination Category B-G-1 will be performed to detect cracking in addition to the VT-3 examination. In each 10-year period during the SPEO, a representative sample of bolts will be inspected. The sample of high-strength bolting greater than one-inch nominal diameter subject to volumetric examination will consist of 17 bolts per unit. The sample shall include the bolting that is most susceptible to age-related degradation (i.e., based on time in service, aggressive environment, etc.).

6. If a component does not exceed the acceptance standards of IWF-3400 but is repaired to as new condition, the sample is increased or modified to include another support that is representative of the remaining population of supports that were not repaired.

A2.31 10 CFR Part 50 Appendix J

Program Description

The *10 CFR Part 50, Appendix J* AMP is an existing performance monitoring program that consists of monitoring leakage rates through the containment pressure retaining boundary, including associated welds, penetrations, isolation valves, and other access openings and attachments. Leakage monitoring activities are credited to indirectly detect cracking, loss of material, loss of preload, and loss of sealing of the containment pressure boundary. Corrective actions are taken if leakage rates exceed acceptance criteria. Consistent with the CLB, the containment leak rate tests are performed in accordance with the regulations and guidance provided in 10 CFR Part 50 Appendix J, Option B; RG 1.163, "*Performance-Based Containment Leak-Test Program*", and NEI 94-01, "*Industry Guideline for Implementing Performance-Based Option of 10 CFR Part 50, Appendix J*", and subject to the requirements of 10 CFR Part 54, "*Requirements for Renewal of Operating Licenses for Nuclear Power Plants*."

Enhancements

None

A2.32 Masonry Walls

Program Description

The *Masonry Walls AMP* is an existing condition monitoring program that is implemented as part of the *Structures Monitoring* (A2.33) AMP and manages cracking, loss of material, and loss of material (spalling and scaling) that could impact the intended function of the masonry walls. The *Masonry Walls* AMP consists of inspections, consistent with Inspection and Enforcement Bulletin 80-11, and plant-specific monitoring, proposed by Information Notice 87-67, for managing shrinkage, separation, gaps, loss of material and cracking of masonry walls such that the evaluation basis is not invalidated and intended functions are maintained.

Enhancements

The *Masonry Walls* AMP will be enhanced to:

1. Update the parameters monitored to identify potential shrinkage and/or separation of masonry walls and include loss of material in addition to the currently managed cracking at joints.

A2.33 Structures Monitoring

Program Description

The *Structures Monitoring* AMP is an existing condition monitoring program that consists of periodic visual inspection and monitoring of the condition of concrete and steel structures, structural components, component supports, and structural commodities to ensure that aging degradation (such as those described in ACI 349.3R, ACI 201.1R, SEI/ASCE 11, and other documents) will be detected, the extent of degradation determined and evaluated, and corrective actions taken prior to loss of intended functions. Structures are monitored on an interval of a nominal five years. The interval may be increased to a nominal ten year frequency with appropriate justification based on the structure, environment and related inspections. Inspections also include seismic joint fillers, elastomeric materials; and reinforcement of masonry walls, and periodic evaluation of groundwater chemistry and opportunistic inspections for the condition of below grade concrete.

Quantitative results (measurements) and qualitative information from periodic inspections are trended with sufficient detail, such as photographs and surveys for the type, severity, extent, and progression of degradation, to ensure that corrective actions can be taken prior to a loss of intended function. The acceptance criteria are derived from applicable consensus codes and standards. For concrete structures, the program includes personnel qualifications and quantitative evaluation criteria of ACI 349.3R.

<u>Enhancements</u>

The *Structures Monitoring* AMP will be enhanced to:

1. Add the following structures to the scope of the program:

    a. Microwave House Structure
    b. Technical Support Building cable vault
    c. 100kv Structure
    d. Protected Service Water Building
    e. Protected Service Water Duct Banks
    f. Borated Water Storage Tank Superstructure
    g. Health Physics Office Building
    h. Administration Building

2. Procedures will be revised to specify that structural components inspected include structural bolting, anchor bolts and embedments, supports and bracings associated with masonry walls, pipe whip restraints and jet impingement shields, transmission towers, panels and other enclosures, racks, sliding surfaces, sump and pool liners, electrical cable trays and conduits, tube tracks, electrical duct banks, manholes, doors, penetration seals, and other elastomeric materials.

3. Expand the monitoring and evaluation of raw water and ground water chemistry, for pH, chlorides, and sulfates, on a frequency not to exceed five years that accounts for seasonal variations (e.g., quarterly monitoring every fifth year), from locations that are representative of the groundwater in contact with structures within the scope of SLR:

    a. Enter adverse results, which exceed water chemistry criteria, into the corrective action program. As part of the corrective actions, if aggressive groundwater is identified that might affect structures in scope for SLR, perform additional water testing at additional locations and perform soil testing in order to confirm the extent, severity, and potential aging mechanisms resulting from the aggressive groundwater/ soil.

b. Develop engineering evaluations to evaluate the water chemistry results to assess the impact, if any, on below-grade concrete, including the potential for further degradation due to the aggressive groundwater, as well as consideration of current conditions. As part of the engineering evaluations, determine if additional actions are warranted, which might include enhanced inspection techniques and/or increased frequency, destructive testing, and focused inspections of representative accessible (leading indicator) or below grade, inaccessible concrete structural elements exposed to aggressive groundwater/soil.
c. Develop the initial engineering evaluations prior to the SPEO. Develop follow-up engineering evaluations on an interval not to exceed five years.
d. If aggressive groundwater and soil is identified, at a minimum, perform focused inspections of representative, accessible (leading indicator) structural elements, or if accessible areas will not be leading indicators for the potential aging mechanisms, excavate and inspect buried concrete elements exposed to aggressive groundwater/ soil.
e. If degraded concrete is identified, as part of the focused inspections of leading indicators (representative, accessible or exposed inaccessible concrete), enter adverse results that exceed ACI 349.3R second tier criteria into the corrective action program, and expose inaccessible concrete so that the extent of the condition can be determined, baseline conditions documented, and additional actions identified such as repairs, new preventative actions, additional evaluations, and future inspections.

4. For structural bolting consisting of ASTM A325, ASTMF1852, and/or ASTM A490, provide guidance for storage, lubricants, and the steps to minimize stress corrosion cracking potential discussed in Section 2 of RCSC (Research Council for Structural Connections) publication, "*Specification for Structural Joints Using ASTM A325 or A490 Bolts*".

5. Provide guidance so that when replacement bolting is required, bolting material, installation torque or tension, and use of lubricants and sealants will be in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339.

6. Provide guidance for proper specification of new high strength bolting material and lubricant to prevent or mitigate degradation and failure of structural bolting in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339.

7. Expand the program to include details regarding inspection and evaluation for steel liners.

8. Provide inspection and evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. The program will be enhanced to explicitly mention the changes in material properties of increase in porosity and permeability, and loss of strength and pattern cracking with darkened edges.

9. Develop a new implementing procedure or revise an existing implementing procedure to address aging management of inaccessible areas exposed to potentially aggressive groundwater/soil environment that will include the following:

    a. Monitor raw water and ground water chemistry, for pH, chlorides, and sulfates, on a frequency not to exceed five years that accounts for seasonal variations (e.g., quarterly monitoring every fifth year), from locations that are representative of the groundwater in contact with structures within the scope of SLR.
    b. Enter adverse results, which exceed water chemistry criteria, into the corrective action program. As part of the corrective actions, if aggressive groundwater is identified that might affect structures in scope for SLR, perform additional water testing at additional locations and perform soil testing in order to confirm the extent, severity, and potential aging mechanisms resulting from the aggressive groundwater/soil.
    c. Develop engineering evaluations to evaluate the water chemistry results to assess the impact, if any, on below-grade concrete, including the potential for further degradation due to the aggressive groundwater, as well as consideration of current conditions. As part of the engineering evaluations, determine if additional actions are warranted, which might include enhanced inspection techniques and/or increased frequency, destructive testing, and focused inspections of representative accessible (leading indicator) or below grade, inaccessible concrete structural elements exposed to aggressive groundwater/soil.
    d. Develop the initial engineering evaluations prior to the SPEO. Develop follow-up engineering evaluations on an interval not to exceed five years.
    e. If aggressive groundwater and soil is identified, at a minimum, perform focused inspections of representative, accessible (leading indicator) structural elements, or if accessible areas will not be leading indicators for the potential aging mechanisms, excavate and inspect buried concrete elements exposed to aggressive groundwater/soil.
    f. If degraded concrete is identified, as part of the focused inspections of leading indicators (representative, accessible or exposed inaccessible concrete), enter adverse results that exceed ACI 349.3R second tier criteria into the corrective action program, and expose inaccessible concrete so that the extent of the condition can be determined, baseline conditions documented, and additional actions identified such as repairs, new preventative actions, additional evaluations, and future inspections.

10. Monitor and trend through-wall groundwater leakage, infiltration volumes, and leakage water chemistry for signs of concrete or steel reinforcement degradation. Develop additional engineering evaluations, which consider more frequent inspections, as well as destructive testing of affected concrete to validate existing concrete properties, and leakage water chemistry results. If leakage volumes allow, consider water chemistry analysis of the leakage pH, along with mineral, chloride, sulfate and iron content in the water.

11. Expand the program to monitor accessible sliding surfaces for indications of significant loss of material due to wear or corrosion, and for accumulation of debris or dirt. Establish acceptance criteria for sliding surfaces as no significant loss of material due to wear or

corrosion, and no debris or dirt that could restrict or prevent sliding of the surfaces, as required by design.

12. Expand the program to monitor elastomeric vibration isolators and bearing pads, structural sealants, and seismic joint fillers for cracking, loss of material, and hardening. Supplement visual inspection of elastomeric elements with tactile inspection to detect hardening, if the intended function is suspect. Establish acceptance criteria for elastomeric pads and vibration isolation elements, structural sealants, and seismic joint fillers, as no loss of material, cracking, or hardening that can lead to loss of isolation or support function.

13. Require that personnel performing inspections and evaluations meet the qualifications specified within ACI 349.3R with respect to knowledge of inservice inspection of concrete and visual acuity requirements.

14. Perform inspections under the enhanced program in order to establish quantitative baseline inspection data to a sufficient detail to allow for trending, prior to the SPEO.

15. Revise inspection procedures to base inspection acceptance criteria on quantitative requirements derived from industry codes and standards, including but not limited to ACI 349.3R, ACI 318, SEI/ASCE 11, or the relevant AISC specifications and consider industry and plant OE. Use justified quantitative acceptance criteria whenever applicable.

16. Provide evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. Base the acceptance criteria for concrete surfaces on the "second-tier" evaluation criteria provided in Chapter 5 of ACI 349.3R.

17. Clarify that loose bolts and nuts are not acceptable unless accepted by engineering evaluation.

A2.34 Inspection of Water-Control Structures Associated with Nuclear Power Plants

Program Description

The *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP is an existing condition monitoring program that consists of inspection and surveillance of the raw water control structures associated with emergency cooling systems, emergency power production or flood control. The scope of the program also includes structural steel, and structural bolting associated with water control structures, steel or wood piles and sheeting required for the stability of embankments and channel slopes, and miscellaneous steel, such as sluice gates and trash racks. In general, parameters monitored are in accordance with Section C.2 of RG 1.127 and quantitative measurements are recorded for findings that exceed the acceptance criteria for applicable parameters monitored or inspected. Inspections are performed at least once every five years for structural components. Structures exposed to aggressive water require additional plant-specific investigation.

The aging management of the condenser circulating water discharge pipe, Keowee intake and penstock, as well as portions of the Keowee powerhouse and condenser circulating water intake structure are within the scope of the *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP. The inspections are performed under the current Inspection program for civil engineering structures and components. Any enhancements described in this AMP apply to the *Structures Monitoring* (A2.33) program with respect to aging management activities associated with the condenser circulating water discharge pipe, Keowee intake, and penstock, as well as portions of the Keowee powerhouse and condenser circulating water intake structure, which are within the scope of this program.

The aging management of dams and dikes at Oconee is within the scope of the *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP. Aging management is performed in accordance with the FERC five year inspection requirements. The inspections of dams and dikes within the scope of this program include inspections of the Keowee river dam; Keowee spillway and left abutment, Keowee intake and powerhouse; little river dam; little river dikes A, B, C, and D; and the Oconee intake canal dike, which are performed in accordance with the requirements contained in *Title 18 of the Code of Federal Regulations, Conservation of Power and Water Resources, Part 12, Safety of Water Power Projects and Project Works, Subpart D* (Inspection by Independent Consultant). Aging management activities include visual inspections by a qualified independent consultant approved by FERC, and submittal of inspection reports with corrective actions that are approved by FERC. The inspections performed under the FERC five year inspection program have been approved by FERC, and are the CLB for Oconee regarding aging management of these dams and dikes. Oconee will continue to comply with these FERC requirements during the SPEO. Specific corrective actions and confirmation of corrective actions are implemented in accordance with the corrective action program. The enhancements described in this AMP do not apply to those structures managed in accordance with FERC requirements.

Enhancements

The *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP will be enhanced to:

1. Provide guidance for structural bolting consisting of ASTM A325, ASTMF1852, and/or ASTM A490, for storage, lubricants, and the steps to minimize stress corrosion cracking potential discussed in Section 2 of RCSC (Research Council for Structural Connections) publication, *“Specification for Structural Joints Using ASTM A325 or A490 Bolts”*.

2. Provide guidance so that when replacement bolting is required, bolting material, installation torque or tension, and use of lubricants and sealants will be in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339.

3. Provide guidance for proper specification of new high strength bolting material and lubricant to prevent or mitigate degradation and failure of structural bolting in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339.

4. Provide inspection and evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. The program will be enhanced to incorporate monitoring for movements (e.g., settlement, heaving, and deflection), conditions at junctions with abutments and embankments, pattern cracking with darkened edges, the changes in material properties of increase in porosity and permeability, and loss of strength.

5. Expand the program to monitor accessible sliding surfaces for indications of significant loss of material due to wear or corrosion, and for accumulation of debris or dirt. Establish acceptance criteria for sliding surfaces as no significant loss of material due to wear or corrosion, and no debris or dirt that could restrict or prevent sliding of the surfaces, as required by design.

6. Require that personnel performing inspections and evaluations meet the qualifications specified within ACI 349.3R with respect to knowledge of inservice inspection of concrete and visual acuity requirements.

7. Create provisions for special inspections immediately following the occurrence of significant natural phenomena, such as large floods, earthquakes, hurricanes, tornadoes, or intense local rainfalls.

8. Require the evaluation of raw water and groundwater chemistry that is sampled from a location that is representative of the water in contact with structures within the scope of SLR by the responsible engineer. This will be done on an interval not to exceed five years and account for seasonal variations (e.g., quarterly monitoring every fifth year).

9. Develop a new implementing procedure or revise an existing implementing procedure to enhance the aging management of inaccessible areas exposed to potentially aggressive groundwater/soil environment that will include the following:

   a. Monitor raw water and ground water chemistry, for pH, chlorides, and sulfates, on a frequency not to exceed five years that accounts for seasonal variations (e.g., quarterly monitoring every fifth year), from locations that are representative of the groundwater in contact with structures within the scope of SLR.
   b. Enter adverse results, which exceed water chemistry criteria, into the corrective action program. As part of the corrective actions, if aggressive groundwater is identified that might affect structures in scope for SLR, perform additional water testing at additional locations and perform soil testing in order to confirm the extent, severity, and potential aging mechanisms resulting from the aggressive groundwater/soil.
   c. Develop engineering evaluations to evaluate the water chemistry results to assess the impact, if any, on below-grade concrete, including the potential for further degradation due to the aggressive groundwater, as well as consideration of current conditions. As part of the engineering evaluations, determine if additional actions are warranted, which might include enhanced inspection techniques and/or increased frequency, destructive testing, and focused inspections of representative accessible

(leading indicator) or below grade, inaccessible concrete structural elements exposed to aggressive groundwater/soil.

d. Develop the initial engineering evaluations prior to the SPEO. Develop follow-up engineering evaluations on an interval not to exceed five years.
e. If aggressive groundwater and soil is identified, at a minimum, perform focused inspections of representative, accessible (leading indicator) structural elements, or if accessible areas will not be leading indicators for the potential aging mechanisms, excavate and inspect buried concrete elements exposed to aggressive groundwater/ soil.
f. If degraded concrete is identified, as part of the focused inspections of leading indicators (representative, accessible or exposed inaccessible concrete), enter adverse results that exceed ACI 349.3R second tier criteria into the corrective action program, and expose inaccessible concrete so that the extent of the condition can be determined, baseline conditions documented, and additional actions identified such as repairs, new preventative actions, additional evaluations, and future inspections.

10. Monitor and trend through-wall groundwater leakage, infiltration volumes, and leakage water chemistry for signs of concrete or steel reinforcement degradation. Develop additional engineering evaluations, which consider more frequent inspections, as well as destructive testing of affected concrete to validate existing concrete properties, and leakage water chemistry results. If leakage volumes allow, consider water chemistry analysis of the leakage pH, along with mineral, chloride, sulfate and iron content in the water.

11. Perform inspections under the enhanced program in order to establish quantitative baseline inspection data to a sufficient detail to allow for trending, prior to the SPEO.

12. Provide evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. Base the acceptance criteria for concrete surfaces on the “second-tier” evaluation criteria provided in Chapter 5 of ACI 349.3R.

13. Clarify that loose bolts and nuts are not acceptable unless accepted by engineering evaluation.

14. Degradation of piles and sheeting are accepted by engineering evaluation or subject to corrective actions.

15. Revise inspection procedures to base inspection acceptance criteria on quantitative requirements derived from industry codes and standards, including but not limited to ACI 349.3R, ACI 318, SEI/ASCE 11, or the relevant AISC specifications and consider industry and plant OE. Use justified quantitative acceptance criteria whenever applicable.

A2.35 Protective Coating Monitoring and Maintenance

Program Description

The *Protective Coating Monitoring and Maintenance* AMP is an existing mitigative and condition monitoring program that manages loss of coating integrity of Service Level 1 coatings inside containment. The program maintains and monitors the aging of Service Level I coatings consistent with RG 1.54, "*Service Level I, II, and III Protective Coatings Applied to Nuclear Power Plants*". The program consists of guidance for selection, application, inspection, and maintenance of protective coatings.

Maintenance of Service Level I coatings applied to carbon steel and concrete surfaces inside containment (e.g., steel liner, structural steel, supports, penetrations, and concrete walls and floors) serves to prevent or minimize the loss of material of carbon steel components due to corrosion and aids in decontamination, but these coatings are not credited for managing the effects of corrosion for the carbon steel containment liner and components. This program ensures that the Service Level I coatings maintain adhesion so as to not affect the intended function of the emergency core cooling systems suction strainers.

The program also provides controls over the amount of unqualified coatings. Unqualified coating may fail in a way to affect the intended function of the emergency core cooling systems suction strainers. Therefore, the quantity of degraded and unqualified coating is controlled and assessed periodically to ensure that the amount of unqualified coating in the primary containment is kept within acceptable design limits to support the post-accident operability of the emergency core cooling systems.

Enhancements

The *Protective Coating Monitoring and Maintenance* AMP will be enhanced to:

1. Revise procedures to explicitly state peeling and physical damage are considered in the condition assessment.

2. Revise procedures to reference ASTM D-5163-08.

A2.36 Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements

Program Description

The *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is an existing condition monitoring program that will continue to manage the aging effect of reduced insulation resistance of accessible electrical cable and connection insulation in adverse localized environments within in-scope structures and which could be subject to the environments' applicable aging effects from heat, radiation, and moisture. An adverse localized environment is defined as a condition in a limited plant area that is significantly more severe than the specified service condition for the cable or connection.

At least once every 10 years, accessible insulated cables and connections installed in adverse localized environments are visually inspected for jacket surface anomalies such as embrittlement, discoloration, cracking, melting, swelling, or surface contamination. Surface anomalies are indications that can be visually monitored to preclude the conductor insulation applicable aging effect. As part of the periodic inspections, previously identified and mitigated adverse localized environments' cumulative aging effects applicable to in-scope cable and connection insulation will be reviewed to confirm that the insulation's intended functions continue to be supported during the SPEO.

Proven test(s) applicable to condition monitoring of the insulation are performed if testing is evaluated to be necessary after visual inspections identify degraded or damaged conditions that may adversely affect the performance of cable or connection insulation intended functions.

Further investigation will be performed on cables and connections per the corrective action program when the acceptance criteria is not met. Corrective actions may include, but are not limited to, testing, shielding or otherwise changing the environment, relocating or replacement.

<u>Enhancements</u>

The *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be enhanced to:

1. As part of the periodic inspections, add review of previously identified and mitigated adverse localized environments' cumulative aging effects applicable to in-scope cable and connection insulation to confirm that the insulation's intended functions continue to be supported during the SPEO.

2. Add a description of potential testing and its sampling: If testing is evaluated to be necessary after visual inspections identify degraded or damaged conditions (e.g. unacceptable surface anomalies) that may adversely affect the performance of cable or connection insulation intended functions, then proven test(s) applicable to condition monitoring of the insulation are performed (e.g., thermography may be included). For a large number of cables identified as degraded, a sample population will be tested. The sample size will be 20% of each affected cable and connection type with a maximum sample size of 25. Among the factors to consider for developing the test sample population are cable or connection type, environment, voltage level, circuit loading, and insulation material which is the most important factor per EPRI guidance. Testing as part of an existing maintenance, calibration, or surveillance program may be credited. The basis for the sample selection will be documented.

3. Add acceptance criteria for potential testing of accessible cables and connections with unacceptable visual inspection results to the Oconee AMP description: Test results are to be within the acceptance criteria, as identified in the Oconee procedures.

A2.37 Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements Used in Instrumentation Circuits

Program Description

The *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification (EQ) Requirements Used in Instrumentation Circuits* AMP is a new performance monitoring program that will manage the effects of reduced insulation resistance of non-EQ cable and connection insulation in instrumentation circuits with sensitive, high voltage, low level current signals and that are subjected to adverse localized environments caused by temperature, radiation, or moisture. The program evaluates electrical insulation material for cables and connections subjected to an adverse localized environment at least once every 10 years. The AMP will apply to the in-scope non-EQ portions of circuits in the area radiation monitoring system (e.g. high range containment area radiation monitors) and the neutron flux monitoring nuclear instrumentation system.

Reduced insulation resistance caused by severe degradation in the cable insulation can be detected by periodically reviewing past calibration or surveillance results before losing the cable or connection intended function. Regular calibration or surveillance testing is already performed for in-scope instrumentation circuits. When the non-EQ cables and connections are included as part of the calibration or surveillance circuit, this AMP will periodically review and evaluate the past calibration or surveillance results (since the last review) to identify the existence of cable and connection insulation aging related degradation.

As an alternative to reviewing calibration or surveillance results, or when the non-EQ cables and connections (cable systems) are not included as part of the calibration or surveillance, a proven cable system test will be performed for the in-scope circuits. Such test will be judged effective in detecting deterioration in the cable system insulation.

Industry and plant-specific OE will be considered in the development and implementation of this program.

Enhancements

None

A2.38 Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements

Program Description

The *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is an existing condition monitoring program that will continue to manage the aging effect of reduced electrical insulation resistance due to exposure to significant moisture.

This AMP applies to the electrical insulation for inaccessible (e.g., underground in buried conduit, embedded ducts or conduits (e.g. duct banks), trenches, vaults, manholes, or direct-buried) non-EQ medium-voltage power cables (operating voltage of 2 kV to 35 kV) within the scope of the program that are potentially exposed to significant moisture. For this program, significant moisture is defined as exposure to moisture that last more than three days (i.e., long-term wetting or submergence over a continuous period) that if left unmanaged, could potentially lead to a loss of intended function.

Periodic actions are taken to prevent in-scope inaccessible medium-voltage power cables from being exposed to significant moisture. Water collection in accessible trenches (e.g. low-points) and conduit manholes containing in-scope medium-voltage cables and conduit ends is monitored via documented inspections, and the water removed as needed. The inspection frequencies have been established based on Oconee OE over time and do not exceed a one year interval. Inspections and de-watering will also be performed after event-driven occurrences such as heavy rain, rapid thawing of heavy ice and snow, or flooding.

In-scope non-EQ inaccessible medium-voltage cables found to be exposed to significant moisture are tested to detect reduced electrical insulation resistance, an aging-effect indicator of insulation age-related degradation. The cable testing includes one or more proven methods, such as dissipation factor (‘tangent-delta’) or similar power factor, AC voltage withstand, partial discharge, step voltage, time-domain reflectometry, frequency-domain reflectometry, insulation resistance with or without polarization index, or other applicable and effective testing. Cables are tested at least once every 6 years. More frequent testing may occur based on test results and OE.

There are no submarine cables or other cables designed for continuous wetting or submergence currently in the scope of this program. Future installed cables of these potential designs would be considered for inclusion in this program, at least for a one-time test.

Enhancements

The *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be enhanced to:

1. Add inspections for water accumulation performed after event driven occurrences, such as heavy rain, rapid thawing of heavy ice and snow, or flooding.

2. For the periodic water accumulation inspections, add documented verification that either automatic or passive drainage systems or manual pumping are effective in preventing medium-voltage cable exposure to significant moisture.

3. Remove from program descriptions the original ‘significant voltage’ portion of exposures to determine the inaccessible medium-voltage cables for testing.

4. Revise the inaccessible medium-voltage cable testing and water-accumulation inspection matrix to include inspection methods, test methods, and acceptance criteria.

A2.39 Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements

Program Description

The *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is a new condition monitoring program that will manage the aging effect of reduced electrical insulation resistance due to exposure to significant moisture.

The AMP will apply to the electrical insulation for inaccessible (e.g., installed underground in buried conduit, cable trenches, cable troughs, duct banks, vaults, manholes, or direct buried) non-EQ instrument and control cables and splices within the scope of SLR that are potentially exposed to significant moisture, including instrument and control cables designed for continuous wetting or submergence. For this program, significant moisture is defined as exposure to moisture that lasts more than three days (i.e., long term wetting or submergence over a continuous period) that if left unmanaged, could potentially lead to a loss of intended function.

Periodic actions will be taken to prevent in-scope inaccessible instrument and control cables from being exposed to significant moisture. Water accumulation in accessible conduit ends, manholes, and trenches (e.g. low points) containing in-scope instrument and control cables will be periodically monitored via documented inspections, and the water removed as needed. The inspection frequencies will be based on Oconee OE with cable wetting or submergence and with water accumulation over time. Inspections and de-watering will be performed at least once annually and after event-driven occurrences such as heavy rain, rapid thawing of heavy ice and snow, or flooding.

Accessible portions (e.g. in manholes) of in-scope inaccessible instrument and control cables will be visually inspected at least once every 6 years, coordinated with the water accumulation inspections, to assess observable jacket age-related degradation that may be indicative of electrical insulation age-related degradation. The inaccessible instrument and control cables that are found to be exposed to significant moisture will be evaluated to determine if testing is required. If testing is needed, then based on cable application and insulation material, one or more type(s) of one-time testing of in-service samples is performed to assess the insulation condition. If testing is required, the specific type of test(s) will be a proven technique capable of detecting reduced insulation resistance of the cable’s insulation system due to wetting or submergence.

Industry and plant-specific OE will be evaluated in the development and implementation of this program.

Enhancements

None

A2.40 Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements

Program Description

The *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification (EQ) Requirements* AMP is a new condition monitoring program that will manage the aging effect of reduced electrical insulation resistance due to exposure to significant moisture.

The AMP will apply to the electrical insulation for inaccessible (e.g., installed underground in buried conduit, cable trenches, cable troughs, duct banks, vaults, manholes, or direct buried) non-EQ low voltage power cables and splices (operating voltage less than 2 kV) within the scope of SLR that are potentially exposed to significant moisture, including low voltage power cables designed for continuous wetting or submergence. For this program, significant moisture is defined as exposure to moisture that lasts more than three days (i.e., long-term wetting or submergence over a continuous period) that if left unmanaged, could potentially lead to a loss of intended function.

Periodic actions will be taken to prevent in-scope inaccessible low voltage power cables from being exposed to significant moisture. Water accumulation in accessible conduit ends, manholes, and trenches (e.g. low-points) containing in-scope low voltage power cables will be periodically monitored via documented inspections, and the water removed as needed. The inspection frequencies will be based on Oconee OE with cable wetting or submergence and with water accumulation over time. Inspections and de-watering will be performed at least once annually and after event driven occurrences such as heavy rain, rapid thawing of heavy ice and snow, or flooding.

Accessible portions (e.g. in manholes) of in-scope inaccessible low voltage power cables will be visually inspected at least once every six years, coordinated with the water accumulation inspections, to assess observable jacket age-related degradation that may be indicative of electrical insulation age-related degradation. The inaccessible low voltage power cables that are found to be exposed to significant moisture will be evaluated to determine if testing is required. If testing is needed, then based on cable application and insulation material, one or more type(s) of one-time testing of in-service samples is performed to assess the insulation condition. If testing is required, the specific type of test(s) will be a proven technique capable of detecting reduced insulation resistance of the cable’s insulation system due to wetting or submergence.

Industry and plant-specific OE will be evaluated in the development and implementation of this program.

Enhancements

None

A2.41 Metal Enclosed Bus

Program Description

The *Metal Enclosed Bus* AMP is a new condition monitoring program that will manage the identified aging effects of in-scope metal enclosed bus. The internal portions of the accessible bus enclosure assemblies will be visually inspected for age-related degradation, including cracks, corrosion, foreign debris, excessive dust buildup, and evidence of water intrusion. The accessible bus insulation will be visually inspected for signs of reduced insulation resistance, such as embrittlement, cracking, chipping, melting, discoloration, swelling, or surface contamination which may indicate overheating or aging degradation. The accessible internal bus insulating supports will be visually inspected for structural integrity and signs of cracks.

Metal enclosed bus external surfaces and external structural supports are managed by the *Structures Monitoring* (A2.33) AMP.

Accessible elastomers (e.g., gaskets, boots, O-rings and sealants) will be inspected for degradation including surface cracking, crazing, scuffing, dimensional change (e.g., “ballooning” and “necking”), shrinkage, discoloration, hardening or loss of strength.

A sample of accessible bolted connections will be inspected for increased resistance of connection by either performing thermography or measuring the connection resistance using a micro-ohmmeter. In addition to thermography or resistance measurement, accessible bolted connections not covered with heat shrink tape or boots are visually inspected for increased resistance of connection (e.g., loose or corroded bolted connection and hardware including cracked or split washers).

As an alternative to thermography or measuring connection resistance of bolted connections, for accessible bolted connections covered with heat shrink tape, sleeving, insulating boots, etc., insulating material may be visually inspected to detect surface anomalies, such as embrittlement, cracking, chipping, melting, discoloration, swelling, or surface contamination.

Industry and plant-specific OE will be considered in the development and implementation of this program.

Enhancements

None

A2.42 Fuse Holders

Program Description

The *Fuse Holders* AMP is a new condition monitoring program. The program applies to fuse holders outside of active devices susceptible to the following aging effects: increased resistance of connection due to chemical contamination, corrosion, and oxidation or fatigue caused by ohmic heating, thermal cycling, electrical transients, frequent removal and replacement, or vibration. The program also manages degradation of electrical insulation for the fuse holders with metallic clamps susceptible to the aging effects identified. Fuse holders inside an active device (e.g. switchgears, power supplies, inverters, battery chargers, and circuit boards) are not within the scope of this program.

The program utilizes visual inspection and testing to identify age-related degradation for both fuse holder electrical insulation material and fuse holder metallic clamps. The specific type of test performed is determined prior to the initial test and is to be a proven test for detecting increased resistance of connection of fuse holder metallic clamps, or other appropriate testing justified in the *Fuse Holders* AMP.

Industry and plant-specific OE will be considered in the development and implementation of this program.

Enhancements

None

A2.43 Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements

Program Description

The *Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is a new condition monitoring program that will manage the aging effect of increased electrical resistance of electrical cable connections (metallic parts).

This program will perform a one-time test, on a representative sampling basis, to confirm the absence of loosening of connections due to thermal cycling, ohmic heating, electrical transients, vibration, chemical contamination, corrosion and oxidation. The following factors will be considered for sampling: voltage level (medium and low voltage), circuit loading (high load), connection type, and location (high temperature, high humidity, vibration, etc.).

Non-EQ electrical cable connections (metallic parts) associated with cables within the scope of the program will be tested prior to the SPEO to provide an indication of the integrity of the cable connections. The specific type of test to be performed will be determined based on the type of connection and will be a proven method for detecting loose connections, such as thermography, contact resistance testing, or other appropriate testing methods without removing the connection insulation such as heat shrink tape, sleeving, insulating boots, etc.

Twenty percent of a connector type population with a maximum sample size of 25 constitutes a representative connector sample size. Otherwise a technical justification of the methodology and sample size used for selecting components under test will be included as part of the programs documentation.

A sample of cable connections within the scope of the program will be tested on a one-time test basis or at least once every five years if only visual inspection is used to provide an indication of the integrity of the cable connections. Depending on the findings of the one-time test, subsequent testing may be performed within ten years of initial testing. The first visual inspections or tests for SLR are to be completed prior to the SPEO.

As an alternative to testing for accessible cable connections that are covered with heat shrink tape, sleeving, insulating boots, etc., a visual inspection of insulation materials to detect surface anomalies, such as embrittlement, cracking, chipping, melting, discoloration, swelling or surface contamination may be performed. When this alternative visual inspection is used to check cable connections, the inspection will be completed prior to the SPEO, and repeated at least every five years, thereafter. The basis for performing only the alternative visual inspection to monitor age-related degradation of cable connections will be documented.

Industry and plant-specific OE will be considered in the development and implementation of this program.

<u>Enhancements</u>

None

A3.0 SUMMARY DESCRIPTIONS OF TIME-LIMITED AGING ANALYSIS AGING MANAGEMENT PROGRAMS

The NUREG-2191 Chapter X AMPs associated with TLAA are described in the following sections. The AMPs are either consistent with generally accepted industry methods as discussed in NUREG-2191 Chapter X or require enhancements. The following list reflects the status of these programs at the time of the SLRA submittal. Commitments for program additions and enhancements are identified in Appendix A6.0 SLR Commitment List.

A3.1 Fatigue Monitoring

Program Description

The *Fatigue Monitoring* AMP is an existing preventative program that manages fatigue or other types of cyclic loading time limited aging analyses (TLAAs) of the reactor pressure vessel components, reactor coolant pressure boundary piping components, and other components per the acceptance criterion in 10 CFR 54.21(c)(1)(iii). The program monitors and tracks the number of occurrences and severity of design basis transients assessed in the applicable fatigue or cyclic loading analyses, including those in applicable cumulative usage factor (CUF) analyses, environmentally-assisted cumulative usage fatigue (CUF_{en}) analyses, ASME Section III fatigue waiver analyses, and cycle-based flaw growth, flaw tolerance, or fracture mechanics analyses.

The Oconee *Fatigue Monitoring* AMP manages cumulative fatigue damage or cracking induced by fatigue or cyclic loading in the applicable structures and components through performance of activities that monitor one or more relevant analysis parameters, such as CUF values, CUF_{en} values, design transient cycle limit values, or predicted flaw size values. Therefore, the program has two aspects, one to verify the continued acceptability of existing analysis through cycle counting or parameter monitoring and the other to provide periodically updated evaluations of the analysis to demonstrate that they continue to meet the appropriate limits.

Fatigue analyses for these components are based upon explicit numbers and amplitudes of thermal and pressure transients. Oconee UFSAR Table 5-2 and Table 5-23 provide a listing of design transients and associated design cycles. The intent of the design basis transient definitions is to bound a wide range of possible events with varying ranges of severity in temperature and pressure.

The program will continue to monitor transient cycles to ensure that LBB analyses remain valid. There are no locations being tracked for HELB exclusion based on fatigue, therefore the program does not apply to HELB.

The program implements appropriate corrective actions (e.g., reanalysis, component or structure inspections, or component or structure repair or replacement activities) when acceptance limits are approached. The program manages cracking due to fatigue or cyclic loading in accordance with UFSAR Section 5.2.1.4 and Technical Specification Section 5.5.6.

Enhancements

The *Fatigue Monitoring* AMP will be enhanced to:

1. Require monitoring and tracking of transient cycles associated with the ASME Code, Section XI, Appendix L analysis be performed between the inspections for each ASME Code, Section XI, Appendix L locations. Consistent with existing program cycle counting, a surveillance limit will be established to initiate corrective action prior to exceeding transient cycle assumptions in the ASME Code, Section XI, Appendix L analysis.

2. Require periodic validation of chemistry parameters used to determine F_{en} factors used.

3. Expand existing corrective action guidance associated with exceeding a cycle counting surveillance limit to recommend consideration of component repair, component replacement, performance of a more rigorous analysis, performance of an ASME Code, Section XI, Appendix L flaw tolerance analysis, or scope expansion to consider other locations with the highest expected CUF_{en} values.

A3.2 Neutron Fluence Monitoring

Program Description

The *Neutron Fluence Monitoring* AMP is an existing condition monitoring program that manages loss of fracture toughness due to neutron fluence of the reactor pressure vessel regions for which neutron fluence is projected to exceed 1.0E+17 n/cm^2 (E>1MeV) during the SPEO to ensure continued validity of neutron fluence analyses and that applicable reactor pressure vessel neutron irradiation embrittlement analysis (i.e., TLAAs) will remain within their applicable limits. Neutron fluence is a time-dependent input parameter for evaluating reduction of fracture toughness due to neutron irradiation embrittlement. This program monitors the reactor pressure vessel and reactor vessel internals neutron fluence to verify the continued acceptability of existing irradiation embrittlement and related analyses. The components evaluated by these analyses are the reactor pressure vessel shell and welds and reactor vessel internal components subject to reactor coolant and neutron flux environment which are fabricated from carbon or low alloy steel with stainless steel cladding, stainless steel, and nickel alloy materials.

The program has two aspects, one to verify the continued acceptability of existing analyses through neutron fluence monitoring, and the other to provide periodically updated evaluations of the analyses involving neutron fluence inputs to demonstrate that they continue to meet the appropriate limits defined in the CLB.

Monitoring is performed to verify the adequacy of neutron fluence projection methods that are defined for the CLB in NRC approved reports. Cavity dosimetry measurements are used to verify the accuracy of fluence calculations and to determine fluence uncertainty values in accordance with RG 1.190, *"Calculational and Dosimetry Methods for Determining Pressure Vessel Neutron Fluence."* For neutron fluence monitoring activities that apply to components located in the beltline region of the reactor pressure vessels, the monitoring methods are performed in a manner consistent with the monitoring methodology guidelines in RG 1.190, *"Calculational and Dosimetry Methods for Determining Pressure Vessel Neutron Fluence."* Neutron fluence monitoring methods that are applied to reactor pressure vessel locations outside of the beltline region of the reactor pressure vessels are justified and are consistent with NRC approved methodology. These methods have been benchmarked with both in-vessel and ex-vessel cavity dosimetry for the beltline region.

Neutron Fluence Monitoring AMP results are compared to the neutron fluence parameter inputs used in the neutron embrittlement analyses for reactor pressure vessel components. This includes, but is not limited to, the neutron fluence inputs for the reactor pressure vessel upper-shelf energy analyses and equivalent margin analyses, pressure-temperature analyses, and low temperature overpressure protection (LTOP) that are required to be performed in accordance in 10 CFR Part 50, Appendix G requirements, and safety analyses that are performed to demonstrate adequate protection of the reactor pressure vessels against the consequences of pressurized thermal shock (PTS) events, as required by 10 CFR 50.61 and applicable to the CLB. Comparisons to the neutron fluence inputs for other analyses (as applicable to the CLB) includes those for RT_{NDT}.

Reactor vessel surveillance capsule dosimetry data obtained in accordance with 10 CFR Part 50, Appendix H requirements and through implementation of the *Reactor Vessel Material Surveillance* AMP (A2.19) provides inputs to and have impacts on the neutron fluence monitoring results that are tracked by this program. In addition, regulatory requirements in the plant technical specifications or in specific regulations of 10 CFR Part 50 apply, including those in 10 CFR Part 50, Appendix G; 10 CFR 50.55a; and the PTS requirements in 10 CFR 50.61, as applicable for the CLB.

Cavity dosimetry measurements are used to verify the accuracy of fluence calculations and to determine fluence uncertainty values. These calculations and related uncertainties determine when the neutron fluence is projected to exceed 1.0E+17 n/cm^2 (E > 1 MeV) for specific reactor vessel items during the SPEO and thus require monitoring to ensure their embrittlement analyses remain below applicable limits. While no additional in-vessel dosimetry is planned, Oconee utilizes cavity dosimetry for Unit 2 as a continuous fluence monitoring device. Cavity dosimetry measurements provide continued experimental data to verify the accuracy of fluence calculations and to determine fluence uncertainty values. Ex-vessel cavity dosimetry is used to monitor neutron fluence because the Oconee units do not currently have in-vessel surveillance capsules. Only the Oconee Unit 2 reactor vessel has installed cavity dosimetry. However, the Oconee Unit 1 and ONS Unit 3 reactor vessel fluence uncertainty values are based on Oconee Unit 2 cavity dosimetry results due to similar design, fabrication, operation, and fuel loading patterns. The use of the Oconee Unit 2 cavity dosimetry for Oconee Unit 1 and Oconee Unit 3 was approved by the NRC in a letter to Duke Power Company dated December 5, 1988 [Reference D. B. Matthews (NRC) letter dated December 5, 1988 to H.B. Tucker (Duke), Subject: "Cavity Dosimetry Program - Oconee Nuclear Station Units 1, 2, and 3", ADAMS Accession Number ML16152A761].

Verification of the uncertainty in assumed reactor vessel fluence values is performed on a cycle-by-cycle basis to ensure neutron fluence projections remain bounding with respect to actual plant operating conditions. The verification is accomplished by performing a review of key reactor vessel fluence input parameters to ensure that any significant changes would be evaluated.

Enhancements

None

A3.3 Environmental Qualification of Electric Equipment

Program Description

The *Environmental Qualification (EQ) of Electric Equipment* AMP is an existing program that manages the qualified life and TLAA analyses of electrical components that are important to safety as defined in 10 CFR 50.49. An aging limit (qualified life) is established for equipment within the program scope and appropriate actions are taken prior to or at the end of the equipment qualified life such that the aging limit is not exceeded. Changes to material activation energy values as part of the reanalysis are justified. The program establishes, demonstrates and documents the qualification level, configuration, maintenance, surveillance and replacement requirements necessary to maintain the qualification conclusions and equipment qualified life.

Enhancements

The *Environmental Qualification of Electric Equipment* AMP will be enhanced to:

1. Add activities to perform visual inspections of accessible, passive EQ electric equipment located in adverse localized environments at least once every 10 years.

2. Establish acceptance criteria for the visual inspection of accessible passive EQ electric equipment located in adverse localized environments.

A3.4 Concrete Containment Unbonded Tendon Prestress

Program Description

The *Concrete Containment Unbonded Tendon Prestress* AMP is an existing program that is part of ONS containment inservice inspection program, which is based on ASME Section XI, Subsection IWL criteria, as supplemented by the requirements of 10 CFR 50.55a(b)(2)(viii). The program monitors and assesses the adequacy of the prestressing force for each tendon group based on type (i.e., hoop, vertical, dome, inverted-U, helical) and other considerations (e.g., geometric dimensions, whether affected by repair/replacement, etc.). The program ensures, during each inspection, that the trend lines of the measured prestressing forces remain above the minimum required value before the next scheduled inspections. Otherwise, corrective actions are taken to ensure containment prestress adequacy. Acceptance criteria follow 10 CFR 50.55a, ASME Code Section XI (Subsection IWL) and include construction of trend lines consistent with NRC Information Notice (IN) 99-10, "*Degradation of Prestressing Tendon Systems in Prestressed Concrete Containments*." RG 1.35.1, "*Determining Prestressing Forces for*

Inspection of Prestressed Concrete Containments," provides guidance for calculating prestressing losses and predicted forces. The program incorporates plant-specific and industry OE.

Enhancements

None

A4.0 SUMMARY DESCRIPTIONS OF TIME-LIMITED AGING ANALYSES EVALUATION

As part of the application for a renewed license, 10 CFR 54.21(c) requires that an evaluation of TLAAs for the SPEO be provided. The TLAAs identified and evaluated to meet these requirements are discussed below.

A4.1 Identification and Evaluation of Time-Limited Aging Analyses

10 CFR 54.21(c)(2) requires that an evaluation of TLAA be provided as part of the application for a renewed operating license. TLAA are defined in 10 CFR 54.3(a) and are evaluated in accordance with 10 CFR 54.21(c)(1).

Additionally, 10 CFR 54.21(c)(2) requires that the application include a list of plant specific exemptions granted pursuant to 10 CFR 50.12 and in effect that are based upon TLAAs as defined in 10 CFR 54.3. It also requires an evaluation that justifies the continuation of these exemptions for the SPEO. No plant-specific exemptions granted pursuant to 10 CFR 50.12 were identified for Oconee that are based upon a TLAA. Therefore, no further evaluation is required for plant-specific exemptions granted pursuant to 10 CFR 50.12.

The following TLAAs have been identified and evaluated to meet 10 CFR 54.21(c) requirements. Summaries of the TLAAs applicable to the SPEO are included in the following sections:

- Reactor Vessel Neutron Embrittlement Analysis (A4.2)
- Metal Fatigue (A4.3)
- Environmental Qualification of Electric Equipment (A4.4)
- Concrete Containment Tendon Prestress (A4.5)
- Containment Liner Plate, Metal Containments, and Penetrations Fatigue Analysis (A4.6)
- Other Plant-Specific Time Limited Aging Analyses (A4.7)

A4.2 Reactor Vessel Neutron Embrittlement Analysis

10 CFR 50.60 requires that all light water reactors meet the fracture toughness, pressure-temperature limits, and materials surveillance program requirements for the reactor coolant pressure boundary as set forth in 10 CFR 50, Appendices G and H. The ONS *Reactor Vessel Material Surveillance* AMP (A2.19), in combination with the ONS *Neutron Fluence Monitoring* AMP (A3.2) will ensure that the TLAA requirements of 10 CFR 50 Appendix G and 10 CFR 50.61 remain valid through the SPEO. The ferritic materials of the reactor vessel are subject to embrittlement due to high energy (E > 1.0 MeV) neutron exposure. Embrittlement means the material has lower toughness (i.e., will absorb less strain energy during a crack or rupture), thus allowing a crack to propagate more easily under thermal and pressure loading. Neutron embrittlement analyses are used to account for the reduction in fracture toughness associated with the cumulative neutron fluence (total number of neutrons that intersect a square centimeter of component area during the life of the plant). Since these neutron embrittlement analyses are

calculated based on plant life, they are identified as TLAAs. The following RPV neutron embrittlement TLAAs have been identified and evaluated to meet 10 CFR 54.21(c) requirements:

- Neutron Fluence Projections
- Upper-Shelf Energy
- Pressurized Thermal Shock
- Pressure Temperature Limits
- Low Temperature Overpressure Protection

A4.2.1 Neutron Fluence Projections

The calculation based fluence analysis methodology contained in BAW-2241P-A, Revision 2 is used to predict the 80-year fluence at reactor vessel shell locations.The BAW-2241P-A, Revision 2 fluence analysis methodology was developed through a full-scale benchmark experiment that was performed at the Davis Besse reactor. The analyses methodologies used to calculate the Units 1, 2, and 3 reactor vessel fluence satisfy the guidance set forth in RG 1.190, *"Calculational and Dosimetry Methods for Determining Pressure Vessel Neutron Fluence."* For the Oconee Nuclear Station, neutron transport calculations, using the methodology from BAW-2241P-A, Revision 2, were completed for Cycles 27-29 for ONS Unit 1, Cycles 25-28 for ONS Unit 2, and Cycles 26-28 for ONS Unit 3, and used to project fast neutron fluence at the reactor vessel shell (i.e., traditional and extended beltline locations) to 72 EFPY. The fluence analyses have been projected to the end of the SPEO and are dispositioned in accordance with 10 CFR 54.21(c)(1)(ii).

A4.2.2 Upper Shelf Energy

Appendix G of 10 CFR 50, Appendix G (Reference 4.2-11), requires that reactor vessel beltline materials "have Charpy upper-shelf energy in the transverse direction for base metal and along the weld for weld material according to the ASME Code, of no less than 75 ft-lb (102 J) initially and must maintain Charpy upper-shelf energy throughout the life of the vessel of no less than 50 ft-lb (68 J) unless it is demonstrated in a manner approved by the Director, Office of Nuclear Reactor Regulation or Director, Office of New Reactors, as appropriate, that lower values of Charpy upper-shelf energy will provide margins of safety against fracture equivalent to those required by Appendix G of Section XI of the ASME Code."

For SLR, the upper-shelf energy values for the traditional beltline and extended beltline materials were determined for the ONS reactor vessel traditional and extended beltline items using methods consistent with RG 1.99, Revision 2. Two methods may be used to predict the decrease in upper-shelf energy with irradiation, depending on the availability of credible surveillance capsule data as defined in RG 1.99, Revision 2. For vessel beltline materials that are not in the surveillance program or for locations with non-credible data, the Charpy upper-shelf energy is assumed to decrease as a function of fluence and copper content, as indicated in RG 1.99, Revision 2 (Position 1.2). When two or more credible surveillance data sets are available from the reactor, they may be used to determine the Charpy upper-shelf energy of the surveillance material. The surveillance data are then used in conjunction with the regulatory guide to predict the change in upper-shelf energy of the reactor vessel material due to irradiation (Position 2.2).

The 72 EFPY RG 1.99, Revision 2 (Position 1.2) upper-shelf energy values of the vessel materials are predicted using the corresponding ¼T fluence projection, copper content of the materials, and Figure 2 in RG 1.99, Revision 2. The predicted Position 2.2 upper-shelf energy values are determined for the reactor vessel materials that are contained in the surveillance program by using surveillance data along with the corresponding ¼T fluence projection. The ¼T fluence projections are ¼T displacement per atom adjusted values unless the attenuation of fluence from the inside wetted surface using RG 1.99, Revision 2, Equation (3), exceed the ¼T displacement per atom adjusted values. The projected upper-shelf energy values were calculated to determine if the Oconee Unit 1, Unit 2, and Unit 3 traditional and extended beltline materials remain above the 50 ft-lb limit at 72 EFPY.

All ONS Unit 1 reactor vessel traditional and extended beltline plate and forging materials maintain an upper-shelf energy value greater than 50 ft-lbs at 72 EFPY. All ONS Unit 1 reactor vessel traditional and extended beltline Linde 80 welds have upper-shelf energy values less than 50 ft-lbs at 72 EFPY and require an equivalent margins analysis to demonstrate that lower values of Charpy upper-shelf energy will provide margins of safety against fracture equivalent to those required by Appendix G of Section XI of the ASME Code.

All ONS Unit 2 reactor vessel traditional and extended beltline forging materials maintain an upper-shelf energy value greater than 50 ft-lbs at 72 EFPY. All ONS Unit 2 reactor vessel traditional and extended beltline Linde 80 welds have upper-shelf energy values less than 50 ft-lbs at 72 EFPY and require an equivalent margins analysis to demonstrate that lower values of Charpy upper-shelf energy will provide margins of safety against fracture equivalent to those required by Appendix G of Section XI of the ASME Code.

All ONS Unit 3 reactor vessel traditional and extended beltline forging materials maintain an upper-shelf energy value greater than 50 ft-lbs at 72 EFPY with the exception of the reactor vessel inlet and outlet nozzle forgings and the transition forging. All reactor vessel traditional and extended beltline Linde 80 welds have upper-shelf energy values less than 50 ft-lbs at 72 EFPY. The reactor vessel inlet and outlet nozzle forgings, transition forging, and traditional beltline and extended beltline Linde 80 welds require an equivalent margins analysis to demonstrate that lower values of Charpy upper-shelf energy will provide margins of safety against fracture equivalent to those required by Appendix G of Section XI of the ASME Code.

Detailed equivalent margins analyses were performed on the required components described for each Oconee unit. In each case a demonstration was provided to support the projection of the ONS Units 1, 2, and 3 USE analyses to the end of the subsequent period of extended operation in accordance with 10 CFR 54.21(c)(1)(ii).

A4.2.3 Pressurized Thermal Shock

10 CFR 50.61 provides rules for fracture toughness requirements for protection against pressurized thermal shock events for pressurized water reactors. 10 CFR 50.61(b)(2)

establishes screening criteria for RT_{PTS} as 270°F for plates, forgings, and longitudinal welds and 300°F for circumferential welds. All the traditional and extended beltline materials in Oconee Units 1, 2, and 3 are below the RT_{PTS} screening criteria values of 270°F for base metal and longitudinal welds, and 300°F for circumferentially oriented welds through the SPEO. The Oconee Units 1, 2, and 3 PTS analyses for traditional and extended beltline locations have been projected to the end of the SPEO and are dispositioned in accordance with 10 CFR 54.21(c)(ii).

A4.2.4 Pressure-Temperature Limits

10 CFR 50 Appendix G requires that the reactor vessel be maintained within established pressure-temperature limits, including heatup and cooldown operations. These limits specify the maximum allowable pressure as a function of reactor coolant temperature. As the reactor vessel is exposed to increased neutron irradiation, its fracture toughness is reduced. The pressure-temperature limits must account for the anticipated reactor vessel fluence.

Duke Energy prepared 72 EFPY (equivalent to 80 years of operation) pressure-temperature limits to demonstrate that the predicted operating window is sufficient to conduct heatups and cooldowns. The 72 EFPY pressure-temperature limits were developed with consideration of traditional and extended beltline materials using the analytical methods and flaw acceptance criteria of topical report BAW-10046A, Revision 2 and ASME Code Section XI, Appendix G (2013 Edition, which permits use of K_{Ic}). It was confirmed that all three Oconee Units will have sufficient operating windows to conduct heatups and cooldowns at 72 EFPY.

The ONS *Reactor Vessel Material Surveillance* AMP (A2.19), ONS *Neutron Fluence Monitoring* AMP (A3.2), and plant Technical Specifications will ensure that updated pressure-temperature limits will be submitted to the NRC for approval prior to exceeding the period of applicability for Units 1, 2, and 3. Since the pressure-temperature limits will be updated through the 10 CFR 50.90 process at a later, more appropriate date, the effects of aging on the intended function(s) of the reactor vessels will be adequately managed for the SPEO and are dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

A4.2.5 Low Temperature Overpressure Protection

Low temperature overpressure protection systems at Oconee Units 1, 2, and 3 are required by Technical Specification Limited Condition for Operation 3.4.12. A pressurizer power operated relief valve provides the automatic relief capability during the design basis mass input and the design basis heat input transients to automatically prevent the reactor coolant system pressure from exceeding the pressure-temperature limit curves based on 10 CFR 50, Appendix G.

The low temperature overpressure enable temperature has been determined for 72 EFPY in accordance with the requirements of ASME Section XI, Appendix G and is 269.2°F for ONS-1, and 307°F for Units 2 and 3, which are below the current Technical Specification requirement of 325°F.

The ONS *Reactor Vessel Material Surveillance* AMP (A2.19), ONS *Neutron Fluence Monitoring* AMP (A3.2), and plant Technical Specifications will ensure that updated low temperature overpressure enable temperature and power operated relief valve setpoint will be submitted to the NRC for approval prior to exceeding the period of applicability for Units 1, 2, and 3. Since the low temperature overpressure enable temperature, power operated relief valve setpoint will be updated through the 10 CFR 50.90 process at a later, appropriate date, the effects of aging on the intended function(s) of the Oconee reactor vessels will be adequately managed for the SPEO and are dispositioned in accordance with 10 CFR 50.54(c)(1)(iii).

A4.3 Metal Fatigue

Fatigue analyses are required on components designed to ASME Code, Section III, Class 1 and USAS (ANSI) B31.7. In addition, certain other codes such as ASME Section III, Class 2 and 3, USAS (ANSI) B31.1, and ASME Section VIII may require a fatigue analysis or assume a stated number of full range thermal and displacement transient cycles. NUREG-2192 also provides examples of components that are likely to have fatigue TLAAs within the current licensing basis that would require evaluation for the subsequent period of extended operation. Searches were performed to identify these and any other potential fatigue TLAAs within the current licensing bases for Oconee Units 1, 2, and 3. Those that are identified as Oconee fatigue TLAAs are evaluated using 80-year transient cycle and cumulative usage projections. The TLAA dispositions are described in the following subsections:

- Transient Cycle Projections for 80 years (A4.3.1)
- Class 1 Fatigue Analysis (including fatigue waivers) (A4.3.2)
- Non-Class 1 Fatigue Analysis (A4.3.3)
- Environmentally-Assisted Fatigue (A4.3.4)
- Analytical Evaluation of Flaws (A4.3.5)
- Weld Overlay Class 1 Fatigue Analysis (A4.3.6)

A4.3.1 Transient Cycle Projections for 80 Years

Fatigue analyses are based upon numbers and amplitudes of thermal and pressure transients. UFSAR Tables 5-2, *"Transient Cycles for RCS Components Except Pressurizer Surge Line"* and UFSAR Table 5-23, *"Operating Design Transient Cycles for Pressurizer Surge Line"* list the design transients and associated design cycles. The intent of the design basis transient definitions is to bound a wide range of possible events with the varying ranges of severity in temperature and pressure. CLB fatigue analyses are based upon the original number of design cycles that have been previously projected to bound 60 years of service. For SLR, the original number of design cycles now been projected to bound 80 years of service. Since the fatigue analyses are based upon the number of cycles, the fatigue analyses discussed in the following sections are considered TLAAs. In order to ensure the design cycles remain bounding in the safety class 1 fatigue analyses, the *Fatigue Monitoring* AMP (A3.1) tracks cycles for significant fatigue transients and ensures corrective action is taken prior to potentially exceeding fatigue design limits.

A4.3.2 Class 1 Fatigue Analysis

Class 1 fatigue analyses were originally performed in accordance with the ASME Code, Section III for reactor coolant system vessels supplied by B&W, USAS B31.7, Class I for B&W supplied piping, and USAS B31.7, Class II for Bechtel supplied piping in ancillary systems attached to B&W supplied components and extending to the first outboard isolation valve. In accordance with the Oconee UFSAR, Section 3.2.2.2, reactor coolant system Class 1 piping (USAS B31.7 Class I and II) was redesigned to the 1983 ASME Section III Code during the steam generator replacement project. The reactor coolant pump casings were designed, fabricated, inspected and tested to meet the intent of the ASME Boiler and Pressure Vessel Code, Section III, for Class A vessels, but are not code stamped. The specific Oconee reactor coolant system component design codes are reported in the Oconee UFSAR, Table 5-4. Each Class 1 fatigue analysis must demonstrate that the cumulative usage factor for the component will not exceed the Code design limit of 1.0 when the component is exposed to all postulated normal and upset design transients.

During the initial LR period, several changes occurred that potentially impact the SLR TLAA evaluation for the reactor coolant system Class 1 components. For example, the following changes have been considered.

- Reactor vessel closure head replacement in 2003-2004 (ONS Units 1, 2, and 3)
- Steam generator replacement 2003-2004 (ONS 1, 2, and 3)
- Alloy 600 primary water stress corrosion cracking mitigation including nozzle repair and/or full structural weld overlay for pressurizer nozzles, pressurizer spray, and pressurizer safety/relief nozzles, both surge line nozzles and the reactor coolant system branch attached piping.
- Measurement uncertainty recapture (ONS 1, 2, and 3)

The following Class 1 components were assessed for impact of 80-year projected cycles on fatigue design:

- Reactor vessel
- Reactor vessel internals
- Once through steam generators
- Reactor coolant pumps
- Pressurizer
- Control rod drive mechanism
- Reactor coolant system piping and connected lines
- Pressurizer surge line

In addition, a detailed fatigue evaluation is not required if Class 1 components conform to the waiver of fatigue requirements per ASME Code, Section III. These fatigue waivers depend on the numbers of anticipated transients over the life of the plant and therefore constitute TLAAs. The original design cycles were postulated to bound 80 years of plant operations. Therefore, the fatigue analyses and fatigue waivers are postulated to remain valid for the subsequent period of extended operation.

In order to ensure the design cycles remain bounding in the fatigue analyses and fatigue waivers, the *Fatigue Monitoring* AMP (A3.1) will track cycles for significant fatigue transients listed in UFSAR Tables 5-2, *"Transient Cycles for RCS Components Except Pressurizer Surge Line"* and UFSAR Table 5-23, *"Operating Design Transient Cycles for Pressurizer Surge Line,"* and ensure corrective action is taken prior to potentially exceeding fatigue design limits. The effects of fatigue on the Class 1 components will be adequately managed by the *Fatigue Monitoring* AMP (A3.1) for the SPEO in accordance with 10 CFR 54.21(c)(1)(iii).

A4.3.3 Non-Class 1 Piping Fatigue Analysis

For the Oconee non-Class 1 mechanical systems within the scope of SLR, only the piping components have been explicitly designed to consider thermal transient cycle count assumptions that must be revalidated for the extended period of operation. These piping systems are designed to ANSI B31.7 Class II and Class III and ANSI B31.1 requirements where a stress range reduction factor is used based on the number of expected thermal cycles during the period of plant operation. If the total number of expected thermal cycles for a piping system is less than 7,000, then a stress range reduction factor of 1.0 is applied. If the total number of expected thermal cycles for a piping system is greater than 7,000, a stress range reduction factor less than 1.0 is applied to reduce the alternating stress range in the piping design. From review of the design basis and projected 80 year cycles, no portions of non-Class 1 piping exceed the allowable number of thermal cycles. The stress range reduction factors applied to the non-Class 1 piping systems design will remain valid for the extended period of operation in accordance with 10 CFR 54.21 (c)(1)(ii).

A4.3.4 Environmentally-Assisted Fatigue (EAF)

As outlined in Section X.M1 of NUREG-2191 and Section 4.3 of NUREG-2192 the effects of the reactor water environment on cumulative usage factor must be examined for a set of sample critical components for the plant. This sample set includes the locations identified in NUREG/CR-6260, *"Application of NUREG/CR-5999 Interim Fatigue Curves to Selected Nuclear Power Plant Components"* and additional plant-specific component locations in the reactor coolant pressure boundary if they may be more limiting than those considered in NUREG/CR-6260. These additional limiting locations are identified through an environmental fatigue screening evaluation. The environmentally assisted fatigue screening process made use of existing fatigue usage values for the ASME Code, Section III components. The environmentally assisted fatigue screening evaluation reviewed the CLB fatigue evaluations for all ASME Code, Section III reactor coolant pressure boundary components and piping and ANSI B31.7 piping, including the NUREG/CR-6260 locations, to determine the lead indicator (also referred to as sentinel) locations for environmentally assisted fatigue. As a result of the environmentally assisted fatigue screening evaluation, there were other locations found that could potentially be more limiting than the NUREG/CR-6260 locations.

Calculations were prepared to document the evaluations of environmentally assisted fatigue for ASME Code, Section III pressure boundary components and piping and ANSI B31.7 piping that contact the reactor coolant and determine fatigue sensitive locations for comparison and ranking. These evaluations are for SLR purposes and do not amend the existing design reports. The effects of fatigue on the intended function(s) of ASME Code, Section III pressure boundary components and piping and ANSI B31.7 piping that contact reactor coolant will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) and the *ASME Section XI Inservice Inspection, Subsection IWB, IWC, and IWD* AMP (B2.1.1) through the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

A4.3.5 Analytical Evaluation of Flaws

The ASME Section XI ISI requirements that involve analytical evaluation of flaws are contained in Subsection IWB for Class 1 pressure retaining components. ISI at Oconee has, in a number of instances, lead to the identification of crack-like indications (primarily in welds). For these indications detected during ISI that exceed acceptance standards in Subsection IWB (1) repairs may be made, (2) affected portions of the component may be replaced, or (3) the flaw may be shown to be acceptable through analytical evaluation.

Acceptance through analytical evaluation requires a prediction of crack growth until the next inspection or the end of service lifetime of the component. Indications that are determined not to grow beyond an acceptable limit during the projected lifetime of the component are justified for continued operation. These crack growth analyses involve the same design thermal transient cycle assumptions considered in the original design. Because the crack growth rate determined by these analyses may further limit the design life of the components, a review of the analyses that were completed to the end of service lifetime of the component are TLAA and must be evaluated to demonstrate acceptability for 80 years of operation.

For SLR, the existing Class 1 flaws were catalogued and have been evaluated against the thermal cycles projected for 80 years. The results of the evaluation show that Class 1 fracture mechanics flaw calculations will remain valid for the SPEO. In order to ensure the design cycles remain bounding in these calculations, the *Fatigue Monitoring* AMP (Section A3.1) will track cycles for significant fatigue transients listed in UFSAR Tables 5-2, *"Transient Cycles for RCS Components Except Pressurizer Surge Line"* and UFSAR Table 5-23, *"Operating Design Transient Cycles for Pressurizer Surge Line,"* and ensure corrective action is taken prior to potentially exceeding cycle limits used in these calculations. The effects of fatigue on flaws analyzed for Class 1 components will be adequately managed by the *Fatigue Monitoring* AMP (Section A3.1) for the SPEO in accordance with 10 CFR 54.21(c)(1)(iii).

A4.3.6 Weld Overlay Class 1 Fatigue Analysis

Structural weld overlays were installed on the pressurizer spray, pressurizer surge, reactor coolant system hot leg surge, reactor coolant system letdown, hot leg decay heat and safety and relief nozzles to eliminate concerns with stress corrosion cracking of Alloy 600. Analyses of the weld overlays for these locations includes both fatigue analyses and postulated flaw growth analyses.

The transient cycles considered in the weld overlays were projected for 80 years of operation and were found to have adequate margin in order to remain valid for the SPEO. The Fatigue Monitoring AMP (B3.1) will track cycles for significant fatigue transients and ensure corrective action is taken prior to potentially exceeding fatigue design limits.

A review of the fatigue flaw growth analyses established the required time frame for inspection of the associated weld overlays. Specifically, 25% sample population of the weld overlays will be inspected for cracking during the SPEO. The examinations will be performed in accordance with the rules outlined in Code Case N-770-5, Item F-1. These inspections will be managed by the ASME Section XI Inservice Inspection, Subsection IWB, IWC, and IWD AMP (B2.1.1).

The effects of fatigue on the intended function(s) of the weld overlays will be adequately managed by the Fatigue Monitoring aging management program (B3.1) and the ASME Section XI Inservice Inspection, Subsection IWB, IWC, and IWD aging management program (B2.1.1) through the SPEO. Therefore, this TLAA is dispositioned in accordance with 10 CFR 54.21(c)(1)(iii).

A4.4 Environmental Qualification of Electric Equipment

Thermal, radiation, and cyclical aging analyses of plant electrical and I&C components, developed to meet 10 CFR 50.49 requirements, have been identified as TLAAs. The NRC nuclear station EQ requirements in 10 CFR 50.49 require that an EQ program be established to demonstrate that certain electrical equipment located in harsh plant environments is qualified to perform applicable safety functions in those harsh environments after the effects of inservice aging. Harsh environments are defined as those areas of the plant that could be subject to the harsh environmental effects of a LOCA, HELB, and post-LOCA radiation. 10 CFR 50.49 requires that the effects of significant aging mechanisms be addressed as part of EQ. The various aspects of design for environmental considerations are described in Oconee UFSAR 3.11 *Environmental Design of Mechanical and Electrical Equipment*.

The EQ program was evaluated against the Division of Operating Reactors (DOR), “Guidelines for Evaluating Qualification of Class 1E Electrical Equipment in Operating Reactors”, Inspection and Enforcement Bulletin (IEB) 79-01B, “Environmental Qualification of Class 1E Equipment”, and IEEE Standard 323-1974, “IEEE Standard for Qualifying Class 1E Equipment for Nuclear Power Generating Stations,” as codified by 10 CFR 50.49. IEEE 323-1974 provides the criteria for safety related equipment (electrical “Class 1E” equipment) and the basis for categorizing equipment important to safety, and defines environmental service conditions.

Reanalysis of an aging evaluation to extend the qualified life of equipment is performed on a routine basis as part of the EQ program. Important attributes for the reanalysis of an aging evaluation include analytical methods, data collection and reduction methods, underlying assumptions, acceptance criteria, and corrective actions (if acceptance criteria are not met).

If the qualified life cannot be extended by reanalysis, the equipment must be refurbished, replaced, or requalified prior to exceeding the period for which the current qualification remains valid. A reanalysis is to be performed in a timely manner such that sufficient time is available to refurbish, replace, or requalify the equipment if the reanalysis is unsuccessful.

The implementation of the enhanced EQ AMP provides reasonable assurance that thermal, radiation, and cyclical aging effects will be adequately managed so that the intended functions of components within the scope of LR will be maintained during the SPEO.

The *Environmental Qualification of Electric Equipment* program (A3.3) will manage the effects of aging for EQ equipment through the SPEO in accordance with 10 CFR 50.49(c)(1)(iii). The program meets the requirements of 10 CFR 50.49 for the applicable electrical equipment important to safety.

A4.5 Concrete Containment Unbonded Tendon Prestress

The Oconee containment buildings are post-tensioned, reinforced concrete structures composed of vertical cylinder walls and a shallow dome, supported on a conventional reinforced concrete base slab. The cylinder wall is prestressed by 176 vertical tendons anchored at the top surface of the upper ring girder at the top of the concrete cylinder and at the bottom of the foundation slab and six groups of 105 hoop tendons plus two additional tendons enclosing 120° of arc for a total of 632 tendons anchored at the six vertical buttresses. The dome is prestressed by three groups of 54 tendons oriented at 120° to each other for a total of 162 tendons anchored at the vertical face of the upper ring girder. Each tendon consists of 90 wires bundled together.

Over time, the containment prestressing forces decrease due to relaxation of the steel tendons and due to creep and shrinkage of the concrete. The containment tendon prestressing forces were calculated during the original design considering the magnitude of the tendon relaxation and concrete creep and shrinkage over the 40-year life of the plant. Oconee UFSAR Section 18.3.3, Containment Inservice Inspection Plan describes the performance of periodic surveillances of individual tendon prestressing values. Predicted lower limit force values are calculated for each tendon prior to the surveillances to estimate the magnitude of the tendon relaxation and concrete creep and shrinkage for the given surveillance period. The prestressing forces are measured and plotted, and trend lines are developed, to ensure the average tendon group prestressing values remain above the respective minimum required values until the next scheduled surveillance. The predicted lower limit force values and regression analyses, utilizing actual measured tendon forces, are used to evaluate the acceptability of the containment structure to perform its intended function over the current 60-year life of the plant, and therefore, are TLAAs requiring evaluation for the SPEO.

For SLR, predicted lower limit lines and trend lines of measured prestressing forces have been established for applicable tendon groups through the SPEO. The predicted final effective preload at the end of 80 years exceeds the minimum required preload for all containment tendons. Consequently, the post- tensioning system will continue to perform its intended function throughout the SPEO. The *Concrete Containment Unbonded Tendon Prestress* AMP (A3.4) and *ASME Section XI, Subsection IWL* AMP (A2.29) will monitor and manage the associated loss of tendon prestressing forces during the SPEO in accordance with 10 CFR 54.21(c)(1)(iii).

A4.6 Containment Liner Plate, Metal Containments, and Penetrations Fatigue Analysis

A4.6.1 Containment Liner Plate

The interior surface of the containments for ONS Units 1, 2, and 3 are lined with a ¼” thick welded steel plate to provide an essentially leak-tight barrier. At all penetrations, the liner plate is thickened to reduce stress concentrations. As described in UFSAR 3.8.1.5.3 *Liner Plate*, the only portions of the liner plate that contain fatigue analysis are those thickened portions at the penetrations. The containment penetration fatigue analysis is contained in Section 4.6.3.

The associated temperature and pressure changes from reactor coolant system heatups and cooldowns and Type A integrated leak rate test are the main contributors to fatigue of the containment liner plate. Combining the total number of cycles for outdoor temperature variations, the total number of Type A tests, and the projected heatups and cooldowns would result in a transient cycle count less than 500 cycles. Therefore, it is concluded that thermal fatigue of the containment liner would be acceptable for the SPEO. The effects of fatigue of the containment liner plate will be adequately managed by the *Fatigue Monitoring* AMP (B3.1) for the SPEO in accordance with 10 CFR 54.21(c)(1)(iii).

A4.6.2 Metal Containment

Not applicable

A4.6.3 Containment Penetrations Fatigue Analysis

The interior surface of the containment is lined with welded steel plate to provide an essentially leak tight barrier. At all penetrations, the liner plate is thickened to reduce stress concentrations of the liner plate. ONS Units 1, 2 and 3 process lines that penetrate the primary containment and experience significant thermal expansion and contraction are solidly anchored to the containment wall. These high temperature lines penetrating the containment wall and liner plate are the main steam and feedwater lines.

The transient cycles considered in the main steam and feedwater penetrations analyses were projected for 80 years of operation and the count found to be adequate for the SPEO. The *Fatigue Monitoring* (A3.1) aging management program will monitor and manage fatigue of the main steam and feedwater penetrations during the SPEO in accordance with 10 CFR 54.21(c)(1)(iii).

A4.7 Other Plant-Specific Time-Limited Aging Analyses

A4.7.1 Reactor Vessel Internals

A4.7.1.1 Reduction in Fracture Toughness Due to Neutron Embrittlement

Framatome Topical Report BAW-10008, Part 1, Revision 1 documents the acceptability of the reactor vessel internals under LOCA and a combination of LOCA and seismic loadings. The effect of irradiation on the material properties and deformation limits for the internals is evaluated with a conclusion that at the end of 40 years the internals will have adequate ductility to absorb local strain at the regions of maximum stress intensity, and that irradiation will not adversely affect deformation limits.

Using the findings from this report, a plant specific evaluation of reactor vessel internals irradiation embrittlement was completed by Oconee in 2012 to address this issue for 60 years.

The NRC staff review of this 60-year evaluation concluded that the licensee had projected the neutron fluence for the reactor vessel Internals using an acceptable methodology consistent with RG 1.190. For subsequent license renewal, reduction in fracture toughness due to neutron embrittlement of the reactor vessel internals relative to the evaluation of BAW-10008, Part 1, Revision 1 must be evaluated for 80 years.

Each reactor vessel Internals item addressed in BAW-10008, Part 1, Revision 1 is assessed in accordance with one of three process steps (i.e., Categories 1-3) for Faulted Conditions to determine if each reactor vessel Internals item should be considered potentially susceptible to an unacceptable amount of reduction of ductility at 72 EFPY. This multi-step assessment was completed for the Oconee reactor vessel internals. Based on the assessments, the effect of irradiation on the material properties and deformation limits of the reactor vessel Internals at all three units at Oconee is acceptable for an 72 EFPY lifetime such that the internals will have adequate ductility to absorb local strain at the regions of maximum stress intensity, and that irradiation will not adversely affect deformation limits under faulted condition loadings for the SPEO. The analyses reported in BAW-10008, Part 1, Revision 1, remain valid for the subsequent period of extended operation and are managed by the PWR Vessel Internals Program (B2.1.7, GALL-SLR XI.M16A), in accordance with 10 CFR 54.21(c)(1)(iii), consistent with the current licensing basis.

A4.7.1.2 Reactor Vessel Internals Flow Induced Vibration Endurance Limits

The reactor vessel internals flow-induced vibration endurance limit assumptions for 60-years were reviewed and updated for applicability to 80-years. The rationale and methods that are applied to SLR for 80-years are identical to those previously established for 60-years and augmented with additional justification to conservatively address environmental assisted fatigue affects utilizing the environmental assisted fatigue criteria developed in NUREG/CR-6909, Revision 1. In addition, the more limiting fatigue curves published in the 2013 edition of the ASME Section III code (compared to the 1986 edition used with the ONS LRA for 60 years) were used in the evaluation.

Flow-induced vibration of the reactor vessel internals was evaluated. The item with the maximum flow-induced vibration stress, and thus the least margin has a stress value that is smaller than the allowable cyclic stress. Therefore, a safety factor exists between the maximum flow-induced vibration stress and the allowable cyclic stress from the fatigue curve for this limiting location. Since this stress is below the endurance limit, the maximum fatigue usage factor associated with flow-induced vibration for the reactor vessel Internals is below the endurance limit for an 80-year life. The reactor vessel internals flow-induced vibration endurance limits will not be exceeded during the SPEO in accordance with 10 CFR 54.21(c)(1)(ii).

A4.7.1.3 Reactor Vessel Internals Irradiation Embrittlement

Framatome Topical Report BAW-10008, Part 1, Revision 1, discussed further in Section 4.7.1.1, documents the acceptability of the reactor vessel Internals under LOCA and a combination of LOCA and seismic loadings for 40 years. Using the findings from this report, a plant-specific evaluation of reactor vessel internals irradiation embrittlement was completed by Oconee in 2012 to address this issue for 60 years. The NRC staff review of this 60-year evaluation concluded that the licensee had projected the neutron fluence for the reactor vessel Internals using an acceptable methodology consistent with RG 1.190. For SLR, neutron fluence of the reactor vessel Internals relative to the evaluation of BAW-10008, Part 1, Revision 1 must be evaluated for 80 years. In addition, a reactor vessel internals functionality assessment of inaccessible components (MRP-227-A/LAI #6), is identified as a TLAA for SLR. Duke Energy resolved this issue for 60 years through Framatome report ANP-3477P.

The projected 72 EFPY fluence values (determined to be equivalent to 80 years) developed for the update of BAW-10008, Part 1, Revision 1 (Section 4.7.1.1) were developed based on extrapolation of 60-year reactor vessel Internals transport calculations that were developed using the RG 1.190 compliant methodology (i.e., deterministic DORT 3-D synthesis methods) developed for the reactor vessel as described in BAW-2241PA, Revision 0. These values are consistent with the fluence estimates reported in MRP-189, Revision 3. Since the BAW-2241PA methodology is mainly concerned with reactor vessel fluence, some specific modeling enhancements were required in order to accurately represent the reactor vessel Internals components.

To meet the requirements of the *Neutron Fluence Monitoring* AMP (A3.2), a reactor vessel internals fluence analysis was completed. A single analysis was prepared to represent all three units, since they all have similar design, fabrication, operation, and fuel loading patterns. From this analysis, the effect of irradiation on the material properties and deformation limits of the reactor vessel Internals at all three units at Oconee was determined to be acceptable for a 72 EFPY lifetime. The reactor vessel internals functionality assessment of inaccessible components (MRP-227-A/LAI #6) will be addressed for 80 years through the *PWR Vessel Internals* (A2.7) AMP. The reactor vessel internals will have adequate ductility to absorb local strain at the regions of maximum stress intensity, and irradiation will not adversely affect deformation limits under faulted condition loadings during the SPEO in accordance with 10 CFR 54.21(c)(1)(ii).

A4.7.2 Reactor Vessel Underclad Cracking

Underclad cracking refers to intergranular separations in the heat affected zones of low alloy base metal under austenitic stainless steel cladding in SA-508, Class 2 reactor vessel forgings manufactured to a coarse grain practice, and clad by high-heat-input submerged arc processes. BAW-10013 contains a fracture mechanics analysis that demonstrates the critical crack size required to initiate fast fracture is several orders of magnitude greater than the assumed maximum flaw size plus predicted flaw growth due to design fatigue cycles. The flaw growth analysis was performed for a 40-year cyclic loading, and an end-of-life assessment of radiation embrittlement (i.e., fluence at 32 EFPY) was used to determine fracture toughness properties. The report concluded that the intergranular separations found in B&W vessels would not lead to vessel failure. This report was accepted by the Atomic Energy Commission (AEC).

In May 1973, RG 1.43, *"Control of Stainless Steel Weld Cladding of Low-Alloy Steel Components"* was issued. The guide states that intergranular separation has been reported only in forgings and plate material of SA-508 Class 2 composition made to coarse grain practice when clad using high-deposition-rate welding processes identified as 'high-heat-input' processes such as the submerged-arc wide-strip and the submerged-arc 6-wire processes. Cracking was not observed in clad SA-508 Class 2 materials clad by 'low-heat-input' processes controlled to minimize heating of the base metal. Further, cracking was not observed in clad SA-533 Grade B Class 1 plate material, which is produced to fine grain practice. Characteristically, the cracking occurs only in the grain-coarsened region of the base-metal heat-affected zone at the weld bead overlap. The guide also notes that the maximum observed dimensions of these subsurface cracks is 0.5 inch long × 0.165 inch deep.

The methodology used to evaluate intergranular separations for the ONS reactor vessels at 80 years is consistent with the methodology reported in the update of BAW-10013 included as Appendix C of BAW-2251A. An Oconee specific analysis was performed for 72 EFPY and MUR conditions using current fracture toughness information, applied stress intensity factor solutions, fatigue crack growth correlations for SA-508 Class 2 materials, and is evaluated in accordance with the methodology prescribed in ASME Section XI, 2013 Edition, IWB-3612.

The analysis was applied to five regions of the reactor vessel: flange top, nozzle belt, shell taper, shell, and transition forging. Since the closure head for each ONS unit has been replaced, and the replacement closure head is not susceptible to UCC, the closure heads were not re-evaluated. Both axial and circumferential oriented flaws were considered in the evaluation. All significant normal and upset condition transients and emergency and faulted condition transients were evaluated in the analysis. The fatigue crack growth analysis considered all the normal and upset condition transients with associated design cycles (80-year design cycles are equivalent to 40- and 60-year design cycles) for the SPEO.

The lowest fracture toughness margin for Level A/B (normal/upset) loading conditions is 3.94 and occurs at the flange top location for the axially oriented flaw, which is higher than the minimum required margin of 3.16 ($\sqrt{10} = 3.16$). The lowest fracture toughness margin for Level C/D (emergency/faulted) loading condition is 1.62 and occurs at the shell taper region due to a circumferentially oriented flaw, which is greater than the minimum required margin of 1.41 ($\sqrt{2} = 1.41$). Therefore, postulated flaws for the underclad cracking in the reactor vessels for all the three Oconee Units remain acceptable at the end of the 72 EFPY service evaluation period.

For the ONS Unit 1, Unit 2, and Unit 3, reactor vessel shells, including the transition forging, nozzle belt and flange, the reactor pressure vessel underclad cracking TLAA have been projected to the end of the subsequent period of extended operation in accordance with 10 CFR 54.21(c)(1)(ii).

A4.7.3 Reactor Coolant Pump Flywheel Fatigue Analysis

Oconee UFSAR Section 5.4.4.2, Flywheel Design Consideration, identified the potential for fatigue crack initiation in the reactor coolant pump motor flywheel bore keyway should a certain threshold of reactor coolant pump motor starts be exceeded. The flywheel has been designed for 10,000 starts. Comparison of the design value to actual and predicted pump starts over 80 years was identified as a TLAA. The SLR evaluation resulted in a total count of 480 projected reactor coolant pump starts after 80 years of operation. This number is based on extrapolating 19 years of reactor coolant pump start data from 2000 to 2019, and then doubling it to demonstrate conservatism and account for future startup variations from unit trips and shutdowns. Since the flywheel is designed for 10,000 starts, the results of this evaluation indicate a safety factor of over 20.

The reactor coolant pump flywheel fatigue analysis TLAA remains valid through the SPEO in accordance with the requirements of 10 CFR 54.21(c)(1)(ii).

A4.7.4 Leak Before Break

The successful application of Leak-Before-Break (LBB) to the Oconee Reactor Coolant System main coolant piping is described in B&WOG topical report entitled, “The B&W Owners Group Leak-Before-Break Evaluation of Margins Against Full Break for RCS Primary Piping of B&W Designed NSSS,” BAW-1847, Revision 1, September 1985. This report provides the technical basis for evaluating postulated flaw growth in the main Reactor Coolant System piping under normal plus faulted loading conditions and was approved by the NRC for the current term of operation. The time-limited aging analyses in BAW-1847, Revision 1, include fatigue flaw growth and the qualitative assessment of thermal aging of cast austenitic stainless steel reactor coolant pump inlet and outlet nozzles.

Fatigue flaw growth evaluations are based on transient definitions defined by the reactor coolant system design specification. The original transient cycles that were defined for 40 years of operation are compared to the projected cycles for 80 years. The comparison indicates that none of the original 40-year transient cycles are projected to be exceeded for 80 years. The transient cycles will be monitored and management by the *Fatigue Monitoring* AMP (A3.1) for the SPEO.

The cast austenitic stainless steel reactor coolant pump inlet and outlet nozzles are susceptible to thermal aging. Thermal aging of cast austenitic stainless steel causes a reduction of fracture toughness. Reduction of fracture toughness of the reactor coolant pump nozzles has been determined to be acceptable for the PEO through a flaw stability analysis. The generic LBB analysis for the B&W operating plants reported in BAW-1847, Revision 1, remains valid for the SPEO in accordance with 10 CFR 54.21(c)(1)(i) for the ONS. Reduction of fracture toughness of the reactor coolant pump discharge and suction nozzles was determined to be acceptable for SPEO based on the update to the flaw stability analysis described above. Although the LBB analysis remains valid, the transient cycles will be monitored and management by the *Fatigue Monitoring* AMP (A3.1) provides additional assurance for the SPEO.

A4.7.5 Crane Load Cycle Limit

A review of design specifications for cranes within the scope of subsequent license renewal was performed to identify those cranes that were designed or otherwise required to meet the intent of Crane Manufacturers Association of America (CMAA) Specification 70-1975, “Specifications for Electric Overhead Traveling Cranes,” and, therefore, have a defined service life as measured in load cycles.

CMAA Specification 70 presents the bounding combinations of the number of load cycles and mean effective load factors for each service class. These define the acceptable service limits for the TLAA. The plant response to NUREG-0612, as guided by NRC Generic Letter 81-07, “Control of Heavy Loads,” indicates that the cranes designed and fabricated in accordance with Electric Overhead Crane Institute (EOCI) Specification 61, “Specifications for Electric Overhead Traveling Cranes”, and compares that design approach to that of CMAA Specification 70, which has superseded EOCI Specification 61. The conclusion reached in the response to NRC Generic

Letter 81-07 is that the: 1) reactor building polar cranes: 2) spent fuel pool cranes; 3) spent fuel pool auxiliary cranes; 4) pump aisle crane; 5) turbine aisle crane; 6) turbine aisle auxiliary crane; and 7) heater bay crane satisfy the design intent of CMAA Specification 70.

Based on the comparison of service classes described in the original design specification (EOCI Specification 61) to CMAA Specification 70, the applicable service class is Class A. CMAA Specification 70 states that a range of load cycles from 20,000 to 100,000 was considered for cranes in Class A (Standby) service thus establishing the envelope for acceptable number of load cycles for this TLAA. The total projected load cycles for the reactor building polar cranes, spent fuel pool cranes, spent fuel pool auxiliary cranes, pump aisle crane, turbine aisle crane, turbine aisle auxiliary crane, and heater bay crane have been demonstrated to remain valid through the SPEO in accordance with the requirements of 10 CFR 54.21(c)(1)(i).

Load Handling System	CMAA Service Class	Maximum Number of Load Cycles	Projected Number of Load cycles for 80 Years
Unit 1 Reactor Building Polar Crane	A	100,000	1,752
Unit 2 Reactor Building Polar Crane	A	100,000	1,752
Unit 3 Reactor Building Polar Crane	A	100,000	1,752
Unit 1/2 Spent Fuel Pool Crane	A	100,000	3,316
Unit 3 Spent Fuel Pool Crane	A	100,000	2,658
Unit 1/2 Spent Fuel Auxiliary Crane	A	100,000	1,880
Unit 3 Spent Fuel Auxiliary Crane	A	100,000	940
Turbine Building Pump Isle Crane	A	100,000	3,820
Turbine Isle Crane	A	100,000	6,992
Turbine Isle Auxiliary Crane	A	100,000	6,992
Heater Bay Crane	A	100,000	3,525

A5.0 PLANT-SPECIFIC AGING MANAGEMENT PROGRAMS

This section provides summaries of a plant-specific program credited for managing the effects of aging.

A5.1 Secondary Shield Wall Tendon Surveillance

Program Description

The *Secondary Shield Wall Tendon Surveillance* AMP is an existing condition monitoring program that manages aging effects associated with the tendons and tendon anchorage in the reactor building secondary shield wall. The secondary shield wall tendon system assures the structural adequacy of the secondary concrete shield wall, which provides structural support, shelter and protection to safety related SSCs. There are no preventive or mitigative actions associated with this program. The program manages for loss of material, cracking, and loss of tendon prestress by conducting visual inspections and tendon lift-off tests in accordance with station procedures. These are performed on three randomly selected horizontal tendons every other outage. Acceptance criteria outlined in station specifications and procedures ensures appropriate corrective actions are taken based on the observed and/or measured conditions. If an inspection identifies a degraded condition associated with a tendon or the tendon anchorage, the corrective action program is utilized to facilitate repair or replacement activities.

Enhancements

The *Secondary Shield Wall Tendon Surveillance* AMP will be enhanced to:

1. Enhance station procedures to include a review of previous visual inspection and lift-off data results for the tendons selected for inspection.

A6.0 SUBSEQUENT LICENSE RENEWAL COMMITMENTS LIST

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
1	*ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* program	The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP is an existing program that will be enhanced to: 1. Revise procedures to require inspections to be performed for components associated with sentinel locations assessed under ASME Code, Section XI, Non-Mandatory Appendix L for the following: • Reactor coolant system pressurizer surge line piping (hot leg elbow). • High pressure injection piping, stop valve-to-check valve (usage bounds high pressure injection nozzle).	B2.1.1	Program enhancements for SLR will be implemented six months prior to the SPEO.
2	*Water Chemistry* program	The existing *Water Chemistry* program is credited.	B2.1.2	Ongoing
3	*Reactor Head Closure Stud Bolting* program	The *Reactor Head Closure Stud Bolting* AMP is an existing program that will be enhanced to: 1. Revise procurement requirements for reactor head closure stud bolting to incorporate guidance from RG 1.65, Revision 1 and NUREG-2191, Chapter XI.M3, to ensure newly procured bolting material does not exceed the limit for maximum measured yield strength of 150 ksi and ultimate tensile strength of 170 ksi.	B2.1.3	Program enhancements for SLR will be implemented six months prior to the SPEO.
4	*Boric Acid Corrosion* program	The existing *Boric Acid Corrosion* program is credited.	B2.1.4	Ongoing
5	*Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid Induced Corrosion in Reactor Coolant Pressure Boundary Components* program	The existing *Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid Induced Corrosion in Reactor Coolant Pressure Boundary Components* program is credited.	B2.1.5	Ongoing

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
6	*Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* program	The *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* program is a new condition monitoring program that will provide assurance that the reactor coolant pressure boundary cast austenitic stainless steel components (i.e., pump casings) with the potential for significant thermal aging embrittlement meet their intended functions. Industry and plant-specific OE will be considered in the development and implementation of this program.	B2.1.6	Program will be implemented six months prior to the SPEO.
7	*PWR Vessel Internals* program	The *PWR Vessel Internals* AMP is an existing program that will be enhanced as follows: 1. The *PWR Vessel Internals* AMP will be updated as necessary to provide guidance for implementing the changes to primary and expansion items in MRP-227, Rev 1-A, Tables 4-1, 4-4 (and Table 5-1 for Element 6 only), as modified by the ONS gap analysis reported in Appendix B2.1.7. (Elements 4 and 6)	B2.1.7	Program enhancements for SLR will be implemented six months prior to the SPEO.
8	*Flow-Accelerated Corrosion* program	The *Flow-Accelerated Corrosion* AMP is an existing program that will be enhanced to reassess infrequently used piping systems excluded from the scope of the program to ensure adequate bases exist to justify this exclusion for the SPEO.	B2.1.8	Program enhancements for SLR will be implemented six months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
9	*Bolting Integrity* program	The *Bolting Integrity* AMP is an existing program that will be enhanced to: 1. Revise applicable procedures and specifications to include reference to EPRI Report 1015336, EPRI Report 1015337, and NUREG-1339, as appropriate. 2. Revise procedures governing the direct visual examination of bolted joints to include inspection parameters such as lighting, distance, and offset. 3. Perform volumetric inspections of non-ASME high strength bolting greater than 2 inches in diameter in accordance with the method described in ASME Code Section XI, Table IWB-2500-1, Examination Category B-G-1. 4. Perform visual inspections of a representative sample of 20 percent of closure bolting where leakage is difficult to detect such as submerged connections or systems containing air/gas or a maximum of 17 bolts for each material and environment population per unit, whichever is less, during each ten year period. If the minimum sample size is not achieved during a ten year period, then alternative inspections may be performed. For submerged bolting, alternative inspections may include (a) diver inspections or (b) remote video inspections. For systems containing air/gas, alternative inspections may include (a) visual inspection for discoloration when leakage from inside the piping system would discolor the external surfaces of the component; (b) monitoring and trending of pressure decay when the bolted connection is located within an isolated boundary; (c) soap bubble testing on the external mating surface of the bolted component; or (d) thermography, when the temperature of the process fluid is higher than ambient conditions around the component.	B2.1.9	Program enhancements for SLR will be implemented six months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		5. Perform additional inspections of a minimum of 20 percent of similar bolting or five additional inspections, whichever is less, when sample based inspections do not meet acceptance criteria. If the additional inspections identify bolting that does not meet acceptance criteria, then an extent of condition and extent of cause analysis will be conducted to determine the further extent of inspections. Additional inspections of similar bolting will be performed at all three units and will occur within the same interval in which the original inspection was conducted. The corrective action program will be used to determine if changes to inspection frequency is appropriate if any inspection results indicate that loss of function will occur prior to the next scheduled inspection.		
10	*Steam Generators* program	The existing *Steam Generators* program is credited.	B2.1.10	Ongoing

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
11	*Open-Cycle Cooling Water* program	The *Open-Cycle Cooling Water System* AMP is an existing program that will be enhanced to: 1. Perform periodic inspection, cleaning, and eddy current testing of the 'A' and 'B' Chiller condensers at least once every five years. 2. Perform a minimum of 20 inspections for recurring internal corrosion in raw water systems every 24 months until the rate of recurring internal corrosion occurrences no longer meets the criteria for recurring internal corrosion as defined in Section 3.3.2.2.7 of NUREG-2192. The selected inspection locations will be periodically reviewed to validate their relevance and usefulness and adjusted as appropriate. Evaluation of the inspection results will include (1) a comparison to the nominal wall thickness or previous wall thickness measurements to determine rate of corrosion degradation; (2) a comparison to the design minimum allowable wall thickness to determine the acceptability of the component for continued use; and (3) a determination of reinspection interval.	B2.1.11	Program enhancements for SLR will be implemented six months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		3. Perform periodic internal visual inspections of the visible portion of the supply and return piping to the radwaste equipment cooling system from the condenser circulating water system intake piping in conjunction with the performance of the intake piping internal coating inspections. Visual inspections will be performed to identify direct evidence of internal degradation and indirect evidence of through wall leakage including the presence of backfill material or gravel within the pipe. 4. Provide additional guidance in procedures for inspections of non-ASME Code components for items such as lighting, distance, offset, surface coverage, presence of protective coatings, and cleaning processes. 5. Provide additional guidance for trending of heat exchanger inspection results to evaluate the adequacy of inspection frequencies. 6. If inspections identify wall-thickness below the minimum required wall thickness and the cause of the aging effect for each applicable material and environment is not corrected by repair or replacement for all components constructed of the same material and exposed to the same environment, additional inspections will be conducted. The number of increased inspections is determined in accordance with the corrective action program; however, no fewer than five additional inspections will be conducted for each inspection that did not meet acceptance criteria, or 20 percent of each applicable material, environment, and aging effect combination is inspected, whichever is less. The additional inspections include inspections at all of the units with the same material, environment, and aging effect combination. 7. Incorporate programmatic guidance contained in engineering support documents into controlled plant procedures subject to administrative controls in accordance with the Duke Energy QA program.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
12	*Closed Treated Water Systems* program	The *Closed Treated Water Systems* AMP is an existing program that will be enhanced to: 1. Perform condition monitoring using techniques (visual, surface, or volumetric) capable of detecting loss of material, cracking, and fouling as appropriate. Perform visual inspections for loss of material and fouling whenever the system boundaries of the closed treated water systems are opened. Perform surface or volumetric examinations when susceptible materials are inspected for cracking. 2. In each ten year period during the SPEO, perform sufficient number of inspections to ensure that the minimum representative sample of 20% of the population up to 17 inspections per unit is met. A population is defined as components having the same material, water treatment program and aging effect combination. Perform inspections on those components that are more likely to be susceptible to aging based on time in service and severity of operating conditions. 3. Perform additional inspections when inspections do not meet acceptance criteria. Perform at least 5 additional inspections for every inspection not meeting acceptance criteria or 20% of each applicable material, environment, and aging effect combination, whichever is less. 4. Provide additional guidance in procedures for inspections of non-ASME code components for items such as lighting, distance, offset, surface coverage, presence of protective coatings, and cleaning processes. 5. Where practical, project the rate of any degradation until the next scheduled inspection or the end of the SPEO (whichever is shorter). Adjust the sampling bases (e.g., selection, size, frequency) as necessary based on the projections.	B2.1.12	Program enhancements for SLR will be implemented six months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		6. If subsequent inspections identify aging effects, the corrective action program will be used to determine the extent of condition and extent of cause to determine further extent of inspections. Perform additional inspections on all units with the same material, environment, and aging effect combinations and within the interval of the original inspection (e.g., refueling outage interval, ten year inspection interval).		
13	*Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* program	The *Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* AMP is an existing program that will be enhanced to: 1. Provide additional procedural guidance to include visual inspections looking for deformation and cracking of bridges, structural members, and structural components. 2. Provide additional procedural guidance to specify bolted connections are monitored for loss of material, cracking, loose or missing bolts or nuts, and other conditions indicative of loss of preload. 3. Include evaluation of findings according to ASME B30.2 or other applicable ASME B30 series in applicable procedures. 4. Enhance maintenance procedures to ensure repairs are performed in accordance with ASME B30.2 or other applicable ASME B30 series in addition to manufacturers literature as necessary.	B2.1.13	Program enhancements for SLR will be implemented six months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
14	*Compressed Air Monitoring* program	The *Compressed Air Monitoring* AMP is an existing program that will be enhanced to perform opportunistic visual inspections of select component internal surfaces exposed to a dry air environment for signs of loss of material due to corrosion. Inspections will be performed by station personnel who have been qualified to the task per approved training procedures and programs. Acceptance criteria will ensure that internal surfaces that show signs of corrosion, that could indicate the potential loss of function of the component, are identified. The program will require corrective actions to be taken if loss of material due to corrosion is identified on internal surfaces of components.	B2.1.14	Program enhancements for SLR will be implemented six months prior to the SPEO.
15	*Fire Protection* program	The *Fire Protection* AMP is an existing program that will be enhanced to perform periodic visual inspection every 18 months for identification of corrosion that may lead to loss of material on the external surfaces of the standby shutdown facility CO_2 fire protection system.	B2.1.15	Program enhancements for SLR will be implemented six months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
16	*Fire Water System* program	The *Fire Water System* AMP is an existing program that will be enhanced to: 1. Perform internal visual inspections of deluge system piping by removing a hydraulically remote nozzle to identify internal corrosion, foreign material, and obstructions to flow. Internal visual inspections will be performed in 50 percent of the deluge systems within the scope of the *Fire Water System* AMP that are not subject to flow testing every five years. During the subsequent five year inspection period, the alternate systems will be inspected such that piping in 100 percent of the deluge systems within the scope of the program is inspected every ten years. Follow-up volumetric wall thickness examinations will be performed if internal visual inspections detect an unexpected level of degradation due to corrosion and corrosion product deposition. 2. Prior to 50 years in service, sprinkler heads will be submitted for field-service testing by a recognized testing laboratory consistent with NFPA 25, 2011 Edition, Section 5.3.1. 3. Perform a one-time volumetric wall thickness inspection on a representative sample deluge system supply piping that is periodically subjected to flow during functional testing. 4. Perform an obstruction investigation in accordance with NFPA 25, 2011 Edition, Section 14.3 if evidence of unacceptable internal flow blockage that could result in failure of system function is identified during internal inspections. When unacceptable internal flow blockage is detected, corrective actions will include removal of the material, an extent of condition determination, review for increased inspections, follow-up examinations, and a flush in accordance with NFPA 25 Annex D.5, *Flushing Procedures*.	B2.1.16	Program enhancements for SLR will be implemented 6 months prior to the SPEO. Inspections or tests that are to be completed prior to SPEO are completed 6 months prior to the SPEO or no later than the last refueling outage prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		5. Revise inspection procedures to provide additional inspection guidance regarding age-related degradation and to include inspection parameters for items such as lighting, distance, offset, presence of protective coatings, and cleaning processes. 6. Perform flow testing of at least one hose station in each building every five years to demonstrate the capability to provide the design pressure at required flow. Flow testing will be performed at the hydraulically most remote hose station, or if an alternative hose station is tested, the acceptance criteria for the test will account for the additional head loss that would occur if the hydraulically most remote hose station were tested such that the results of the flow test are representative of the limiting location. If acceptance criteria are not met, at least two additional tests shall be performed within five years. If subsequent tests do not meet acceptance criteria, an extent of condition and extent of cause analysis is conducted to determine the further extent of tests. The additional tests include at least one test at one of the other units with the same material, environment, and aging effect combination. 7. Perform external visual inspections of the elevated water storage tank in accordance with Section 9.2.5.5 of NFPA 25, 2011 Edition at least once every two years. 8. Perform flushing of the mainline strainers following system actuation in accordance with Section 10.2.7 of NFPA 25, 2011 Edition.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		9. Perform main drain testing of the deluge system risers at least once every two years. Main drain testing of deluge systems will be performed in accordance with the procedure described Sections 13.2.5 and A.13.2.5 of NFPA 25, 2011 Edition. When there is a ten percent reduction in full flow pressure when compared to the original acceptance test or previously performed tests, the cause of the reduction shall be identified and corrected if necessary. If acceptance criteria are not met, at least two additional tests shall be performed within two years. If subsequent tests do not meet acceptance criteria, an extent of condition and extent of cause analysis is conducted to determine the further extent of tests. The additional tests include at least one test at one of the other units with the same material, environment, and aging effect combination. 10. Acceptance criteria and corrective actions for internal inspections of the elevated water storage tank will be in accordance with the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers and Tanks* program. Tank wall thickness measurements will be conducted if interior pitting or general corrosion (beyond minor surface rust) is detected.		
17	*Outdoor and Large Atmospheric Metallic Storage Tanks* program	The *Outdoor and Large Atmospheric Metallic Storage Tanks* AMP is a new condition monitoring program that manages loss of material on the external surfaces of the Unit 1,2 and 3 borated water storage tanks and ensures there is no significant degradation of the tank bottoms. These are indoor large volume tanks that contain water and are designed with internal pressures approximating atmospheric that are sited on concrete. This program includes preventive measures to mitigate corrosion by protecting the external surfaces of the steel components in accordance with standard industry practices.	B2.1.17	The program for SLR will be implemented six months prior to the SPEO or no later than the last refueling outage prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
18	*Fuel Oil Chemistry* program	The *Fuel Oil Chemistry* AMP is an existing program that will be enhanced to: 1. Monitor the standby shutdown facility fuel oil day tank quarterly for the presence of water by draining oil from the bottom of the tank and remove the water, if found. 2. Monitor the fuel oil stored in the standby shutdown facility fuel oil day tank quarterly for the presence of bacteria and fungus. 3. Perform volumetric wall thickness measurement of the standby shutdown facility fuel oil day tank if evidence of degradation is identified visually during the 10 year internal inspection.	B2.1.18	Program enhancements for SLR will be implemented six months prior to the SPEO or no later than the last refueling outage prior to the SPEO.
19	*Reactor Vessel Material Surveillance* program	The existing *Reactor Vessel Material Surveillance* AMP is credited.	B2.1.19	Ongoing
20	*One-Time Inspection* program	The *One-Time Inspection* AMP is a new condition monitoring program consisting of a one-time inspection of selected components to verify: a. the system wide effectiveness of an AMP that is designed to prevent or minimize aging to the extent that it will not cause the loss of intended function during the SPEO; b. the insignificance of an aging effect; and c. the long-term loss of material that will not cause a loss of intended function for steel components exposed to environments that do not include corrosion inhibitors as a preventive action. Industry and plant specific OE will be considered in the development and implementation of the program.	B2.1.20	Program will be implemented and inspections begin 10 years before the SPEO. Inspections that are to be completed prior to the SPEO are completed 6 months prior to the SPEO or no later than the last refueling outage prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
21	*Selective Leaching* program	The *Selective Leaching* AMP is a new condition monitoring program that will monitor components constructed of materials which are susceptible to selective leaching. The *Selective Leaching* program includes a one-time inspection for susceptible components exposed to closed-cycle cooling water and treated water environments, as well as opportunistic and periodic inspections for susceptible components exposed to raw water, waste water, and soil (which may include groundwater) environments. Industry and plant-specific OE will be considered in the development and implementation of this program.	B2.1.21	Program will be implemented no later than 10 years prior to the SPEO. The one-time inspections and initial periodic inspections are required to be performed within the 10 years prior to the SPEO, and no later than 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
22	*ASME Code Class 1 Small-Bore Piping* program	The *ASME Code Class 1 Small-Bore Piping* AMP is a new condition monitoring program that augments the existing ASME Code, Section XI requirements and is applicable to ASME Code Class 1 small-bore piping and systems with a nominal pipe size diameter less than four inches and greater than or equal to one inch. This program provides for volumetric examination of a sample of full penetration (butt) welds and partial penetration (socket) welds in Class 1 piping to manage cracking due to stress corrosion cracking or thermal or vibratory fatigue loading. Volumetric examinations will employ techniques that have been demonstrated to be capable of detecting flaws and discontinuities in the examination volume of interest. The extent and schedule for volumetric examination is based on plant-specific OE and whether actions have been implemented that effectively mitigate the cause(s) of any past cracking. The program provides for periodic inspection of a sample of the population of welds (butt welds or socket welds) that have experienced cracking and have not implemented corrective actions to effectively mitigate the cause(s) of the cracking. Industry and plant-specific OE will be considered in the development and implementation of this program.	B2.1.22	Program will be implemented within the 6 years prior to the SPEO. The one-time inspections and initial periodic inspections will be performed within the 6 years prior to the SPEO. These inspections will be completed no later than 6 months prior to the SPEO or no later than the last refueling outage prior to the SPEO. Subsequent periodic inspections will be performed every 10 years during the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
23	*External Surfaces Monitoring of Mechanical Components* program	The *External Surfaces Monitoring of Mechanical Components* AMP is a new condition monitoring program that will manage the aging effects of: • loss of material, cracking, and reduction of heat transfer of metallic components; • hardening or loss of strength, loss of material, and cracking or blistering of polymeric components; • hardening or loss of strength, and loss of material of elastomeric components; • loss of material, cracking, and loss of preload for HVAC closure bolting; and • reduced thermal insulation resistance. Periodic visual inspections, not to exceed a refueling outage interval, of metallic, polymeric, and elastomeric components, and insulation metallic jacketing (or protective outer layer if metal jacketing is not used) will be conducted. Industry and plant-specific OE will be considered in the development and implementation of this program.	B2.1.23	The program for SLR will be implemented six months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
24	*Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components* program	The *Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components* AMP is a new condition monitoring program that will manage loss of material and cracking of metallic components, as well as loss of material, cracking, blistering, hardening and loss of strength of polymeric and elastomeric materials. The program also manages loss of coating integrity for certain components that do not perform a pressure boundary intended function and where loss of coating integrity would not impact the intended functions of downstream components. Reduction of heat transfer and flow blockage will also be managed. This program will consist of visual inspections of all accessible internal surfaces of piping, piping components, ducting, heat exchanger components, polymeric and elastomeric components, and other mechanical components. Periodic visual (VT-1) or surface examinations will be performed to detect cracking of stainless steel components exposed to a diesel exhaust, potable raw water, and waste water and in copper alloys exposed to waste water. Industry and plant-specific OE will be considered in the development and implementation of this program.	B2.1.24	The program for SLR will be implemented six months prior to the SPEO.
25	*Lubricating Oil Analysis* program	The *Lubricating Oil Analysis* AMP is an existing program that will be enhanced to update procedures to specify that in all cases, phase-separated water in any amount is not acceptable.	B2.1.25	Program enhancements for SLR will be implemented six months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
26	*Buried and Underground Piping and Tanks* program	The *Buried and Underground Piping and Tanks* AMP is an existing program that will be enhanced to: 1. Install a cathodic protection system in accordance with NACE SP0169-2007 for buried carbon steel piping within the scope of this program. 2. Complete a modification to abandon the buried copper alloy instrument air system piping within the scope of this program. 3. Annual cathodic protection system monitoring will be performed with a maximum grace period of two months. The system will be monitored at least once during each calendar year. 4. Utilize an inspection method that has been demonstrated to be capable of detecting cracking for uncoated stainless steel piping and when visual inspections of coated stainless steel piping detect coating degradation or damage which could potentially result in stress corrosion cracking of the base material. Indications of cracking will be evaluated in accordance with applicable codes and plant-specific design criteria. 5. Perform wall thickness measurement if visual inspections identify evidence of corrosion beyond minor surface rusting for both coated and uncoated metallic piping or tanks. The results of the wall thickness measurement will be used to calculate a corrosion rate and project wall thickness through the end of the SPEO. If the depth or extent of degradation of the base metal could have resulted in a loss of pressure boundary function when the loss of material is extrapolated to the end of the SPEO, then additional inspections will be performed as follows: When measured pipe wall thickness, projected to the end of the SPEO,	B2.1.26	Program enhancements for SLR will be implemented and inspections begin 10 years before the SPEO and inspections required during the 10 year interval prior to the SPEO will be completed no later than 6 months prior to the SPEO. The cathodic protection system for buried steel piping will be installed no later than 5 years prior to the SPEO. Modification to abandon the buried copper alloy instrument air system piping will be implemented no later than 6 months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		does not meet the minimum pipe wall thickness requirements due to external corrosion, the number of inspections within the affected piping category will be doubled or increased by five, whichever is smaller. If adverse indications are found in the expanded sample, an extent of condition and extent of cause analysis to determine the further extent of inspections. Timing of any additional inspections will be based on the severity of the identified degradation and the consequences of leakage or loss of function. Any additional inspections will be performed within the same 10-year inspection interval in which the original degradation was identified, or within four years after the end of the 10-year interval if the degradation was identified in the latter half of the 10-year interval. Expansion of sample size may be limited by the extent of piping subject to the observed degradation mechanism or if the piping system or portion of the system is replaced or otherwise mitigated within the same 10-year inspection interval in which the original degradation was identified or within four years after the end of the 10-year interval, if the degradation was identified in the latter half of the 10-year interval. 6. Perform inspections of buried steel condenser circulating water system piping at least once every ten years. The minimum number of inspections will be determined based on the effectiveness of preventive actions in accordance with NUREG-2191, Table XI.M41-2. Ten linear feet of piping will be exposed for each inspection. Inspections of the large diameter condenser circulating water system intake piping will expose a quadrant (i.e., 9 to 12 o'clock or 12 to 3 o'clock) of the piping. External inspections of the large diameter condenser circulating water system intake piping will be supplemented by low frequency		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		electromagnetic testing performed from the internal surface of the same section of piping that is externally inspected with follow-up ultrasonic wall thickness measurements performed of areas identified as low points during low frequency electromagnetic testing. 7. Perform visual inspections of at least two ten-linear foot sections of buried uncoated stainless steel piping at least once every ten years. Piping inspection locations will be selected based on risk (i.e., susceptibility to degradation and consequences of failure). 8. Perform visual inspections of at least four ten linear foot sections of underground coated steel piping at least once every ten years. Piping inspection locations will be selected based on risk (i.e., susceptibility to degradation and consequences of failure). 9. Internal volumetric inspections of the standby shutdown facility diesel engine fuel oil tank will cover at least 25% of the surface area of the tank and include at least some of both the top and bottom of the tank. 10. Personnel performing inspections of buried coated piping and tanks will either: 1) possess an Association for Materials Protection and Performance coating inspector program level 2 or level 3 inspector qualification, 2) complete the EPRI *Comprehensive Coatings Course* and complete the EPRI *Buried Pipe Condition Assessment and Repair Training Computed Based Training Course*, or 3) be qualified as a coatings specialist in accordance with ASTM D7108.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		11. If significant coating damage is identified during visual inspections, then perform an evaluation to determine if the coating damage was caused by nonconforming backfill. If it is determined that the coating damage was caused by nonconforming backfill, then conduct an extent of condition evaluation to determine the extent of degraded backfill in the vicinity of the observed damage.		
27	*Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* program	The *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* AMP is a new condition monitoring program that manages degradation of internal coatings/linings exposed to raw water, treated water, treated borated water, or lubricating oil that can lead to loss of material of base metals or downstream effects such as reduction in flow, pressure, or heat transfer when coatings/ linings become debris. Industry and plant-specific OE will be considered in the development and implementation of this program.	B2.1.27	Program will be implemented no later than 10 years prior to the SPEO. Baseline inspections that may be required in the 10 year period prior to the SPEO will be completed no later than six months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
28	*ASME Section XI, Subsection IWE* program	The *ASME Section XI, Subsection IWE* AMP is an existing program that will be enhanced to: 1. Specify that for "high strength" structural bolting consisting of ASTM A325, ASTM F1852, and/or ASTM A490 bolts, the preventive actions for storage, lubrication, and stress corrosion cracking potential discussed in Section 2 of RCSC (Research Council for Structural Connections) publication "*Specification for Structural Joints Using ASTM A325 or ASTM A490 Bolts*", will be used. 2. Include inspection attributes for the aging mechanisms listed in NUREG-2191. For non-coated surfaces this includes evidence of cracking, discoloration, wear, pitting, excessive corrosion, arc strikes, gouges, surface discontinuities, dents, and other signs of surface irregularities including discernible liner plate bulges. For painted or coated surfaces this includes evidence of flaking, blistering, peeling, discoloration, and other signs of potential distress of the underlying metal shell or liner system, including discernible liner plate bulges. 3. Specify a one-time volumetric examination of metal liner surfaces that are inaccessible from one side if triggered by plant-specific OE. The trigger for this supplemental examination is a plant-specific occurrence or recurrence of measurable metal liner corrosion (base metal material loss exceeding 10% of nominal plate thickness) initiated on the inaccessible side or areas, identified since the date of issuance of the first renewed license. This supplemental volumetric examination consists of a sample of one-foot square locations that include both randomly-selected and focused areas most likely to experience degradation based on OE and/or other relevant considerations such as environment. The supplemental volumetric examinations for each unit will occur within two refueling outages after identifying the trigger for the examination. Any identified degradation is addressed in accordance with the	B2.1.28	Program enhancements for SLR will be implemented no later than 6 months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		applicable provisions of the ASME Section XI, Subsection IWE program. The sample size, locations, and any needed scope expansion (based on findings) for this one-time set of volumetric examinations should be determined on a plant-specific basis to demonstrate statistically with 95% confidence that 95% of the accessible portion of the containment liner is not experiencing corrosion degradation with greater than 10% loss of nominal thickness.		
29	*ASME Section XI, Subsection IWL* program	The *ASME Section XI, Subsection IWL* AMP is an existing program that will be enhanced to: 1. Incorporate monitoring for changes in material properties of increase in porosity and permeability, and loss of strength and pattern cracking with darkened edges. 2. Specify that inspection results are documented and compared to previous results to identify changes from prior inspections.	B2.1.29	Program enhancements for SLR will be implemented no later than 6 months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
30	*ASME Section XI, Subsection IWF* program	The *ASME Section XI, Subsection IWF* AMP is an existing program that will be enhanced to: 1. Perform periodic evaluations of the acceptability of inaccessible areas of supports (e.g., portions of supports encased in concrete, buried underground, or encapsulated by guard pipe), when conditions exist in accessible areas that could indicate the presence of, or result in, degradation to inaccessible areas of supports. Perform these evaluations once every ten years during the SPEO. 2. Procedures will be revised to specify that for structural bolting consisting of ASTM A325, ASTMF1852, and/or ASTM A490, the preventative actions for storage, lubricants, and stress corrosion cracking potential discussed in Section 2 of RCSC (Research Council for Structural Connections) publication, "*Specification for Structural Joints Using ASTM A325 or A490 Bolts*," will be used. 3. Procedures will be revised to specify that whenever replacement of bolting is required, bolting material, installation torque or tension, and use of lubricants and sealants will be in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339. 4. Perform a one-time inspection within five years prior to entering the SPEO of an additional 5% of the sample populations for Class 1, 2, and 3 piping supports. The additional supports will be selected from the remaining population of IWF piping supports and will include components that are most susceptible to age-related degradation.	B2.1.30	Program enhancements for SLR will be implemented and a one-time inspection of an additional 5% of the sample size specified in Table IWF-2500-1 for Class 1, 2, and 3 piping supports is conducted within 5 years prior to the SPEO, and is to be completed prior to the SPEO. Other enhancements are completed 6 months prior to the SPEO or no later than the last refueling outage prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		5. Procedures will be revised to specify that, for NSSS component supports, high strength bolting greater than one inch nominal diameter, volumetric examination comparable to that of ASME Code, Section XI, Table IWB-2500-1, Examination Category B-G-1 will be performed to detect cracking in addition to VT-3 examination. In each 10 year period during the SPEO, a representative sample of bolts will be inspected. The sample of high strength bolting greater than one inch nominal diameter subject to volumetric examination will consist of 17 bolts per unit. The sample shall include the bolting that is most susceptible to age-related degradation (i.e., based on time in service, aggressive environment, etc). 6. If a component does not exceed the acceptance standards of IWF-3400 but is repaired to as-new condition, the sample is increased or modified to include another support that is representative of the remaining population of supports that were not repaired.		
31	*10 CFR Part 50, Appendix J* program	The existing *10 CFR Part 50, Appendix J* program is credited.	B2.1.31	Ongoing
32	*Masonry Walls* program	The *Masonry Walls* AMP is an existing program that will be enhanced to update the parameters monitored to identify potential shrinkage and/or separation of masonry walls and include loss of material in addition to the currently managed cracking at joints.	B2.1.32	Program enhancements for SLR will be implemented no later than 6 months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
33	*Structures Monitoring* program	The *Structures Monitoring* AMP is an existing program that will be enhanced to: 1. Add the following structures to the scope of the program: a. Microwave House Structure b. Technical Support Building Cable Vault c. 100 kV Structure d. Protected Service Water Building e. Protected Service Water Duct Banks f. Borated Water Storage Tank Superstructure g. HP Office Building h. Administration Building 2. Procedures will be revised to specify that structural components inspected include structural bolting, anchor bolts and embedments, supports and bracings associated with masonry walls, pipe whip restraints and jet impingement shields, transmission towers, panels and other enclosures, racks, sliding surfaces, sump and pool liners, electrical cable trays and conduits, tube tracks, electrical duct banks, manholes, doors, penetration seals, and other elastomeric materials.	B2.1.33	Program enhancements for SLR will be implemented no later than 6 months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		3. Expand the monitoring and evaluation of raw water and ground water chemistry, for pH, chlorides, and sulfates, on a frequency not to exceed five years that accounts for seasonal variations (e.g., quarterly monitoring every fifth year), from locations that are representative of the groundwater in contact with structures within the scope of SLR. a. Enter adverse results, which exceed water chemistry criteria, into the corrective action program. As part of the corrective actions, if aggressive groundwater is identified that might affect structures in scope for SLR, perform additional water testing at additional locations and perform soil testing in order to confirm the extent, severity, and potential aging mechanisms resulting from the aggressive groundwater/soil. b. Develop engineering evaluations to evaluate the water chemistry results to assess the impact, if any, on below-grade concrete, including the potential for further degradation due to the aggressive groundwater, as well as consideration of current conditions. As part of the engineering evaluations, determine if additional actions are warranted, which might include enhanced inspection techniques and/or increased frequency, destructive testing, and focused inspections of representative accessible (leading indicator) or below-grade, inaccessible concrete structural elements exposed to aggressive groundwater/soil. c. Develop the initial engineering evaluations prior to the SPEO. Develop follow-up engineering evaluations on an interval not to exceed five years.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		d. If aggressive groundwater and soil is identified, at a minimum, perform focused inspections of representative, accessible (leading indicator) structural elements, or if accessible areas will not be leading indicators for the potential aging mechanisms, excavate and inspect buried concrete elements exposed to aggressive groundwater/soil. e. If degraded concrete is identified, as part of the focused inspections of leading indicators (representative, accessible or exposed inaccessible concrete), enter adverse results that exceed ACI 349.3R second tier criteria into the corrective action program, and expose inaccessible concrete so that the extent of the condition can be determined, baseline conditions documented, and additional actions identified such as repairs, new preventive actions, additional evaluations, and future inspections. 4. For structural bolting consisting of ASTM A325, ASTMF1852, and/or ASTM A490, provide guidance for storage, lubricants, and the steps to minimize stress corrosion cracking potential discussed in Section 2 of RCSC (Research Council for Structural Connections) publication, "*Specification for Structural Joints Using ASTM A325 or A490 Bolts*". 5. Provide guidance so that when replacement bolting is required, bolting material, installation torque or tension, and use of lubricants and sealants will be in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		6. Provide guidance for proper specification of new high strength bolting material and lubricant to prevent or mitigate degradation and failure of structural bolting in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339. 7. Expand the program to include details regarding inspection and evaluation for steel liners. 8. Provide inspection and evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. The program will be enhanced to explicitly mention the changes in material properties of increase in porosity and permeability, and loss of strength and pattern cracking with darkened edges. 9. Develop a new implementing procedure or revise an existing implementing procedure to address aging management of inaccessible areas exposed to potentially aggressive groundwater/soil environment that will include the following: a. Monitor raw water and ground water chemistry, for pH, chlorides, and sulfates, on a frequency not to exceed five years that accounts for seasonal variations (e.g., quarterly monitoring every fifth year), from locations that are representative of the groundwater in contact with structures within the scope of SLR. b. Enter adverse results, which exceed water chemistry criteria, into the corrective action program. As part of the corrective actions, if aggressive groundwater is identified that might affect structures in scope for SLR, perform additional water testing at additional locations and perform soil testing in order to confirm the extent, severity, and potential aging mechanisms resulting from the aggressive groundwater/soil.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		c. Develop engineering evaluations to evaluate the water chemistry results to assess the impact, if any, on below-grade concrete, including the potential for further degradation due to the aggressive groundwater, as well as consideration of current conditions. As part of the engineering evaluations, determine if additional actions are warranted, which might include enhanced inspection techniques and/or increased frequency, destructive testing, and focused inspections of representative accessible (leading indicator) or below grade, inaccessible concrete structural elements exposed to aggressive groundwater/soil. d. Develop the initial engineering evaluations prior to the SPEO. Develop follow-up engineering evaluations on an interval not to exceed five years. e. If aggressive groundwater and soil is identified, at a minimum, perform focused inspections of representative, accessible (leading indicator) structural elements, or if accessible areas will not be leading indicators for the potential aging mechanisms, excavate and inspect buried concrete elements exposed to aggressive groundwater/soil. f. If degraded concrete is identified, as part of the focused inspections of leading indicators (representative, accessible or exposed inaccessible concrete), enter adverse results that exceed ACI 349.3R second tier criteria into the corrective action program, and expose inaccessible concrete so that the extent of the condition can be determined, baseline conditions documented, and additional actions identified such as repairs, new preventative actions, additional evaluations, and future inspections.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		10. Monitor and trend through-wall groundwater leakage, infiltration volumes, and leakage water chemistry for signs of concrete or steel reinforcement degradation. Develop additional engineering evaluations, which consider more frequent inspections, as well as destructive testing of affected concrete to validate existing concrete properties, and leakage water chemistry results. If leakage volumes allow, consider water chemistry analysis of the leakage pH, along with mineral, chloride, sulfate and iron content in the water. 11. Expand the program to monitor accessible sliding surfaces for indications of significant loss of material due to wear or corrosion, and for accumulation of debris or dirt. Establish acceptance criteria for sliding surfaces as no significant loss of material due to wear or corrosion, and no debris or dirt that could restrict or prevent sliding of the surfaces, as required by design. 12. Expand the program to monitor elastomeric vibration isolators and bearing pads, structural sealants, and seismic joint fillers for cracking, loss of material, and hardening. Supplement visual inspection of elastomeric elements with tactile inspection to detect hardening, if the intended function is suspect. Establish acceptance criteria, for elastomeric pads and vibration isolation elements, structural sealants, and seismic joint fillers, as no loss of material, cracking, or hardening that can lead to loss of isolation or support function. 13. Require that personnel performing inspections and evaluations meet the qualifications specified within ACI 349.3R with respect to knowledge of inservice inspection of concrete and visual acuity requirements. 14. Perform inspections under the enhanced program in order to establish quantitative baseline inspection data to a sufficient detail to allow for trending, prior to the SPEO.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		15. Revise inspection procedures to base inspection acceptance criteria on quantitative requirements derived from industry codes and standards, including but not limited to ACI 349.3R, ACI 318, SEI/ASCE 11, or the relevant AISC specifications and consider industry and plant OE. Use justified quantitative acceptance criteria whenever applicable. 16. Provide evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. Base the acceptance criteria for concrete surfaces on the “second-tier” evaluation criteria provided in Chapter 5 of ACI 349.3R. 17. Clarify that loose bolts and nuts are not acceptable unless accepted by engineering evaluation.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
34	*Inspection of Water Control Structures Associated With Nuclear Power Plants* program	The *Inspection of Water Control Structures Associated With Nuclear Power Plants* AMP is an existing program that will be enhanced to: 1. Provide guidance for structural bolting consisting of ASTM A325, ASTMF1852, and/or ASTM A490, for storage, lubricants, and the steps to minimize stress corrosion cracking potential discussed in Section 2 of RCSC (Research Council for Structural Connections) publication, *"Specification for Structural Joints Using ASTM A325 or A490 Bolts"*. 2. Provide guidance so that when replacement bolting is required, bolting material, installation torque or tension, and use of lubricants and sealants will be in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339. 3. Provide guidance for proper specification of new high strength bolting material and lubricant to prevent or mitigate degradation and failure of structural bolting in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339.	B2.1.34	Program enhancements for SLR will be implemented no later than 6 months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		4. Provide inspection and evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. The program will be enhanced to incorporate monitoring for movements (e.g., settlement, heaving, and deflection), conditions at junctions with abutments and embankments, pattern cracking with darkened edges, the changes in material properties of increase in porosity and permeability, and loss of strength. 5. Expand the program to monitor accessible sliding surfaces for indications of significant loss of material due to wear or corrosion, and for accumulation of debris or dirt. Establish acceptance criteria for sliding surfaces as no significant loss of material due to wear or corrosion, and no debris or dirt that could restrict or prevent sliding of the surfaces, as required by design. 6. Require that personnel performing inspections and evaluations meet the qualifications specified within ACI 349.3R with respect to knowledge of inservice inspection of concrete and visual acuity requirements. 7. Create provisions for special inspections immediately following the occurrence of significant natural phenomena, such as large floods, earthquakes, hurricanes, tornadoes, or intense local rainfalls. 8. Require the evaluation of raw water and groundwater chemistry that is sampled from a location that is representative of the water in contact with structures within the scope of SLR by the responsible engineer. This will be done on an interval not to exceed five years and account for seasonal variations (e.g., quarterly monitoring every fifth year).		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		9. Develop a new implementing procedure or revise an existing implementing procedure to enhance the aging management of inaccessible areas exposed to potentially aggressive groundwater/soil environment that will include the following: a. Monitor raw water and ground water chemistry, for pH, chlorides, and sulfates, on a frequency not to exceed five years that accounts for seasonal variations (e.g., quarterly monitoring every fifth year), from locations that are representative of the groundwater in contact with structures within the scope of SLR. b. Enter adverse results, which exceed water chemistry criteria, into the corrective action program. As part of the corrective actions, if aggressive groundwater is identified that might affect structures in scope for SLR, perform additional water testing at additional locations and perform soil testing in order to confirm the extent, severity, and potential aging mechanisms resulting from the aggressive groundwater/soil. c. Develop engineering evaluations to evaluate the water chemistry results to assess the impact, if any, on below-grade concrete, including the potential for further degradation due to the aggressive groundwater, as well as consideration of current conditions. As part of the engineering evaluations, determine if additional actions are warranted, which might include enhanced inspection techniques and/or increased frequency, destructive testing, and focused inspections of representative accessible (leading indicator) or below grade, inaccessible concrete structural elements exposed to aggressive groundwater/soil.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		d. Develop the initial engineering evaluations prior to the SPEO. Develop follow-up engineering evaluations on an interval not to exceed five years. e. If aggressive groundwater and soil is identified, at a minimum, perform focused inspections of representative, accessible (leading indicator) structural elements, or if accessible areas will not be leading indicators for the potential aging mechanisms, excavate and inspect buried concrete elements exposed to aggressive groundwater/soil. f. If degraded concrete is identified, as part of the focused inspections of leading indicators (representative, accessible or exposed inaccessible concrete), enter adverse results that exceed ACI 349.3R second tier criteria into the corrective action program, and expose inaccessible concrete so that the extent of the condition can be determined, baseline conditions documented, and additional actions identified such as repairs, new preventative actions, additional evaluations, and future inspections. 10. Monitor and trend through-wall groundwater leakage, infiltration volumes, and leakage water chemistry for signs of concrete or steel reinforcement degradation. Develop additional engineering evaluations, which consider more frequent inspections, as well as destructive testing of affected concrete to validate existing concrete properties, and leakage water chemistry results. If leakage volumes allow, consider water chemistry analysis of the leakage pH, along with mineral, chloride, sulfate and iron content in the water. 11. Perform inspections under the enhanced program in order to establish quantitative baseline inspection data to a sufficient detail to allow for trending, prior to the SPEO.		

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
		12. Provide evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. Base the acceptance criteria for concrete surfaces on the “second-tier” evaluation criteria provided in Chapter 5 of ACI 349.3R. 13. Clarify that loose bolts and nuts are not acceptable unless accepted by engineering evaluation. 14. Degradation of piles and sheeting are accepted by engineering evaluation or subject to corrective actions. 15. Revise inspection procedures to base inspection acceptance criteria on quantitative requirements derived from industry codes and standards, including but not limited to ACI 349.3R, ACI 318, SEI/ASCE 11, or the relevant AISC specifications and consider industry and plant OE. Use justified quantitative acceptance criteria whenever applicable.		
35	*Protective Coating Monitoring and Maintenance* program	The *Protective Coating Monitoring and Maintenance* AMP is an existing program that will be enhanced to: 1. Revise procedures to explicitly state peeling and physical damage are considered in the condition assessment. 2. Revise procedures to reference ASTM D-5163-08.	B2.1.35	Program enhancements for SLR will be implemented no later than 6 months prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
36	*Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* program	The *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is an existing program that will be enhanced to: 1. As part of the periodic inspections, add review of previously identified and mitigated adverse localized environments' cumulative aging effects applicable to in-scope cable and connection insulation to confirm that the insulation's intended functions continue to be supported during the SPEO. 2. Add a description of potential testing and its sampling: If testing is evaluated to be necessary after visual inspections identify degraded or damaged conditions (e.g. unacceptable surface anomalies) that may adversely affect the performance of cable or connection insulation intended functions, then proven test(s) applicable to condition monitoring of the insulation are performed (e.g., thermography may be included). For a large number of cables identified as degraded, a sample population will be tested. The sample size will be 20 percent of each affected cable and connection type with a maximum sample size of 25. Among the factors to consider for developing the test sample population are cable or connection type, environment, voltage level, circuit loading, and insulation material which is the most important factor per EPRI guidance. Testing as part of an existing maintenance, calibration, or surveillance program may be credited. The basis for the sample selection will be documented. 3. Add acceptance criteria for potential testing of accessible cables and connections with unacceptable visual inspection results to the Oconee AMP description: Test results are to be within the acceptance criteria, as identified in the Oconee procedures.	B2.1.36	Program enhancements for SLR will be implemented no later than 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
37	*Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification (EQ) Requirements Used in Instrumentation Circuits* program	The *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification (EQ) Requirements Used in Instrumentation Circuits* AMP is a new program that will manage the effects of reduced insulation resistance of non-EQ cable and connection insulation in instrumentation circuits with sensitive, high voltage, low level current signals and that are subjected to adverse localized environments caused by temperature, radiation, or moisture. The program evaluates electrical insulation material for cables and connections subjected to an adverse localized environment at least once every 10 years. The AMP will apply to the in-scope non-EQ portions of circuits in the area radiation monitoring system (e.g. high range containment area radiation monitors) and the neutron flux monitoring nuclear instrumentation system. Industry and plant-specific OE will be considered in the development and implementation of the program.	B2.1.37	Program for SLR will be implemented 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
38	*Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* program	The *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is an existing program that will be enhanced to: 1. Add inspections for water accumulation performed after event-driven occurrences, such as heavy rain, rapid thawing of heavy ice and snow, or flooding. 2. For the periodic water accumulation inspections, add documented verification that either automatic or passive drainage systems or manual pumping are effective in preventing medium-voltage cable exposure to significant moisture. 3. Remove from program descriptions the original 'significant voltage' portion of exposures to determine the inaccessible medium-voltage cables for testing. 4. Revise the inaccessible medium-voltage cable testing and water accumulation inspection matrix to include inspection methods, test methods, and acceptance criteria.	B2.1.38	Program enhancements for SLR will be implemented no later than 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.
39	*Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* program	The *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is a new condition monitoring program that will manage the aging effect of reduced electrical insulation resistance due to exposure to significant moisture. The program will apply to the electrical insulation for inaccessible (e.g., installed underground in buried conduits, cable trenches, cable troughs, duct banks, vaults, manholes, or direct buried), non-EQ in-scope instrument and control cables and splices that are exposed to significant moisture. Industry and plant-specific OE will be considered in the development of this program.	B2.1.39	Program will be implemented 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
40	*Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* program	The *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is a new condition monitoring program that will manage the aging effects of reduced electrical insulation resistance due to exposure to significant moisture. The program will apply to the electrical insulation for inaccessible (e.g., installed underground in buried conduits, cable trenches, cable troughs, duct banks, vaults, manholes, or direct buried), non-EQ in-scope low voltage power cables (operating voltage less than 2 kV), exposed to significant moisture. Industry and plant-specific OE will be evaluated in the development of this program.	B2.1.40	Program will be implemented 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.
41	*Metal Enclosed Bus* program	The *Metal Enclosed Bus* AMP is a new condition monitoring program that uses inspections and sampling and will manage the identified aging effects of in-scope metal enclosed bus. Industry and plant-specific OE will be considered in the development and implementation of this program.	B2.1.41	The program will be implemented no later than 6 months prior to the SPEO. Initial inspections and resistance measurements will be performed no later than 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.
42	*Fuse Holders* program	The *Fuse Holders* AMP is a new condition monitoring program that will manage susceptibility to the following aging effects: increased resistance of connection due to chemical contamination, corrosion, and oxidation or fatigue caused by ohmic heating, thermal cycling, electrical transients, frequent removal and replacement, or vibration. The program also manages degradation of electrical insulation for the fuse holders with metallic clamps susceptible to the aging effects identified. Industry and plant-specific OE will be considered in the development and implementation of this program.	B2.1.42	The program for SLR will be implemented no later than 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
43	*Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* program	The *Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* program is a new condition monitoring program that will manage aging effects by testing a representative sample of electrical connectors prior to the SPEO. The results will be evaluated to determine if there is a need for subsequent periodic testing on a 10-year frequency. Industry and plant-specific OE will be considered in the development and implementation of this program.	B2.1.43	The program for SLR will be implemented and testing of a representative sample of electrical connectors completed, no later than 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.
44	*Fatigue Monitoring* program	The *Fatigue Monitoring* AMP is an existing program that will be enhanced to: 1. Require monitoring and tracking of transient cycles associated with the ASME Code, Section XI, Appendix L analysis be performed between the inspections for each ASME Code, Section XI, Appendix L locations. Consistent with existing program cycle counting, a surveillance limit will be established to initiate corrective action prior to exceeding transient cycle assumptions in the ASME Code, Section XI, Appendix L analysis. 2. Require periodic validation of chemistry parameters used to determine F_{en} factors used. 3. Expand existing corrective action guidance associated with exceeding a cycle counting surveillance limit to recommend consideration of component repair, component replacement, performance of a more rigorous analysis, performance of an ASME Code, Section XI, Appendix L flaw tolerance analysis, or scope expansion to consider other locations with the highest expected CUF_{en} values.	B3.1	Program enhancements for SLR will be implemented no later than six months prior to the SPEO.
45	*Neutron Fluence Monitoring* program	The existing *Neutron Fluence Monitoring* program is credited.	B3.2	Ongoing

Table A6.0-1: Subsequent License Renewal Commitments

#	Program	Commitment	AMP	Implementation
46	*Environmental Qualification of Electric Equipment* program	The *Environmental Qualification of Electric Equipment* AMP is an existing program that will be enhanced to: 1. Add activities to perform visual inspections of accessible, passive EQ electric equipment located in adverse localized environments at least once every 10 years. 2. Establish acceptance criteria for the visual inspection of accessible passive EQ electric equipment located in adverse localized environments.	B3.3	Program enhancements for SLR will be implemented no later than 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.
47	*Concrete Containment Unbonded Tendon Prestress* program	The existing *Concrete Containment Unbonded Tendon Prestress* program is credited.	B3.4	Ongoing
48	*Secondary Shield Wall Tendon Surveillance* program	The *Secondary Shield Wall Tendon Surveillance* AMP is an existing program that will be enhanced to revise station procedures to include a review of previous visual inspection and lift-off data results for the tendons selected for inspection.	B4.1	Program enhancements for SLR will be implemented no later than 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.

Appendix B

AGING MANAGEMENT PROGRAM

B1.0 INTRODUCTION

B1.1 OVERVIEW

SLR AMP descriptions are provided in this appendix for each program that has been credited for managing the effects of aging based upon the aging management review results provided in Sections 3.1 through 3.6.

In general, there are four types of AMPs:

1. Prevention programs preclude aging effects from occurring.

2. Mitigation programs slow the effects of aging.

3. Condition monitoring programs inspect/examine for the presence and extent of aging.

4. Performance monitoring programs test the ability of a structure or component to perform its intended function.

More than one type of AMP may be implemented for a component to ensure that aging effects are managed.

Part of the demonstration that the effects of aging are adequately managed is to evaluate credited programs and activities against certain required attributes. Each of the AMPs described in this section has 10 elements which are consistent with the attributes described in Appendix A.1, *"Aging Management Review - Generic (Branch Technical Position RLSB-1)"* and in Table A.1-1 *"Elements of an Aging Management Program for Subsequent License Renewal"* of NUREG-2192. The 10-element detail is not provided when the program is deemed to be consistent with the assumptions made in NUREG-2191. The 10-element detail is only provided when the program is plant-specific.

Existing initial LR aging management activities were used as a starting point for SLR AMPs. For initial LR, ONS addressed license renewal before the publication of the GALL. In fact, much of the foundation of GALL comes from the structure of the Initial LR work and lessons learned from review of these materials. Similar to efforts described in GALL-SLR, programmatic aging management activities were identified for those components whose materials and environment combinations could lead to aging effects that, if left unmanaged, could result in loss of component intended function. Results of that work are not significantly different that the results herein. Initial Oconee LR resulted in the crediting of 45 existing aging management programs and activities and 5 new programs and activities. The majority of these programs and activities will carry forward into the SPEO, noting that GALL-SLR recombines some of these existing programs and activities under new program titles. Where new and existing programs are credited for SLR, the programs are in alignment with contemporary guidance.

For SLR, whenever an initial LR aging management activity did not exist, credit has been taken for other existing plant programs. As such, existing programs and activities associated with a system, structure, component, or commodity grouping were reviewed to determine whether they include the necessary actions to adequately manage the effects of aging during the SPEO.

Existing plant programs were often based on a regulatory commitment or requirement, rather than aging management. Many of these existing programs required for initial LR included the 10-element attributes, and have been demonstrated to adequately manage the identified aging effects. If an existing program is not believed to adequately manage an identified aging effect during the SPEO, then the program will be enhanced as necessary as discussed further below. Occasionally, the creation of a new program has been deemed necessary for purposes of SLR.

Included in Appendix A6.0, Table A6.0-1, SLR Commitments, are commitments for SLR with the associated implementation schedule for when Duke Energy plans to complete each commitment.

B1.2 METHOD OF DISCUSSION

Each of the AMPs in Sections B2.1.1 through B3.4 are consistent with the assumptions in Sections X and XI of NUREG-2191, or are consistent with exceptions and/or enhancements, and contain the following:

1. Program Description summary of the overall program form and function.
2. NUREG-2191 Consistency statement about the program.
3. Discussion of any exceptions to the NUREG-2191 program with a justification.
4. Discussion of any enhancements or additions to ensure consistency with NUREG-2191 along with a proposed schedule for completion.
5. OE information specific to the program. This includes both plant-specific and industry OE.
6. Conclusion with a bases statement of reasonable assurance that the existing program is effective, or will be effective when implemented, if new or enhanced.

The plant-specific AMPs are described in terms of the 10 program elements in NUREG-2192, Section A.1.2.3 *"Aging Management Program Elements"*.

B1.3 QUALITY ASSURANCE PROGRAM AND ADMINISTRATIVE CONTROLS

The QA Program is described in the Duke Energy Corporation Topical Report DUKE-QAPD-001-A, *"Quality Assurance Program Description, Operating Fleet"* which implements the requirements of 10 CFR 50, Appendix B, *"Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants."* The QA Program is consistent with the summary in Appendix A.2, *"Quality Assurance for Aging Management Programs (Branch Technical Position IQMB-1)"* of NUREG-2192. The QA Program includes the three elements of corrective actions, confirmation process, and administrative controls, which are applicable to the safety related and non-safety related structures, components and commodity groups that are subject to aging management review. Generically the three elements are applicable as follows:

Corrective Actions:

Results that do not meet acceptance criteria are addressed as conditions adverse to quality or significant conditions adverse to quality under Sections 17.3.1.6, 17.3.2.13, and D17.3.2.13 *"Corrective Action,"* of DUKE-QAPD-001-A. The corrective action program is implemented in accordance with the requirements of 10 CFR 50, Appendix B, Criterion XVI and Topical Report DUKE-QAPD-001-A. A single program is used regardless of the safety classification of the structure or component. Conditions adverse to quality, such as failures, malfunctions, deviations, defective material and equipment, and non-conformances, are promptly identified and corrected. Corrective actions are implemented through the initiation of a nuclear condition report for actual or potential problems, correction of an equipment deficiency, or the need for corrective maintenance. Site documents that implement AMPs for LR direct that a nuclear condition report be prepared in accordance with those procedures whenever non-conforming conditions are found (i.e., the acceptance criteria are not met). The corrective action procedures specify steps for promptly reporting, evaluating, and correcting conditions adverse to quality and significant conditions adverse to quality commensurate with the significance of the SSC or activity. Consistent with the significance of the identified condition, these steps include: (1) deficiency identification, (2) deficiency review, impact on operations and reportability determination, (3) nuclear condition report review, trending and classification (including appropriate cause determination along with any warranted extent of condition and extent of cause), (4) corrective action determinations, assignments, and implementation, (5) assessment of effectiveness of correction, and (6) nuclear condition report closure.

In the case of significant conditions adverse to quality, measures are implemented to ensure that: (a) senior station management is notified; (b) cause is determined; (c) corrective action is taken to preclude repetition; (d) the cause and corrective actions are documented and reported to station management; and (e) corrective action is taken in a timely and accurate manner.

Confirmation Process:

The focus of the confirmation process is on the follow-up actions that must be taken to verify effective implementation of corrective actions and preclude repetition of adverse conditions. The Duke Energy corrective action program includes measures for timely evaluation of adverse conditions and implementation of corrective actions.

The program stresses that verification of implementation and close-out of corrective action documentation take place and contains measures to monitor these activities by site and oversight personnel. Plant procedures include provisions for timely evaluation of adverse conditions and implementation of corrective actions required, including root cause evaluations and prevention of repetition where appropriate (e.g.; significant conditions adverse to quality). These procedures provide for tracking, coordinating, monitoring, reviewing, verifying, validating and approving corrective actions, and ensure that corrective actions have been effectively implemented. The corrective action process is also monitored for potentially adverse trends. Identification of a potentially adverse trend due to recurring or repetitive unacceptable conditions will result in the initiation of a nuclear condition report. The AMPs required for SLR would also result in identification of related unsatisfactory conditions due to ineffective corrective action. Since the same 10 CFR 50, Appendix B corrective actions and confirmation process are applied for non-conforming safety related and non-safety related structures and components subject to aging management review for SLR, the confirmation process is consistent with the NUREG-2191 elements.

Administrative Controls:

Information on the Duke Energy organizational structure, responsibilities, authorities, and personnel qualification requirements is provided in the UFSAR and in the QA Program. The organizational structure, responsibilities, authorities, and personnel qualification requirements conform to 10 CFR 50, Appendix B, Criterion I. The QA Program provides orderly and uniform administrative and managerial controls for safe operation of its nuclear stations. Administrative controls apply to applicable activities, documents, procedures, and instructions regardless of the safety classification of the associated system, structure, component, or commodity group.

Document control processes are implemented in accordance with the requirements of 10 CFR 50, Appendix B, Criterion VI. Measures are provided to assure that documents, including revisions or changes, are properly reviewed by independent personnel, approved, and distributed prior to use; this includes those for the activities performed under the programs credited for aging management. Administrative controls also provide for formal review and approval of corrective actions. The administrative controls apply to both safety related and non-safety related structures, components and commodity groups which are subject to aging management review.

B1.4 OPERATING EXPERIENCE

OE from internal (also referred to as plant-specific) and external (also referred to as industry) sources is captured and systematically reviewed on an ongoing basis in accordance with the QA Program, which meets the requirements of 10 CFR 50, Appendix B, and with the OE Program, which meets the requirements of NUREG-0737, *"Clarification of TMI Action Plan Requirements,"* Item I.C.5, *"Procedures for Feedback of OE to Plant Staff."* The OE Program interfaces with, and relies on, active participation in the INPO OE program, as endorsed by the NRC.

OE is used at ONS to enhance plant programs, prevent repeat events, and prevent events that are similar to those that have occurred at other plants. As a part of the Duke Energy fleet, ONS receives OE (internal and external) daily.

The OE process includes screening, evaluation, and acting on OE documents and information to prevent or mitigate the consequences of similar events. The OE process includes review of OE from internal and external sources. External OE includes INPO documents, NRC documents (e.g., Information Notices, Regulatory Issues Summaries, and Interim Staff Guidance), and other documents (e.g., Licensee Event Reports and 10 CFR Part 21 reports, as well as relevant research and development information). Relevant research and development sources include: (a) industry consensus standards development organizations (e.g., ASME, IEEE, ACI, API, NACE, International Organization for Standardization); (b) Electric Power Research Institute (EPRI); (c) generic communications issued by the staff based on research conducted by national labs used by the NRC; and (d) NSSS vendor and owner's groups. In addition, the license renewal interim staff guidance documents and revisions to the Generic Aging Lessons Learned for Subsequent License Renewal (GALL-SLR) Report are considered as sources of industry OE and evaluated accordingly. Internal OE includes relevant items from the corrective action program and other lessons learned from internal events as captured in program health reports and program assessments.

The Duke Energy fleet OE program that is implemented at ONS is an ongoing program that conforms to the recommendations of LR-ISG-2011-05, "Ongoing Review of Operating Experience," and is consistent with the expectations outlined in NUREG-2192 (SRP-SLR), Appendix A.4, "Operating Experience for Aging Management Programs." The systematic review of plant-specific and industry OE concerning aging management and age-related degradation ensures that the LR AMPs are, and will continue to be, effective in managing the aging effects for which they are credited. OE involving age-related degradation is tracked and trended such that adverse trends are entered into the corrective action program for evaluation. Potential aging issues associated with SSCs within the scope of LR are evaluated with regard to: (a) materials of construction, (b) operating environment, (c) aging effects, (d) aging mechanisms, and (e) AMPs, to determine if changes to AMPs or new AMPs are needed. Existing AMPs are enhanced, or new AMPs are developed, when it is determined through the evaluation of OE that the effects of aging may not be adequately managed. AMPs are informed by the review of OE on an ongoing basis, regardless of the AMPs implementation schedule. Guidelines have been established for reporting plant-specific OE regarding age-related degradation and aging management to the industry through the INPO consolidated event system, consistent with the guidance in NEI 14-13, *"Use of Industry OE for Age-Related Degradation and Aging Management Programs."* In addition, the Duke Energy process requires assessments of the effectiveness of AMPs/activities to be conducted on a periodic basis that is not to exceed once every five years. If there is an indication that the effects of aging are not being adequately managed, then a corrective action is entered into the 10 CFR Part 50, Appendix B, corrective action program to either enhance the AMPs or develop and implement new AMPs, as appropriate. The AMP effectiveness reviews are performed consistent with the guidance of NEI 14-12, *"Aging Management Program Effectiveness."*

Each AMP summary in this appendix contains examples of OE relevant to the program. This information is obtained through the review of plant-specific OE captured by the corrective action program, program assessments, and program health reports, as well as the review of industry OE. New programs utilized plant-specific and/or industry OE, as applicable, and the AMP summaries in this appendix discuss the OE and associated corrective actions as they relate to implementing the new program. Consistent with the guidance in Section 6 of Appendix B of NEI 17-01, "Industry Guideline for Implementing the Requirements of 10 CFR 54 for Subsequent License Renewal," effectiveness reviews of initial LR AMPs/activities were performed, and are presented within the SLRA Appendix B AMP subsections that are most related to those initial LR aging management activities. The OE summary for each AMP in this appendix identifies past corrective actions, some of which have resulted in program enhancements and provides objective evidence that the effects of aging have been, and will continue to be, adequately managed so that the intended functions of the structures and components within the scope of each program will be adequately maintained during the SPEO.

B1.5 NUREG-2191 AMP CORRELATION

The correlation between NUREG-2191, "*Generic Aging Lessons Learned for Subsequent License Renewal (GALL-SLR) Report,"* programs and the programs that have been credited for managing the effects of aging in the SLRA are shown in Table B1-1. For the programs, links to the sections that include the program descriptions are provided.

B2.1 AGING MANAGEMENT PROGRAM DETAILS

B2.1.1 ASME SECTION XI INSERVICE INSPECTION, SUBSECTIONS IWB, IWC, AND IWD

Program Description

The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP is an existing condition monitoring program that manages the aging effects of cracking, loss of fracture toughness, and loss of material. The program consists of periodic volumetric, surface, and/or visual examination, and leakage tests of ASME Code, Section XI Class 1, 2, and 3 pressure retaining components, including welds, pump casings, valve bodies, integral attachments, and pressure retaining bolting for assessment, identification of signs of degradation, and establishment of corrective actions.

The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP implements the required component examination schedule in accordance with ASME Code Section XI, Subsection IWB-2400, IWC-2400 or IWD-2400 and examination categories, applicable components, examination methods, acceptance standards, and frequency of examination as specified in ASME Code, Section XI Tables IWB-2500-1, IWC-2500-1, and IWD-2500-1 for Class 1, 2, and 3 components, respectively. The examination methods specified in ASME Code, Section XI, Tables IWB-2500-1, IWC-2500-1, and IWD-2500-1 are based on approved industry standards for detecting degradation of components.

Indications and relevant conditions detected during examinations are documented in the corrective action program and evaluated in accordance with ASME Code, Section XI, Articles IWB-3000 for Class 1, IWC-3000 for Class 2, and IWD-3000 for Class 3. The program directs that repair and replacement activities be performed in accordance with ASME Code, Section XI, Subsection IWA-4000. Additional examinations not required by the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* program, but using ASME Code, Section XI inspection techniques and acceptance criteria, are performed in accordance with the augmented inspection program.

10 CFR 50.55a, *Codes and Standards*, specifies the regulatory requirements related to inservice inspection, repair/replacement, and augmented examination of systems and components in nuclear power plants. During the fifth inservice inspection interval, ONS inservice inspections are performed consistent with the requirements of ASME Code, Section XI, 2007 Edition with the 2008 Addenda, as approved in 10 CFR 50.55a. In accordance with 10 CFR 50.55a(g)(4)(ii), the inservice inspection program is updated during each successive 120 month inspection interval to comply with the requirements of the edition of the Code that is applicable twelve months before the start of the inspection interval. ASME Code editions and addenda will be used consistent with the provisions of 10 CFR 50.55a during the SPEO. Any deviation from ASME Code, Section XI requirements must be approved by the NRC per relief request or alternate request (such as, RIS 2004-12 process).

A risk informed inservice inspection program has been implemented using ASME Code, Section XI, Code Case N-716-1 "*Alternative Classification and Examination Requirements, Section XI, Division 1*". This methodology includes Class 1 piping welds and Class 2 components (excluding attachment welds and supports). The risk informed inservice inspection program has been incorporated into the inservice inspection schedule.

The effects of aging due to fatigue for the pressurizer surge line and high pressure injection system piping subject to environmentally assisted fatigue will be managed through the *ASME Section XI, Inservice Inspection, Subsections IWB, IWC, and IWD* program by conducting inspections in accordance with ASME Code, Section XI, Non-mandatory Appendix L.

NUREG-2192 permits inspections as a management method for fatigue as long as a flaw tolerance evaluation is performed to determine the acceptable time between inspections. As described in SLRA Section 4.3.4, *Environmentally-Assisted Fatigue*, and the *Fatigue Monitoring* AMP (B3.1), a flaw tolerance evaluation was performed for components associated with sentinel locations assessed under ASME Code, Section XI, Nonmandatory Appendix L. The flaw tolerance evaluation was used to establish an appropriate inspection frequency that is consistent with the typical 10-year inservice inspection program. As a result of the evaluation, the effects of fatigue for two of the sentinel piping locations (pressurizer surge line and high pressure Injection piping) will be managed by the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* program during the SPEO.

Inspections will be performed for components associated with the following sentinel locations assessed in accordance with ASME Code, Section XI, Non-mandatory Appendix L:

- Reactor coolant system pressurizer surge line piping (hot leg elbow).
- High pressure injection piping, stop valve-to-check valve (usage bounds high pressure injection nozzle).

The ASME Code, Section XI, Appendix L inspections identified in SLRA Section 4.3 (Table 4.3.4-3) will be conducted by the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* program to ensure structural integrity of the subject piping. Each weld in the inspection population will be volumetrically inspected using ASME Code required techniques at least once prior to establishing the inspection interval schedule for Units 1, 2, and 3 ASME Code, Section XI, Appendix L locations.

The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP includes all component inspection activities required by ASME Code, Section XI, Subsections IWB, IWC, and IWD except for those component inspection activities that are covered by the following LR AMPs that include augmented requirements:

- *Reactor Head Closure Stud Bolting* (B2.1.3)
- *Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components* (B2.1.5)
- *PWR Vessel Internals* (B2.1.7)
- *Bolting Integrity* (B2.1.9)
- *Steam Generators* (B2.1.10)
- *ASME Code Class 1 Small-Bore Piping* (B2.1.22)
- *ASME Section XI, Subsection IWF* (B2.1.30)

Additional examinations, not required by the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP but using ASME Code, Section XI inspection techniques and acceptance criteria, are identified in the ONS augmented inspection program and are included in the inservice inspection schedule for the following:

- Generic Letter 85-20 Exams - high pressure injection nozzle safe end examination.
- Thermal fatigue exams for pressurizer surge line
- Thermal fatigue IEB 88-08 exams - thermal stress piping examinations
- Thermal fatigue exams per MRP-192
- Thermal fatigue exams per MRP-146
- Supplemental high pressure injection ultrasonic exams - safe end to pipe butt weld for Units 1, 2 or 3 B2 high pressure injection line
- HELB main feedwater pipe welds and integral welded attachment exams - main feedwater piping in the east and west penetration room
- HELB exams for main feedwater and main steam supports - main feedwater and main steam piping supports and attachment welds
- HELB exams for main steam pipe welds and integral welded attachment exams - main steam piping welds and attachment welds in the east penetration room
- HELB exams for main feedwater rupture restraint - main feedwater attachment welds on rupture restraints at penetrations 25 and 27

Three other aspects of the augmented inspections are included in non-inservice inspection programs. Inspections of the PWR reactor vessel head are described in the *Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components* program. Inspections of the PWR vessel internals are described in the *PWR Vessel Internals* program. Inspections of the high pressure injection system piping elbow to detect wall thinning due to cavitation are described in the *Flow Accelerated Corrosion* program.

<u>NUREG-2191 Consistency</u>

The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* program is an existing program that will be consistent with NUREG-2191 Chapter XI.M1, ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD.

<u>Exception to NUREG-2191</u>

None

<u>Enhancements</u>

Prior to the SPEO, the following enhancement(s) will be implemented in the following program element: Detection of Aging Effects (Element 4).

1. Procedures will be revised to require inspections to be performed for components associated with sentinel locations assessed in accordance with ASME Code, Section XI, Non-Mandatory Appendix L:

a. Reactor coolant system pressurizer surge line piping (hot leg elbow).
b. High pressure injection piping, stop valve-to-check valve (usage bounds high pressure injection nozzle).

<u>Operating Experience</u>

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In January 2010, an independent assessment of the ONS ISI Program was performed. A comprehensive, detailed review of the documentation (for Class 1, 2, and 3 components) was performed to determine if the required ASME Code Section XI examinations were being completed for the current ten year interval. The assessment review covered the time period of October 2007 through August 2009. There were no findings or discrepancies identified during the assessment for Oconee Unit 1, 2 or 3; but the assessment resulted in several programmatic and editorial recommendations to improve the existing ONS ISI program.

   Oconee implemented all recommendations from the assessment which resulted in several significant improvements to the ISI program such as development of an ISI program basis document to capture pertinent programmatic information. The primary purpose of the ISI program basis document is to provide a detailed technical basis for the ISI program plan. As a result, preparation and maintenance of this ISI program basis document ensures the program improvements established as a result of the assessment would be maintained throughout current and future ISI intervals.

   The ISI program basis document is a “living” document and is updated on a regular basis to ensure the ISI program plan and the ISI database reflects the current configuration of the plant and follows 10 CFR 50.55a and ASME Code Section XI requirements. An important feature of the ISI program basis document is to capture the technical knowledge and decisions made by fleet and site ISI personnel during implementation of the ISI program. Documentation of technical positions and technical assessments developed to implement the ISI program is critical to ensure that implementing details are clearly understood and maintained for current and future ISI personnel. The ISI program basis document provides a permanent location for the archival of this technical knowledge.

   OE example 1 provides objective evidence that the process of performing assessments of the ONS ISI program is effective at identifying areas for improvement and that recommendations are appropriately implemented into the program. Continued implementation of the *ASME Section XI Inservice Inspection Subsections IWB, IWC, and IWD* AMP, including performing program assessments, will ensure that the ISI program will continue to be implemented in accordance with program requirements during the SPEO.

2. In July 2012, a LR readiness assessment was performed in preparation for the NRC Phase 2 Post Approval Site Inspection for License Renewal (IP-71003 inspection). The assessment team concluded that the ONS ISI program is managing the effects of aging in accordance with commitments made during the first PEO. An area for improvement related to program oversight was identified during the assessment. As a result, clearer program ownership was established between the Duke corporate engineering team and the site regarding different aspects of the program with overall program ownership residing with corporate engineering and implementation owned by the site. The corporate and ONS site engineers now have a better understanding of how to work together collaboratively to support the ongoing effectiveness of the ISI program.

   OE example 2 provides objective evidence that the ISI program is effectively managing aging in accordance with LR commitments. In addition, this example shows that program assessments are effectively used to improve the program.

3. In November 2013, a reactor coolant system pressure boundary leak was identified at a high pressure injection line nozzle during a Unit 1 reactor building walkdown. An entry was made into the corrective action program and shutdown to Mode 5 was initiated in accordance with Technical Specifications. The leak was from a circumferential crack in the safe end-to-pipe butt weld located between the high pressure injection nozzle and the reactor coolant system loop injection block valve.

   A twenty one day outage was required to complete the initial investigation and the weld repairs. A root cause performed determined the cause was mechanical vibration-induced high-cycle fatigue which caused a through-wall crack. Contributing causes were that the system design resulted in higher than desired system vibration on the high pressure injection line and inadequate administrative guidance for conduct of augmented examinations. During analyses used to support the root cause evaluation for the safe end-to-pipe leak in the fall of 2013, the potential for flow cavitation (and subsequent erosion of the high pressure injection piping elbows immediately downstream of the in-line flow orifices) was identified. This cavitation degradation is believed to be the result of the high pressure injection full flow tests that are performed at the end of each refueling outage to verify the operation of the high pressure injection system and confirm it can deliver the required flow rates for various high pressure injection nozzle configurations. Cavitation is likely with flow rates above 100 gpm through the 0.78” orifices.

   Corrective actions were initiated to prevent recurrence including the following:

   - Leaking weld replaced
   - Increased frequency of high pressure injection piping ultrasonic inspections
   - Inspected all high pressure injection lines using diverse techniques
   - Implemented a means, in program governance procedures, to ensure the critical elements of the inspection procedures used to implement augmented inspections are incorporated into superseding procedures
   - Revised all program procedures to incorporate root cause lessons learned

   As outlined above, significant program improvements were made including increased rigor and improved basis documentation information for all augmented ISI examinations performed at ONS. These AMP improvements were made to ensure aging effects are properly evaluated and future examinations are scheduled commensurate with the safety significance of the component. The following two augmented exams were added for ONS Unit 1, 2 and 3 to manage aging effects and prevent recurrence.

- High pressure injection nozzle volumetric inspections of safe end to pipe butt welds to identify cracking.
- High pressure injection system piping elbow ultrasonic testing wall thickness measurements for wall thinning due to cavitation (NOTE: Since these examinations are required to manage the potential aging effect for cavitation erosion of the elbows just downstream of the high pressure injection flow orifices, these are included as part of the *Flow Accelerated Corrosion* AMP).

OE example 3 provides objective evidence that the corrective action program was used effectively to identify the cause of the weld failure, identify the population of welds within the extent of condition, and implement appropriate comprehensive corrective actions, including additional augmented examinations and programmatic enhancements.

4. In November 2014, during the Unit 1 outage, extent of condition ultrasonic examinations were performed based on the Unit 1 pressure boundary leak that was identified at a high pressure injection nozzle in 2013. ASME Section XI Code rejectable indications were detected on the exterior curve of the first elbow in the drain line off the Unit 1 reactor coolant system cold leg. The issue was documented in the corrective action program for evaluation and follow-up actions. The degraded condition was a 17% through-wall leak on the 1.5 inch drain line elbow due to thermal fatigue failure. Corrective actions completed included replacing the leaking elbow and adjacent piping prior to restart from the 2014 outage, performing examinations at other susceptible drain line locations, and revising program documentation to include more frequent examinations of the drain line elbows. As a result, examinations at this location are performed every refueling outage in accordance with the ONS Augmented Inservice Inspection Schedule.

   OE example 4 provides objective evidence that the inspections performed by the ASME Section XI Inservice Inspection Subsections IWB, IWC, and IWD AMP can identify degraded conditions prior to loss of intended function and that appropriate corrective actions, including component replacement, are taken when unacceptable conditions are identified.

5. In November 2017, during a Unit 2 refueling outage following reactor coolant pump and motor replacement, three linear indications were identified in a reactor coolant pump seal injection line elbow. Specifically, nondestructive examinations identified three linear indications on the 90° socket weld fitting near the nozzle connection to the reactor coolant pump seal. Two of the indications were located on the outside diameter of the fitting oriented circumferentially around the fitting. The third indication started circumferentially and transitioned to running axially towards the weld across the face of the socket weld fitting up to the toe of the weld. As a result, the weld was rejected. Two of the three indications were removed by grinding; however, one indication remained even after grinding to the maximum allowable 1/16” depth. The fitting was, therefore, cut out and replaced. A metallurgical analysis was performed and concluded that the indication of

interest was a forging lap that originated during fabrication and was not a service induced flaw. The evidence of a blunt, wide crevice tip implied that the defect was not growing.

Additional cause analysis evaluation findings are described as follows:

- The stress loading of this elbow is very low (20% of allowable). Given that, design operational loadings (as well as seismic loading) would not have initiated these linear indications.
- The evaluation concluded this was not a thermal fatigue-initiated indication.
- Reactor coolant pump operating vibration was eliminated as a potential cause since vibration induced cracking would have resulted in a through-wall crack prior to when the inspection was performed.
- The flaws identified are not associated with any service-induced degradation mechanism and are not a new degradation mechanism that would affect the categorization of this piping segment in accordance with Code Case N-716-1.

OE example 5 provides objective evidence that appropriate evaluations are performed when unacceptable indications are identified such that potential impacts on inspection scope and frequency can be properly assessed.

6. In August 2020, AMP effectiveness reviews were performed for the *Inservice Inspection* program and the *Program to Inspect the High Pressure Injection Connections to the Reactor Coolant System*. The subject ONS program aging management activities were evaluated against the performance criteria identified in NEI 14-12, *"Aging Management Program Effectiveness"*. The effectiveness reviews included augmented inspection activities as well as a review of the risk informed ISI portion of the ISI program. The review concluded that both programs are meeting the requirements of NEI 14-12. No gaps were identified during the effectiveness review.

   OE example 6 provides objective evidence that the current ISI program is effectively managing aging and meeting all current license renewal commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the SPEO.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *ASME Section XI Inservice Inspection Subsections IWB, IWC, and IWD* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.2 WATER CHEMISTRY

Program Description

The *Water Chemistry* AMP is an existing program that mitigates aging effects of loss of material due to corrosion, cracking due to stress corrosion cracking, and related mechanisms, and reduction of heat transfer due to fouling in components exposed to a reactor coolant, steam, treated borated water, treated water or secondary feedwater environment. Chemistry programs are used to control water chemistry for parameters such as conductivity, chloride, fluoride, and sulfate that accelerate corrosion.

The scope of the primary water chemistry portion of the *Water Chemistry* AMP includes monitoring and control of the chemical environment in the reactor coolant system and related pressurized water reactor interfacing systems. The scope of the secondary water chemistry portion of the *Water Chemistry* AMP includes monitoring and control of the chemical environment in the steam generator secondary side and the secondary cycle systems. The *Water Chemistry* AMP is consistent with EPRI Report 3002000505, “Pressurized Water Reactor Primary Water Chemistry Guidelines,” Revision 7 and EPRI Report 3002010645, “Pressurized Water Reactor Secondary Water Chemistry Guidelines,” Revision 8.

The ONS primary and secondary water chemistry control strategies are set forth in strategic plans and implemented by procedures. The programmatic control of the chemical environment ensures that the aging effects due to contaminants are limited. The methods used to manage both the primary and secondary chemical environments rely on the principles of: (1) limiting the concentration of chemical species known to cause corrosion and (2) addition of chemical species known to inhibit material degradation by their influence on pH and dissolved oxygen levels.

The primary portion of the *Water Chemistry* AMP is consistent with EPRI Report 3002000505 and includes specific limits for pH, lithium, fluoride, chloride, sulfate, dissolved oxygen, and other parameters. Zinc injection is used for source term reduction in the primary systems. Control of reactor coolant and related interfacing system contaminants is maintained by using micron and submicron filters and mixed bed demineralizers, which provide mechanical filtration and ion exchange functions to remove contaminants. Filters remove corrosion products that are generated by the general equilibrium corrosion of system materials. Lithium hydroxide addition is used to control reactor coolant pH, while hydrogen addition is utilized for oxygen scavenging.

The secondary portion of the *Water Chemistry* AMP is consistent with EPRI Report 3002010645 and includes specific limits for chloride, sulfate, sodium, hydrazine, dissolved oxygen, total iron, pH, conductivity, and other parameters. Chemical control of the secondary systems is established and maintained by removing contaminants with condensate and moisture separator drain demineralizers during startup and mechanical filtration during power operations. Chemical addition of approved amines (e.g., ethanolamine-ETA), is utilized for pH control. Hydrazine is used to scavenge oxygen in secondary systems.

Water chemistry control is generally effective in areas of intermediate and high flow where mixing takes place and the monitoring samples are representative of actual conditions. For low flow areas and stagnant portions of the systems, sampling may not be as effective in determining local chemical environment conditions. A one-time inspection prior to the period of SLR of a representative group of components will provide verification of the effectiveness of the *Water Chemistry* AMP in these low flow areas. This inspection will be performed as part of the *One-Time Inspection* AMP (B2.1.20) for the verification of the effectiveness of the *Water Chemistry* AMP.

NUREG-2191 Consistency

The *Water Chemistry* AMP is an existing program that is consistent with the ten elements of NUREG-2191, Section XI.M2, Water Chemistry, as modified by SLR-ISG-Mechanical-2021-02-MECHANICAL *“Updated Aging Management Criteria for Mechanical Portions of the SLR Guidance,”* with enhancements described below.

Exception to NUREG-2191

None.

Enhancements

None.

Operating Experience

Based on a broad search of pertinent ONS OE, the following examples provide objective evidence that the *Water Chemistry* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In September 2018, ONS chemistry personnel determined that procedure steps for manual calculation of reactor coolant midband lithium were inaccurate. This procedure issue was documented in the corrective action program to evaluate and resolve through appropriate follow up actions. The chemistry procedure enclosure for manual calculation of midband lithium and action level 1 limits contained an error for desired boron value and midband calculations. The error was found when comparing the same boron values and calculations found in the ONS primary chemistry strategic plan, as required by *EPRI PWR Primary Water Guidelines*. The manual calculation procedures were not updated to reflect the most recent change to the primary chemistry strategic plan guidance.

   This issue was documented in the corrective action program for further evaluation and follow up action. The impact of the midband calculation error in current station guidance was reviewed to determine whether the calculated limits could have led to a lithium value that exceeded limits. Calculation of the reactor coolant lithium midband allows for optimum control of lithium in the reactor coolant system and is used to establish the upper and lower control limits. Since the lithium midband and limits are calculated using an automated computer program, there was no concern that any limits had been exceeded.

This manual calculation enclosure would only be used if this computer program calculation was not available.

An extent of condition was performed which determined that at no time, since the revision of the primary chemistry strategic plan, has the manual calculation procedure been used on any ONS unit to calculate the lithium midband and limits. Additional follow-up actions included:

- procedure change requests were initiated to correct the errors.
- the subject chemistry procedure enclosures were placed on hold until the procedure changes for all three units were completed.
- direction was added in the primary chemistry turnover documentation to use the calculation in the correct procedure, if required.
- notified chemistry management.

OE example 1 provides objective evidence that the corrective action program is used to evaluate and resolve technical issues to ensure AMP effectiveness. This also demonstrates that appropriate immediate actions as well as follow up actions are taken until all technical or programmatic issues are resolved.

2. In November 2018, during startup from a Unit 1 outage, feedwater sodium exceeded the EPRI Action Level 2 value of 3 parts per billion (ppb) when sodium reached a value of 3.02 ppb. A corrective action program entry was made to document the ONS secondary chemistry out-of-specification event and determine follow-up actions. Actions included entering the abnormal procedure for chemistry out of specification due to feedwater sodium levels. Other corrective actions included placing additional demineralizer filters in service to lower the system sodium and allow startup to continue. Notifications were made to appropriate operations station personnel (control room supervisor, station technical advisor, and station manager). Sampling and data trending continued until values returned to normal levels (< 1 ppb). EPRI Action Level 3 was not reached since the maximum sodium level reached was 5.68 ppb and returned to < 5 ppb in less than an hour.

   The cause of the event was determined to be main turbine maintenance practices during the refueling outage which caused a source of sodium to enter the hotwell and condenser which was then transported into the feedwater system. As a result of this event, main turbine maintenance practices were improved to ensure cleanliness and prevent impurities in systems.

   OE example 2 provides objective evidence that water chemistry parameters are monitored, and corrective actions are taken to ensure that industry guidelines and station procedural requirements are maintained.

3. In October 2019, a chemistry self-assessment was performed to review station instrument trending and commenting practices. It was determined that, in some cases, actions to resolve instrument quality control violations are not being consistently documented, as described in chemistry guidance for analytical quality control. An entry

was made into the corrective action program to document the issues found during the self-assessment.

As a result of this corrective action item, program procedure improvements were made to ensure specific documentation actions described in the chemistry procedure are completed including documenting the investigation and cause and resolution as well as documenting the status of associated sample analysis data and whether data was accepted or rejected. This program improvement item to capture causes and resolutions of instrument failure resulted in enhancing the program such that instrument failures can be diagnosed and returned to service sooner. Evaluation of the issue determined that no inaccurate analytical data was produced. Follow-up corrective actions included a recommended action to establish a standard template as a guide for when chemistry instruments fail quality control checks in order to consistently capture failure causes and resolutions. Additional corrective actions included enhancing chemistry turnover process to clearly communicated instrumentation status.

OE example 3 provides objective evidence that program issues are identified and documented in the corrective action program for further evaluation and follow up actions. This example demonstrates the corrective action program is effectively used to establish improvements to strengthen the *Water Chemistry* AMP.

4. In December 2019, Unit 2 reactor coolant boron and lithium samples were found to be outside pH_T 6.9 limit for criticality. Although primary chemistry action level 1 was not exceeded (Lithium was found to be outside of pH_T 6.9 at 3.27 ppm), the issue was documented in the corrective action program to evaluate and determine follow up corrective actions. Corrective actions included the following:

   - re-sampling of boron and lithium.
   - lithium recheck was validated.
   - cause evaluation performed (the marginal drop between samples determined to be the normal purification demineralizer not being at equilibrium with Unit 2 reactor coolant system).
   - lithium addition to the Unit 2 letdown storage tank initiated to bring lithium back above pH_T 6.9.

   OE example 4 provides objective evidence that water chemistry parameters are monitored, and appropriate immediate and follow up corrective actions are taken to ensure that industry guidelines and station procedural requirements are maintained.

5. In January 2020, a chemistry training self-assessment was performed to review chemistry personnel qualifications and the effectiveness of qualification guides. This resulted in several training improvements for training related to silica analysis, secondary dissolved gas analysis and sodium analysis. This issue was entered into the corrective action program for further evaluation and follow up action. Additional corrective actions included an improvement of the qualification card to evaluate task prerequisite knowledge previously taught in chemistry fundamentals. This corrective action led to an improvement

in chemistry qualification fundamental training to include tasks such as silica analysis, secondary dissolved gas sampling and sodium analysis.

OE example 5 provides objective evidence that assessments are periodically performed for the *Water Chemistry* AMP and that the corrective action program is effectively used to evaluate and implement program improvements when appropriate.

6. In August 2020, an AMP effectiveness review of the Water Chemistry AMP was performed. The AMP was evaluated against the performance criteria identified in NEI 14-12, *"Aging Management Program Effectiveness."* The review concluded that the Water Chemistry program is meeting the requirements of NEI 14-12. No gaps were identified during the effectiveness review.

   This effectiveness review provides objective evidence that the current Water Chemistry program is effectively managing aging and meeting all current license renewal commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the subsequent period of operation.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Water Chemistry* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, re-evaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Water Chemistry* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

<u>Conclusion</u>

The implementation of the *Water Chemistry* AMP provides reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.3 REACTOR HEAD CLOSURE STUD BOLTING

Program Description

The *Reactor Head Closure Stud Bolting* AMP is an existing condition monitoring and preventive program that includes ASME Code, Section XI examinations of the reactor head closure stud assembly (closure studs, nuts and washers) and the threads of the reactor vessel flange to manage cracking and loss of material. The *Reactor Head Closure Stud Bolting* AMP is implemented as part of the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* (B2.1.1) AMP. The program is consistent with the examination and inspection requirements specified in ASME Code, Section XI, Subsection IWB, Table IWB-2500-1. The extent and schedule for examining and testing the reactor head closure stud bolting components is specified in Table IWB-2500-1 for B-G-1 components, "*Pressure Retaining Bolting Greater than 2 Inches in Diameter*."

The *Reactor Head Closure Stud Bolting* AMP implements ASME Code, Section XI inspection requirements through the ONS ISI program plan. The current Inservice Inspection Program for the fifth 10 year inspection interval is based on the 2007 ASME Code, Section XI, including 2008 addenda. Future 120 month inspection intervals will incorporate the requirements specified in the version of the ASME Code referenced in 10 CFR 50.55a twelve months before the start of the Inservice Inspection interval. The *Reactor Head Closure Stud Bolting* AMP includes preventive measures to address reactor head closure stud bolting degradation consistent with those identified in the RG 1.65, Revision 1, "Material and Inspection for Reactor Vessel Closure Studs."

The *Reactor Head Closure Stud Bolting* program uses visual and volumetric examinations in accordance with the general requirements of ASME Code, Section XI, Article IWA-2000. The reactor vessel head closure studs and threads in the reactor vessel flange receive a volumetric examination (with exceptions as allowed by NRC approved relief requests to eliminate volumetric examinations of the flange threads during the fifth inspection intervals), and the surfaces of nuts and washers at the reactor vessel flange are inspected using a visual examination (VT-1). The reactor vessel flange connection is within the ASME Code Class 1 pressure-retaining boundary that receives a visual examination (VT-2) per Exam Category B-P during the system leakage test that is performed during each refueling outage.

The reactor head closure stud materials (including nuts, washers and spares) are fabricated from ASTM A-540, Grade B23 alloy steel, Class 3 (ASME Code Case 1335-2) which requires a minimum yield strength of 130 ksi and a minimum tensile strength of 145 ksi. As a result, the installed and spare reactor head closure studs, nuts, and washers (and spares) may have strength values that could exceed the RG 1.65 limits of 150 ksi (yield strength) and 170 ksi (ultimate tensile strength).

Based on Certified Material Test Report data, the installed Unit 1 and Unit 2 studs, nuts, and washers are fabricated with material that may have ultimate tensile strength greater than or equal to 170 ksi. The Unit 3 stud materials are fabricated with material that has a measured ultimate tensile strength less than 170 ksi. The Certified Material Test Report documentation for all fifteen spares indicates an average measured yield strength of greater than 150 ksi. As a result, all installed studs on Unit 1 and 2 and all spare reactor head closure studs present a potential concern for stress corrosion cracking based on the limits stipulated in RG 1.65. The *Reactor*

Head Closure Stud Bolting AMP includes other preventive measures described in RG 1.65 to prevent cracking. Preventive measures for the program include the following attributes:

- Metal-plated stud bolting is not used, which could cause degradation due to corrosion or hydrogen embrittlement;
- A phosphate surface treatment was applied to the studs, nuts, and washers during fabrication to inhibit corrosion; and
- An approved stable lubricant is applied to the studs, nuts, and washers whenever the reactor head is installed. The lubricant used does not contain molybdenum disulfide which has been shown to be a potential contributor to stress corrosion cracking.

To address the potential for SCC for the reactor head closure studs that are installed, ultrasonic examinations are performed during each ASME Code, Section XI, inspection interval. For the spare studs that have strength values that could exceed the RG 1.65 limits of 150 ksi (yield strength) and 170 ksi (ultimate tensile strength), the potential for SCC will not be a concern unless those spares were to be placed into service. At that time, the potential for SCC will be addressed by the ultrasonic examinations which continue to be performed in accordance with ASME Code, Section XI.

Any indication of degradation in reactor head closure stud bolting is documented in the corrective action program and evaluated in accordance with ASME Code, Section XI, Subsection IWB-3100 for Class 1 components by comparing ISI results with the acceptance standards of IWB-3400 and IWB- 3500. Flaw indications or relevant degraded conditions are evaluated in accordance with IWB-3515 or IWB-3517 as indicated in Table IWB-2500-1 and Table 3410-1 of ASME Code, Section XI.

The ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD program will continue to include volumetric examination per ASME Code, Section XI, Table IWB-2500-1, Examination Category B-G-1 and, therefore, will continue to be effective in managing cracking during the SPEO for existing studs and for spare studs upon installation.

<u>NUREG-2191 Consistency</u>

The *Reactor Head Closure Stud Bolting* AMP is an existing program that is consistent with the ten elements of the NUREG-2191 Chapter XI.M3, *Reactor Head Closure Stud Bolting*, with the exceptions and enhancements listed below.

<u>Exception 1 to NUREG-2191</u>

Program Element Affected: Preventive Actions (Element 2)

1. NUREG-2191 indicates in Chapter XI.M3, *Reactor Head Closure Stud Bolting*, that the program relies on the recommendations of RG 1.65, Revision 1, April 2010. RG 1.65, Revision 1, which recommends that actual measured yield strength should not exceed 150 ksi for newly installed studs or 170 ksi ultimate tensile strength for existing studs.

The ONS installed and spare reactor head closure studs were not procured under specifications that limited the measured maximum yield and ultimate tensile strengths, which may present a concern for SCC.

For installed studs, Certified Material Test Reports for the materials used for fabrication of the existing ONS reactor head closure studs installed on Unit 1 (Heat Number 6780366) and Unit 2 (Heat Number 6880366) include some test results indicating that the installed studs may have ultimate tensile strength greater than or equal to 170 ksi. Certified Material Test Reports for materials used for fabrication of existing reactor head closure studs installed on Unit 3 (Heat Number 159628) indicate ultimate tensile strength of less than 170 ksi for all materials.

For newly installed studs, there are twelve spare studs from Heat Number 6780366 and three spare studs from Heat Number 159628 that may have measured yield strength of greater than 150 ksi.

Therefore, the ONS program takes exception (on Unit 1 and 2 only) to the recommendation that existing installed studs' ultimate tensile strength should not exceed 170 ksi, and for newly installed studs (for all fifteen spare stud materials) on any unit, the program takes exception that newly installed studs should not exceed 150 ksi.

Justification for Exception 1

The ONS reactor vessels are designed in accordance with the ASME Boiler and Pressure Vessel Code, Section III, 1965 edition with Summer 1967 Addenda. The design requirement for this bolting material is for the average Charpy V impact energy to be greater than 30 ft-lbs. The materials used to fabricate all installed stud bolting components meet this design requirement.

Although the ONS Unit 1 and 2 studs do not strictly satisfy the threshold limits of 170 ksi ultimate tensile strength for installed studs (reported threshold limit where stress corrosion cracking may be a concern), only 6 of 16 ultimate tensile strength test results reported on the ONS Certified Material Test Reports for the material heats used for Units 1 and 2 studs are greater than 170 ksi. The average of all the ultimate tensile strength test results for Oconee Unit 2 installed studs is 169.9 ksi and the average for the Unit 3 installed studs is 164.8 which are both below the threshold of 170 ksi. Only Unit 1 installed studs have an average of greater than 170 ksi (average 172.9 ksi), and while Unit 1 Certified Material Test Reports stud data revealed an average of 172.9 ksi (172,886 psi), the maximum Rockwell C (R_C) hardness value for the Unit 1 studs was reported as 36 R_C which is less than the EPRI NP-5769, *Degradation and Failure of Bolting in Nuclear Power Plants*, Volume 2 threshold of 41 R_C below which stress corrosion cracking does not present a concern.

The following Certified Material Test Reports data is summarized below for the studs on each ONS Unit:

Unit 1

Only 3 out of 8 ultimate tensile strength test results reported on the Certified Material Test Reports for the heat number used for the Unit 1 studs are greater than 170 ksi. The average of all the measured ultimate tensile strength test results for the Unit 1 studs is 172.9 ksi. This data applies to all 60 installed Oconee Unit 1 studs.

Unit 2

Only 3 out of 8 ultimate tensile strength test results reported on the Certified Material Test Reports for the heat number used for the Unit 2 studs are greater than 170 ksiksi. The average of all the measured ultimate tensile strength test results for the Unit 2 studs is 169.9 ksi. This data applies to all 60 Oconee Unit 2 installed studs.

Unit 3

None of the values for the ultimate tensile strength test results reported on the Certified Material Test Reports for the heats used for the Unit 3 studs are greater than or equal to 170 ksi. The average of all the measured ultimate tensile strength test results for the Unit 3 studs is 164.8 ksi. This data applies to all 60 Oconee Unit 3 installed studs.

Nuts and Washers for Units 1, 2, and 3:

None of the values for the ultimate tensile strength test results are greater than 170 ksi. The average of all measured ultimate tensile strength test results (for the nuts and washers) is 154.8 ksi. The average measured yield strength for the nuts and washers is 144.95 ksi.

Spare Studs:

All fifteen spare studs (potential newly installed studs) may exceed the measured yield threshold of 150 ksi. For twelve spare studs, the average maximum reported yield strength is 153.3 ksi, and for three spare studs, the average maximum reported yield strength is 150.9 ksi.

All other preventive measures listed in NUREG-2191 Chapter XI.M3, *Reactor Head Closure Stud Bolting* that reduce the potential for cracking are met, including the following:

- Metal-plated stud bolting is not used, which could cause degradation due to corrosion or hydrogen embrittlement;
- A phosphate surface treatment was applied to the studs, nuts, and washers during fabrication to inhibit corrosion;
- An approved stable lubricant is applied to the studs, nuts, and washers whenever the reactor head is installed. The lubricant used does not contain molybdenum disulfide which has been shown to be a potential contributor to stress corrosion cracking.

The *Oconee Reactor Head Closure Studs* AMP includes the ISI examinations required by ASME Section XI to detect cracking, loss of material, and leakage.

The ONS program includes periodic examination of studs, nuts, and washers; and visual leakage examinations during system pressure tests. Pressure boundary retaining components in examination category B-P receive a visual examination (VT-2) during system leakage tests.

Ultrasonic examinations are performed for installed reactor head closure studs each inspection interval, in accordance with ASME Code, Section XI, to address the potential for stress corrosion cracking. Any indication of degradation in closure stud bolting is documented in the corrective action program and evaluated in accordance with ASME Code, Section XI, Subsection IWB-3100 by comparing ISI results with the acceptance standards of ASME Code, Section XI, Subsections IWB-3400 and IWB-3500. There have been no cracking indications identified by ONS ISI program examinations of reactor head closure bolting components, indicating that the current program has been effective to manage cracking.

The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* program will continue to include volumetric examination per ASME Code, Section XI, Table IWB-2500-1, Examination Category B-G-1 and, therefore, will continue to be effective in managing cracking during the SPEO for existing studs and for spare studs upon installation. EPRI Report 3002014589, *“Technical Basis for Optimization of the Volumetric Examination Frequency for Reactor Vessel Studs”* states that cracking has only been confirmed at only one plant, a BWR. Ultrasonic testing indications indicative of cracking have been detected at two other BWR plants, one of which was determined to be general corrosion rather than cracking. There has been no reported cracking of reactor vessel head closure studs at PWR plants.

Exception 2 to NUREG-2191

Program Element Affected: Corrective Actions (Element 7)

2. NUREG-2191 recommends, as a corrective action that can reduce the potential for stress corrosion cracking, the maximum measured yield strength of replacement material should be limited as recommended in RG 1.65, Revision 1. RG 1.65, Revision 1 specified that the material used for closure studs and nuts have measured yield strength less that 150 ksi.

The spare (potential replacement) reactor head closure studs (currently, 15 spares are stored in a warehouse at ONS) are fabricated from SA-540 Grade B23 alloy steel which requires a minimum yield strength of 130 ksi and a minimum tensile strength of 145 ksi. The Certified Material Test Report data for the spare studs includes several sets of test results that include yield strength data for each heat used to fabricate the studs.

Certified Material Test Reports for the materials used for fabrication of the potential replacement reactor head closure studs in the warehouse include test results with measured yield strength greater than or equal to 150 ksi. Twelve spare studs have an average maximum reported yield strength of 153.3 ksi and three spare studs have an average maximum reported yield strength of 150.9 ksi. Therefore, all fifteen potential newly installed studs may exceed the threshold of 150 ksi where stress corrosion cracking may be a concern

Justification for Exception 2

Oconee Unit 1, 2 and 3 reactor vessel stud bolting materials were fabricated in a manner consistent with the recommendations of the RG 1.65. Potential replacement reactor head closure studs and nuts already procured and stored in the warehouse slightly exceed the strength criteria of 150 ksi measured yield strength.

Although the potential newly installed stud components may exceed the 150 ksi yield strength threshold, all other preventive measures listed in NUREG-2191 Chapter XI.M3, *Reactor Head Closure Stud Bolting* that reduce the potential for cracking are met, including the following:

- Metal-plated stud bolting is not used, which could cause degradation due to corrosion or hydrogen embrittlement;
- A phosphate surface treatment was applied to the studs, nuts, and washers during fabrication to inhibit corrosion;
- An approved stable lubricant is applied to the studs, nuts, and washers whenever the reactor head is installed. The lubricant used does not contain molybdenum disulfide which has been shown to be a potential contributor to stress corrosion cracking.

Volumetric inspections will be performed on the ONS installed studs, in accordance with ASME Code, Section XI, each inspection interval to detect any indication of cracking. If any of the spare studs are installed, any indication of degradation in the newly installed closure stud bolting will be evaluated in accordance with ASME Code, Section XI, Subsection IWB-3100 by comparing ISI results with the acceptance standards of ASME Code, Section XI, Subsections IWB-3400 and IWB-3500.

The *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* program will continue to include volumetric examination per ASME Code, Section XI, Table IWB-2500-1, Examination Category B-G-1 and, therefore, will continue to be effective in managing cracking during the SPEO for existing studs and for spare studs upon installation.

Enhancements

The following enhancements will be implemented in the following program elements:

Preventive Actions (Element 2) and Corrective Actions (Element 7)

1. Procurement requirements for reactor head closure stud bolting will be revised to incorporate guidance from RG 1.65, Revision 1 and NUREG-2191, Chapter XI.M3, to ensure newly procured bolting material does not exceed the limit for maximum measured yield strength of 150 ksi and measured ultimate tensile strength of 170 ksi.

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Reactor Head Closure Stud Bolting* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In April 2011, an entry was made into the corrective action program to document the engineering evaluation of the indications identified on the Unit 1 reactor vessel head studs and washers. The following Unit 1 reactor vessel studs and washers were identified as having minor damage to threads or load bearing surfaces:

   - One stud had minor scratches in two locations on upper portion of threads;
   - One stud had a gouge on upper starter thread, scratch across six threads near top, and 1.5 inches of lower starter thread missing; and
   - One washer had minor indentations on the load bearing portion of the upper surface. These indentions were dressed in a whetstone to remove any raised metal.
   - Several other washers exhibited minor pitting on the non-load bearing surfaces.

   The minor damage noted on the washers above was determined to be acceptable for continued use since the condition will not impair the washers from performing their function and as a result, are acceptable, as-is. The damage noted on the two studs above was evaluated against the guidance in vendor calculation for the Evaluation of Oconee Units 1, 2, and 3 reactor vessels bolting. The evaluation determined that these studs are acceptable for continued use since the minor scratches and damage will not impact the studs from performing their component intended function.

   OE example 1 demonstrates that the reactor head closure stud bolting components (including washers) are inspected in accordance with ASME Code Section XI requirements using examination techniques that would identify cracking and loss of material and any potential adverse conditions are entered into the corrective action program.

2. In March 2013, a corrective action item was initiated for a program performance gap review to be performed for Regulatory Issue Summary 2011-05, *"License Renewal Aging Management Program comparison against Generic Aging Lessons Learned,"* Revision 2 to review key updates and changes to NUREG-1801, *"Generic Aging Lessons Learned (GALL) Report",* Revision 2, issued December 2010. The RIS summarized the significant updates to aging management guidance, detailed in Revision 2 of NUREG-2191, which included a revision to Chapter XI.M3, "*Reactor Head Closure Stud Bolting*."

   The revision to Chapter XI.M3, *"Reactor Head Closure Stud Bolting"* updated the program to include the more appropriate yield strength designation for high-strength bolts, which reflects information in the reference document, NUREG-1339, *"Resolution of Generic Safety Issue 29: Bolting Degradation or Failure in Nuclear Plants,"* issued June 1990. In addition, the revision specifically identified that molybdenum disulfide is a potential contributor to stress corrosion cracking and should not be used. The two identified updates to NUREG 2191 Chapter XI.M3, *"Reactor Head Closure Stud Bolting"* are related to:

   - Limits on actual measured yield strengths for the bolting material, and
   - The non-allowance of the use of molybdenum disulfide (MoS2) as a lubricant.

   Engineering performed a gap evaluation for ONS to review key updates to the NUREG-2191 Chapter XI.M3 program. Specifically, the following actions were performed as part of the engineering evaluation:

   - Reviewed certified material test reports for the studs and nuts at the site for each unit to obtain actual yield strength and hardness values (this information was found in the receipt inspection package associated with each reactor vessel).
   - Determined that ONS reactor head closure studs, nuts and washers are A-540, Grade B23 (Code Case 1336) and that ONS studs, nuts and washers do not strictly satisfy the 150 ksi limit on yield stress which is reported as the threshold limit where SCC may be a concern.
   - Reviewed the following applicable industry reports to determine:
     - NUREG-1339 specifies a yield strength limit of 150 ksi. Where material yield strength is less than this value, there are no concerns with a SCC failure mechanism
     - EPRI Report NP-5769, Volume 2, page 7-16, indicates that bolting materials with a hardness level of 41 R_C and lower (equivalent Brinell hardness < 388) present no concerns with SCC.
     - EPRI MRP-150, Materials Handbook for Nuclear Plant Pressure Boundary Applications (2013) which states the use of lubricants containing sulfur or chlorine may increase potential for stress corrosion cracking.
   - Performed a review of external OE including past and current plant maintenance practices and ASME code inspection requirements which revealed SA-540 Grade

B23 and B24 bolting material is not generally susceptible to SCC unless compounded with other detrimental factors.

- An internal OE search was done for the Duke sites for SA-540, SA540 or AISI 4340 which revealed no failures associated with this material.
- An additional search of external OE indicates no failures associated with SA-540 materials. Studs and nuts are volumetrically examined (Ultrasonic Test) each inspection interval. These examinations are distributed between the three inspection periods per interval.
- Determined that although use of molybdenum disulfide products were used at ONS in the past, plant procedures have eliminated the use of these lubricants and no cracking indications have been identified on any studs.
- The studs and nuts at ONS are machine cleaned and relubricated each refueling outage.

The engineering review concluded that since the studs, nuts and washers on each unit at ONS are visually examined each refueling outage, a flaw would be identifiable by this examination. In addition, the identification of an indication exceeding ASME Section XI code acceptance limits would require additional examinations during the refueling outage of discovery. Also, as part of ongoing program procedures, continued external OE would be reviewed to determine if additional actions are needed in the future.

OE example 2 provides objective evidence that the corrective action program is effectively used to evaluate OE, including regulatory guidance updates, to inform and enhance AMPs. This demonstrates that appropriate actions are taken to evaluate technical issues to ensure ongoing program effectiveness.

3. In December 2013, an entry was made to the corrective action program to evaluate required actions and document receipt of *EPRI Nondestructive Evaluation Program Letter 2013 - 09, ALERT: Notification of Noncompliance Performance Demonstration Initiative (PDI) - Implementation of Bolting Qualifications not in compliance with ASME Code, Appendix VIII*, Supplement 8, dated December 18, 2013. The EPRI Performance Demonstration Initiative is an industry effort to promote rigor, consistency, and effectiveness in ultrasonic non-destructive evaluation technology. The EPRI Performance Demonstration Initiative bolting qualification program is intended to provide an acceptable method for completing the examinations.

   In the Fall of 2013, as documented in this corrective action item and RIS 2015-01, discrepancies between the ASME Section XI Appendix VIII, Supplement 8 (prior to 2015 edition) requirements and the PDI bolting qualification program were identified during a program internal audit. ASME Section XI, Appendix VIII, Supplement 8 provides the requirements for the examination and acceptance of safety classes 1 and 2, pressure retaining bolting greater than 2.0 inches in diameter. The specific bolting locations affected on Oconee Units 1, 2, and 3 included the reactor vessel closure studs. ASME Code Section XI, Appendix VIII, Supplement 8 requires full-scale section bolt or stud specimens containing the beam path be used to demonstrate scanning techniques. Specifically, Supplement 8 requires the qualification specimen “be of similar chemical composition, tensile properties, and metallurgical structure as the bolt or stud to be examined” and that the scan surface of the qualification specimen have a configuration similar to the bolt or stud to be examined. This requirement is unlike other supplements in Appendix VIII that allow the use of a range of configurations that represent “typical” conditions for demonstrating scanning techniques. EPRI, as administrator of the Performance Demonstration Initiative program, used mockups technically representative of bolt and stud configurations and material types known to exist in the fleet. These representative mockups may not have met the Supplement 8 requirements for all cases for which the mockups were used.

EPRI performed a technical evaluation and determined that examinations performed in accordance with the requirements of the Performance Demonstration Initiative qualified bolting examination procedures would provide the licensee reasonable assurance that flaws of safety significance would have been detected consistent with the intent of the Code requirements. Therefore, while the Performance Demonstration Initiative qualification procedure does not strictly comply with ASME Section XI, Appendix VIII, Supplement 8, the differences identified do not degrade a reasonable assurance of operability.

Although there was no operability concern, Oconee reperformed volumetric examinations on all reactor pressure vessel studs on all three units. The exams were performed in accordance with the blind demonstration requirements and mockup requirements. Oconee reinspected all reactor pressure vessel studs with satisfactory results in the next outage for each unit. There were no relevant indications from any of the Oconee inspections performed on Units 1, 2, or 3.

OE example 3 provides objective evidence that industry OE and updates are documented, reviewed and evaluated in the corrective action program. This example also demonstrates that reactor head closure stud bolting components are inspected in accordance with ASME Code Section XI requirements using examination techniques that would identify cracking and loss of material. The reactor head closure stud bolting components were verified to be in good material condition.

4. In April 2016, during the inspection and cleaning of the Unit 3 reactor head studs, nuts and washers, minor wear was identified on the mating surface of a reactor head stud washer. The issue was documented in the corrective action program to evaluate as a potential indication and determine corrective actions. Maintenance took photographs of this damage and contacted engineering to perform an evaluation. Engineering concluded that the outer indications were outside the region of the washer that is loaded and would not impact the ability of the washer to perform its function. In addition, engineering determined the smaller wear indication toward the inner radius of the washer exhibits no raised metal which would interfere with proper loading of the washer to nut interface. For those reasons, the reactor vessel stud washer was evaluated as acceptable for continued use and returned to service.

   OE example 4 demonstrates that the reactor head closure stud bolting components (including washers) are inspected in accordance with ASME Code Section XI requirements using examination techniques that would identify cracking and loss of material and any potential adverse conditions are entered into the corrective action program and appropriately evaluated by engineering.

5. In August 2020, an AMP effectiveness review was performed for the ISI Program (UFSAR Section 18.3.12) including a review of activities for the reactor head closure stud bolting inspections. The ISI program aging management activities were evaluated against the performance criteria identified in NEI 14-12, “Aging Management Program Effectiveness.” The review concluded that the ISI program is meeting the requirements of NEI 14-12. No gaps were identified during the effectiveness review related to reactor head closure stud bolting activities.

   OE example 5 provides objective evidence that the current ISI program is meeting all current license renewal commitments and effectively managing aging effects of reactor head closure stud bolting components in accordance with ASME Section XI requirements. This provides reasonable assurance that ongoing program effectiveness will continue in the subsequent period of operation.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Reactor Head Closure Stud Bolting* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, re-evaluation, repairs, performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Reactor Head Closure Stud Bolting* AMP, with noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.4 BORIC ACID CORROSION

Program Description

The *Boric Acid Corrosion* AMP is an existing condition monitoring program that manages loss of material due to leaking borated water on external surfaces of structures and components (including electrical equipment/junction boxes) within the scope of SLR that are susceptible to boric acid corrosion. The program applies to susceptible components in the reactor building and auxiliary building where boric acid leakage is a concern. The program includes provisions to identify leakage through inspection and examination. When leakage is identified, a visual inspection is performed that identifies the leakage pathway and any boron deposits on adjacent structures, components, and supports so that leakage cleanup can begin, and corrective actions can be initiated, as necessary. When it is determined that an evaluation is necessary, it is performed in a timely manner. Follow up inspections may be performed to ensure that the corrective actions were adequate and addressed the identified age related degradation.

The *Boric Acid Corrosion* program relies, in part, on GL 88-05, *"Boric Acid Corrosion of Carbon Steel Reactor Pressure Boundary Components in PWR Plants,"* for guidance to identify, evaluate, and correct borated water leaks that could cause corrosion damage to reactor coolant pressure boundary components. Borated water leakage from components outside the scope of the program established in response to GL 88-05 may affect other components within the scope of SLR. Therefore, this program includes components within the scope of SLR exposed to an air environment with potential borated water leakage that are susceptible to boric acid corrosion.

The *Boric Acid Corrosion* program is consistent with both GL 88-05 as well as Section 7 of WCAP-15988-NP, Revision 2, *"Generic Guidance for an Effective Boric Acid Inspection Program for Pressurized Water Reactors".* Additionally, the *Boric Acid Corrosion* program interfaces with the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* program (B2.1.1) which includes ISI pressure tests performed in Accordance with ASME Code, Section XI requirements. These interfaces with other site programs and activities ensures that borated water leakage that is encountered by means other than this program is evaluated and corrected. Specific attributes from WCAP-15988-NP are addressed in implementing procedures, and are included in, but not limited to, the following listing:

- The program is established and implemented in accordance with regulatory commitments, and mandatory and recommended industry requirements.
- The program identifies inspection locations that are susceptible to potential borated water leakage. Susceptible materials for boric acid corrosion include carbon steel, low-alloy steel, and cast iron; Inconel alloy base metal and welds (due to Primary Water Stress Corrosion Cracking); and certain copper alloys (containing >15% zinc).
- Locations that are susceptible to boric acid corrosion are inspected by programs other than the *Boric Acid Corrosion* program. The effects of boric acid corrosion on reactor coolant pressure boundary materials in the vicinity of nickel alloy components are managed by the *Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components* (B2.1.5) AMP. Bare metal visual examinations that are described in the *Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components* (B2.1.5) program determine the

presence of borated water leakage on the reactor vessel upper head penetration nozzles and the bottom-mounted instrumentation nozzles. Interfaces with the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* (B2.1.1) program include results from visual inspections for loss of material due to boric acid corrosion.

- Program ownership and responsibility is established which includes personnel qualification and appropriate *Boric Acid Corrosion* program training. Visual inspections are performed by qualified individuals who are tasked with performing focused inspections for boric acid leakage. Also, computer based training is provided to individuals who may observe evidence of borated water leakage. Evidence of borated water leakage exists as the presence of boron deposits or moisture. Discolored boron deposits may be an indication of potential boric acid corrosion.
- Routine walkdowns, performed each day by plant operators and radiation protection personnel note any evidence of borated water leakage. Additional plant walkdowns are performed by engineering. Focused inspections are performed during refueling outages by operations and engineering personnel to identify evidence of borated water leakage.
- Results of inspections to identify occurrences of borated water leakage during refueling outages are documented in the corrective action program. Any borated water leakage evaluated and additional actions are taken to remediate the leakage.
- Any obstructions to visual inspection are removed for inspection, unless a technical justification for not performing the visual inspection is documented. For leakage examinations of borated systems components with external insulation, or for joints that are not visible due to being located under insulation, the surrounding areas of the floor, equipment surfaces, or exposed surfaces of the insulation are examined for evidence of borated water leakage. An initial inspection determines the extent of insulation removal that is required in order to properly perform the examination for evidence of leakage. In some situations (such as for bolted connections which are within the scope of ASME Section XI), removal of insulation may be required in order to perform the borated water leakage inspection. For leakage at an insulated bolted connection in a system that is borated for purposes of reactivity control, the bolting is evaluated by engineering, as necessary, in accordance with ASME Section XI, Subsection IWA 5250 and Code Case N-566-2, “Corrective Action for Leakage Identified at Bolted Connections.”
- The *Boric Acid Corrosion* program identifies sources of borated water leakage, and the pathway and potential targets (i.e., adjacent structures and components) that could be adversely affected by borated water leakage. OE has shown that likely locations for borated water leakage include valve packings, body to bonnet gaskets, bolted connections, and fittings.
- Screening, evaluating and dispositioning leaks including data collection and documentation including appropriate corrective and mitigating actions. Leakage that exceeds the screening threshold identified in the *Boric Acid Corrosion* program requires initiation of an engineering evaluation. Engineering evaluations are performed to determine the impact of leakage on the integrity of the borated system pressure boundary or adjacent structures and components. Engineering evaluations determine whether degradation of susceptible structures or components has occurred, whether repair or replacement of structures or components (perhaps using

corrosion resistant materials) is needed, or whether the observed condition is acceptable without repair.

- Program inspections are performed inside containment to look for evidence of boron deposits on components such as control rod drive mechanisms and fans, containment air recirculation fan coils and reactor building cooling units. In addition, to identify potential borated water leaks inside containment that have not been detected during walkdowns and maintenance, the program also requires a collective significance review to be performed which reviews attributes to assist with identification of potential borated water leaks inside containment. These attributes include, but are not limited to, indications from reactor coolant system water inventory balancing, containment air cooler thermal performance, containment air particulate radiation monitors, containment noble gas radiation monitors, containment humidity and temperature monitors and air filter change out frequency and appearance of filter at change out (e.g., for boric acid or reddish-brown color which may be an indication of corrosion).
- The program is periodically assessed to determine program compliance with established processes, procedures, and requirements to ensure ongoing program effectiveness. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

<u>NUREG-2191 Consistency</u>

The *Boric Acid Corrosion* program is an existing program that is consistent with NUREG-2191 Chapter XI.M10, Boric Acid Corrosion.

<u>Exception to NUREG-2191</u>

None

<u>Enhancements</u>

None

<u>Operating Experience</u>

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Boric Acid Corrosion* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In May 2012, a fleet wide focused self-assessment was performed, to review VT-2 visual inspection documentation and evaluation adequacy. The purpose of the assessment was to review ASME Code compliance, site program procedure compliance and effectiveness, and documentation adequacy regarding the performance of boric acid

engineering evaluations on bolting materials exposed to borated water leakage. The assessment reviewed the following:

- Compliance with ASME Code requirements related to leakage examination,
- Appropriate ASME Code actions were taken when leakage was discovered, and
- Adequacy of ASME Code Case N-566-2 evaluations when that option was used.

The assessment team identified several improvements to program processes and procedures. Corrective actions were generated to address all assessment recommendations. All corrective actions were completed which resulted in several programmatic improvements to the program including improved procedures for boric acid engineering evaluations and required actions when borated water leakage is identified.

OE example 1 provides objective evidence the program is periodically assessed to determine program compliance with established processes, procedures, and requirements to ensure ongoing program effectiveness. This provides reasonable assurance that plant OE will be used to ensure program effectiveness in the SPEO.

2. In March 2013, during remote video inspection of the Oconee Unit 1&2 purification and deborating demineralizer room, boron deposits were discovered on and around the demineralizer. A corrective action entry was made to document and evaluate the borated water leakage. In accordance with the *Boric Acid Corrosion* program, engineering performed a boric acid evaluation to determine the extent of any borated water leakage and establish follow-up corrective actions. The source of the leak was the manway gasket on the top of the demineralizer. The leak did not appear active at the time of the video inspection performed in June 2013. The boric acid corrosion evaluation identified all source and target materials and estimated corrosion rates based on the borated water leakage condition. Once engineering documented the borated water leakage (identified source and target components), the boron was cleaned from all affected components to perform a more thorough inspection of the carbon steel manway gasket bolting components

   Based on existing degradation and projected conservative estimated corrosion rates, the engineering evaluation determined that sufficient margin exists to ensure intended functions are maintained through the initial period of extended operation (i.e., through 2033). Corrosion rates are expected to be low, even for continuously wet conditions, due to the low temperature environment. Engineering determined that the bolting on the manway is expected to have over 10 times the required capacity at the end of the initial period of extended operation. This room is a highly contaminated area that cannot routinely be entered for inspection. A preventive maintenance activity was created as a follow up action to periodically monitor the condition and review expected corrosion rates to ensure aging effects will continue to be managed.

   OE example 2 demonstrates that the corrective action program is effectively used to initiate appropriate actions including actions to identify borated water leakage and evaluate boric acid corrosion. This provides reasonable assurance that plant OE will be used as a feedback mechanism to ensure aging effects are managed in the SPEO.

3. In July 2014, a fleet self-assessment was performed to evaluate the *Boric Acid Corrosion* AMP against industry standards, strengths, and good practices, and to determine procedural and regulatory compliance. The fleet program documents were evaluated against regulatory commitments and guidance, as well as NEI 03-08 and WCAP-15988-NP industry requirements. Other aspects of the self-assessment were to determine whether boric acid leakage is promptly identified and documented in the corrective action program, to determine whether boric acid leakage evaluations are performed and documented in a timely manner, to determine whether minor leaks are cleaned and regularly monitored for change in condition, and to determine whether safety significant/ excessive leakage is corrected/mitigated in a timely manner. Procedure compliance, inspections of infrequently accessed areas, trending processes and training qualifications and certifications were also reviewed.

   No issues were identified with respect to compliance with industry program guidance documents. The self-assessment confirmed that all required program functions are being completed effectively and no gaps were identified. The team found several examples where clarification of existing program procedure, training, and administrative documentation details could be enhanced, and other opportunities to apply industry best practices for program improvement. Improvements implemented included program procedure revisions to enhance infrequently accessed area inspections. Maintenance procedures were revised to add a step to look for borated water leakage accumulations in the letdown filter pits and to generate work requests, as necessary, for leak repair and evaluation. A new preventive maintenance activity was also added to periodically lift the borated water storage tank trench covers and inspect the trench for boric acid deposits or corrosion deposits on a two-year frequency. Other improvements implemented included enhancements to the general employee boric acid training module such as more examples and information on the potential consequences of leaks, boric acid inspector module improvements, and other information added to improve general awareness of borated water leak identification.

   OE example 3 provides objective evidence that the Boric Acid Corrosion program is effectively managing aging by ensuring program effectiveness through self-assessments.

4. In October 2014, a site-specific assessment was conducted to independently review the quality of ONS boric acid corrosion engineering evaluations to identify any gaps and ensure compliance with regulatory commitments as well as plant and industry guidance. Documentation of the review results were documented in the corrective action program. A review of a sample of six evaluations performed during the operating cycle confirmed that all procedure requirements have been met and no discrepancies were identified. The engineering independent assessment confirmed that ONS boric acid corrosion evaluations are being completed effectively in accordance with plant, industry and regulatory requirements.

   OE example 4 provides objective evidence that the *Boric Acid Corrosion* AMP includes periodic self-assessments to critically assess program compliance which provides reasonable assurance that ongoing program effectiveness will be maintained in the SPEO.

5. In July 2016, a fleet wide focused self-assessment of the Boric Acid Corrosion program was conducted. Areas reviewed included borated water leak identification from multiple site organizations, inspection rounds and walkdowns, adequacy of leak identification documentation, corrective action program entry and timeliness, elapsed time between leak discovery and leak screening, screening process adequacy, active leak containment, borated water deposit/residue cleaning, periodic leak monitoring, and maintenance resolution of borated water leakage issues.

   The assessment team identified one area for improvement for ONS, and eight recommendations to enhance the overall fleet program. There were no cross-functional problems or program performance objective failures. The area for improvement was identified for ONS maintenance inactive leak screening timeliness, specifically regarding the timeliness between the initial leak discovery documented in a work request and the performance of the “inspect, assess, and clean” process in the maintenance procedure which identifies conditions that require a boric acid evaluation. The program procedure specifies a two-week expectation for completion of leak screening and assessment following leak identification. A review of the backlog list indicated that the ONS fluid leak management maintenance team is addressing active leakage cases in a timely manner. However, a backlog primarily consisting of inactive leaks, as indicated by dry white deposits, had developed. This backlog developed due to turnover of personnel. A corrective action was completed to address the backlog and timeliness issue for ONS. Implementation of recommendations identified during the self-assessment resulted in several procedural improvements and clarifications as well as an action completed to implement best practices for maintenance borated water leak screening practices. Overall, the team concluded that the assessed program areas were reflective of good performance.

   OE example 5 provides objective evidence that the *Boric Acid Corrosion* program performs thorough and intrusive program self-assessments to review the compliance and adequacy of programmatic functions and that appropriate actions are taken to improve program performance, when required. This provides reasonable assurance that program effectiveness will be maintained, and aging effects will be managed in the SPEO.

6. In December 2017, a corrective action entry was initiated by operations (found during operator rounds) due to active leakage observed around a Unit 2 high pressure injection pump shaft. The borated water leakage item was documented with pictures and a corrective action was initiated for engineering to perform a boric acid corrosion evaluation.

   In accordance with the *Boric Acid Corrosion* program requirements, engineering performed a boric acid corrosion evaluation on the high-pressure injection pump shaft borated water leakage. The engineering boric acid evaluation included a description of leakage source and leakage path; description and estimated volume of boron deposits (on source and target components); estimated volume and leakage rates; identification of materials affected; and determination of degradation on source and target components. The evaluation determined that no damage, wastage or pitting was occurring on source or targets due to borated water leakage. As a result, it was determined that the borated water leakage did not affect the equipment's ability to perform intended functions. Since there were historical leaks in the fluid leak management database, subsequent quarterly monitoring and inspection requirements were established.

OE example 6 provides objective evidence that the corrective action program is used to document borated water leakage identified during operator rounds. This also demonstrates that boric acid evaluations are performed in accordance with plant and industry guidance. This provides reasonable assurance that the *Boric Acid Corrosion* program will continue to effectively manage aging in the SPEO.

7. In February 2018, maintenance made an entry to the corrective action program to document an active leak identified on a Unit 1 test connection and tubing connection. In accordance with the *Boric Acid Corrosion* Program, engineering performed a borated water leakage evaluation.

   The evaluation included identification of the leakage source and targets, identification of the materials of all affected equipment (both source and targets), description of leakage path including a description of boron deposits on source and target components, including estimated volume and leakage rates, and identification of any degradation of source and target components. Since there was insulation covering some of the target components, it was determined that the insulation would have to be removed to complete the cleaning and final evaluation. Insulation was removed and final cleaning and evaluation was completed. The evaluation determined there were no signs of significant material degradation and potential corrosion rates for current and future expected conditions are negligible. Additional corrective actions included documentation of the leak in the fluid leak management database and generation of a work request to perform repairs. Maintenance tightened the leaking connections and monitored the leak for an additional two months to confirm that the leak was no longer active.

   OE example 7 demonstrates how the ONS *Boric Acid Corrosion* AMP effectively documents plant issues in the corrective action program to establish appropriate actions. The corrective action program was used effectively to identify the cause, evaluate the borated water leakage, and implement appropriate comprehensive corrective actions.

8. In September 2020, an aging management program effectiveness review was performed for the *Boric Acid Corrosion* program. The *Boric Acid Corrosion* program was evaluated against the performance criteria identified in NEI 14-12 “Aging Management Program Effectiveness.” The review concluded that the *Boric Acid Corrosion* program is meeting the requirements of NEI 14-12. No gaps were identified during the effectiveness review.

   OE example 8 provides objective evidence that the current *Boric Acid Corrosion* program is effectively managing aging and meeting all current license renewal commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the subsequent period of operation.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Boric Acid Corrosion* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions requiring additional inspections, re-evaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Boric Acid Corrosion* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Boric Acid Corrosion* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.5 CRACKING OF NICKEL ALLOY COMPONENTS AND LOSS OF MATERIAL DUE TO BORIC ACID INDUCED CORROSION IN REACTOR COOLANT PRESSURE BOUNDARY COMPONENTS

Program Description

The *Cracking of Nickel Alloy Components and Loss of Material Due to Boric Acid Induced Corrosion in Reactor Coolant Pressure Boundary Components* AMP is an existing condition monitoring program that manages cracking due to primary water stress corrosion cracking for components or welds constructed from Alloy 600/82/182 and exposed to pressurized water reactor primary coolant at elevated temperatures. Initiation and growth of cracks resulting from primary water stress corrosion cracking can occur as a function of variables which include, but are not limited to, temperature, stress, microstructure, time, and water chemistry. This program is used in conjunction with the *Water Chemistry* (B2.1.2) program.

The *Cracking of Nickel Alloy Components and Loss of Material Due to Boric Acid Induced Corrosion in Reactor Coolant Pressure Boundary Components* AMP is based on the EPRI guidance document MRP-126, “Materials Reliability Program: Generic Guidance for Alloy 600 Management.” Bare metal visual, surface, and volumetric examinations are used to detect the presence of primary water stress corrosion cracking. Inspections are performed periodically.

The nickel alloy components that are examined due to susceptibility to primary water stress corrosion cracking include the reactor vessel bottom mounted instrumentation nozzles, small bore hot leg connections and small bore cold leg connections (ASME Code Case N-722, as incorporated by reference in 10 CFR 50.55a).

Nickel alloy components, for which primary water stress corrosion cracking has been mitigated by use of a full structural weld overlay of Alloy 52/152 material, are examined in accordance with ASME Code Case N-770 (Category F), as incorporated by reference in 10 CFR 50.55a. These components include the Unit 1, 2, and 3 pressurizer surge nozzle, hot leg surge nozzle, pressurizer safety relief valve nozzle, pressurizer spray, letdown nozzle and decay heat nozzle. Other susceptible nickel-alloy components that require examination in accordance with ASME Code Case N-770, as incorporated by reference in 10 CFR 50.55a, include unmitigated hot leg components, cold leg components, and core flood nozzle dissimilar weld butt welds.

Other nickel alloy components that are examined, but are resistant to primary water stress corrosion cracking, include the reactor vessel head penetration nozzles and J-groove welds (ASME Code Case N-729, as incorporated by reference in 10 CFR 50.55a). Inspections are also performed for Alloy 600 full penetration branch connection weld metal buildup for material susceptible to primary water stress corrosion cracking in accordance with ASME Code Case N-853.

The *Cracking of Nickel Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components* AMP inspects components that are susceptible to corrosion due to borated water leakage from nearby or adjacent nickel alloy components previously described. Findings of borated water leakage or boric acid on Alloy 600/ 82/182 components are documented in accordance with the *Boric Acid Corrosion* program. The *Water Chemistry* program monitors and controls water environments consistent with industry guidelines to ensure that the reactor coolant water environments are favorable to mitigate primary water stress corrosion cracking in nickel alloy components.

NUREG-2191 Consistency

The *Cracking of Nickel Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components* AMP is an existing program that is consistent with NUREG-2191, Section XI.M11B, *Cracking of Nickel Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components*.

Exceptions to NUREG 2191

None.

Enhancements

None.

Operating Experience

Based on a broad search of pertinent ONS OE, the following examples provide objective evidence that the *Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2003 and 2004, the ONS (Unit 1, 2 and 3) original reactor vessel heads were replaced with heads containing Alloy 690 materials that are resistant to primary water stress corrosion cracking (PWSCC) where Alloy 600 was used previously.

   The ONS Unit 1 replacement reactor vessel head containing PWSCC-resistant materials was installed in September 2003 at which time a pre-service inspection was performed. The first bare metal visual augmented inservice inspection on the replacement reactor pressure vessel head was performed in April 2008. A volumetric exam was also performed on the ONS Unit 1 reactor vessel head in the Fall of 2012. Additional reactor pressure vessel head surface bare metal visual inspections (Code Case N-729) were performed in November 2012, November 2016, and November 2020. No signs of degradation or penetration leakage were identified.

   The ONS Unit 2 replacement reactor vessel head containing PWSCC-resistant materials was installed in March 2004 at which time a pre-service inspection was performed. The first bare metal visual augmented inservice inspection on the replacement reactor pressure vessel head was performed in November 2008. A volumetric exam was performed on the ONS Unit 2 reactor vessel head in the Fall of 2013. Additional reactor pressure vessel head surface bare metal visual inspections (Code Case N-729) were performed in November 2011, October 2015, and October 2019. No signs of degradation or penetration leakage were identified.

The ONS Unit 3 replacement reactor vessel head containing PWSCC-resistant materials was installed in April 2003 at which time a pre-service inspection was performed. The first bare metal visual augmented inservice inspection on the replacement reactor pressure vessel head was performed in November 2007. A volumetric exam was also performed on the ONS Unit 3 reactor vessel head in the Spring of 2012. Additional reactor pressure vessel head surface bare metal visual inspections (Code Case N-729) were performed in May 2012, April 2016, and April 2020. No signs of degradation or penetration leakage were identified.

OE example 1 demonstrates that the existing program is performing mitigation through component replacement as well as performing inspections in accordance with regulatory and ASME Code requirements.

2. In January 2005, an entry was made in the corrective action program to determine required actions to comply with industry guidance contained in EPRI MRP-126, *Generic Guidance for Alloy 600 Management*. MRP-126 provides guidance for plants to use in developing their individual Alloy 600 management plans including key elements and useful resources for developing and implementing a plant-specific plan. As a result of this corrective action item, ONS updated the Alloy 600 program to add detail on how each of the ten AMP elements are being met. The Alloy 600 program plan included a combination of potential mitigation options such as replacement, full structural overlay, or mechanical stress improvement. ONS documented mitigation strategies planned to maintain the function of each Alloy 600/82/182 component for the remaining life of the plant. ONS mitigation activities were specifically selected based on the individual requirements of each location. In addition, a list of Alloy 600 degradation experience for the industry was compiled and included in the ONS Alloy 600 engineering support document.

   OE example 2 provides objective evidence that industry OE reviews are documented in the corrective action program to evaluate and make necessary program enhancements, as necessary. This example also demonstrates that OE is used as a primary feedback mechanism for the Alloy 600 program which will ensure ongoing program effectiveness.

3. In 2009 and 2010, baseline ASME code case visual inspections were completed for the Unit 1, Unit 2, and Unit 3 lower head bottom mounted instrumentation nozzles without any adverse findings or degradation identified. The most recent lower reactor vessel head bottom mounted instrumentation nozzle visual examinations were performed in the Fall of 2018 for Unit 1, Fall of 2017 for Unit 2, and Spring of 2020 for Unit 3. All exams were acceptable and found no indications of age related degradation.

   OE example 3 provides objective evidence that required reactor vessel lower head inspections are being performed in accordance with 10 CFR 50.55a using the methods recommended to identify aging effects. Future inspections are scheduled, as required, to ensure aging effects are identified prior to loss of intended function.

4. In June 2011, a corrective action program entry was made to evaluate the revision to 10 CFR 50.55a and initiate corrective actions, as necessary, to ensure timely implementation. The NRC also incorporated by reference (with conditions on their use) ASME Boiler and Pressure Vessel Code Case N-722-1, *Additional Examinations for PWR Pressure Retaining Welds in Class 1 Components Fabricated with Alloy 600/82/182 Materials*, and ASME Boiler and Pressure Vessel Code Case N-770-1, *Alternative Examination Requirements and Acceptance Standards for Class 1 PWR Piping and Vessel Nozzle Butt Welds Fabricated With UNS N06082 or UNS W86182 Weld Filler Material With or Without Application of Listed Mitigation Activities*. Corrective actions documented evaluations of ASME Code Cases N-722, N-770, and the conditions published in the NRC final rulemaking.

   ONS specific actions included performing an evaluation of the impact of the changes to 10 CFR 50.55a related to implementation of Code Cases N-722-1 and N-770-1. Corrective actions completed included revising program documents to comply with conditions imposed on inspection program requirements. This corrective action also evaluated and completed the necessary actions to transition from MRP-139, Revision 1 to ASME Code Case N-770-1 with conditions imposed under 10 CFR 50.55a. The ONS augmented inservice inspection plan was updated with the new requirements and details related to applicable ASME Code Case compliance.

   OE example 4 provides objective evidence that the corrective action program is effectively used to evaluate and complete required actions to respond and comply with updated industry and regulatory requirements in a timely manner.

5. In May 2012, a corrective action entry was initiated in the corrective action program to evaluate industry OE contained in EPRI letters NDE 2012-02 and 2012-03. The EPRI letters were written to address an ultrasonic examination that did not detect the presence of axial indications that were later discovered during machining of a pressurized water reactor component. The major contributor was determined to be a weakness in the plant-specific non-destructive examination program which did not provide adequate oversight of technicians performing the inspections. Applicable ONS non-destructive examination processes and procedures were reviewed, including prerequisites for critical high profile examinations. Program enhancements were made to the following: procedures, training, personnel qualifications, prejob briefing information, component configuration verification, inspection mockup requirements, calibration techniques, required equipment validation to meet inspection requirements, and inspection results data review requirements. In addition, multiple non-destructive examination Level III reviews of EPRI Technical Report 1018181, *EPRI Guidelines for conducting Ultrasonic Examinations of Dissimilar Metal Welds* were performed to verify all associated ONS non-destructive examination guidance is aligned with this industry guidance. Other actions included adding this industry OE to future examination prejob briefings as well as applicable training materials.

   OE example 5 demonstrates the effective use of industry OE and the corrective action program to identify programmatic gaps, perform extent of condition reviews, and take timely corrective action to ensure aging effects are identified and component intended functions are maintained during the PEO.

6. In July 2012, a self-assessment was performed to review the status of LR commitment completion and readiness for the License Renewal IP-71003 NRC Phase 2 inspection. Reviews were conducted to verify open commitments were completed and previously closed commitments had not been adversely impacted by changes to the facility, programs or documents. The assessment team concluded that the Alloy 600 AMP adequately documented and completed required LR commitments. No performance deficiencies or gaps were identified. A strength was noted for program owner knowledge and consistently incorporating industry OE related to managing aging to enhance the program effectiveness.

   OE example 6 provides objective evidence that self assessments of LR activities and programs, including Alloy 600, are periodically performed to review and self-identify any required actions that are needed for continuous improvement.

7. In August 2012, the NRC performed an inspection in accordance with inspection procedure, IP-71003, and the results were documented in the corrective action program. One of the commitment items selected for inspection sample included the Alloy 600 AMP. The NRC noted the following in their inspection report:

   - This Commitment specified that prior to the PEO, ONS would implement an Alloy 600 AMP to manage cracking due to primary water stress corrosion cracking of Alloy 600 and Alloy 82/182 locations, including the Alloy 82/182 cladding in the hot leg flowmeter element. The ONS LR application identified primary water stress corrosion cracking as the applicable aging effect for reactor coolant system Alloy 600 components and Alloy 82/182 weld metal. The original Alloy 600 program, described in the LR application, relies on engineering evaluations to predict the most susceptible components, coupled with periodic volumetric nondestructive examinations to confirm the predictions. Duke Energy committed to completing inspections of the five most susceptible locations prior to ONS Unit 1 PEO (February 6, 2013). Subsequent to the issuance of the ONS renewed operating license, in September 2008, 10 CFR 50.55a mandated long term inspection requirements specified in the ASME B&PV Code Case N-722. The NRC issued Bulletin 2004-1 and endorsed EPRI's Materials Reliability Program 139 report. These documents provided guidance for the mitigation or inspection of Alloy 82/182 butt welds in reactor coolant system piping greater than four inches in diameter.
   - ONS updated the Alloy 600 Program to incorporate these additional requirements and MRP-139 guidelines. The current ONS Alloy 600 Program includes preemptive measures to replace Alloy 600 components with Alloy 690 or stainless steel components and apply full structural weld overlays over Alloy 82/182 welds using alloy 52/152 weld metal, based on service temperature. The Program also included periodic visual and volumetric examinations to detect cracking of Alloy 600/82/182 components and welds. The inspectors reviewed the licensing basis, program basis documents, implementing procedures, corrective actions, the UFSAR, inspection records; and interviewed the responsible plant personnel regarding these documents. The inspectors determined that the implementation of the current Alloy 600 Program activities provides reasonable assurance that ONS will effectively manage Alloy 600/

82/182 aging of reactor coolant system components and welds susceptible to primary water stress corrosion cracking during the PEO.

OE example 7 provides objective evidence that first LR program commitments have been properly implemented. This also demonstrates that the current Alloy 600 AMP continues to maintain program effectiveness by meeting all regulatory and industry requirements which include periodic visual and volumetric examinations to detect cracking of Alloy 600/ 82/182 components and welds. Continued implementation of the ONS Alloy 600 inspection activities provides reasonable assurance that ONS will effectively manage the aging effects in susceptible nickel alloy components prior to loss of intended function during the SPEO.

8. In December 2014, a corrective action item was initiated to track the development and communication of a comprehensive fleet Alloy 600 plan for management of remaining Alloy 600 locations by mitigation or examination. Corrective actions included the fleet Alloy 600 engineering program lead working with all Duke Energy sites to identify which Alloy 600 locations require mitigation and selection of an optimal mitigation method for those locations, determination of which locations can be adequately managed through continued examination, and documentation of the technical basis for these decisions. As part of these actions, a review of compliance with MRP-126 was performed. Site specific recommendations were documented and presented to senior management at each site. All actions were assigned and completed as a result of this corrective action entry which resulted in several Alloy 600 programmatic enhancements at each site.

ONS specific activities included development of a comprehensive Alloy 600 plan for management of remaining Alloy 600 locations by mitigation or examination. This plan included identifying which Alloy 600 locations require mitigation, selection of an optimal mitigation method for those locations, determination of which locations can be adequately managed through continued examination, and documentation of the technical basis for these decisions. ONS developed a detailed listing of Alloy 600 component examinations with the Alloy 600 pressure boundary components and locations, unique weld numbers for each location, where applicable, and the operating temperature of each component or location. The Oconee Alloy 600 program implements a long range strategy that includes continual inspection, mitigation, or replacement for specific Alloy 600 locations not previously mitigated. This Alloy 600 program plan information is considered a living plan that is modified, as needed, to account for changes in strategy, mitigation and inspection technology, or OE to ensure program effectiveness is maintained and industry and regulatory requirements are met.

OE example 8 provides objective evidence that the AMP manager critically self assesses Alloy 600 program performance and self identifies actions that support continuous improvement to ensure ongoing program effectiveness.

9. In October 2016, an Alloy 600 program self-assessment was performed to review programmatic, industry, and regulatory compliance. No gaps or areas for improvement were noted. Recommendations were identified which led to enhancing program guidance to ensure the Alloy 600 program continues to meet the intent of MRP-126 as an NEI 03-08 mandatory initiative, aligns with requirements of 10 CFR 50.55a, and has clear

programmatic responsibilities defined. Other enhancements included improvements to ensure ongoing health and performance of the Alloy 600 program.

OE example 9 demonstrates that the initial LR Alloy 600 aging management activity is being effectively managed during the PEO. Programmatic controls to perform periodic program self-assessments are currently in place to ensure the AMP will continue to enhance the program to further improve the effectiveness of the program during the initial PEO and SPEO.

10. In January 2019, an entry into the corrective action program was made to review NRC Regulatory Issue Summary 2018-06, Clarification of the Requirements for Reactor Pressure Vessel Upper Head Bare Metal Visual Examinations. The NRC issued this regulatory issue summary to clarify the requirements for bare-metal visual examination to meet the requirements of Notes 1 and 4 in Table 1 of ASME Code Case N-729-4, "*Alternative Examination Requirements for PWR Reactor Vessel Upper Heads with Nozzles Having Pressure-Retaining Partial-Penetration Welds Section XI, Division 1*." As identified in the regulatory issue summary, two recent industry events illustrate how the requirements of Code Case N-729-4 can be misinterpreted by licensees. Although these events did not occur at ONS, this industry OE is directly applicable to ONS activities where visual inspection of the reactor vessel closure head is performed to identify evidence of pressure boundary leakage and, as such, this item was evaluated for applicability to the Duke Energy fleet, including ONS.

    As a result of this OE, fleet procedures for performing the bare metal visual examinations were reviewed to ensure relevant conditions are clearly defined to ensure compliance with ASME Code Case N-729-4, Subsection 3142.1(b). These procedural requirements were reviewed to ensure examination of the as-found condition is performed prior to any removal or cleaning of boron deposits and clear steps are described to address how to proceed with the as found condition of reactor vessel heads. Procedural guidance was verified to state that relevant conditions include very small boron deposits or dusting of boron.

    OE example 10 provides objective evidence that regulatory issues and industry OE are entered into the corrective action program and evaluated to ensure appropriate actions are taken to evaluate and modify the program, as required, to ensure ongoing compliance with regulatory requirements.

11. In July 2020, an AMP effectiveness review was performed for the ISI program which included a review of Alloy 600 program inspection activities. The Oconee ISI aging management activities were evaluated against the performance criteria identified in NEI 14-12, "*Aging Management Program Effectiveness*". The ISI AMP effectiveness review included a review of the most recent augmented inspection activities performed for nickel alloy components and welds. No gaps were identified by this effectiveness review and no degradation was identified for any of the nickel alloy augmented inspections performed.

    OE example 11 provides objective evidence that the current ONS Alloy 600 Program is effectively managing aging and meeting all current LR commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the SPEO.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Cracking of Nickel Alloy Components and Loss of Material Due to Boric Acid Induced Corrosion in Reactor Coolant Pressure Boundary Components* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Cracking of Nickel Alloy Components and Loss of Material Due to Boric Acid Induced Corrosion in Reactor Coolant Pressure Boundary Components* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Cracking of Nickel Alloy Components and Loss of Material Due to Boric Acid Induced Corrosion in Reactor Coolant Pressure Boundary Components* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.6 THERMAL AGING EMBRITTLEMENT OF CAST AUSTENITIC STAINLESS STEEL (CASS)

Program Description

The *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* aging management program is a new condition monitoring program that provides reasonable assurance that specific reactor coolant pressure boundary CASS components susceptible to thermal aging embrittlement will continue to perform their intended function consistent with the current licensing basis during the SPEO. The specific reactor coolant system (Class 1) pressure boundary components consist of those made from CASS with service conditions above 250°C (482°F), including valve bodies and pump casings and covers. Oconee does not have Class 1 piping or fittings fabricated from CASS. Additionally, reactor vessel internal components fabricated from CASS are not within the scope of this aging management program and are managed by the *PWR Vessel Internals* (B2.1.7) aging management program.

For Class 1 CASS valve bodies with service conditions above 250°C (482°F), a screening for significance of thermal aging embrittlement is not required based on the results of the assessment documented in the letter dated May 19, 2000, from Christopher Grimes, NRC, to Douglas Walters, NEI (ADAMS Accession Number ML15223A635). The existing ASME Code, Section XI inspection requirements are adequate to manage thermal aging embrittlement for these valve bodies. The Section XI inspection requirements are implemented at Oconee through the Oconee *ASME Section XI Inservice Inspection, Subsections IWB, IWC and IWD* (B2.1.1) AMP.

For Class 1 CASS reactor coolant pump casings and covers with service conditions above 250°C (482°F), a screening for significance is performed as a first step to determine if thermal aging embrittlement is a potentially significant aging effect. This screening considers casting method, molybdenum content, and percent ferrite in each casting. For Class 1 CASS reactor coolant pump casings and covers that screen out, thermal aging embrittlement is considered not to be a potentially significant aging effect, and no additional actions are required under this program.

For Class 1 CASS reactor coolant pump casings and covers that screen in, thermal aging is considered to be potentially significant. Consequently, those materials are susceptible to thermal aging embrittlement. This screening was completed for the various reactor coolant pump casing and covers. Results of this screening identified four reactor coolant pump material heats that are susceptible to thermal aging embrittlement. As a second step, Oconee applied the alternative described in NUREG-2191 and addressed the flaw tolerance of the four reactor coolant pump material heats that were identified by screening to be susceptible. Specifically, the original flaw tolerance evaluation performed as a part of ASME Code Case N-481 was updated for subsequent license renewal. A bounding flaw tolerance evaluation for these four heats of materials was performed. The result successfully demonstrated that thermal aging embrittlement of these four heats of material have adequate fracture toughness to address thermal aging embrittlement for the SPEO. The successful result also means that no additional inspections or evaluations are required to address thermal aging embrittlement for the SPEO.

NUREG-2191 Consistency

The *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* is a new program that will be consistent with the ten elements of AMP XI.M12, *“Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)”* specified in NUREG-2191 (GALL- SLR), as modified by SLR-ISG-2021-02-MECHANICAL, *“Updated Aging Management Criteria for Mechanical Portions of Subsequent License Renewal Guidance, Interim Staff Guidance.”*

Exception to NUREG-2191

None

Enhancements

None

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO.

1. OE related to effective program implementation is available in the discussion of the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* AMP.

   OE example 1 provided objective evidence that the process of performing assessments is effective at identifying areas for improvement and that recommendations are appropriately implemented into the program. This will ensure that the implementation of the *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* AMP, including performing program assessments will ensure that *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* program will be implemented in accordance with program requirements during the SPEO.

2. Unit 2 Decay Heat suction line valve 3LP-2, manufactured from A351-CF8M, was inspected during refueling outage O3R26 (Spring 2012) when the valve was disassembled for maintenance. No recordable indications were identified. Unit 1 Core Flood valve 1CF-14, manufactured from A-351-CF8M, was inspected during refueling outage O1R28 (Fall 2014) when the valve was disassembled for maintenance. No recordable indications were identified.

   OE example 2 provides objective evidence that the ASME Section XI Inservice Inspection (ISI) program is effectively utilized to perform required examinations of cast austenitic stainless steel valve bodies that are within the scope of the *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* program.

A search of industry operating experience was performed, and no industry operating experience specific to thermal aging embrittlement in CASS components was identified.

The above examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the current licensing basis during the SPEO.

B2.1.7 PWR VESSEL INTERNALS

Program Description

The *PWR Vessel Internals* AMP is an existing condition monitoring program that manages change in dimensions due to void swelling, cracking, reduction of fracture toughness, loss of material, and loss of preload for the reactor vessel internals. The aging effect of cracking includes stress corrosion cracking, primary water stress corrosion cracking, irradiation-assisted stress corrosion cracking, and cracking due to fatigue/cyclic loading. Degradation due to loss of material can be induced by wear, and reduction of fracture toughness is the result of thermal aging embrittlement and neutron irradiation embrittlement. Potential causes for the aging effect of changes in dimensions are void swelling or distortion, and loss of preload can result from thermal and irradiation-enhanced stress relaxation and irradiation-enhanced creep.

The *PWR Vessel Internals* AMP relies on implementation of the inspection and evaluation guidelines in MRP-227-A. The MRP-227-A documents requirements imposed by the industry under NEI 03-08, to manage reactor vessel internals aging. The ONS reactor vessel internals inspection plan was approved by the NRC in an SER dated June 19, 2015 and is described in the Oconee UFSAR, Revision 28, Section 18.3.20. The ONS reactor vessel internals inspection plan is not affected by the ONS measurement uncertainty recapture power increase.

In accordance with NUREG-2191, AMP XI.M16A, a gap analysis is to be performed for SLRA with a focus on the component items and/or welds whose screening and/or severity of age-related degradation mechanisms changes for 60-80 years. The gap analysis is required to be based on MRP-227-A; however, since the release of MRP-227-A, the industry has prepared a revision to MRP-227 (MRP-227 Revision 1-A) and the NRC has reviewed this revision and provided its approval. The NRC SER contained in MRP-227, Revision 1-A states: *"The NRC staff finds MRP-227, Revision 1, as modified by this SE and subject to the Applicant/Licensee Action Item detailed in Section 4.0 of this SE, provides an acceptable baseline or starting point for an AMP for SLR subject to a gap analysis as described in the SRP-SLR Section 3.1.2.2.9 and GALL-SLR, AMP XI.M16A. An exception to GALL-SLR AMP XI.16A must be identified in such cases."*

The NRC has developed interim staff guidance (ISG), which updates the GALL-SLR report and standard review plan (SRP)-SLR to reflect the revised inspection and evaluation (I&E) guidelines of MRP-227, Revision 1-A. Therefore, it is appropriate to prepare the ONS gap analysis using MRP-227, Revision 1-A.

In accordance with MRP-227, Revision 1-A, the selection of reactor vessel internals items to be inspected is based on a four-step ranking process that includes the designations of *"Primary"*, *"Expansion"*, and *"Existing Programs"* (such as ASME Code, Section XI, Examination Category B-N-3 examinations of core support structures), and *"no additional measures"*. The program includes expanding examinations (i.e., *"Expansion"* components) if the observed extent of degradation for the *"Primary"* items exceeds acceptance criteria. The identified examinations for reactor vessel internals items provide reasonable assurance that the effects of age-related degradation mechanisms will be managed during the SPEO.

Gap Analysis Results

For the 80-year operating period (72 EFPY for Oconee), a gap analysis was completed that incorporates screening, categorizing, and ranking results from MRP-189, Revision 3 and engineering evaluation and assessment of age-related degradation from MRP-229 to identify revisions and/or additional inspections not listed in MRP-227, Revision 1-A. The Oconee gap analysis methodology is similar to the Westinghouse gap analysis methodology, which integrates the interim guidance from MRP 2018-022 to identify additional inspections not listed in MRP-227, Revision 1-A.

Revisions to MRP-227, Revision 1-A, for SLR Based on Time-Dependent Age-Related Degradation Mechanisms

The ONS gap analysis relies on MRP-189, Revision 3, which reports screening, categorization, and ranking of PWR internals items and welds for susceptibility and significance to time-dependent age-related degradation mechanisms for SLR for B&W designed PWRs using the screening criteria developed in Appendices A-H of MRP-175, Revision 1. Time-dependent age-related degradation mechanisms applicable to reactor vessel internals items that must be considered for SLR include irradiation-assisted stress corrosion cracking, metal fatigue, thermal aging embrittlement, irradiation embrittlement, void swelling, and irradiation-enhanced stress relaxation and irradiation-enhanced creep.

Screening criteria that require neutron exposure as an input were developed in MRP-175, Revision 1, based on a review of test data and construction of lower bound curves (e.g., Figure B-6, Plot of stress vs. neutron exposure to be used as screening criteria for irradiation-assisted stress corrosion cracking). This non-statistical bounding approach does not provide guidance for determination of uncertainty in the neutron exposure used as an input to the screening criteria. Therefore, a reasonable approach for SLR relative to the damage correlations reported in MRP-175, Revision 1, is to utilize best estimate neutron exposure at 72 EFPY as reported in MRP-189, Revision 3, which is consistent with the treatment of neutron exposure for 60-years reported in MRP-227, Revision 1-A.

Reactor Vessel Internals Neutron Exposure (displacements per atom) at 72 EFPY

As discussed in MRP-189, Revision 3, Sections 3.2, Item C and 3.3, Item B, neutron exposures are best-estimate values in units of displacements per atom at the end of 80 calendar years of operation, which are projected from existing 60-year documentation. In most instances, displacements per atom values reported in MRP-189, Revision 3, are obtained from a conservative extrapolation of discrete ordinate transport 60-year best estimate analyses to 80-years to bound the B&W fleet. The 60-year discrete ordinate transport displacements per atom values were obtained using methods that comply with Regulatory Guide 1.190 for the reactor vessel as reported in BAW-2241NP-A, Revision 2.

To support SLR, Duke Energy completed 72 EFPY Oconee-specific neutron exposure (displacements per atom) calculations for the ONS reactor vessel internals using both 2-D discrete ordinate transport methods and 3-D Monte Carlo N-Particle method. While the discrete ordinate transport methodology is compliant with RG 1.190 for the reactor pressure vessel (RPV), it is recognized that there are regions internal to the RPV where the discrete ordinate transport model may not give results of sufficient accuracy, so the Monte Carlo N-Particle method was also used for comparison. For conservatism, a 1.64% (2% assumed for conservatism) measurement uncertainty recapture power uprate was assumed.

These 72 EFPY best estimate evaluations (i.e., maximum of discrete ordinate transport and Monte Carlo N-Particle for each reactor internals component item and weld) were compared to the inputs reported in MRP-189, Revision 3. All MRP-189, Revision 3 values were found to be appropriate after comparison to the 72 EFPY ONS-specific displacements per atom values for the reactor vessel internals base metal and weld metal items.

Reactor Vessel Internals Metal Fatigue at 80-Years

As discussed in Section 4.5.1 of BAW-2248A, the ONS reactor vessel internals were designed and constructed prior to the development of ASME Code requirements for core support structures. As such, fatigue cumulative usage factors were not calculated during original construction and are only available for a select number of replacement bolting items; therefore, cumulative usage factor values were not available, with the exception of replacement bolting, for fatigue screening using the MRP-175, Revision 1 screening criterion for fatigue. This screening criterion is based on cumulative usage factor value.

As described in MRP-189, Revision 3, Section 3.2, Item H and Section 3.3, Item F, in order to support fatigue screening for SLR, an Oconee-specific finite element model of the reactor vessel internals was created. The finite element model was utilized to develop a ranking of the reactor vessel internals items with respect to susceptibility to fatigue by using stresses of the modeled component items and welds considering dead weight with and without fuel, preload, thermal transients, gamma heating, hydraulic loads, and loads associated with core clamping (including reactor vessel ledge radial motions). This evaluation only considered reactor vessel internals items and welds critical for core support, safe shutdown, or maintaining a coolable geometry. Items that do not affect any of these three functions were only included if their presence affects the loading on a critical item or weld. In addition, reactor vessel internals items that were screened in for fatigue in the previous revision, MRP-189, Revision 2 for 60-years, (e.g., the baffle-to-former bolts) remain screened in for SLR, and were not modeled in detail for the fatigue ranking analysis.

Of the component items considered in this fatigue ranking evaluation, the core barrel cylinder was found to be the most potentially susceptible. A fatigue calculation of the ONS core barrel cylinder confirmed that the cumulative usage factor value for the core barrel cylinder is less than one (1). Therefore, the fatigue age-related degradation mechanism does not screen in for the ONS component items considered in the fatigue ranking evaluation.

Applicability of MRP-227, Revision 1-A to ONS

As noted in the NRC safety evaluation to MRP-227, Revision 1-A, Section 3.6.1, confirmation of four items contained in Section 2.4 of MRP-227, Revision 1-A, Applicant/

Licensee Action Item 1, *"Applicability of FMECA and Functionality Analysis Assumptions,"* is required for 60-years. Compliance with these requirements was demonstrated for 60-years relative to MRP-227, Revision 1-A and, at present, will not change for the SPEO.

1. 30 years of operation with high-leakage core loading patterns (fresh fuel assemblies loaded in peripheral locations) followed by implementation of a low-leakage fuel management strategy for the remaining 30 years of operation, as well as the average core power levels and proximity of active fuel to the upper core support plate satisfies limits as described in Appendix B for Westinghouse/Combustion Engineering plants;

2. The power plant has operated for the majority of its lifetime as a base-loaded unit and is currently operating as a base-loaded power plant, in that the unit operates at fixed thermal power levels and does not usually vary power on a calendar or load demand schedule;

3. No design changes beyond those identified in general industry guidance or recommended by the original vendors; and

4. The components and material class of each functional component are as listed in the latest revision of MRP-189 or MRP-191, as applicable to the individual plant design

The following listing identifies the changes that are included in the *PWR Vessel Internals* AMP for SLR based on the Oconee gap analysis, which considered time-dependent damage mechanisms discussed above. The changes SLR for Oconee are made relative to MRP-227, Revision 1-A, Table 4-1 (*Primary*), Table 4-4 (*Expansion*), and Table 5-1 (*Examination Acceptance* and *Expansion Criteria*); all remaining entries in MRP-227, Revision 1-A, Table 4-1, Table 4-4, and Table 5-1 are not revised. Note there are no *Existing Programs* for the B&W units in MRP-227, Revision 1-A or for Oconee.

Revisions to MRP-227, Revision 1-A, Table 4-1, B&W Plants Primary, for the ONS Units

The following listing identifies the changes that are included in the *PWR Vessel Internals* AMP:

- General: removed visual VT-3 examination of high-strength bolt locking devices.

- Examination method/frequency for the plenum cover assembly and core support shield assembly (Item B1) was updated. The initial one-time physical measurement required by the MRP-227 guideline is complete for all Oconee units; no relevant indications have been observed. Subsequent visual (VT-3) examination are to be performed during each 10-year ISI interval.

- Examination coverage for the plenum cover assembly and core support shield assembly (Item B1) was updated. Accessible top surfaces of the plenum cover support ring/plenum cover weldment rib pads and CSS top flange when the RV closure head and plenum assembly were removed as areas for examination.

- The expansion link to vent valve bodies for the control rod guide tube assembly, control rod guide tube spacer castings (Item B2) was removed. It has been determined that the vent valve bodies are not susceptible to thermal aging embrittlement (see MRP-189, Revision 3, Section 3.2, Item J.2). There is no expansion link for the control rod guide tube assembly, control rod guide tube spacer castings (Item B2).

- New age-related degradation mechanisms were added for the core support shield assembly, upper core barrel bolts (Item B7). The new age-related degradation mechanisms are irradiation-enhanced stress relaxation and irradiation-enhanced creep, fatigue, and wear.

- An expansion link note was added for the core support shield assembly, upper core barrel bolts (Item B7). The note states that the primary-expansion relationship between the upper core barrel, lower core barrel, and flow-distributor bolts and the upper thermal shield and lower thermal shield bolts/studs is for stress corrosion cracking only.

- A new expansion link note was added for the core barrel assembly, lower core barrel bolts (Item B8). The note states that the primary-expansion relationship between the upper core barrel, lower core barrel, and flow distributor bolts and the upper thermal shield and lower thermal shield bolts/studs is for stress corrosion cracking only.

- A new age-related mechanism was added for the core barrel assembly, baffle-to-former bolts (Item B9). The new age-related degradation mechanism is void swelling.

- An expansion link note was added for the core barrel assembly, baffle-to-former bolts (Item B9). The note states that the core barrel-to-former bolts are Category A for void swelling, so expansion does not apply.

- A new age-related degradation mechanism was added for the core barrel assembly, baffle plates (Item B10). The new age-related degradation mechanism is void swelling.

- Expansion links for the core barrel assembly, baffle plates (Item B10) were revised. core barrel cylinder (including vertical and circumferential seam welds) and lower grid rib section were removed as expansion links. Former plates were retained as an expansion link.

- An expansion link note was added for the flow distributor assembly, flow distributor bolts (Item B12). The note states the Primary-Expansion relationship between the upper core barrel, lower core barrel, and flow distributor bolts and the upper thermal shield and lower thermal shield bolts/studs/nuts is for stress corrosion cracking only.

- An age-related degradation mechanism was removed for the incore monitoring instrumentation guide tube assembly, incore monitoring instrumentation guide tube spiders, incore monitoring instrumentation guide tube spider-to-lower grid rib section welds (Item B15). Thermal aging embrittlement was removed as an applicable degradation mechanism for the incore monitoring instrumentation spiders as ferrite screening has determined that these items are not susceptible to thermal aging embrittlement.

- A new expansion link for the incore monitoring instrumentation guide tube assembly, incore monitoring instrumentation guide tube spiders, incore monitoring instrumentation guide tube spider-to-lower grid rib section welds (Item B15) was added. The new expansion link is upper grid fuel assembly support pad items: pad, Alloy X-750 dowel, cap screws, and their locking welds (Item B15.2).

- Examination coverage for the incore monitoring instrumentation guide tube assembly, incore monitoring instrumentation guide tube spiders, incore monitoring instrumentation guide tube spider-to-lower grid rib section welds (Item B15) was clarified. Clarification of the meaning of adjacent was provided along with a corresponding note.

- New Primary Items were added:

    - Core barrel assembly: core barrel cylinder top flange circumferential weld heat affected zone (Unit 2 only) (Item B16)
    - Core barrel assembly: core barrel cylinder center circumferential weld regions (Unit 2 only) (Item B17)
    - Lower grid rib assembly: lower grid rib section (Item B18)

The new Primary Items have the following Attributes:

Table B2.1.7-1: MRP-227-1-A Table 4-1, B&W Plants Primary Items

Primary Component Item	Applicability	Effect (Mechanism)	Expansion Link	Examination Method/ Frequency	Examination Coverage
B16.Core Barrel Assembly Core Barrel cylinder top flange circumferential weld HAZ	ONS Unit 2	Cracking (SCC, IE), including the detection of surface-breaking crack-like indications	None	Enhanced visual (EVT-1) examination, ultrasonic (UT) examination, or eddy current (ECT) examination no later than two refueling outages from the beginning of the LR period. Subsequent examination during each 10- year ISI interval Alternately, in lieu of examination, this item can be addressed by evaluation that is submitted for NRC Staff approval.	100% of the accessible OD surfaces of ¾" of the adjacent base metal to the core barrel cylinder top flange weld.
B17.Core Barrel Assembly Core barrel cylinder center circumferential weld region	ONS Unit 2	Cracking (IASCC, IE), including the detection of surface-breaking crack-like indications and/or readily detectable cracking.	None	Enhanced visual (EVT-1) examination, ultrasonic (UT) examination, or eddy current (ECT) examination no later than two refueling outages from the beginning of the license renewal period. Subsequent examination during each 10- year ISI interval. Alternately, in lieu of examination, this item can be addressed by evaluation that is submitted for NRC Staff approval.	100% of the accessible weld length of the OD of the center circumferential weld and ¾" of the adjacent base metal.
B18.Lower Grid Assembly Lower grid rib section	ONS Unit 1 ONS Unit 2 ONS Unit 3	Cracking (IE), including the detection of readily detectable cracking	None	Visual (VT-3) examination no later than two refueling outages from the beginning of the LR period. Subsequent examination during each 10- year ISI interval.	100% of accessible surfaces of ¼" of the adjacent base metal of the lower grid rib section to the spider-to-lower grid rib section welds

Revisions to MRP-227, Revision 1-A, Table 4-4, B&W Plants Expansion, for the ONS Units

The following listing identifies the changes that are included in the ONS *PWR Vessel Internals* AMP:

- General: Removed visual VT-3 examination of high-strength bolt locking devices.
- Vent valve assembly, vent valve bodies (Item B2.1) was removed as an expansion Item as it has been determined that these component items are not susceptible to thermal aging embrittlement (see MRP-189, Revision 3, Section 3.2, Item J.2).
- A new age-related degradation mechanism for the core barrel assembly, baffle-to-baffle bolts (Item B9.1) was added. The new age-related degradation mechanism is void swelling.
- A new age-related degradation mechanism for the core barrel assembly, former plates (Item B10.2) was added. The new age-related degradation mechanism is void swelling.
- Core barrel cylinder (including vertical and center circumferential seam welds) (Item B10.1) was reclassified as “No additional Measures” for ONS Unit 1 and ONS Unit 3. The vertical seam welds were also reclassified as “No Additional Measures” for ONS Unit 2. The top flange circumferential weld heat affected zone and center circumferential weld region were reclassified as Primary Items for ONS Unit 2 only.
- Lower grid rib section (Item B10.3) was reclassified as a primary item.
- Examination method/frequency for the lower grid assembly, lower thermal shield studs (Item B8.1) was updated. The updated examination method is a new visual (VT-3) examination of the lower thermal shield nuts.
- New expansion items were added based on a revision to primary item incore monitoring instrumentation guide tube spiders and spider-to-lower grid rib section welds (Item B15).

The new expansion items have the following attributes:

Table B2.1.7-2: MRP-227-1-A Table 4-4, B&W Plants Expansion Items

Expansion Component Item	Applicability	Effect (Mechanism)	Primary Link	Examination Method/ Frequency	Examination Coverage
Upper Grid Assembly B15.2.Upper grid fuel assembly support pad component items: pad, Alloy X-750 dowel, cap screws, and their locking welds	ONS Unit 1 ONS Unit 2 ONS Unit 3	Cracking (IE), including the detection of separated or missing welds, missing support pads, dowels, cap screws and locking welds, or misalignment of the support pads	B15.a. incore monitoring instrumentation guide tube spiders and B15.b. incore monitoring instrumentation guide tube spider-to-lower grid rib section welds	Visual (VT-3) examination. Subsequent examination during each 10-year ISI interval unless an applicant/ licensee provides an evaluation for NRC Staff approval that justifies a longer interval between inspections	Accessible surfaces of the pads, dowels, cap screws, and associated welds for 100% of the upper grid fuel assembly support pads.

Revisions to MRP-227, Revision 1-A, Table 4-7, B&W Plants Existing Programs

For 60-years, no existing generic industry programs were considered sufficiently specific for monitoring the aging effects addressed by MRP-227, Revision 1-A, for B&W plants. Therefore, no reactor vessel internals items for B&W plants were placed into the existing programs group, and there is no Table 4-7. This conclusion has not changed for SLR.

Revisions to MRP-227, Revision 1-A, Table 5-1, B&W Plants Acceptance and Expansion Criteria

The following listing identifies the changes that are included in the *PWR Vessel Internals* AMP:

- General: removed references to visual VT-3 examination of high-strength bolt locking devices.
- The expansion link to vent valve bodies for the control rod guide tube assembly spacer castings (Item B2) was removed.
- Expansion criteria wording for the core barrel assembly, upper core barrel bolts (Item B7) was updated to include expansion to 100% of the lower thermal shield nuts.
- Expansion Criteria wording for the core barrel assembly, lower core barrel bolts (Item B8) was updated to include expansion to 100% of the lower thermal shield nuts.
- Expansion links to the core barrel cylinder (including vertical and center circumferential seam welds) (Item B10.1) and lower grid rib section (Item B10.3) for the core barrel assembly, baffle plates (Item B10) were removed.
- Expansion criteria for core barrel assembly, baffle plates (Item B10) was updated. The expansion criteria was updated to remove the expansion links to core barrel cylinder (including vertical and center circumferential seam welds) (Item B10.1) and lower grid rib section (Item B10.3) from the wording.
- Expansion criteria wording for the flow distributor assembly, flow distributor bolts (Item B12) was updated to include expansion to 100% of the lower thermal shield nuts.
- An expansion link for the incore monitoring instrumentation guide tube assembly, incore monitoring instrumentation guide tube spiders, and incore monitoring instrumentation guide tube spider-to-lower grid rib section welds (Item B15), was added. The expansion link added was upper grid fuel assembly support pad items: pad, Alloy X-750 dowel, cap screws, and their locking welds (Item B15.2). This item expands from the existing expansion item lower grid assembly, lower grid fuel assembly support pad component items: pad, pad-to-rib section welds, Alloy X-750 dowel, cap screws, and their locking welds (Item B15.1) as a secondary expansion as shown in the table below.

- New primary items were added:
  - Core barrel assembly, core barrel cylinder top flange circumferential weld heat affected zone (ONS Unit 2 only) (Item B16)
  - Core barrel assembly, core barrel cylinder center circumferential weld region (ONS Unit 2 only) (Item B17)
  - Lower Grid Assembly, lower grid rib section (B18)

The new Primary Items have the following Attributes:

Table B2.1.7-3: MRP-227-1-A Table 5-1, B&W Plants Acceptance and Expansion Criteria

Primary Component Item	Applicability	Primary Item Examination Criteria	Expansion Link	Expansion Criteria	Expansion Item Examination Acceptance Criteria
B16.Core Barrel Assembly Core Barrel cylinder top flange circumferential weld heat affected zone	ONS Unit 2	Enhanced visual (EVT-1) examination, ultrasonic (UT) examination, or eddy current (ECT) examination. The specific relevant condition is a detectable crack-like surface indication	None	None	None
B17.Core Barrel Assembly Core barrel cylinder center circumferential weld region	ONS Unit 2	Enhanced visual (EVT-1) examination, ultrasonic (UT) examination, or eddy current (ECT) examination. The specific relevant condition is a detectable crack-like surface indication	None	None	None
B18.Lower Grid Assembly Lower grid rib section	ONS Unit 1 ONS Unit 2 ONS Unit 3	Visual (VT-3) examination. The specific relevant condition is readily detectable cracking in the lower grid rib section.	None	None	None

Table B2.1.7-3: MRP-227-1-A Table 5-1, B&W Plants Acceptance and Expansion Criteria

Primary Component Item	Applicability	Primary Item Examination Criteria	Expansion Link	Expansion Criteria	Expansion Item Examination Acceptance Criteria
B15.Incore Monitoring Instrumentation Guide Tube Assembly a. Incore Monitoring Instrumentation guide tube spiders b. Incore Monitoring Instrumentation guide tube spider-to-lower grid rib section welds	ONS Unit 1 ONS Unit 2 ONS Unit 3	a.) Visual (VT-3) examination. The specific relevant conditions for the Incore Monitoring Instrumentation guide tube spiders are fractured or missing spider arms or a spider arm that does not align with the lower grid fuel assembly support pad screw (as viewed from the top). b.) Visual (VT-3) examination. The specific relevant conditions for the Incore Monitoring Instrumentation spider-to-lower grid rib section welds are separated or missing welds.	B15.1 Lower grid fuel assembly support pad component items: pad, pad-to-rib section welds, Alloy X-750 dowel, cap screw, and their locking welds. B15.2.Upper grid fuel assembly support pad items: pad, Alloy X-750 dowel, cap screws, and their locking welds.	Confirmed evidence of relevant conditions at two or more Incore Monitoring Instrumentation guide tube spider locations or Incore Monitoring Instrumentation guide tube spider-to-lower grid rib section welds shall require that the VT-3 examination be expanded to include accessible surfaces of the pads, dowels, cap screws, and associated welds for 100% of the lower fuel assembly support pads by the completion of the next refueling outage. Confirmed evidence of relevant conditions at two or more accessible surfaces of the pads, dowels, cap screws, and associated welds for 100% of the lower fuel assembly support pads shall require that the VT-3 examination be expanded to include accessible surfaces of the pads, dowels, cap screws, and associated welds for 100% of the upper fuel assembly support pads by the completion of the next refueling outage.	The specific relevant conditions for the VT-3 of the upper and lower grid fuel assembly support pad component items (pads, pad-to-rib section welds, Alloy X-750 dowels, cap screws, and their locking welds) are separated or missing welds, missing support pads, dowels, cap screws and locking welds, or misalignment of the support pads.

The *PWR Vessel Internals* AMP was implemented to support the PEO (60-years). The program requirements and implementation procedures have been previously reviewed and evaluated by the NRC Staff and a determination was made that the effects of aging will be adequately managed. Revisions to the ONS *PWR Vessel Internals* AMP as identified herein through the gap analysis, will ensure that the effects of aging will be adequately managed so that the reactor vessel internals intended function(s) will be maintained consistent with the CLB for the SPEO, as required by 10 CFR 54.21(a)(3).

NUREG-2191 Consistency

The *PWR Vessel Internals* AMP is an existing program that, following enhancements, will be consistent with NUREG-2191, Section XI.M16A, *PWR Vessel Internals*, as modified by SLR-ISG-2021-01-PWRVI, *Updated Aging Management Criteria for Reactor Vessel Internal Components for Pressurized-Water Reactors*, with the enhancements noted below.

Exception to NUREG-2191

None

Enhancements

The following enhancement(s) will be implemented to the following program element(s): Detection of Aging Effects (Element 4) and Acceptance Criteria (Element 6)

1. The *PWR Vessel Internals* AMP will be updated as necessary to provide guidance for implementing the changes to primary and expansion items in MRP-227, Rev 1-A, Tables 4-1, 4-4 (and Table 5-1 for Element 6 only), as modified by the ONS gap analysis for SLR reported in Appendix B2.1.7 of the ONS SLRA. (Elements 4 and 6)

Operating Experience

Based on a broad search of pertinent ONS and industry OE, the following examples provide objective evidence that the *PWR Vessel Internals* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2013, an INPO PWR materials review was conducted and included a review of the *PWR Vessel Internals* AMP. The review found that extensive preparations for Internals inspections for license renewal and 10-year interval inservice inspections resulted in the inspection of thousands of items in the reactor vessel and vessel internals during one refueling outage. The preparations included the use of integrated station and vendor planning, risk assessments, engineering preparations, contingency planning, repair plans, and remote non-destructive examination tooling. The review concluded that the extensive degree of inspection planning and execution was a beneficial practice.

OE example 1 provides objective evidence that the ONS program manager critically self-assesses program performance and self-identifies actions that support continuous improvement.

2. In 2014, an indication in the Oconee Unit 1 lower grid rib section was discovered while inspecting an adjacent component. Prior to discovery of the indication, inspection of the lower grid rib section was not required by MRP-227-A. As a result of this inspection finding, the lower grid rib section was added as an expansion component to MRP-227, Revision 1-A and is being upgraded to a primary item for SLR.

   OE example 2 provides objective evidence that plant-specific OE that potentially involves aging is evaluated and used to adjust the program as necessary.

3. In 2020, an AMP effectiveness review (AR 2336986-19) was performed for the *PWR Vessel Internals* AMP (UFSAR Section 18.3.20). The purpose of the review was to ensure that the *PWR Vessel Internals* AMP remained effective at detecting, monitoring, and managing the effects of aging so that in-scope components will continue to perform their intended functions during the period of extended operation. The review concluded that (a) every license renewal commitment had been resolved, and that planned updates to the program were being tracked; (b) initial exams for all components were performed in the fourth ISI Interval for each unit; (c) all relevant indications found during the inspections were entered into the corrective action program for resolution, and (d) all inspection results were transmitted to the EPRI materials reliability program within six months of the inspections.

   OE example 3 provides objective evidence that first LR program commitments and activities are being properly implemented to identify and manage aging effects of in-scope components. The corrective action program is being effectively used to evaluate and correct the identified deficiencies. Continued implementation of the program will assure degraded conditions will be identified and corrected during the SPEO.

OE examples 4 through 6 below represent industry events that have been evaluated using the corrective action program to identify potential impacts to the *PWR Vessel Internals* AMP. The ONS program manager actively participates in industry initiatives that evaluate and provide resolution of applicable OE items, such that adjustments to the program can occur. Through use of the corrective action program, these actions ensure that aging effects are addressed such that in-scope components will continue to perform their intended functions.

4. There is a history of baffle-to-former bolt ultrasonic test indications in the industry, likely due to irradiation-assisted stress corrosion cracking and/or fatigue affecting the bolts. For the initial MRP-227 inspections, this has primarily affected certain Westinghouse-designed units; guidance from the industry has been evaluated by the NRC. Evaluation in 2016 for potential impacts to ONS found that the ONS Internals design does not present the same characteristics that are attributed to the baffle-to-former bolt failures observed in certain Westinghouse units. It was concluded that the MRP-227 guidance concerning baffle-to-former bolt inspections was adequate at the time, and no additional actions were necessary.

5. During the spring 2018 MRP-227-A inspection of the core support barrel welds at a Combustion Engineering designed PWR, visual indications of cracking were observed adjacent to the middle girth weld and middle axial weld of the core support barrel, in and near the high neutron fluence core beltline region. A supplemental volumetric inspection of the area confirmed that the indications were flaws with some depth, and that none of the flaws had propagated through-wall. To date, no apparent cause has been determined, but the observations may be due to irradiation-assisted stress corrosion cracking. This OE resulted in further review of the B&W fabrication records including those for ONS. As a part of the records search, it was found that weld repairs occurred following post-weld stress relief of the ONS Unit 2 core barrel welds. The ONS program manager is actively involved in the industry response to this ongoing issue and is using the corrective action program to identify potential impacts and actions for the program, including a determination of the timing for inspections and improvements in core barrel inspection techniques.

6. Thermal shield attachment bolting failures have occurred recently at a Westinghouse 4-Loop downflow plant. While this condition does not impact the ability to achieve and remain in safe shutdown, operators of Westinghouse-designed PWR plants could likely identify this condition during their refueling outages which may impede access to the fuel assemblies for defueling operations. Evaluation in 2019 for potential impacts to ONS concluded that severed bolts will be prevented from backing out due to the B&W design. No further programmatic actions were found to be necessary.

OE examples 7 through 10 below describe relevant indications found during recent *PWR Vessel Internals* AMP inspections at ONS and the actions taken using the corrective action program. OE examples 7 through 10 provide objective evidence that program inspections, along with implementation of the corrective action program, effectively monitors in-scope structures and components to assure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO

7. Oconee Unit 1, 2012: (a) a crack-like indication was found on the vent valve jack-screw of one vent valve; (b) five lower core barrel bolts with crack-like indications were discovered during ultrasonic testing; (c) one lower core barrel bolt locking device was found with a missing weld on one side and a small weld on the other side; (d) four baffle-to-former bolts were not inspectable due to large welds on locking bars; and (e) one flow distributor bolt with a crack-like indication was discovered during ultrasonic testing. The corrective action program was used to address the relevant conditions identified during the examination. A causal evaluation found that the vent valve condition was legacy damage caused by contact with the plenum assembly as it was being manipulated during previous refueling outages. Contact between the vent valve and plenum assembly was found to be caused by inadequacies associated with the Internals lifting equipment; the lifting equipment issues were resolved. Other corrective actions included (a) extent-of-condition inspection of vent valves for the other ONS units (completed), (b) a procedural change to verify the correct vent valve jack screw configuration to help prevent damage during lifting of the plenum assembly (completed), and (c) an evaluation which showed that the accident analysis for core bypass flow bounded potential leakage past the damaged vent valve (completed). The vent valve was replaced. Actions to address the conditions found for other internals components included (a) structural evaluations (completed), (b)

evaluations of potential impacts to fuel performance (completed), and (c) loose parts evaluations (completed). These evaluations identified no impacts to the safe operation of the plant or to the ability of the Internals to perform their intended functions.

8. Oconee Unit 1, 2020: (a) twenty-five baffle-to-former bolts with crack-like indications were discovered during ultrasonic testing; (b) four baffle-to-former bolts were not inspectable due to large welds on locking bars (same results as those found in 2012); (c) a crack-like indication on the locking bar of one baffle-to-former bolt was discovered during ultrasonic testing. The corrective action program was used to address the relevant conditions identified during the examination. Actions taken to disposition the inspection results included (a) the use of structural analysis tools that considered the intact bolting pattern and projected failure simulations (completed), (b) one-cycle justification for continued operation (completed), (c) loose parts evaluation (completed), and (d) evaluation of programmatic changes to prevent loss of intended function (ongoing). The results of these evaluations identified no impacts to the safe operation of the plant or to the ability of the Internals to perform their intended functions.

9. Oconee Unit 2, 2013: (a) various issues were found with the vent valve jack-screw locking devices (see OE example 7); (b) one lower core barrel bolt with a crack-like indication was discovered during ultrasonic testing; (c) one barrel-to-former bolt was not inspectable due to incorrect probe seating; (d) two flow distributor bolts with crack-like indications were discovered during ultrasonic testing. The corrective action program was used to address the relevant conditions identified during the examinations. A causal evaluation found that the vent valve condition was legacy damage caused by contact with the plenum assembly as it was being manipulated during previous refueling outages. Contact between the vent valve and plenum assembly was found to be caused by inadequacies associated with the Internals lifting equipment; the lifting equipment issues were resolved. Other actions included an evaluation which showed that the accident analysis for core bypass flow bounded potential leakage past the damaged vent valve (completed). The vent valve was replaced. Actions to address the conditions found for other internals components included (a) structural evaluations (completed), (b) evaluations of potential impacts to fuel performance (completed), and (c) loose parts evaluations (completed). These evaluations identified no impacts to the safe operation of the plant or to the ability of the Internals to perform their intended functions.

10. Oconee Unit 3, 2014: (a) various issues were found with vent valve jack-screw locking devices (see OE example 7); (b) two upper core barrel bolts with crack-like indications were discovered during ultrasonic testing (same results as those found in 1984, 1985, and 1987); (c) three lower core barrel bolts with crack-like indications were discovered during ultrasonic testing (same results as those found in 1987); (d) one barrel-to-former bolt with a crack-like indication was discovered during ultrasonic testing; (e) one barrel-to-former bolt was not inspectable due to incorrect probe seating; (f) one flow distributor bolt with a crack-like indication was discovered during ultrasonic testing; (g) one incore monitoring instrumentation (IMI) guide tube spider casting weld was found with a linear indication just below the vertical weld toe in the base material of the lower grid; and (h) one incore monitoring instrumentation guide tube spider casting weld was found with a linear indication coming from the top of the casting at the weld toe and going downward into the casting material. The inspection of the lower grid section was considered to be an

ASME Section XI, Examination Category B-N-3 component, and not considered to be associated with an MRP-227-A primary item. Using the corrective action program, an evaluation found the vent valves to be acceptable for continued operation, and recommended that vent valve condition should be monitored during future valve exercise operations; this recommendation was captured in a procedure revision to re-examine the vent valves each refueling outage to verify the condition has not changed (completed). The IMI guide tube condition was addressed for acceptability for continued operation using the corrective action program with a structural and loose parts evaluation (completed). Actions to address the conditions found for other internals components included (a) structural evaluations (completed), (b) evaluations of potential impacts to fuel performance (completed), and (c) loose parts evaluations (completed). These evaluations identified no impacts to the safe operation of the plant or to the ability of the Internals to perform their intended functions.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *PWR Vessel Internals* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *PWR Vessel Internals* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry operating experience.

<u>Conclusion</u>

The implementation of the *PWR Vessel Internals* AMP will provide reasonable assurance that aging effects of the Oconee reactor vessel internals will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.8 FLOW-ACCELERATED CORROSION

Program Description

The *Flow-Accelerated Corrosion* AMP is an existing condition monitoring program that manages wall thinning caused by flow-accelerated corrosion in carbon steel piping and piping components exposed to reactor coolant, steam, and treated water environments. The program is based on commitments made in response to NRC GL 89-08, *"Erosion/Corrosion-Induced Pipe Wall Thinning,"* and relies on implementation of the Electric Power Research Institute (EPRI) guidelines in the Nuclear Safety Analysis Center (NSAC)-202L, Revision 4 for an effective flow-accelerated corrosion program.

CHECWORKS™ is used to predict component wear rates and remaining service life in the systems susceptible to flow-accelerated corrosion which provides reasonable assurance that structural integrity will be maintained between inspections. The model is revised if any changes in operating conditions or other factors that affect flow-accelerated corrosion (e.g., plant chemistry, power uprate) have occurred since the model was last updated. Changes may also result from plant modifications that effect flow-accelerated corrosion behavior such as material changes, the addition of piping systems, piping system configuration changes, and the addition or replacement of in-line components. The CHECWORKS™ model is also refined by importing actual volumetric inspection data thickness measurements and re-running wear rate analyses. This improves the predictive capability of the model to ensure that intended functions are maintained.

The program also manages wall thinning caused by mechanisms other than flow-accelerated corrosion in carbon steel and stainless steel piping and piping components exposed to treated water and treated borated water environments in situations where periodic monitoring is used in lieu of eliminating the cause of various erosion mechanisms.

The program includes: (a) identifying all susceptible piping systems and components; (b) developing flow-accelerated corrosion predictive models to reflect component geometries, materials, and operating parameters; (c) performing analysis of flow-accelerated corrosion models and, with consideration of OE, selecting a sample of components for inspections; (d) inspecting components; (e) evaluating and trending inspection data to determine the need for inspection sample expansion, repairs, or replacements, and to schedule future inspections; and (f) incorporating inspection data to refine flow-accelerated corrosion models.

Flow-accelerated corrosion inspections and inspections performed for wall thinning caused by mechanisms other than flow-accelerated corrosion that do not meet acceptance criteria are evaluated in accordance with the corrective action program.

NUREG-2191 Consistency

The *Flow-Accelerated Corrosion* AMP is an existing program that will be consistent with the ten elements of AMP XI.M17, *"Flow Accelerated Corrosion"* specified in NUREG-2191 with the enhancement described below.

Exception to NUREG-2191

None

Enhancements

The following enhancement will be implemented in the following program element: Detection of Aging Effects (Element 4)

1. Reassess infrequently used piping systems excluded from the scope of the program to ensure adequate bases exist to justify this exclusion for the SPEO. (Element 4)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Flow-Accelerated Corrosion* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In September 2020, in accordance with NEI 14-12, a program effectiveness review was performed of the *Flow Accelerated Corrosion* program, as described in UFSAR Section 18.3.9. The purpose of the effectiveness review was to confirm that the intent of the existing AMP, which is to monitor the condition of flow-accelerated corrosion susceptible piping within the scope of LR, is being effectively implemented during the first PEO. The key aspects of the program were reviewed. The review confirmed that the program has been implemented in accordance with the commitments made when the original station operating license was renewed and that aging management activities have been completed as scheduled. Multiple aspects of the program were assessed, including the following: commitment management, implementing activity completion and results documentation, corrective actions, and OE. The effectiveness review found the *Flow Accelerated Corrosion* program is effective and intended functions will continue to be maintained consistent with the CLB for the SPEO.

   OE example 1 demonstrates that the *Flow Accelerated Corrosion* program is periodically reviewed for effectiveness. Continued implementation of the program will ensure degraded conditions will be identified and corrected during the SPEO.

2. In June 2012 during work activities to repair a pinhole leak in piping downstream of a test throttle valve, cavitation damage was identified. The valve and the affected piping are used during testing of an Oconee Unit 3 motor driven emergency feedwater pump. The valve and a portion of the downstream piping were replaced during the repair with stainless steel material to mitigate the effects of cavitation.

   The affected piping and valve were not subject to inspection by the *Flow Accelerated Corrosion* program because they had screened out for two reasons: 1) the temperature is less than 200^{o}F as well as single phase, and 2) the line containing the test valve is in service less than 2% of the plant operating time because it is used for testing.

A corrective action was generated to either modify the piping to eliminate cavitation or create preventive maintenance activities to periodically inspect points to monitor test valve and the downstream piping for cavitation. Preventive maintenance activities were created to monitor inspection points for the test valve and the downstream piping for cavitation as well as for the same locations on Oconee Unit 1 and Unit 2. Subsequent inspections were performed in 2017 for all three units and included 100% scan ultrasonic testing of the subject piping to ensure that any localized degradation due to cavitation was detected. Evaluation of the results of these inspections concluded the piping would remain fit for service through the next scheduled inspection in 2023.

OE example 2 provides objective evidence that plant-specific OE that potentially involves aging is evaluated and used to adjust the program as necessary. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality, address extent of conditions, and implement appropriate long-term actions.

3. In May 2016 several condenser tubes were identified to have experienced erosion on the tube outer diameter in the Oconee Unit 3 main condenser and there was concern the tubes may erode to the point portions of the tubes may become loose parts in the condenser. The issue was entered into the corrective action program for evaluation of the potentially adverse condition. The tubes identified as having erosion, the 1st and 2nd outermost rows of tubes, had previously been plugged based upon eddy-current test results and were no longer in service.

   A walkdown inside the condenser was executed to perform a close up visual inspection of the tubes that exhibited indications of external erosion. Additionally, eroded tubes were physically checked by grasping the tube and shaking to validate the tubes had rigidity and structural integrity. An engineering evaluation determined no tubes should be removed based on the visual and hands on inspection. It was also observed that the presence of out of service tubes along the periphery of tube bundles provides a level of protection to the in service tubes from steam erosion and potential impacts from foreign material intrusion.

   Condenser tubes that remain in service will continue to be periodically eddy-current tested for integrity and plugged when determined by an engineering evaluation. Out of service condenser tubes will be visually inspected periodically and evaluated for removal when erosion is identified.

   OE example 3 provides objective evidence that program inspections will effectively monitor in-scope SSCs to ensure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO. This OE also demonstrates the effectiveness of the corrective action program to identify and evaluate adverse conditions, and to drive appropriate enhancements in station programs and procedures.

4. In January 2019, a small bore piping leak occurred on Oconee Unit 2 upstream of a valve in Oconee Unit 2 moisture separator reheater 2nd stage reheater vent piping. There was no threat to unit operation and an extent of condition evaluation was performed. The leak was identified as a weld defect and a leak repair enclosure installed. However, a corrective action was initiated to drive the replacement of this piping during a future outage since the sister piping on Unit 1 and 3 had previously been replaced. The subject piping was subsequently replaced during the fall 2019 Unit 2 refueling outage. This was not a flow-accelerated corrosion induced leak, but the flow-accelerated corrosion program took the opportunity to proactively replace pipe since it was susceptible. The corrective action also proactively initiated work activities to have the 2nd stage reheater vent piping replaced with a flow-accelerated corrosion resistant material for all other Unit 2 moisture separator reheaters.

   OE example 4 demonstrates how the Oconee *Flow-Accelerated Corrosion* AMP effectively applies the corrective action program to identify and evaluate conditions adverse to quality. This example also demonstrates that the corrective action program is used effectively to implement appropriate long-term actions. The result was repair and upgrade of the piping to flow-accelerated corrosion resistant material at the next refueling outage as well as scope expansion to upgrade the piping of similar configuration to mitigate the possibility of a similar occurrence in the future.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Flow-Accelerated Corrosion* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Flow-Accelerated Corrosion* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

<u>Conclusion</u>

The implementation of the *Flow-Accelerated Corrosion* AMP, with the noted enhancement, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.9 BOLTING INTEGRITY

Program Description

The *Bolting Integrity* AMP is an existing condition monitoring program which manages loss of preload, cracking, and loss of material of safety related and non-safety related closure bolting on pressure-retaining components. The program utilizes recommendations and guidelines delineated in NUREG-1339, EPRI NP-5769, TR-1015336, and TR-1015337 for material selection, use of approved lubricants, proper torqueing, and leakage evaluations which are implemented during plant surveillance and maintenance activities.

The program activities provide for aging management of closure bolting on pressure-retaining components within the scope of SLR. The program includes periodic inspection of closure bolting on pressure-retaining components for indication of loss of preload, cracking, and loss of material. The program also credits visual inspection of pressure-retaining bolted joints in ASME Class 1, 2, and 3 systems for leakage and age-related degradation during system pressure tests performed in accordance with ASME Section XI. In addition, the *Bolting Integrity* AMP credits volumetric, surface, and visual inspections of ASME Section XI Class 1, 2, and 3 bolts, nuts, washers, and other associated bolting components performed in accordance with *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* (B2.1.1). The integrity of ASME and non-ASME pressure-retaining bolted joints which contain fluids such as water, oil, or steam is assessed by detection of visible leakage, evidence of past leakage, or other age-related degradation during walkdowns and maintenance activities. Conditions such as: degraded bolts, nuts and threads; active leakage; high noise levels; loose or missing bolts and nuts; evidence of past leakage; damaged insulation; discoloration; or other age-related degradation are documented in the corrective action program where the condition is evaluated. Resulting actions could include: operability evaluation, cause determination, extent of condition evaluation, additional or more frequent inspections, and replacement. This could include, when practical, projections of identified corrosion or degradation rates until the next scheduled inspection or replacement. Inspections are performed by personnel qualified in accordance with station procedures and programs to perform the specified task. Inspections within the scope of the ASME Code follow procedures consistent with the ASME Code. Non-ASME Code inspections follow station procedures that will include inspection parameters for items such as lighting, distance, and offset, which provide an adequate examination.

The program will perform periodic inspections of a representative sample of submerged closure bolting and closure bolting on pressure-retaining components within the scope of SLR that contain air or gas where leakage is difficult to detect. A representative sample is defined as twenty percent of closure bolting or a maximum of seventeen bolts for each material and environment population per unit. This sample size is appropriate because design, operating, and environmental conditions between the units are similar enough such that the aging effects are not occurring differently. All three units are of comparable age and changes to water chemistry practices, to plant equipment, and operating conditions have been implemented in a consistent manner across all three units. Water chemistry programs monitor various chemistry parameters and require out-of-spec conditions to be corrected under the corrective action program in a timely manner. Raw water systems for all three units draw from the same source, Lake Keowee. Therefore, a reduced sample size will provide a representative sample of the condition of the plant equipment and the existence of the aging effects involved.

The program also includes preventive measures such as use of EPRI guidance for the installation, makeup, and material selections of bolted joints; prohibition of the use of lubricants containing molybdenum disulfide; and minimizing the use of high strength bolting to preclude or minimize loss of preload and cracking.

High strength closure bolting greater than two inches in diameter (regardless of code classification) with yield strength greater than or equal to 150 ksi (1,034 MPa) will be visually inspected for aging affects and inspected volumetrically in accordance with ASME Code Section XI, Table IWB-2500-1, Examination Category B-G-1.

For sample based inspections in which acceptance criteria is not met the condition will be entered into the corrective action program. Conditions such as: loss of material; cracking; loss of preload; degraded threads; active leakage; loose or missing bolts or nuts; and evidence of past leakage will be documented and evaluated in the corrective action program. The degraded conditions will be evaluated relative to extent of condition against the total population of bolts under similar service conditions, to confirm the timing and extent of subsequent inspections to ensure the components' intended functions will be maintained throughout the SPEO. Site procedures will be enhanced such that, when required, there will be five additional inspections for each inspection that did not meet acceptance criteria or twenty percent of similar bolting (i.e., bolting with similar material, environment, and aging effect), whichever is less unless the cause of the aging effect is corrected by repair or replacement of all bolting constructed of the same material and exposed to the same service environment. The additional inspections will be completed within the inspection interval for which the original sample based inspections are conducted. The corrective action program will be used to adjust inspection frequencies based on projected degradation rates, if applicable, to ensure that loss of function does not occur prior to the next scheduled inspection.

The following bolting is not managed by the *Bolting Integrity* AMP.

1. The bolting components for the reactor vessel closure head are managed by the *Reactor Head Closure Stud Bolting* (B2.1.3) program.

2. The Primary Containment (MC) pressure-retaining bolting is managed as part of the *ASME Section XI, Subsection IWE* (B2.1.28) program.

3. ASME Class 1, 2, 3, and MC piping and components support bolting, including NSSS component supports, is managed as part of the *ASME Section XI, Subsection IWF* (B2.1.30) program.

4. Structural bolting, other than ASME Class 1, 2, 3, and MC piping and component supports bolting is managed as part of the Structures Monitoring (B2.1.33) program, or the *Inspection of Water-Control Structures Associated with Nuclear Power Plants* (B2.1.34) program.

5. Crane and hoist bolting is managed by the *Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* (B2.1.13) program.

6. Heating and ventilation system bolted joints are managed by the *External Surfaces Monitoring of Mechanical Components* (B2.1.23) program.

7. Pressure-retaining bolting in a buried environment or underground with restricted access are inspected in conjunction with buried piping and component inspections performed as part of the *Buried and Underground Piping and Tanks* (B2.1.26) program.

NUREG-2191 Consistency

The Oconee *Bolting Integrity* AMP will be consistent with the ten elements of AMP recommendations provided in NUREG-2191, Section XI.M18, "*Bolting Integrity*" with the enhancements listed below.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented in the following program elements: Preventive Actions (Element 2), Parameters Monitored or Inspected (Element 3), Detection of Aging Effects (Element 4), and Corrective Actions (Element 7)

1. Revise applicable procedures and specifications to include reference to EPRI Report 1015336, EPRI Report 1015337, and NUREG-1339, as appropriate. (Element 2)

2. Revise procedures governing the direct visual examination of bolted joints to include inspection parameters such as lighting, distance, and offset. (Element 4)

3. Perform volumetric inspections of non-ASME high-strength bolting greater than two inches in diameter in accordance with the method described in ASME Code Section XI, Table IWB-2500-1, Examination Category B-G-1. (Elements 3 and 4)

4. Perform visual inspections of a representative sample of twenty percent of closure bolting where leakage is difficult to detect such as submerged connections or systems containing air/gas or a maximum of seventeen bolts for each material and environment population per unit, whichever is less, during each ten year period. If the minimum sample size is not achieved during a ten year period, then alternative inspections may be performed. For submerged bolting, alternative inspections may include (a) diver inspections or (b) remote video inspections. For systems containing air/gas, alternative inspections may include (a) visual inspection for discoloration when leakage from inside the piping system would discolor the external surfaces of the component; (b) monitoring and trending of pressure decay when the bolted connection is located within an isolated boundary; (c) soap bubble testing on the external mating surface of the bolted component; or (d) thermography, when the temperature of the process fluid is higher than ambient conditions around the component. (Element 4)

5. Perform additional inspections of a minimum of twenty percent of similar bolting or five additional inspections, whichever is less, when sample based inspections do not meet acceptance criteria. If the additional inspections identify bolting that does not meet acceptance criteria, then an extent of condition and extent of cause analysis will be conducted to determine the further extent of inspections. Additional inspections of similar bolting will be performed at all three units and will occur within the same interval in which the original inspection was conducted. The corrective action program will be used to determine if changes to inspection frequency is appropriate if any inspection results indicate that loss of function will occur prior to the next scheduled inspection. (Element 7)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Bolting Integrity* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. During the Spring 2011 Unit 1 refueling outage, while work was being performed in containment, loose bolting was identified on the pressurizer vent and nitrogen isolation valve, which was located in the area where work was being performed. The issue was entered into the station corrective action program to have the issue investigated and resolved. The bolting was removed and re-torqued prior to restarting the unit following the refueling outage.

   OE example 1 provides objective evidence that station maintenance practices and the corrective action program effectively monitor and maintain the condition of bolting to ensure that these components will be able to continue to perform their intended functions during the SPEO.

2. In August 2012, the NRC issued Information Notice 2012-15, “Use of Seal Cap Enclosures to Mitigate Leakage from Joints that Use A-286 Bolts,” to inform licensees of the potential issues associated with the installation of seal cap enclosures to mitigate leakage from A-286 bolted connections. An unintended consequence of installation of seal cap enclosures was cracking due to the stress corrosion cracking resulting from submergence of Alloy A-286 (Grade 660) flange bolting in leaked primary coolant. The environment inside of an enclosure that is installed on a leaking flange is not necessarily similar to the high-purity, low-oxygen environment inside a PWR reactor coolant system. Electrochemical reactions that cause stress corrosion cracking are likely to occur with the A-286 bolting and enclosure attachment welds.

   Based on a plant review, it was determined that there are no valves at Oconee that have seal cap enclosures installed. In addition, leak repair devices such as seal cap enclosures described in this industry OE are treated as a temporary fix requiring further follow-up action to permanently correct the problem.

OE example 2 provides objective evidence that industry OE relevant to aging management is evaluated and used to adjust the program as necessary.

3. In May 2012, significant corrosion was identified on carbon steel flange bolting for two low pressure service water system flexible hoses. The issue was documented in the corrective action program and a work request was initiated to replace the carbon steel bolting with stainless steel during the next refueling outage. The flanges for the flexible hoses are stainless steel and showed no indication of degradation. The carbon steel bolting was replaced with stainless steel during the Spring 2014 Unit 3 refueling outage.

   OE example 3 provides objective evidence that the corrective action program is appropriately utilized to evaluate degraded conditions and initiate appropriate corrective actions to prevent recurrence.

4. In April 2017, during VT-2 examinations of a nearby component, dry boron was identified on two valves. The issue was entered into the station corrective action program for resolution. Work orders were created for each of the valves to clean up the boron and remove insulation to inspect. Leaks were identified at the body to bonnet interface. The areas were cleaned and inspected for corrosion, no corrosion was identified as both valves and bolting were made of materials that are not susceptible to boric acid corrosion. The bolting for both valves were re-torqued to the appropriate values in accordance with station procedures. The issue was documented in the station fluid leak management database.

   OE example 4 provides objective evidence that existing inspection activities credited by this program and the corrective action program effectively monitor and maintain the condition of bolting to assure that these components will be able to continue to perform their intended functions during the SPEO.

5. In December 2017, during the performance of a radiation protection survey, a leak was observed coming from the Unit 1 borated water storage tank manway. The issue was investigated and it was determined that there was an active leak of approximately one drop every two to three minutes from a manway bolt. The issue was entered into the corrective action program and the station's fluid leak management database. A work request was issued to re-torque the manway bolting. The borated water storage tank manway bolting was re-torqued, and the area was monitored to confirm that leakage had ceased.

   OE example 5 provides objective evidence that system leakage monitoring by station personnel during normal work activities is effective in identifying evidence of minor leakage that could indicate degraded bolting. The example also provides objective evidence that the corrective action program is appropriately utilized to ensure appropriate corrective actions are performed.

6. In January 2018, several small defects were identified in 5/16" bolting for the Keowee Unit 1 turbine guide bearing oil system heat exchanger end bell. The defects are outside of the thread engagement area and do not impact the integrity of the joint. The condition was

documented in the corrective action program for evaluation. The bolting was evaluated and determined to be acceptable for continued service.

OE example 6 provides objective evidence that opportunistic inspections of component closure bolting performed during normal maintenance activities are capable of detecting minor issues prior to loss of intended function.

7. A review of ten years (January 2011 through January 2021) of condenser circulating water system pump diver inspections was performed which identified no significant issues with the submerged bolting for these pumps. The four pumps at each of the three units have been inspected four to five times over the ten years that have been reviewed. Inspections have identified a layer of surface corrosion and corrosion nodules on the bolting and pump column which is typical in a submerged raw water environment. No significant loss of material which could impact intended functions has been detected.

   Marine growth and biofouling material have also been identified. No loose, missing, or broken submerged bolting has been detected in any of the inspections completed over the ten year review period.

   OE example 7 provides objective evidence that appropriate inspections are performed to monitor the condition of submerged bolting and that significant aging which could impact intended functions of this bolting is not occurring.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Bolting Integrity* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, re-evaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Bolting Integrity* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Bolting Integrity* AMP, with the enhancements noted above, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.10 STEAM GENERATORS

Program Description

The *Steam Generators* AMP is an existing condition monitoring program that manages the aging effects of cracking, loss of material (e.g., wall thinning), and reduction of heat transfer for the steam generators. The scope of the program includes primary-side components (e.g., tubes, plugs, lower/upper heads, tubesheet, etc.), and secondary-side components that are contained within the steam generator. The program performs volumetric inspections for the tubes, and visual inspections for the other primary-side and secondary-side components. The visual inspections of steam generator components in the scope of this AMP are performed in accordance with the degradation assessment that is prepared as each steam generator is scheduled for examination. The Oconee program does not address divider plate assemblies since the design of the steam generators in all three units does not include these components.

The *Steam Generators* AMP uses industry endorsed guidance regarding tube inspections, evaluation and repair, and leakage monitoring techniques to ensure tube integrity of the steam generators. Aging is managed through assessment of potential degradation mechanisms, inspections, tube integrity assessments, plugging and repairs, primary-to-secondary leakage monitoring, maintenance of secondary side component integrity, primary-side and secondary-side water chemistry, and foreign material exclusion. Implementing procedures specify the performance criteria for tube integrity, condition monitoring requirements, inspection scope and frequency, acceptance criteria for the plugging or repair of flawed tubes, acceptable tube repair methods, leakage monitoring requirements, and operational leakage and accident-induced leakage requirements from Technical Specifications.

Provisions in the *Steam Generators* AMP address reporting criteria, inspection scope and frequency, assessments, plugging criteria, and water chemistry monitoring to maintain consistency with established requirements. Those requirements appear in the following documents:

- Technical Specifications
- Maintenance Rule (10 CFR 50.65)
- EPRI 3002007571, *"Steam Generator Integrity Assessment Guidelines"*
- EPRI 3002007572, *"PWR Steam Generator Examination Guidelines"*
- EPRI Technical Report TR1022832, *"PWR Primary-to-Secondary Leak Guidelines"*
- EPRI 3002007856, *"Steam Generator In-Situ Pressure Test Guidelines."*

The EPRI guidelines provide a generic industry program to implement the expectations from NEI 97-06, Revision 3, *"Steam Generator Program Guidelines."*

The Oconee *Steam Generators* AMP complies with the guidance provided in NEI 97-06, *Steam Generator Program Guidelines*, and its referenced industry guideline documents for inspections, personnel qualification, and technique qualification. NEI 97-06 was developed by the industry to meet 10 CFR 50.65 maintenance rule and other applicable regulatory requirements and establish the elements of an effective steam generator management program. The frequency of examinations and acceptance criteria are specified in Oconee Technical Specifications.

The original steam generators were replaced for Unit 1 in 2003 and for Unit 2 and 3 in 2004. Each replacement steam generator on the three units have tubes constructed of thermally treated Alloy 690 material to improve reliability and minimize aging.

The *Steam Generators* AMP includes plant-specific steam generator degradation assessments that identify existing and potential degradation mechanisms and associated aging effects that could impact the integrity of the steam generators. The degradation assessment identifies qualified tube inspection techniques and defines the scope of inspections that are appropriate for the detection and characterization of those aging effects, which consist of cracking, loss of material (e.g., wall thinning), and reduction of heat transfer. As stated in the degradation assessment, steam generator inspections are performed every 72 effective full power months or at least every third refueling outage (whichever results in more frequent inspections) for each steam generator, thus satisfying the Oconee Technical Specifications and industry guidance for inspections to be performed at least every 72 effective full power months or every third refueling outage, whichever results in more frequent inspections. The minimum number of tubes inspected at each scheduled inspection shall be the number of tubes in all steam generators divided by the number of steam generator inspection outages scheduled in each inspection period. Since the inspection scope to date at Oconee has been 100% on each generator for each unit during each refueling outage, inspection interval requirements have been readily met.

The degradation assessment includes a review of relevant industry and plant-specific OE which has occurred since the previous degradation assessment was performed. The degradation assessment review determines the existence of any unaddressed mechanism that could adversely affect steam generator primary-side or secondary-side integrity, as well as the effects of any chemistry excursions or transients that could affect existing degradation mechanisms. An excursion of secondary chemistry could lead to fouling of heat transfer surfaces and a reduction of heat transfer thermal performance.

The aging effects managed by the *Steam Generators* AMP include cracking, loss of material (e.g., wall thinning), and reduction of heat transfer for the steam generators. The scope of the program includes primary-side components (e.g., tubes, plugs, lower/upper heads, tubesheet, etc.), and secondary-side components that are contained within the steam generator. The program uses volumetric inspections for the tubes, and visual inspections for the other primary-side and secondary-side components. The visual inspections of steam generator components are performed in accordance with the degradation assessment that is prepared as each steam generator is scheduled for examination, including steam generator head primary side stainless steel cladding surfaces. The primary side surfaces of Oconee replacement once through steam generator tubesheets are clad with nickel alloy and the Alloy 690 thermally treated tubes are joined to the tubesheet with autogenous welds. General steam generator inspection activities are credited to identify rust stains indicative of degradation (loss of material) of tubesheet or tube-to-tubesheet weld primary side surfaces.

The *Steam Generators* AMP includes preventive measures to mitigate aging related degradation through foreign material exclusion as a means to inhibit tube degradation due to wear. Identification of deposits on the secondary side of the steam generator, and the subsequent removal of sludge deposits helps prevent tube degradation. As an additional preventive measure, the *Water Chemistry* program monitors and controls reactor water chemistry and secondary water chemistry for the steam generators consistent with EPRI 3002000505, *"PWR*

Primary Water Chemistry Guidelines," and EPRI 3002010645, *"PWR Secondary Water Chemistry Guidelines"*.

Oconee Technical Specifications include the following requirements which have been incorporated in the *Steam Generators* program:

- Conducting condition monitoring assessments for each refueling outage during which steam generator tubes are inspected or plugged.
- Maintaining steam generator tube integrity by meeting performance criteria for tube structural integrity, accident-induced leakage, and operational leakage.
- Installing plugs in tubes found by inservice inspection to contain flaws with a depth equal to, or exceeding, 40% of the nominal tube wall thickness.
- Performing periodic inspections of steam generator tubes. Inspection scope, methods, and interval ensure that tube integrity is maintained until the next planned inspection.
- Monitoring primary-to-secondary leakage.
- Monitoring secondary water chemistry to ensure controls are in place to inhibit steam generator tube degradation.

Non-destructive examination techniques are used to inspect tubing materials in order to identify tubes that may need to be removed from service in accordance with technical specifications. The *Steam Generators* program utilizes volumetric examination techniques for the tubes, and visual examinations for other primary-side and secondary-side components. The *Steam Generators* program defines specific examination techniques, and describes criteria for the qualification of personnel, and for the acquisition and analysis of data. Assessment of tube integrity and plugging criteria of flawed tubes is in accordance with the technical specifications and the *Steam Generators* program implementing procedures. Tube plugs with indications of aging are evaluated for corrective actions in accordance with the corrective action program and the *Steam Generators* program.

Condition monitoring assessments are performed to determine whether structural and accident leakage criteria have been satisfied during the previous operating cycle(s). Operational assessments are performed after inspections are completed to verify that structural and leakage integrity will be maintained for the operating interval between inspections, which is selected in accordance with Technical Specifications and EPRI *Steam Generator Integrity Assessment Guidelines*. Comparison of the results of the condition monitoring assessment with the predictions of the previous operational assessment provides feedback for evaluation of the adequacy of the operational assessment and additional insights that can be incorporated into the next operational assessment. The condition monitoring, and performance monitoring methods, are effective in detecting the applicable aging effects, and the frequency of monitoring is adequate to prevent significant age-related degradation.

<u>NUREG-2191 Consistency</u>

The Oconee *Steam Generators* AMP is an existing program that is consistent with the ten elements of AMP XI.M19, "Steam Generators" specified in NUREG-2191 (GALL-SLR).

<u>Exception to NUREG-2191</u>

None

<u>Enhancements</u>

None

<u>Operating Experience</u>

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Steam Generators* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2005, during the first inservice inspection of the Oconee Unit 1 replacement once through steam generators, widespread tube wear caused by tube vibration was detected at support plate intersections. An entry was made into the corrective action program to document, evaluate and perform actions, as necessary. Completed corrective actions included performing an inspection of all tubes on both the 1A and 1B steam generator, operability assessment, root cause analysis involving a detailed review of the thermal hydraulic, structural, and operating conditions of the replacement once through steam generators, and flaw analysis and growth rate determination. In addition, eddy current testing field data of the observed wear was studied and additional field data was collected in support of the root cause analysis. The root cause investigation concluded that the tube wear was a result of inadequate lateral support resulting from tube to support plate relative alignment. This design allowed too much freedom of movement, which enabled small excitation forces to cause tube vibration. This tube vibration resulted in low load, high cycle impact of the tubes with the support plates which produced wear scars on the tubes. As a corrective action, a high-confidence tube plugging predictive model was developed and validated to confirm steam generator service life and support a managed approach with all Oconee replacement once through steam generators going forward. A tube plugging projection model that fully considers design specific tube wear mechanisms is continually applied and validated as part of Oconee *Steam Generators* AMP degradation assessment, condition monitoring, and operational assessment activities. An extent of condition was also performed which concluded that the replacement once through steam generators for all three Oconee units are susceptible to the same tube vibration induced degradation mechanism.

   A separate entry was made into the corrective action program to document the operability evaluation and condition of Units 2 and 3 steam generators. Corrective actions initiated and completed included the implementation of a monitoring activity to recognize and evaluate any changes in plant operation (e.g., power reductions) that could impact the assumptions made regarding the steam generator tube-to-tube support plate wear rates. Other actions included inspecting all tubes in both Unit 2 and 3 for baseline wear information and validation of wear rate assumptions. While the tube wear observed on

Units 2 and 3 steam generators was less widespread, the pattern of wear and geometry of the wear scars was essentially the same, suggesting the same phenomenon is occurring on all units. An additional action involving all three Oconee units included establishing a steam generator health report action plan to monitor the operation of Oconee Units 1, 2, and 3 for any changes (e.g., reduced power for extended period of time) that could affect the assumptions made regarding the tube-to-tube support plate wear rates in the replacement steam generators.

OE example 1 provides objective evidence that plant-specific OE, that potentially involves aging, is evaluated and used to modify the *Steam Generators* program. This example also demonstrates that proper extent of condition is performed to initiate additional corrective actions, as needed.

2. In September 2009, the NRC issued RIS 2009-04, *"Steam Generator Tube Inspection Requirements,"* to clarify the regulatory position on the implementation of the steam generator tube inspection requirements contained within plant's Technical Specifications. An item was entered into the corrective action program to evaluate the RIS across the Duke Energy fleet. The Oconee Technical Specifications and *Steam Generators* aging management activities were reviewed and found to be consistent with the guidance and interpretations provided in RIS 2009-04. No further action was needed.

   OE example 2 demonstrates the effective use of the corrective action program to identify and evaluate updated industry steam generator inspection and maintenance guidance and to adjust programs, as necessary.

3. In November 2011, during the first inservice inspection of replacement once through steam generators at a domestic PWR facility, tube-to-tube contact wear was identified and reported as industry OE. An entry was made to the corrective action program to evaluate and initiate corrective actions for each Oconee unit, as necessary. As a result, the Oconee *Steam Generators* AMP was modified to update the potential degradation mechanisms and improve the detection criteria.

   OE example 3 demonstrates the effective use of industry OE and the corrective action program to identify degraded conditions and to adjust programs, as necessary.

4. In the fall of 2014, a corrective action program entry was made to evaluate the non-destructive examination results for the Oconee 1A steam generator. The results collected during the fall outage indicated that tube wear was under predicted by the operational assessment analysis performed following the previous fall 2012 inspection. The measured wear indication for one tube was 59% through wall. The indication was under predicted by 1.4% through wall. The operational assessment performed following the previous inspection predicted the largest wear indication would be 57.6% through wall during the fall 2014 outage. The tube met the acceptance criterion and was within the margin of error for the operational assessment. In response to this under prediction observation, the growth rate assumptions applied in operational assessments were adjusted upward to make more bounding predictions.

OE example 4 provides objective evidence that the program manager critically self-assesses program performance and self-identifies actions in the corrective action program that support continuous improvement.

5. In 2016, a corrective action was initiated to evaluate actions that could be taken to address spiral wound gasket material foreign material intrusion events into the Oconee 1A steam generator. An engineering evaluation determined that the 1A1, 1B1, 1B2, 2B1 and 2B2 feedwater manway gaskets should be replaced with a similar 304SS, spiral-wound gasket that incorporates an inner retaining ring that prevents deterioration in a manner that generates foreign material.

   OE example 5 provides objective evidence that the existing AMP activities are being effectively implemented to identify and manage aging effects of in scope components and that the results of inspection activities are used to inform and enhance the program. Deficiencies identified during inspection activities are entered into the corrective action program and appropriate corrective actions are taken to evaluate and address deficiencies.

6. In 2016, a corrective action program entry was made to document a cladding defect found during inspections in a recirculating steam generator at Catawba Nuclear Station. This inspection was being performed in response to NSAL-12-1 and NRC Information Notice 13-20 industry OE. As a result of this OE at another Duke site (Catawba), the Oconee *Steam Generators* AMP was modified to improve the inspection program. Although the Catawba recirculating steam generators are of a different design than the Oconee replacement once through steam generators, the OE is applicable to the primary side surfaces of once through steam generator upper/lower heads at Oconee. Following the discovery of the cladding anomaly in the Catawba steam generator, replacement once through steam generator upper/lower head primary side stainless steel cladding visual inspections were performed at Oconee with the following enhancements:

   - The inspections covered all the visible upper/lower head primary side surfaces.
   - Lighting utilized was comparable to the enhanced Catawba inspection practice to ensure adequate illumination to identify any rust colored stains or dark discolorations on the primary side surfaces of the upper/lower heads
   - Cameras capable of detecting rust colored staining and discolorations of the cladding that are indicative of possible cladding issues were deployed

   To date there have been no findings of stainless-steel cladding degradation at any Oconee or other once through steam generator installation.

   OE example 6 demonstrates the effective use of industry OE and the corrective action program to identify degraded conditions, perform extent of condition reviews, and take timely corrective action to ensure aging effects and conditions adverse to quality are identified, and to assure steam generator components continue to perform their intended functions.

7. In November 2017, a corrective action program entry was made to document the foreign material found on the primary side bottom head bowl of the Oconee 2B steam generator.

The foreign object found was confirmed to be a piece of fuel grid strap measuring approximately ¾ inch by ½ inch long. The debris was likely dislodged from a tube during eddy current testing. The material was evaluated by the metallurgical lab and determined to be a piece of legacy fuel grid strap debris from a previous fuel cycle (2011 or prior). The foreign object was removed from the system, and a complete visual inspection of the 2B hot leg and cold bowl stainless steel liner and primary tube-sheet face was performed during the Oconee Unit 2 fall 2017 refueling outage. No indications of damaged primary side cladding were noted. This foreign material intrusion event had the potential to damage tubes, but no tube damage was identified by non-destructive examination of the tubes. No issues were noted beyond expected wear.

OE example 7 demonstrates that condition reports are initiated in the corrective action program and that appropriate cause evaluations and inspections are being performed in response to identified primary side foreign material intrusion events. This OE provides objective evidence that program inspections, along with the corrective action program, will effectively monitor in scope steam generator components to assure that these components will continue to perform their intended functions during the SPEO.

8. In August 2020, an AMP effectiveness review was performed on the *Steam Generators* program. The AMP was evaluated against the performance criteria identified in NEI 14-12, *"Aging Management Program Effectiveness."* The review concluded that the steam generators program is meeting the requirements of NEI 14-12. No gaps were identified by the effectiveness review.

   This effectiveness review provides objective evidence that the current *Steam Generators* program is effectively managing aging and meeting all current LR commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the SPEO.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Steam Generators* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, re-evaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Steam Generators* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Steam Generators* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.11 OPEN-CYCLE COOLING WATER SYSTEM

Program Description

The *Open-Cycle Cooling Water System* AMP is an existing preventive, mitigative, condition monitoring and performance monitoring program based on the implementation of NRC GL 89-13, and includes non-safety related portions of the open cycle cooling water system. The program includes: (a) surveillance and control to significantly reduce the incidence of flow blockage problems as a result of biofouling, (b) tests to verify heat transfer of heat exchangers, (c) periodic inspection and maintenance so that corrosion, erosion, cracking, fouling, and biofouling cannot degrade the performance of systems serviced by the open cycle cooling water systems, and (d) reevaluation, repair, or replacement of components that do not meet minimum wall thickness requirements. The program applies to components constructed of various materials including steel, gray cast iron, ductile iron, stainless steel, and copper alloys exposed to raw water from Lake Keowee. There is no cementitious or polymeric piping within the scope of the program. This program includes guidance beyond the requirements contained in NRC GL 89-13, such as inputs from industry reports and documents (e.g., EPRI documents) that address OE such that aging effects are adequately managed.

The program manages piping, piping components, and heat exchanger components in safety related and non-safety related raw water systems that are exposed to a raw water environment for loss of material, cracking, reduction of heat transfer, and flow blockage. The program also manages loss of coating integrity for certain components that do not perform a pressure boundary intended function and where loss of coating integrity would not impact the intended functions of downstream components. System and component testing, flushing, visual inspections, and nondestructive examination are conducted to ensure that identified aging effects are managed such that system and component intended functions and integrity are maintained.

The program includes those plant systems that transfer heat from safety related SSCs to the ultimate heat sink as defined in GL 89-13. Periodic heat transfer testing, visual inspection, and cleaning of safety related heat exchangers with a heat transfer intended function is performed in accordance with the site commitments to GL 89-13 to verify heat transfer capabilities. Test results and the results of visual inspections that do not meet acceptance criteria are evaluated in accordance with the corrective action program. The results of heat transfer testing are trended to verify adequacy of testing frequencies.

Safety related piping is nondestructively examined to ensure that there is no loss of material which could result in loss of intended function. Examinations that do not meet acceptance criteria are evaluated in accordance with the corrective action program. For ongoing degradation due to specific aging mechanisms (e.g., microbiologically influenced corrosion), the program includes trending of wall thickness measurements at susceptible locations to adjust the monitoring frequency and the number of inspection locations.

Personnel qualified in accordance with station procedures and programs to perform the specified task are utilized to perform testing and nondestructive examinations of equipment within the scope of this program. Inspections within the scope of the ASME Code follow procedures consistent with the ASME Code.

Aging effects associated with non-service water raw water systems (e.g., filtered water system, drinking water system) are managed by the *Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components* (B2.1.24) program.

Aging of water-based fire suppression systems, other than recurring internal corrosion, is managed by the *Fire Water System* (B2.1.16) program.

NUREG-2191 Consistency

The *Open-Cycle Cooling Water System* AMP is an existing program that will be consistent with NUREG-2191 Section XI.M20, *Open-Cycle Cooling Water System* with enhancements and exceptions, as described below

Exception 1 to NUREG-2191

Program Element Affected: Scope of Program (Element 1)

1. The *Open-Cycle Cooling Water System* AMP will manage recurring internal corrosion of steel piping in the station's water-based fire suppression systems in addition to the scope specified in NUREG-2191, Section XI.M20.

   Justification for Exception 1

   A review of Oconee OE indicates that recurring internal corrosion, as defined in Section 3.3.2.2.7 of NUREG-2192, is occurring in steel piping exposed to raw water from Lake Keowee. This includes open-cycle cooling water systems and water-based fire suppression systems which are both supplied from Lake Keowee. The water-based fire suppression systems are of similar design and construction as the open-cycle cooling water systems managed by this program. Since the material of construction and service environment are equivalent between the open-cycle cooling water systems and the water-based fire suppression systems, managing recurring internal corrosion of these systems as a single population is appropriate.

   The Oconee *Open-Cycle Cooling Water System* AMP will manage recurring internal corrosion of steel piping exposed to raw water through sample-based volumetric inspections. A minimum of twenty inspections will be performed every 24 months until the rate of recurring internal corrosion occurrences no longer meets the criteria for recurring internal corrosion as defined in Section 3.3.2.2.7 of NUREG-2192. Inspections will be performed in both open-cycle cooling water systems and water-based fire suppression systems in representative sample locations with conditions that are characteristic of the conditions found throughout raw water filled systems at Oconee. Inspection results will be extrapolated to similar locations throughout all the raw water systems within the scope of SLR and used to assess the general condition of piping exposed to raw water. This characteristic-based approach recognizes the commonality among the component materials of construction and the environment to which they are exposed.

Enhancements

The following enhancements will be implemented in the following program elements: Parameters Monitored or Inspected (Element 3), Detection of Aging Effects (Element 4), Monitoring and Trending (Element 5), Corrective Actions (Element 7), and Administrative Controls (Element 9)

1. Perform periodic inspection, cleaning, and eddy current testing of the ‘A’ and ‘B’ Chiller condensers at least once every five years. (Element 3)

2. Perform a minimum of twenty inspections for recurring internal corrosion in raw water systems every 24 months until the rate of recurring internal corrosion occurrences no longer meets the criteria for recurring internal corrosion as defined in Section 3.3.2.2.7 of NUREG-2192. The selected inspection locations will be periodically reviewed to validate their relevance and usefulness and adjusted as appropriate. Evaluation of the inspection results will include (1) a comparison to the nominal wall thickness or previous wall thickness measurements to determine rate of corrosion degradation; (2) a comparison to the design minimum allowable wall thickness to determine the acceptability of the component for continued use; and (3) a determination of re-inspection interval. (Element 3, 4, 5 and 7)

3. Perform periodic internal visual inspections of the visible portion of the supply and return piping to the radwaste equipment cooling system from the condenser circulating water system intake piping in conjunction with the performance of the intake piping internal coating inspections. Visual inspections will be performed to identify direct evidence of internal degradation and indirect evidence of through wall leakage including the presence of backfill material or gravel within the pipe. (Elements 3 and 4)

4. Provide additional guidance in procedures for inspections of non-ASME Code components for items such as lighting, distance, offset, surface coverage, presence of protective coatings, and cleaning processes. (Element 4)

5. Provide additional guidance for trending of heat exchanger inspection results to evaluate the adequacy of inspection frequencies. (Element 5)

6. If inspections identify wall-thickness below the minimum required wall thickness and the cause of the aging effect for each applicable material and environment is not corrected by repair or replacement for all components constructed of the same material and exposed to the same environment, additional inspections will be conducted. The number of increased inspections is determined in accordance with the corrective action program; however, no fewer than five additional inspections will be conducted for each inspection that did not meet acceptance criteria, or 20 percent of each applicable material, environment, and aging effect combination is inspected, whichever is less. The additional inspections include inspections at all of the units with the same material, environment, and aging effect combination. (Element 7)

7. Incorporate programmatic guidance contained in engineering support documents into controlled plant procedures subject to administrative controls in accordance with the Duke Energy QA Program. (Element 9)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Open-Cycle Cooling Water System* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2019, a self-assessment of LR aging management activities was performed which included a detailed review of select AMPs and commitments. In 2020, an effectiveness review of existing AMPs and activities required by commitments made during the first LR was performed for all programs and activities not adequately assessed during the 2019 self-assessment. Although the *Open-Cycle Cooling Water System* AMP is not one of the existing AMPs documented in Chapter 18 of the Oconee UFSAR, there are multiple programs and aging management activities developed for the first LR that are relevant to this program, some of which were included in the 2019 self-assessment while others were addressed during the 2020 AMP effectiveness reviews. These Chapter 18 programs and aging management activities include: heat exchanger performance testing activities (UFSAR Section 18.3.11), chilled water refrigeration unit preventive maintenance activity (UFSAR Section 18.3.17.2), decay heat cooler tubing examination (UFSAR Section 18.3.17.7), jacket water heat exchanger preventive maintenance activity (UFSAR Section 18.3.17.9), Keowee turbine generator cooling water system strainer inspection (UFSAR Section 18.3.17.10), main condenser tubing examination (UFSAR Section 18.3.17.11), reactor building cooling unit tubing inspection (UFSAR Section 18.3.17.13), standby shutdown facility HVAC coolers preventive maintenance activity (UFSAR Section 18.3.17.15), Keowee turbine guide bearing oil cooler examination (UFSAR Section 18.3.17.22), and service water piping corrosion program (UFSAR Section 18.3.21). The relevant results of the 2019 assessment and 2020 effectiveness reviews are summarized below.

   The overall results of the 2019 assessment and 2020 effectiveness reviews confirmed that the various programs and activities are being implemented as described in Chapter 18 of the Oconee UFSAR. In addition, reviews of the corrective action program performed during the evaluation of these AMPs and activities did not identify any significant aging issues or failures that would require changes or enhancement to the existing programs. The review also confirmed that when changes were made to commitments or implementing activities, the impact on aging was considered, with one exception described below. Based on the above, it is concluded that the existing AMPs and activities have been effective at managing age-related degradation of raw water system components at Oconee.

   Most of the discrepancies identified during this review were related to documentation and record keeping. For example, the basis for scheduled preventive maintenance activities, as documented in the Oconee work management system, often lacked sufficient detail to determine the specific activities required by commitment. This represents a challenge to the work management process (e.g., when evaluating potential preventive maintenance changes or deferrals) but has not resulted in any missed commitments. The review also identified instances where completed inspection records were not submitted to permanent records as required. The issues related to documentation and record keeping have been entered into the corrective action program to evaluate opportunities for process improvements.

In one instance, an aging management activity was changed without fully evaluating the impact on aging and commitment compliance. In 2018, the ‘A’ chiller was replaced. Aging of the condenser for the chiller is managed by the chilled water refrigeration unit preventive maintenance activity (UFSAR Section 18.3.17.2). Following the replacement of the ‘A’ chiller, several preventive maintenance recurring work orders were retired due to differences between the original chiller design and the replacement. The retired preventive maintenance recurring work orders included four year cleaning and eddy current testing which is credited in UFSAR Chapter 18 for aging management of the chiller condenser. Based on the four year frequency, cleaning and eddy current testing of the condenser would not be required until 2022. This issue has been documented in the corrective action program to review the preventive maintenance changes and determine if the preventive maintenance recurring work orders will be reestablished or if a commitment change will be processed.

Finally, the review identified discrepancies or potential discrepancies between aging management implementation details as described in NUREG-1723, Safety Evaluation Report related to the LR of Oconee Units 1, 2, and 3 and Oconee implementing documents. These issues have been documented in the corrective action program for evaluation and appropriate changes to the implementing documents will be made, as required.

OE example 1 provides objective evidence that the existing AMPs and activities related to the *Open-Cycle Cooling Water System* AMP are being effectively implemented to manage aging effects of in scope raw water system piping and components. This example also demonstrates that effectiveness reviews of AMPs are appropriately used to recognize and correct potential gaps in AMP implementation and identify areas for improvement.

2. In 2003, a comprehensive study was performed to address the risk of potential leakage of non-isolable portions of the low pressure service water system within the reactor building due to the extended plant operating life of 60 years. This study involved development of an internal corrosion model to predict the number of expected system leaks within the Unit 1 reactor building through the end of the PEO and predict when they will occur. The Unit 1 results are representative of all three units based on the similarity of Unit 1, 2, and 3 systems. The internal corrosion model estimated the probability of leakage attributable to general or localized corrosion based on OE, piping design, flow conditions, water chemistry, and operating temperatures. Although no leaks had occurred to date, the results of this study indicated that leakage from carbon steel low pressure service water system piping four-inch diameter or less was expected prior to the end of the first PEO.

Based on the results of this study, a long range plan was developed to pro-actively replace carbon steel low pressure service water system piping, four-inch diameter or less, located within the reactor building, prior to the development of through wall leaks which could require an emergent maintenance outage for repair. The plan includes replacement of piping to and from the reactor coolant pump motor coolers with upgraded stainless steel piping and like-for-like replacement of the piping to and from the reactor building auxiliary coolers. Replacement of the reactor building auxiliary cooler piping with stainless steel could not be performed due the higher coefficient of thermal expansion of stainless steel as compared to carbon steel which would lead to increased loading of piping supports at the piping design temperature.

This project includes the replacement of over a total of over 2000 linear feet of piping. As of September 2020, approximately 875 linear feet of piping has been replaced. The remaining piping replacements are scheduled to occur during upcoming refueling outages. There have been no through wall leaks in the remaining original piping that is scheduled for replacement.

OE example 2 provides objective evidence that the *Open-Cycle Cooling Water System* AMP takes proactive action to address long term aging concerns prior to loss of intended function.

3. The *Open-Cycle Cooling Water System* AMP includes annual monitoring for the presence of Asiatic clams at 38 locations throughout raw water systems at Oconee. Sample locations include various hydrants, pumps, and heat exchangers supplied by raw water from Lake Keowee. Asiatic clams are detected by flushing water through a filter screen which collects any clams present in the sample. Once collected the number and volume of clams is recorded for trending. For each sample location, the acceptance criteria are less than or equal to 30 total clams and less than or equal to a one-half cup volume of clams.

   A review of sampling data has been performed for years 2011 through 2020. Over 600 samples were collected to detect the presence of Asiatic clams within raw water systems over that ten year period. Over that time period, no sample results exceeded acceptance criteria. The sample results do not indicate any increasing trend in the number or volume of Asiatic clams present in samples and most samples identified zero clams.

   In addition, long term monitoring of Lake Keowee is performed to determine changes in Asiatic clam populations and detect the presence of other invasive species, such as zebra mussels. This includes monitoring Asiatic clam population density each refueling outage for all three units. During each outage, twelve samples are collected in total at the intake structure. For each of the four condenser circulating water pumps: one is taken on the lake side of the intake screens, one on the plant side of the intake screens, and one from the pump pits. The most recent sampling results, through the Unit 3 2020 spring refueling outage, show Asiatic clam populations consistent with previous monitoring years.

   The results of both system and lake monitoring are periodically reviewed and evaluated for changes that could adversely impact the potential flow blockage. This review is documented in a station calculation. As of the most recent update of this calculation in 2019, the review concluded that there is no indication of changes in Asiatic clam populations, presence of hydrilla, or introduction of zebra mussels.

OE example 3 provides objective evidence indicating that the potential for flow blockage due to macro-biological fouling does not exist for raw water systems within the scope of this program. In addition, the OE demonstrates that sufficient sampling is performed such that if populations of Asiatic clams increase or the introduction of new invasive species occurs, then the program will be able to detect these changes and take appropriate corrective actions prior to impact on system intended functions.

4. A review of Oconee OE over a 10-year period (January 2011 through January 2021) has revealed recurring internal corrosion in steel piping exposed to raw water from Lake Keowee. Through wall leakage due to localized piping degradation have occurred on several occasions. Generally, leaks have occurred in stagnant or intermittent flow locations. For leaks where metallurgical lab or biological lab analysis has been performed, the cause of leakage has been attributed to pitting and galvanic corrosion with microbiologically influenced corrosion identified as a contributor or potential contributor in some instances. When leakage has been identified, the issue has been entered into the corrective action program and appropriate corrective actions have been taken including increased inspections, piping repair or replacement, and modifications to install more corrosion resistant piping materials.

   In addition, there have been several occasions over the ten year review period where wall thickness measurements have identified remaining wall thickness less than pre-established screening criteria or less than 50 percent of nominal wall thickness. General corrosion rates at Oconee are typically on the order of one to two mil per year due to the high quality of raw water from Lake Keowee. Challenges to required minimum wall thickness are normally due to localized corrosion. The specific corrosion mechanism cannot be definitively established through wall-thickness measurements and so are conservatively assumed to be indicative of recurring internal corrosion as defined in Section 3.3.2.2.7 of NUREG-2192. When wall-thickness below conservative screening criteria has been identified, the issue has been entered into the corrective action program and appropriate corrective actions have been taken including reevaluation of required minimum wall thickness, piping repair or replacement, and modifications to install more corrosion resistant piping materials.

   The existing *Open-Cycle Cooling Water System* AMP relies on periodic wall-thickness measurements to monitor the condition of raw water system piping. The number and locations of inspections are determined based on susceptibility to corrosion and consequence of failure. Currently, there is no minimum required number of periodic wall thickness measurements. However, the program will be enhanced to require a minimum of 20 wall thickness measurements every 24 months until the rate of recurring internal corrosion occurrences no longer meets the criteria for recurring internal corrosion as defined in Section 3.3.2.2.7 of NUREG-2192. The selected inspection locations will be periodically reviewed to validate their relevance and usefulness and adjusted as appropriate. Evaluation of the inspection results will include (1) a comparison to the nominal wall thickness or previous wall thickness measurements to determine rate of corrosion degradation; (2) a comparison to the design minimum allowable wall thickness to determine the acceptability of the component for continued use; and (3) a determination of re-inspection interval.

OE example 4 provides objective evidence that plant OE is reviewed and evaluated for indications of recurring internal corrosion and appropriate corrective actions are taken to ensure aging is adequately managed.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Open-Cycle Cooling Water System* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation, or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Open-Cycle Cooling Water System* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Open-Cycle Cooling Water System* AMP, with the enhancements noted above, will provide reasonable assurance that the identified aging effects will be adequately managed such that intended functions of components within the scope of LR are maintained consistent with the CLB during the SPEO.

B2.1.12 CLOSED TREATED WATER SYSTEM

Program Description

The *Closed Treated Water Systems* program is an existing program that manages the aging effects of cracking, loss of material and reduction in heat transfer. The program consists of: a) water treatment, including use of corrosion inhibitors, to modify the chemical composition of the water such that the effects of corrosion are minimized, b) chemical testing to ensure water treatment maintains water chemistry within acceptable guidelines, and c) inspections to determine the presence or extent of degradation. The program includes coupon testing to measure corrosion rates and microbiological testing. The program uses the guidance in EPRI Report 3002000590, "*Closed Cooling Water Chemistry Guideline*", as applicable.

Systems and components managed by the *Closed Treated Water Systems* program include: alternate chilled water system, chilled water (vital loads) system, chilled water (non-vital loads) system, component cooling system, recirculating cooling water system, the standby shutdown facility diesel jacket water cooling system, and systems that interface with these systems.

The *Closed Treated Water Systems* program is implemented through procedures. The program utilizes a molybdate-based water treatment program to mitigate the effects of aging of components exposed to a closed treated water environment. Water sample analysis is performed periodically to ensure water chemistry parameters are maintained within limits specified in procedures and which are based on guidelines in EPRI Report 3002000590. Monitoring of chemistry parameters also ensures that contaminants are maintained below limits to minimize corrosion. Periodic and opportunistic visual inspections to monitor the condition of components are performed whenever the system boundaries are opened. A representative sample of components is selected based on the likelihood of loss of material, cracking, or reduction of heat transfer in each ten year period during the SPEO. At a minimum, a representative sample of 20% of the population (defined as components having the same material, water treatment program and aging effect combination) or a maximum of 17 components per population for each unit will be inspected. At least 20% of the surface area will be inspected for each component. For components measured in linear feet, such as piping, inspection of one foot axial length section is equivalent to one component inspection. Any combination of components or one foot sections of piping can be counted towards the representative sample size.

When the sample size is not based on the percentage of the population, the total number of inspections may be reduced to seventeen components per population for each unit at three-unit sites such as Oconee. This is acceptable because design, operating, and environmental conditions between the units are similar enough such that the aging effects are not occurring differently. All three units are of comparable age, and changes to water chemistry practices, operating conditions, etc., have been implemented in a consistent manner across all three units. A measurement uncertainty recapture power uprate license amendment request was approved by the NRC in January 2021 (ADAMS Accession Number ML20335A001). Implementation of the measurement uncertainty recapture power uprate will not substantively change operating conditions such that the rate of aging effects managed by this program would be affected. No other power uprates have been implemented on any of the Oconee Units. Water chemistry programs monitor various chemistry parameters and require out-of-spec conditions to be corrected under the corrective action program in a timely manner. Oconee has only one standby shutdown facility diesel generator, such that distribution of diesel generator run times is not an issue. Therefore, a reduced maximum sample population size will provide a representative sample of the condition of the plant equipment and the existence of the aging effects involved.

Inspections focus on the bounding or lead components most susceptible to aging due to time in service and severity of operating conditions.

Heat transfer capability of heat exchanger surfaces will be evaluated by either visual inspections to determine surface cleanliness or function testing to verify that design heat removal rates are maintained.

If any inspections do not meet the acceptance criteria, additional inspections will be conducted, unless the cause of the aging effect for the applicable material and environment combination is corrected by repair or replacement. There will be no fewer than five additional inspections for each inspection that does not meet the acceptance criteria or 20% of the applicable material, environment and aging effect combination is inspected, whichever is less. If any subsequent inspections do not meet acceptance criteria, an extent of condition and extent of cause analysis will be conducted to determine the further extent of inspections. Additional samples will be inspected for any recurring degradation to ensure corrective actions appropriately address the associated causes. The additional inspections will be completed within the interval (e.g., refueling outage interval, 10-year inspection interval) in which the original inspection was conducted.

The additional inspections will include inspections of components for the same material, environment, and aging effect combination from all three units. The additional inspections will be conducted within the interval (e.g., refueling outage interval, ten year inspection interval) in which the original inspection is conducted. Inspections and tests will be performed by personnel qualified in accordance with site procedures and programs to perform the specified task. Inspections within the scope of ASME Code will follow procedures consistent with the ASME Code. Non-ASME Code inspection procedures will include guidance for items such as lighting, distance, offset, surface coverage, presence of protective coatings, and cleaning processes.

NUREG-2191 Consistency

The Oconee *Closed Treated Water Systems* AMP is an existing program that will be consistent with the ten elements of AMP XI.M21A, "*Closed Treated Water Systems*" specified in NUREG-2191 (GALL-SLR), as modified by SLR-ISG-2021-02-MECHANICAL, "*Updated Aging Management Criteria for Mechanical Portions of the Subsequent License Renewal Guidance*," with enhancements described below.

Exception to NUREG-2191

None

Enhancements

The following enhancement(s) will be implemented in the following program element(s): Parameters Monitored or Inspected (Element 3), Detection of Aging Effects (Element 4), Monitoring and Trending (Element 5), Corrective Actions (Element 7)

1. Perform condition monitoring using techniques (visual, surface, or volumetric) capable of detecting loss of material, cracking, and fouling as appropriate. Perform visual inspections for loss of material and fouling whenever the system boundaries of the closed treated water systems are opened. Perform surface or volumetric examinations when susceptible materials are inspected for cracking (Elements 3 and 4).

2. In each ten year period during the SPEO, perform sufficient number of inspections to ensure that the minimum representative sample of 20% of the population up to 17 inspections per unit is met. A population is defined as components having the same material, water treatment program and aging effect combination. Perform inspections on those components that are more likely to be susceptible to aging based on time in service and severity of operating conditions (Element 4).

3. Perform additional inspections when inspections do not meet acceptance criteria. Perform at least 5 additional inspections for every inspection not meeting acceptance criteria or 20% of each applicable material, environment, and aging effect combination, whichever is less (Elements 4 and 7).

4. Provide additional guidance in procedures for inspections of non-ASME Code components for items such as lighting, distance, offset, surface coverage, presence of protective coatings, and cleaning processes (Element 4).

5. Where practical, project the rate of any degradation until the next scheduled inspection or the end of the SPEO (whichever is shorter). Adjust the sampling bases (e.g., selection, size, frequency) as necessary based on the projections (Element 5).

6. If subsequent inspections identify aging effects, the corrective action program will be used to determine the extent of condition and extent of cause to determine the further extent of inspections. Perform additional inspections on all units with the same material, environment, and aging effect combinations and within the interval of the original inspection (e.g., refueling outage interval, ten year inspection interval). (Element 7).

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Closed Treated Water Systems* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2013 and 2014, corrosion rate measurements from coupon testing were performed for the Component Cooling Water, Recirculating Cooling Water, Chilled Water (Vital Loads), and Chilled Water (Non-Vital Loads). Results from these tests showed very low corrosion rates in these systems as summarized below:

   - The Units 1, 2, and 3 Component Cooling System showed no measurable corrosion response for copper, brass, carbon steel, and stainless steels. Cast iron coupons were the only material to show a corrosion response with corrosion rate on all three units well below 0.3 mil/yr. Corrosion rates below 0.3 mil/yr are considered to be in the "good" category (i.e., lowest corrosion rate category) as defined in EPRI Report 3002000590 Table 8-1.
   - The Unit 1/2 and Unit 3 Recirculating Cooling Water System showed no measurable corrosion response for stainless steel and admiralty brass. Steels were the only material to exhibit a detectable corrosion rate, with corrosion rates well below 0.3 mil/yr.
   - The Chilled Water (Vital Loads) and Chilled Water (Non-Vital Loads) showed no measurable corrosion response for steel and copper.

   OE example 1 demonstrates that corrosion rate monitoring of closed treated water systems is being performed in accordance with industry guidelines and that corrosion coupon surveillances are effective in monitoring effectiveness of water treatment programs and identifying aging effects prior to loss of intended function.

2. In 2014, pH in the A and B standby shutdown facility diesel jacket water cooling system was found out of specification below the action level 1 limit of 9.0. In accordance with chemistry procedures, caustic chemical addition was performed to bring pH back into specification. The cause of the decrease in pH was attributed to an engine coolant addition following an annual standby shutdown facility diesel outage. During this outage, the entire diesel jacket water inventory was drained and replaced with newly mixed coolant. Following the completion of the diesel outage, a performance test of the standby shutdown facility diesel was completed, and the standby shutdown facility Diesel Jacket Water Cooling System was sampled for total iron and total copper only. Further investigations determined that work instructions and chemistry procedures did not provide sufficient guidance as to the parameters that were to be sampled following the post maintenance run. The standby shutdown facility diesel jacket water cooling system was not sampled again until 22 days after the outage, resulting in the control parameter remaining out of specification for an extended period of time.

   The possibility that the coolant was diluted following the coolant addition was ruled out as no demineralized water additions were performed, thus leading to the conclusion that insufficient quantity of sodium hydroxide was added during the coolant premixing to raise the pH within specification. Coolant is premixed in drums for the addition to the standby shutdown facility diesel jacket water cooling system. The procedure for premixing the coolant did not provide instructions on the quantity of sodium hydroxide to be added or to verify afterwards that pH and other chemistry parameters were within specification.

   A contributing cause was determined to be the lack of qualified personnel to perform the sampling task during times when the standby shutdown facility diesels were running.

Standby shutdown facility diesel runs are normally conducted during weekends and backshifts, periods when qualified resources were not available to conduct sampling.

Resulting corrective actions were initiated to: 1) revise procedures to require a post-chemical addition sampling/analysis within a specified period of time to verify that chemical additions adjusted chemistry as desired, and 2) ensure sampling and analysis of the standby shutdown facility diesel jacket water cooling system is performed while running and appropriate personnel qualified to the task are available.

OE example 2 provides objective evidence that the water treatment program effectively monitors in scope treated water systems to assure that water treatment program processes and specifications are maintained and adjusted as necessary. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to implement corrective actions to improve program performance.

3. In 2016, a data review identified a long-term trend of increasing copper and ammonia in the Unit 1/2 and Unit 3 recirculating cooling water system. The trend indicated copper was increasing in parallel with ammonia. The cause of increasing ammonia in the recirculating cooling water system, as well as in other closed treated water systems, is suspected to be produced from bacteria under a sludge or slime layer that is not detectable using the typical biological growth detection technique. Investigations concluded that the cause of the increasing ammonia was not due to leakage from a secondary system source. The best option for the treatment for increasing ammonia is to add glutaraldehyde (H-550). Glutaraldehyde is a biocide that controls microbiological growth and reacts with and removes ammonia present in the bulk water above the sludge/slime layers. The increasing ammonia trend was corrected for the recirculating cooling water system following the biocide addition.

   OE example 3 provides objective evidence that the program manager critically self-assesses program performance and self-identifies actions that support continuous improvement. This example also demonstrates the effective use of the corrective action program and industry OE to take timely and effective corrective actions to correct deficiencies that could adversely affect closed treated water system intended functions during the SPEO.

4. In August 2020, an AMP effectiveness review of license renewal aging management activities was performed, which included a detailed review of select AMPs and commitments. Although the *Closed Treated Water Systems* program is not an aging management program identified in UFSAR Chapter 18, the program encompasses programs and aging management activities developed for the first license renewal. These Chapter 18 programs and aging management activities include: *Chemistry Control* program (UFSAR Section 18.3.2) and the *Jacket Water Heat Exchanger* preventive maintenance activity (UFSAR Section 18.3.17.9). The AMP and preventive maintenance activity were evaluated against the performance criteria identified in NEI 14-12, “Aging Management Program Effectiveness.” The review concluded that the *Chemistry Control* program and *Jacket Water Heat Exchanger* preventive maintenance activity are meeting the requirements of NEI 14-12. No gaps were identified by the effectiveness review.

This effectiveness review provides objective evidence that current programs and activities encompassed by the *Closed Treated Water Systems* program are effectively managing aging and meeting all current LR commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the SPEO.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Closed Treated Water Systems* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Closed Treated Water System* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Closed Treated Water Systems* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.13 INSPECTION OF OVERHEAD HEAVY LOAD AND LIGHT LOAD (RELATED TO REFUELING) HANDLING SYSTEMS

Program Description

The *Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* AMP is an existing monitoring program that provides for periodic visual inspections of cranes and hoists in the scope of 10 CFR 54.4. The program includes structural components that make up the bridge, the trolley, the rail system, structural bolting, and lifting devices, and includes cranes and hoists that meet the provisions of NUREG-0612, "*Control of Heavy Loads at Nuclear Power Plants*." These cranes must also comply with the maintenance rule requirements provided in 10 CFR 50.65.

The AMP includes periodic visual inspections to detect degradation of bridge, rail, and trolley structural components and bolted connections. The program relies on the guidance in NUREG-0612, ASME B30.2, "*Overhead and Gantry Cranes (Top Running Bridge, Single or Multiple Girder, Top Running Trolley Hoist)*," and other appropriate standards in the ASME/ANSI B30 series to manage aging. The inspection frequency for cranes is based on the guidance provided by ASME B30.2. The inspection frequency for hoists is based on guidance provided by ASME B30.16, "*Overhead Underhung and Stationary Hoists*."

NUREG-2191 Consistency

The *Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* AMP is an existing program that will be consistent with the ten elements of AMP XI.M23, *"Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems,"* specified in NUREG-2191 (GALL-SLR) with enhancements as described below.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented in the following program elements: Parameters Monitored/Inspected (Element 3), Detection of Aging Effects (Element 4), Acceptance Criteria (Element 6), and Corrective Actions (Element 7)

1. Provide additional procedural guidance to include visual inspections looking for deformation and cracking of bridges, structural members, and structural components (Elements 3, 4 and 6).

2. Provide additional procedural guidance to specify bolted connections are monitored for loss of material, cracking, loose or missing bolts or nuts, and other conditions indicative of loss of preload (Elements 3, 4 and 6).

3. Include evaluation of findings according to ASME B30.2 or other applicable ASME B30 series in applicable procedures (Element 6).

4. Enhance maintenance procedures to ensure repairs are performed in accordance with manufacturers literature and ASME B30.2 or other applicable ASME B30 series (Element 7).

<u>Operating Experience</u>

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. It was identified in 2015 that the Polar Crane inspections were not being performed in accordance with ASME B30.17. There were two visual inspections scheduled in the work management system associated with the polar crane; one for the periodic maintenance set to a 2 year frequency (on a refueling outage basis), and one to perform the structural steel inspections set on a 6 year frequency. ASME B30.17 requires such inspections be performed each outage, prior to use. A condition report was initiated in the corrective action program and corrective actions implemented to revise the applicable maintenance procedure and work management system activity schedule to require Polar Crane structural steel inspections each outage (prior to use).

   OE example 1 provides objective evidence that the program manager critically self-assesses program performance, identifies deficiencies and initiates appropriate corrective actions to evaluate and correct deficiencies using the corrective action program.

2. Maintenance technicians identified corrosion/rust on the Keowee intake crane structure during a 2017 visual inspection. Engineering evaluated the corrosion and noted the corrosion was primarily at the welded seams at the diamond plate decking and a result of constant exposure to the elements/humid/wet environment. There was no significant metal loss and the crane was deemed fully operable. A work request was generated in the work management system to strip the area of corrosion and recoat.

   The *Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* program inspections are effective in identifying aging effects prior to loss of intended function. OE example 2 also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to monitor and trend the conditions.

3. In September 2020, an aging management program effectiveness review was performed on the *Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* program. The *Overhead Heavy Load and Light Load (Related to Refueling) Handling*

Systems program was evaluated against the performance criteria identified in NEI 14-12 “Aging Management Program Effectiveness.” The review concluded that the *Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* program is meeting the requirements of NEI 14-12. No gaps were identified during the effectiveness review. This effectiveness review provides objective evidence that the current *Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* program is effectively managing aging and meeting all current license renewal commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the subsequent period of operation.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Periodic assessments of the *Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.14 COMPRESSED AIR MONITORING

Program Description

The *Compressed Air Monitoring* AMP is an existing preventive and condition monitoring program that manages loss of material downstream of the instrument air dryers. The program provides reasonable assurance of the integrity of instrument air system components exposed to a dry air environment. Program activities include air quality checks at various locations to ensure that moisture (water), particulates, and hydrocarbons (oil) are maintained within the specified limits. The program also includes performance of opportunistic inspections of the internal surfaces of select compressed air system components for signs of loss of material due to corrosion. The program manages loss of material in carbon steel, stainless steel, galvanized steel, copper alloy, and copper alloy (>15% Zn) piping, piping components, valve bodies, tanks and filter housings in an air-dry internal environment.

The AMP is based on the Oconee responses to NRC GL 88-14, *"Instrument Air Supply Problems"* and INPOs SOER 88-01, *"Instrument Air System Failures"*. The program also incorporates the air quality provisions provided in EPRI's *Compressed Air System Maintenance Guide* (Report 1006677) and ANSI/ISA-7.0.01-1996, *Instrument Society of America Quality Standard for Instrument Air.* The program is informed by guidance in the American Society of Mechanical Engineers (ASME) operations and maintenance standards and guides (ASME OM-2012, Division 2, Part 28).

The *Compressed Air Monitoring* AMP credits periodic tests and preventive maintenance inspections of compressed air system components to detect the effects of corrosion and presence of contaminants. The program ensures that air quality test data is reviewed and compared to test acceptance criteria to determine if limits have been exceeded. Air quality analysis results are checked for unusual trends. Test data are analyzed and compared to data from previous tests to provide for the timely detection of aging effects on passive components. Opportunistic visual inspections of accessible internal surfaces will be performed to identify signs of corrosion and abnormal corrosion products that might indicate a loss of material within the system. Results from inspections are compared with established acceptance criteria to provide for timely detection of aging effects. Monitoring methods are effective in detecting the applicable aging effects, and the frequency of monitoring is adequate to prevent significant age-related degradation. Tests and inspections provide assurance that systems and components within the scope of the program continue to perform their intended function.

Deficiencies are documented in the corrective action program and evaluations are performed for test or inspection results that do not satisfy established criteria. The corrective action program ensures that conditions adverse to quality are promptly corrected. The corrective action program is implemented in accordance with the requirements of the 10 CFR Part 50, Appendix B quality assurance program.

NUREG-2191 Consistency

The *Compressed Air Monitoring* AMP is an existing program that will be consistent with the ten elements of AMP XI.M24, *"Compressed Air Monitoring"* specified in NUREG-2191 (GALL-SLR) with enhancements described below.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented in the following program elements: Detection of Aging Effects (Element 4), Monitoring and Trending (Element 5), Acceptance Criteria (Element 6) and Corrective Action (Element 7):

1. Perform opportunistic visual inspections of select component internal surfaces exposed to a dry air environment for signs of loss of material due to corrosion. Inspections will be performed by station personnel who have been qualified to the task per approved training procedures and programs. Acceptance criteria will ensure that internal surfaces that show signs of corrosion, that could indicate the potential loss of function of the component, are identified. The program will require corrective actions to be taken if loss of material due to corrosion is identified on internal surfaces of components. (Elements 4, 5, 6, and 7)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Compressed Air Monitoring* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. As part of the current *Compressed Air Monitoring* AMP, the primary instrument air system quality test is used to monitor for oil content. At one time, little or no oil was generally detected in the system air samples. At an industry users group meeting in 2011, another utility shared that test equipment used to accomplish air quality sampling may not be suited for detecting synthetic oil. Synthetic oil was used in the system compressors at Oconee. The Oconee program manager validated the information with the test equipment vendor and a condition report was initiated in the corrective action program to document the situation. The information was also shared with the nuclear industry.

   Ultimately, the oil sampling method was changed to meet the requirements of ANSI CGAG-7.1-2004 and as noted in EPRI *Compressed Air System Maintenance Guide*, (1006677). Use of the revised sample method resulted in oil samples results ranging from 0.017 to 0.79 ppm. This method required a revision to the test acceptance criteria to align with the ANSI Standard of <1 ppm.

   OE example 1 provides objective evidence that the program manager critically self-assesses program performance and self-identifies actions that support continuous improvement. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality.

2. In December 2013, a corrective action was initiated requesting that the Oconee compressed air monitoring program owner compare existing instrument air quality guidance to revised INPO Significant OE Report (SOER) 88-1 recommendations and to make changes as necessary. The compressed air monitoring program owner performed the review and instituted several program changes. The frequency of monitoring of system dew point was increased from once per day to once per shift. In addition, the basis for the frequency of air quality testing was reviewed and confirmed. Improved test methods were also evaluated. Results of the instrument air quality guidance comparison to the revised INPO SOER 88-1 recommendations were documented in the corrective action program.

   OE example 2 provides objective evidence that industry OE that involves aging is evaluated and used to adjust the program as necessary.

3. In November of 2016, an operator on turbine building rounds identified that the B primary instrument air system dryer had *"High Dew Point"* and *"Fail to Shift"* alarm status. A -24^{o}F high dew point condition prompted an automatic swap from the in stream right desiccant tower to the left desiccant tower which resulted in the "Fail to Shift" alarm. As a result, the primary instrument air compressor was shut down and a condition report and a work request were written.

   Maintenance and engineering personnel inspected the dryer and concluded that a dryer valve was not closing as expected. The valve was disassembled, and it was discovered that the lower disc nut had backed off and allowed the disc to dislodge from the stem. The valve was successfully reassembled with replacement parts. The valve procedure was changed to require a higher strength thread sealant to be used on the disc nut.

   OE example 3 provides objective evidence that the existing AMP activities are being effectively implemented to identify and manage aging effects of in scope components and that the results of inspection activities are used to inform and enhance the program. Deficiencies identified during inspection activities are entered into the corrective action program and appropriate actions are taken to evaluate and correct deficiencies.

4. In May of 2019, performance of the primary instrument air system quality test resulted in the acceptance criteria for particulate concentration not being met. The sample taken at the primary instrument air filter A location produced particles that were ten microns in size which exceeded the one micron criteria specified in the procedure. As a result, a condition report and a work request were written. The work request noted that the test results did not create an operational concern as critical systems are equipped with air filtration capability of five microns or smaller.

   Subsequent evaluation by engineering concluded that the sample tubing was not adequately purged prior to taking the sample. The inadequate purge was deemed to be the result of a training deficiency that resulted from the turnover of performance of the test from one organization to another. A training request form was submitted to address the training issue. The primary instrument air system quality test was re-performed with an adequate purge of the sample tubing with acceptable results.

OE example 4 provides objective evidence that the existing AMP activities are being effectively implemented to identify and manage aging effects of in scope components and that the results of inspection activities are used to inform and enhance the program. Deficiencies identified during inspection activities are entered into the corrective action program and appropriate corrective actions are taken to evaluate and correct the deficiencies.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Compressed Air Monitoring* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Compressed Air Monitoring* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Compressed Air Monitoring* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.15 FIRE PROTECTION

Program Description

The *Fire Protection* AMP is an existing condition and performance monitoring program that manages the identified aging effects for the fire barriers and the standby shutdown facility fire protection CO_2 system and associated components through the use of periodic inspections and functional testing to detect aging effects prior to loss of intended functions. System tests and inspections are performed by qualified personnel in accordance with guidance from NFPA Codes and Standards. The program applies to piping, piping components, and fire barriers (doors and dampers, penetration seals, walls, and slabs). Fire Protection component materials include carbon steel, galvanized steel, stainless steel, concrete, concrete block, grout, fireproofing materials, and elastomers.

The *Fire Protection* program monitoring methods are effective in detecting the applicable aging effects and the frequency of monitoring is adequate to prevent significant degradation. The program utilizes visual inspections of fire barrier penetration seals for signs of degradation such as cracking/shrinking, wear, seal separation from walls and components, and punctures, through periodic inspection. The program specifies visual examinations of the fire barrier walls, ceilings, and floors in structures within the scope of LR for signs of degradation such as loss of material and cracking/spalling. Periodic visual inspections are used to manage the aging effects of fire doors and fire damper assemblies. Fire doors are functionally tested. Inspection and testing frequencies are consistent with Oconee Selected Licensee Commitments. These inspections and tests are implemented through station procedures and recurring task work orders. Unacceptable conditions are entered into the corrective action program for proper disposition.

The program includes functional testing of standby shutdown facility fire protection CO_2 system components. The program also provides for aging management of external surfaces of the standby shutdown facility fire protection CO_2 system components that are within the scope of LR through periodic visual inspections for corrosion that may lead to loss of material.

NUREG-2191 Consistency

The Oconee *Fire Protection* AMP is an existing program that will be consistent with the ten elements of AMP XI.M26, *"Fire Protection Program"* specified in NUREG-2191 (GALL-SLR) with enhancements, as described below.

Exception to NUREG-2191

None

Enhancements

The following enhancement(s) will be implemented in the respective program element(s): Parameters Monitored or Inspected (Element 3), Detection of Aging Effects (Element 4), and Acceptance Criteria (Element 6).

The *Fire Protection* AMP will be enhanced to perform periodic visual inspection every 18 months for identification of corrosion that may lead to loss of material on the external surfaces of the standby shutdown facility fire protection CO_2 system.

<u>Operating Experience</u>

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Fire Protection* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. A corrective action program entry was made in April 2009 to document a concern regarding air potentially coming through a fire barrier penetration in the Turbine Building. A follow-up inspection found that the spare 2 inch diameter pipe sleeve penetration had no penetrants and was filled with approximately 16 inches of Dow Corning silicon foam. The condition of the cell structure of the foam was found to be acceptable. Based on inspection, there was good compression between the foam and the surface of the pipe sleeve and there was very little depth to any delamination occurring between the sleeve and the foam material. The source of the air flow perceived to be coming through the penetration was a floor opening/gap that allows natural circulation of air from the Turbine Building basement to proceed up past the penetration. No further action was required.

2. A corrective action program entry was made in August 2009 to document a finding identified during routine fire barrier inspections per procedure. The inspection identified a fire barrier between the Turbine Building and East Penetration Room which was degraded as a result of a damming board, which forms a portions of the fire barrier, found to have fallen off. An impairment was entered, and a continuous fire watch was established. Repairs were completed on the same shift per instructions provided in the inspection procedure for repair and reinstallation of damming material.

3. A corrective action program entry was made in January 2015 to address a degraded seal found during maintenance inspections of a Unit 1 cable room door (a commercial fire door). A follow up inspection was performed and found a cracked and degraded threshold seal between the threshold and the bottom of the door. Due to the very small size of the threshold gap, an evaluation determined that the fire door, in the as found configuration, was fully capable of meeting required design functions. A work request was issued to repair the material condition of the seal.

4. A corrective action program entry was made in July of 2010 to document a condition that affected the crossover fire dampers in the Unit 1, Unit 2 and Unit 3 penetration rooms. The dampers were found to have paint on them that potentially interfered with their operation. The paint on all three units' dampers appeared to be from incidental paint brush strokes that were made while painting the penetration room walls. Selected

Licensee Commitment 16.9.5 B was entered for inoperable Oconee Unit 1, 2, and 3 fire dampers with no fire detection within 15 feet on only one side of the damper. Hourly fire tours were initiated per the Selected Licensee Commitment required actions, and fire impairments were implemented until corrective actions were completed. The paint was removed, and the dampers were restored to their normal configuration. As part of the corrective action, a test was written to demonstrate that the “gravity” drop fire dampers would function as required with paint in the damper tracks. The test confirmed that the dampers functioned as expected.

These examples demonstrate site awareness of *Fire Protection* AMP requirements and the need to maintain the operability of fire barriers. The OE also demonstrates the use of compensatory measures while fire protection deficiencies are corrected and reflects the ongoing use of the corrective action program to capture and resolve items that might be associated with deficiencies/degradation of credited fire barriers.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Fire Protection* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Fire Protection* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Fire Protection* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.16 FIRE WATER SYSTEM

Program Description

The *Fire Water System* AMP is an existing condition monitoring program that manages loss of material and flow blockage for water-based fire protection systems that consist of sprinklers, nozzles, valve bodies, fire pump casings, hydrants, hose stations, standpipes, aboveground and underground piping and piping components, strainers, and the elevated water storage tank. The program also manages loss of coating integrity of the internal coating of the elevated water storage tank. This program relies on flow testing, visual inspections, and volumetric examination to ensure that loss of material due to due to general, pitting and crevice corrosion, microbiologically influenced corrosion, or fouling, and flow blockage due to fouling is adequately managed.

The high pressure service water system is normally maintained at required operating pressure and is monitored such that loss of system pressure is detected. The Keowee fire detection/ protection system is normally charged by static head from Lake Keowee. System flow downstream of the Keowee fire pump is monitored such that leakage from a normally stagnant line would be detected. Monitoring of operating parameters of the high pressure service water system and Keowee fire detection/protection system ensure prompt corrective actions can be initiated if leakage occurs.

The system flow testing, visual inspections and volumetric inspections ensure that aging effects are managed such that the system intended functions are maintained. Flow testing results are reviewed and trended to identify degrading trends prior to loss of system function. Inspections and tests are performed by personnel qualified in accordance with station procedures and programs to perform the specified task. The program ensures that testing and inspection activities have been performed and documented. Abnormal results are entered into the corrective action program for review and resolution.

The *Fire Water System* program will include testing of a representative sample of the sprinklers prior to fifty years in service consistent with the 2011 Edition of NFPA 25, *"Standard for the Inspection, Testing and Maintenance of Water-Based Fire Protection Systems,"* Section 5.3.1. Performance of the initial 50-year tests will be determined based on the date of the sprinkler system installation.

Portions of water-based fire protection system components that have been wetted but are normally maintained dry were designed and installed with a configuration and pitch to allow draining. Walkdowns and review of design documents have been performed to verify proper draining of dry pre-action sprinkler systems and deluge systems. Station procedures for these systems include guidance to remove drain plugs and open drain valves to ensure systems are fully drained following actuation. Therefore, augmented testing in addition to that specified in NFPA 25 is not required.

Age-related degradation of the external surfaces of underground fire main piping is managed by the *Buried and Underground Piping and Tanks* (B2.1.26) AMP. Age-related degradation of the internal surface of the cement-lined buried fire header is managed by the *Internal Coatings/ Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* (B2.1.27) AMP.

Acceptance criteria and corrective actions for the elevated water storage tank internal coating inspections are implemented by the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* (B2.1.27) program.

Recurring internal corrosion of steel water-based fire suppression system piping exposed to raw water from Lake Keowee is managed by the *Open-Cycle Cooling Water System* (B2.1.11) program.

NUREG-2191 Consistency

The *Fire Water System* AMP is an existing program that will be consistent with the ten elements of AMP XI.M27, "*Fire Water System,"* specified in NUREG-2191 with the exceptions and enhancements noted below.

Exception 1 to NUREG-2191

Program Element Affected: Detection of Aging Effects (Element 4)

1. NUREG 2191, Table XI.M27-1 recommends flow testing of the hydraulically most remote hose connection of each zone of the automatic standpipe system to verify the water supply can provide the design pressure at the required flow. The Oconee *Fire Water System* AMP will allow flow testing at hose connections other than the hydraulically most remote location.

   Justification for Exception 1

   As described in Section A.6.3.1.1 of NFPA 25, 2011 Edition, the hydraulically most remote hose stations are generally located at upper elevations. However, internal sediment and fouling is generally more prevalent at system low points. The program will allow for flow testing of hose stations at or near system low points where flow blockage due to fouling is most likely to occur. Testing of lower elevation hose stations also allows for additional flushing of the system piping most susceptible to accumulation of silt and debris such that the impact of fouling on system performance is mitigated. Further, Oconee fire suppression system design does not include a typical standpipe system where multiple hose stations on each floor are supplied through a single standpipe equipped with a control valve and alarm check valve. Instead, hose stations are supplied locally from the building header. The three-year flow test of the fire suppression system headers ensures that adequate water supply is available locally to hose stations throughout the station. If the hose station selected for testing is other than the hydraulically most remote, the acceptance criteria for the flow test will be set to account for the additional head loss that would be experienced if the hydraulically most remote hose station were tested such that the results of the flow test are representative of the limiting location.

Exception 2 to NUREG-2191

Program Element Affected: Detection of Aging Effects (Element 4)

2. NUREG 2191, Table XI.M27-1 recommends testing of deluge systems for which the nature of the equipment in the area being protected is such that water cannot be discharged in accordance with Section 10.3.4.3.1.1 of NFPA 25, 2011 Edition. The recommended deluge system test involves visual inspection to ensure that spray nozzles are correctly positioned and passing air through the spray nozzles to ensure that the nozzles are not obstructed. Visual inspections will be performed to verify spray nozzles are correctly positioned. Air discharge testing will not be performed for deluge systems at ONS that are not designed with connections to attach compressed air to the system which would allow for air flow testing.

   Justification for Exception 2

   Deluge systems that will not be tested in accordance with Section 10.3.4.3 of NFPA 25, 2011 Edition will be subject to alternative testing and inspection to ensure that the intent of the recommendations in NUREG 2191, Table XI.M27-1 is met. Each deluge system that is not air discharge tested is periodically trip tested every two years to verify the deluge valves operate as required. Periodic main drain testing will be performed at each deluge valve which will ensure that the flow path supplying water to the deluge system is not excessively fouled and will clear the line supplying the system of any accumulated debris. Significant age-related degradation is not expected of piping downstream of the deluge valve since the piping is maintained dry and has been verified to properly drain. Internal inspections have been performed at system low points where water accumulation could have occurred, and age-related degradation would be most likely. These inspections were performed after the systems had been in service for over 40 years and identified no signs of aging beyond minor surface rusting. The upstream and downstream piping attached to the deluge valve in each system will be internally inspected during periodic disassembly of the deluge valve performed every five years. Internal visual inspections will be performed to ensure branch lines supplying individual spray nozzles are not experiencing significant aging such as loss of material due to corrosion or flow blockage due to fouling. Internal visual inspections will be performed similar to those required by Section 14.2 of NFPA 25, 2011 Edition for sprinkler system branch lines that are likewise not able to be flow tested. Every five years a spray nozzle will be removed from one branch line in 50% of the deluge systems that are not flow tested to allow for internal visual inspection. The combination of testing and inspections will ensure that deluge systems that are not subject to discharge testing will be capable of providing adequate fire suppression capacity in the area being protected.

Exception 3 to NUREG-2191

Program Element Affected: Detection of Aging Effects (Element 4)

3. NUREG 2191, Table XI.M27-1 recommends periodic internal inspections of sprinkler system branch line piping consistent with Section 14.2 of NFPA 25, 2011 Edition.

Periodic internal inspections of the sprinkler system branch lines within the scope of the Oconee *Fire Water System* AMP will not be performed.

Justification for Exception 3

The only sprinkler systems within the scope of the *Fire Water System* AMP are the manually actuated dry pipe sprinkler systems providing fire suppression to the cable room, cable shaft level 3, and cable shaft level 4 & 5. Each of these systems is designed with two locked closed valves isolating the sprinkler system from the supply header. A tell-tale drain with a normally open drain valve is located at a system low point downstream of the two locked closed valves upstream of the riser supplying the sprinkler system spray header. The isolation valves are verified locked closed, the tell-tale drain valve is verified open, and the tell-tale is inspected for leakage monthly. These systems are not subject to periodic wetting as experienced by automatic dry pipe sprinkler systems during testing of the alarm check valve. A review of station OE has not identified any instances where these systems have been actuated. The sprinkler systems for the cable room, cable shaft level 3, and cable shaft level 4 and 5 are not subject to significant internal corrosion or flow blockage due to fouling since they are maintained dry and are not subject to periodic wetting during testing.

Enhancements

The following enhancements shall be implemented in the respective program elements:

Parameters Monitored or Inspected (Element 3), Detection of Aging Effects (Element 4), Monitoring and Trending (Element 5), Acceptance Criteria (Element 6), and Corrective Actions (Element 7)

1. Perform internal visual inspections of deluge system piping by removing a hydraulically remote nozzle to identify internal corrosion, foreign material, and obstructions to flow. Internal visual inspections will be performed in 50 percent of the deluge systems within the scope of the *Fire Water System* AMP that are not subject to flow testing every five years. During the subsequent five year inspection period, the alternate systems will be inspected such that piping in 100 percent of the deluge systems within the scope of the program is inspected every ten years. Follow-up volumetric wall thickness examinations will be performed if internal visual inspections detect an unexpected level of degradation due to corrosion and corrosion product deposition.

2. Prior to fifty years in service, sprinkler heads will be submitted for field-service testing by a recognized testing laboratory consistent with NFPA 25, 2011 Edition, Section 5.3.1.

3. Perform a one-time volumetric wall thickness inspection on a representative sample deluge system supply piping that is periodically subjected to flow during functional testing.

4. Perform an obstruction investigation consistent with NFPA 25, 2011 Edition, Section 14.3 if evidence of unacceptable internal flow blockage that could result in failure of system

function is identified during internal inspections. When unacceptable internal flow blockage is detected, corrective actions will include removal of the material, an extent of condition determination, review for increased inspections, follow-up examinations, and a flush consistent with NFPA 25 Annex D.5, *Flushing Procedures*.

5. Revise inspection procedures to provide additional inspection guidance regarding age-related degradation and to include inspection parameters for items such as lighting, distance, offset, presence of protective coatings, and cleaning processes.

6. Perform flow testing of at least one hose station in each building every five years to demonstrate the capability to provide the design pressure at required flow. Flow testing will be performed at the hydraulically most remote hose station or, if an alternative hose station is tested, the acceptance criteria for the test will account for the additional head loss that would occur if the hydraulically most remote hose station were tested such that the results of the flow test are representative of the limiting location. If acceptance criteria are not met, at least two additional tests shall be performed within five years. If subsequent tests do not meet acceptance criteria, an extent of condition and extent of cause analysis is conducted to determine the further extent of tests. The additional tests include at least one test at one of the other units with the same material, environment, and aging effect combination.

7. Perform external visual inspections of the elevated water storage tank consistent with Section 9.2.5.5 of NFPA 25, 2011 Edition at least once every two years.

8. Perform flushing of the mainline strainers following system actuation consistent with Section 10.2.7 of NFPA 25, 2011 Edition.

9. Perform main drain testing of the deluge system risers at least once every two years. Main drain testing of deluge systems will be performed consistent with the procedure described Sections 13.2.5 and A.13.2.5 of NFPA 25, 2011 Edition. When there is a ten percent reduction in full flow pressure when compared to the original acceptance test or previously performed tests, the cause of the reduction shall be identified and corrected if necessary. If acceptance criteria are not met, at least two additional tests shall be performed within two years. If subsequent tests do not meet acceptance criteria, an extent of condition and extent of cause analysis is conducted to determine the further extent of tests. The additional tests include at least one test at one of the other units with the same material, environment, and aging effect combination.

10. Acceptance criteria and corrective actions for internal inspections of the elevated water storage tank will be in accordance with the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers and Tanks* program. Tank wall thickness measurements will be conducted if interior pitting or general corrosion (beyond minor surface rust) is detected.

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Fire Water System* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In August 2011 a pinhole leak was discovered on a section of four-inch high pressure service water system header piping on the first floor of the auxiliary building. When the segment of piping was removed during the repair in April 2012, significant corrosion and tuberculation was identified on the internal surface of the pipe. The removed segment of piping and a sample of the corrosion product was sent for laboratory analysis which indicated that microbiologically influenced corrosion contributed to the through wall leak. The corrosion product and tuberculation within the piping appeared to restrict the flow area by approximately fifty percent. Following discovery of the issue, an extent of condition review was performed. Given that the materials of construction, service life, and service conditions are similar throughout the high pressure service water system and in the Keowee fire detection/protection system, it was assumed that a similar buildup of corrosion products is possible throughout other portions of the water-based fire suppression systems. The supply headers in the turbine building are 16-inch or eight-inch. The supply header at the Keowee hydroelectric station is eight-inch. Since the supply headers in the turbine building and at the Keowee hydroelectric station are significantly larger than the auxiliary building headers, it was determined that the impact on the performance of fire suppression equipment in the auxiliary building due to flow restriction was bounding.

   A plan was developed to assess the functionality of the station water-based fire suppression system. The functionality assessment consisted of review of system design requirements, review of recent testing results, and performance of additional flow testing to verify the system remained capable of performing its design function. The 2012 performance of the triennial system flow test confirmed the auxiliary building high pressure service water system headers were able to provide flow in excess of their design requirement. A review of data from previous triennial flow tests showed no degrading trend in system performance.

   Additional flow testing was performed at seven hose stations located in the auxiliary building. At least one hose station was tested on each of the five auxiliary building main cross headers. Two hose stations were tested on the first floor where the issue was identified. The results of the flow tests showed that each of the hose stations were capable of providing flow at the rate and pressure required by design. The fire hose nozzles were inspected for debris following the hose station flow tests to address the potential of corrosion product breaking loose and blocking downstream nozzles or sprinkler heads. The nozzles used during the flow tests pass water through orifices smaller than the orifices in system sprinkler heads and spray nozzles. Several thousand gallons of water was passed through the fire hose nozzles during the flow tests and no clogging of the nozzles was observed during any of the tests. Debris that was collected in the nozzles during the flow tests was evaluated and determined to be small enough to pass through a sprinkler head or deluge system spray nozzle.

Based on the above, it was determined that the fire suppression equipment in the auxiliary building remained functional and capable of performing design functions. To ensure future reliability of the system, approximately 300 feet of four-inch header piping in the auxiliary building was replaced. The smaller diameter piping to hose stations supplied by this section of header piping was also replaced. Additional testing and inspections were performed to assess the extent of system piping experiencing similar degradation and the impact on system performance.

Internal visual inspections were performed to directly assess the condition of the internal surface of water-based fire suppression system piping. Internal inspections included a borescope inspection of the four-inch header, branch lines supplying individual hose stations, and a representative sample of small diameter piping in sprinkler and deluge systems through a removed sprinkler head or spray nozzle. The results of recently performed unrelated internal inspections of the deluge systems for the Unit 3 auxiliary and startup transformers and the Keowee hydroelectric station main transformer were also reviewed. Other than the auxiliary building four-inch header piping, internal inspections identified no excessive internal corrosion or fouling. Ultrasonic testing of the four-inch header in the vicinity of the through wall leak location showed adequate remaining wall thickness. A review of system flow testing data from 2012 through 2020 has been performed and did not identify any trend that would indicate performance degradation due to age-related degradation such as corrosion product buildup, fouling, or flow blockage.

OE example 1 provides objective evidence that degraded conditions are entered into the corrective action program and that appropriate actions are taken to assess the impact on system intended functions and perform repairs, as required, to ensure system intended functions are maintained.

2. In January 2012, the flow test of the Keowee fire detection/protection system failed to meet acceptance criteria due to insufficient flow. The flow test is performed by actuating the deluge system for the Keowee hydroelectric station main transformer which is the most demanding fire suppression system in the Keowee fire detection/protection system. Data recorded during the test indicated that the fire protection pump was operating as designed based on comparison of the discharge flow rate and total developed head to the pump curve. The main line strainer for the deluge system was inspected and the strainer and attached piping were found to be clean with no obstructions. Approximately fifteen feet of piping directly downstream of the deluge was inspected by borescope. No evidence of blockage or corrosion product buildup was identified. The fire protection pump was unavailable to perform an adequate system flush so instead, approximately 60 of the 68 nozzles in the system were removed, inspected, and cleaned. Two were found to be blocked and twelve were found to be unblocked but have some amount of corrosion product present. The flow test was reperformed following the cleaning and re-installation of the deluge nozzles. Three nozzles were found to be blocked during the test. The test did not meet acceptance criteria due to two adjacent nozzles being blocked.

Additional borescope inspections of the deluge system piping were performed including small diameter branch piping through removed nozzles and found the piping to be clean and free of significant corrosion. All of the three-inch and four-inch header piping and most of the vertical supply piping was inspected and minimal scaling was identified. Two sections of small diameter piping was conservatively replaced due to the presence of some flake-type material identified during borescope inspection. Multiple high velocity flushes of the system were performed by removing nozzles to ensure a high enough flow velocity was achieved during the flush to remove any loose corrosion product or debris.

Following the completion of the corrective actions described above, the system was successfully retested, and all acceptance criteria were met. Blockage of deluge nozzles has also been experienced in other transformer deluge systems. To address this issue, the procedures that direct the deluge system spray testing were revised to include guidance for performing high velocity flushes of the system to remove any accumulated corrosion product or foreign material. The revised procedures direct flow measurement during flushes to ensure that adequate flow velocity is achieved. If flow measurement is not performed, then the procedures require the removal of approximately one quarter of the system nozzles and several one inch or larger fittings at the direction of engineering.

OE example 2 provides objective evidence that system testing performed by the *Fire Water System* AMP is capable of detecting degraded system performance and that appropriate corrective actions are taken when degraded conditions are identified. OE example 2 also shows that program procedures are revised to include improved guidance when issues common to multiple water-based fire suppression systems are identified.

3. The high pressure service water system, including the buried fire header, is monitored for leakage by isolating the jockey pump so normal system loads are supplied by the elevated water storage tank and monitoring the drain down rate of the tank. This test has been performed annually since 2013. The results of the elevated water storage tank drain down test since 2013 have been reviewed. Following the 2015 drain down test, a condition report was generated to document a drain down rate significantly lower than experienced during previous tests. It was determined that the lower than expected drain down rate was due to the primary instrument air compressor being out of service. The high pressure service water system normally provides approximately 80 gallons per minute of cooling water to the primary instrument air compressor. Other than during the 2015 performance of the test, the measured drain down rate of the tank was as expected based on the normal system loads during each performance of the test which indicates that system leakage is not occurring.

   OE example 3 provides objective evidence that unusual or unexpected testing results are documented in the corrective action program such that changes in system operation or performance are appropriately evaluated.

4. A review of Oconee OE over a ten year period has revealed recurring internal corrosion in steel piping exposed to raw water within the scope of the *Fire Water System* AMP. Through wall leakage due to localized piping degradation have occurred on several occasions. When leakage has been identified, the issue has been entered into the corrective action program and appropriate corrective actions have been taken including

increased inspections, piping repair or replacement, and modifications to install more corrosion resistant piping materials.

In addition, there have been several occasions over the ten year review period where wall thickness measurements have identified remaining wall thickness less than preestablished screening criteria or less than 50% of nominal wall thickness. General corrosion rates at Oconee are typically on the order of one to two mil per year due to the high quality of raw water from Lake Keowee. Challenges to required minimum wall thickness are normally due to localized corrosion. The specific corrosion mechanism cannot be definitively established through wall-thickness measurements and so are conservatively assumed to be indicative of recurring internal corrosion as defined in Section 3.3.2.2.7 of NUREG-2192. When wall-thickness below conservative screening criteria has been identified, the issue has been entered into the corrective action program and appropriate corrective actions have been taken including reevaluation of required minimum wall thickness, piping repair or replacement, and modifications to install more corrosion resistant piping materials.

Recurring internal corrosion of water-based fire suppression system piping will be managed by the *Open-Cycle Cooling Water System* (B2.1.11) AMP. The material of construction and service environment are equivalent between the open-cycle cooling water systems and the water-based fire suppression systems and, therefore, managing recurring internal corrosion of these systems as a single population is appropriate. The *Open-Cycle Cooling Water System* (B2.1.11) program will inspect a representative sample of locations with conditions that are characteristic of the conditions found throughout raw water filled systems at Oconee. The results of these inspections are then extrapolated to similar locations throughout all the raw water systems within the scope of SLR. This characteristic-based approach recognizes the commonality among the component materials of construction and the environment to which they are exposed.

OE example 4 provides objective evidence that plant OE is reviewed and evaluated for indications of recurring internal corrosion and appropriate corrective actions are taken to ensure aging is adequately managed.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Fire Water System* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Fire Water System* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry operating experience.

Conclusion

The implementation of the *Fire Water System* AMP, with the noted enhancements above, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.17 OUTDOOR AND LARGE ATMOSPHERIC METALLIC STORAGE TANKS

Program Description

The *Outdoor and Large Atmospheric Metallic Storage Tanks* AMP is a new condition monitoring program that manages loss of material on the external surfaces of the Unit 1,2 and 3 borated water storage tanks and ensures there is no significant degradation of the tank bottoms. These are indoor large volume tanks that contain water and are designed with internal pressures approximating atmospheric that are sited on concrete. This program includes preventive measures to mitigate corrosion by protecting the external surfaces of the steel components in accordance with standard industry practices.

Oconee has no outdoor aboveground tanks constructed on concrete or soil, and no indoor tanks that sit on, or are embedded in, concrete where specific OE indicates that the tank surfaces are periodically exposed to moisture.

These tanks contain treated borated water, are constructed of carbon steel, are coated both internally and externally as a preventive measure to mitigate corrosion, and are supported on a concrete foundation, such that the bottoms of the tanks are inaccessible for direct visual inspection. Each borated water storage tank is surrounded by two external layers of metal siding that house fiberglass insulation in between. Between the tank surface and the inner metal siding there is a 6” air gap. Around the bottom portions of the tank in the air gap, there are two 1” thick Tempmat insulation blankets pressed against the tank surface. There is no sealant or caulking at the tank and concrete interface as the tank is located indoors.

This program manages loss of material by conducting periodic external surface visual inspections, and tank bottom volumetric inspections on a frequency of ten years or less. Cracking is not a predicted aging effect due to the carbon steel construction. These inspections ensure significant degradation is not occurring. The periodic inspection results are compared to the acceptance criteria to allow corrective actions to be taken prior to loss of intended function.

The *Outdoor and Large Atmospheric Metallic Storage Tanks* AMP does not manage loss of coating integrity for internal coating or linings. The activities to manage the aging effects for internal coatings or linings is managed by the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* (B2.1.27) AMP. The *Structures Monitoring* AMP (A2.33) will manage the tank concrete foundations and the borated water storage tank superstructures that serve as missile barriers.

The *Outdoor and Large Atmospheric Metallic Storage Tanks* AMP will perform the following activities:

- Conduct external tank surface inspections on a minimum of 20% of the tank on a ten year frequency.
- Conduct subsequent visual inspections every refueling outage. These inspections consist of a visual examination of the outer protective metal siding around the tank to identify indications of siding damage or water intrusion. If this inspection reveals new damage or water intrusion, then the shielding will be removed around that location to

ensure no damage to the tank has occurred. If no new damage is identified, then the inspection is complete.

- Perform a volumetric inspection of the borated water storage tank bottom, at least once every 10 years during the SPEO.

Non-ASME Code inspections are conducted in accordance with site procedures that include inspection parameters for items such as lighting, distance, offset, surface coverage.

<u>NUREG-2191 Consistency</u>

The *Outdoor and Large Atmospheric Metallic Storage Tanks* AMP will be consistent with the ten elements of AMP XI.M29, *"Outdoor and Large Atmospheric Metallic Storage Tanks"* specified in NUREG-2191.

<u>Exception to NUREG-2191</u>

None

<u>Enhancements</u>

None

<u>Operating Experience</u>

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *Outdoor and Large Atmospheric Metallic Storage Tanks* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO.

1. During a planned refueling outage in the fall of 2011 when the Unit 2 borated water storage tank was drained, a physical walkdown and visual inspection of the internal coating was performed. This inspection identified minor areas where the coating had blistered, but there was no indication of a through wall coating breach. A work order was generated to remove, inspect, and re-coat the area of concern. During this process, no loss of tank material was identified. The inspection determined that the internal coating was in good condition.

   OE example 1 demonstrates that inspections of the borated water storage tanks are being performed in accordance with industry guidelines and those inspections are effective in identifying aging effects prior to loss of intended function.

2. The Unit 3 borated water storage tank anchor bolts were visually inspected in the spring of 2014 to detect loss of material. To perform this visual inspection, two layers of metal siding and a layer of insulation were removed to expose the lower tank surface and the anchor bolts. During the inspection of the tank anchor bolts, visible areas of the tank exterior were also inspected. Minor corrosion, with no material loss was identified on the tank exterior. The areas on the tank exterior with minor corrosion were cleaned and re-

coated. Subsequently, preventive maintenance inspection activities were scheduled in the facility work management system to inspect the lower portion of each Unit 1, 2, and 3 borated water storage tank exterior for corrosion.

This example demonstrates that inspections of the borated water storage tanks are being performed in accordance with industry guidelines and that those inspections are effective in identifying aging effects prior to loss of intended function. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to monitor and trend the conditions.

3. During a planned refueling outage in the Spring of 2016 when the Unit 3 borated water storage tank was drained, a physical walkdown and visual inspection of the interior of the tank was performed. The interior coating was inspected for loss of coating, flaking, or blistering, and the tank bottom was evaluated for loss of material by utilizing an ultrasonic testing machine. The evaluation report noted, small blisters in the coatings but no indication of a through coating breach was identified. Overall the condition of the coating was very good. Qualified personnel performed tank bottom thickness measurements across the entire bottom of the tank. All of the measurement readings were above nominal tank bottom thickness thresholds and no adverse loss of material trends were identified. The overall condition of the tank bottom was very good. There were no issues that were required to be resolved.

   This inspection confirms the tank interior and bottom are not degrading over time. OE example 3 demonstrates that inspections of the borated water storage tanks are being perform in accordance with industry guidelines and that those inspections are effective in identifying aging effects prior to loss of intended function.

4. During a planned refueling outage in the fall of 2016 when the Unit 1 borated water storage tank was drained, a physical walkdown and visual inspection of the interior of the tank was performed. The interior coating was inspected for loss of coating, flaking, or blistering, and the tank bottom was evaluated for loss of material by utilizing an ultrasonic testing machine. The evaluation report noted, small blisters in the coatings but no indication of a through coating breach was identified. The site coatings engineer determined the overall condition of the coating was very good. Qualified personnel performed tank bottom thickness measurements across the entire bottom of the tank. All of the measurement readings were above nominal tank bottom thickness thresholds and no adverse loss of material trends were identified. Overall the tank bottom was in very good condition and was recommended for continued service until the next scheduled inspection, currently every 3rd refueling outage. There were no issues that were required to be resolved. This inspection confirms the tank interior and bottom are not degrading over time.

   OE example 4 demonstrates that inspections of the borated water storage tanks are being performed in accordance with industry guidelines and that those inspections are effective in identifying aging effects prior to loss of intended function.

The above examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *Outdoor and Large Atmospheric Metallic Storage Tanks* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *Outdoor and Large Atmospheric Metallic Storage Tanks* AMP will be performed to identify the areas that may need further improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Outdoor and Large Atmospheric Metallic Storage Tanks* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.18 FUEL OIL CHEMISTRY

Program Description

The *Fuel Oil Chemistry* AMP is an existing mitigative and condition monitoring program that relies on a combination of surveillance and maintenance procedures to manage loss of material from tanks, piping and components in a fuel oil environment and to maintain fuel oil quality. The program includes activities which provide assurance that contaminates are maintained at acceptable levels in fuel oil systems and components.

The fuel oil tanks within the scope of this program include:

- standby shutdown facility fuel oil storage tank
- standby shutdown facility fuel oil day tank

These fuel oil storage tanks do not have internal coatings. These fuel oil tanks are maintained by monitoring and controlling fuel oil contaminants in accordance with Technical Specification 5.5.14, Standby Shutdown Facility (SSF) Diesel Fuel Oil Testing Program and SR 3.10.1.8 Surveillance Requirement.

In accordance with the technical specifications, the acceptance criteria for each new fuel and stored fuel testing parameter has been established based on the following ASTM Standards:

- ASTM D2709 Standard Test Method for Water and Sediment in Middle Distillate Fuels by Centrifuge (fuel shipments, standby shutdown facility fuel oil storage tank, standby shutdown facility fuel oil day tank)
- ASTM D6217 Standard Test Method for Particulate Contamination in Middle Distillate Fuels by Laboratory Filtration (fuel shipments, standby shutdown facility fuel oil storage tank, standby shutdown facility fuel oil day tank)
- ASTM D4507 Standard Practice for Manual Sampling of Petroleum and Petroleum Products
- ASTM D975, Standard Specification for Diesel Fuel Oils.

The standby shutdown facility fuel oil storage tank and the standby shutdown facility fuel oil day tank are periodically drained of water and accumulated sediment, cleaned, and inspected on a 10 year frequency. Inspections will continue to be performed during the 10 year period prior to the SPEO and every ten years during the SPEO. The standby shutdown facility fuel oil storage tank is also monitored quarterly for the presence of water by draining oil from the bottom of the tank and the water is removed, if found. The activities effectively manage the effects of aging and maintain potentially harmful contaminants at low concentrations.

An approved biocide is added to all new fuel received at the site as a preventive measure. Samples of stored fuel are periodically evaluated for biological organisms and boron, which serves as an indication of biocide concentration. If necessary, additional biocide is added, for example, if concentration of the approved biocide in the fuel is low.

The One-Time Inspection (B2.1.20) program supplements this program by verifying the effectiveness of mitigative actions to ensure that degradation is not occurring and component intended functions are maintained during the SPEO.

NUREG-2191 Consistency

The Oconee *Fuel Oil Chemistry* AMP is an existing program that will be consistent with the ten elements of AMP XI.M30, "Fuel Oil Chemistry" specified in NUREG-2191 (GALL-SLR) with the enhancements noted below.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented in the following program element: Preventative Actions (Element 2), Parameters Monitored or Inspected (Element 3), Detection of Aging Effects (Element 4), Monitoring and Trending (Element 5), Acceptance Criteria (Element 6), and Corrective Actions (Element 7)

1. Monitor the standby shutdown facility fuel oil day tank quarterly for the presence of water by draining oil from the bottom of the tank and remove the water, if found. (Elements 2, 3 and 7)

2. Monitor the fuel oil stored in the standby shutdown facility fuel oil day tank quarterly for the presence of bacteria and fungus. (Elements 2, 3, 4, 5 and 6)

3. Perform volumetric wall thickness measurement of the standby shutdown facility fuel oil day tank if evidence of degradation is identified visually during the 10 year internal inspection. (Elements 3 and 4)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Fuel Oil Chemistry* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In August 2012, pitting corrosion was identified on the ONS SSF Fuel Oil Storage Tank during a ten year 100% internal visual inspection of the tank. This tank is carbon steel with 0.375 inch nominal wall thickness and is externally coated but not internally lined. Following discovery of the pits, the entire internal surface of the tank, except for directly under the scaffold legs, was inspected by low frequency electromagnetic testing. One defect not previously observed during visual inspection was identified by low frequency

electromagnetic testing. Ultrasonic wall-thickness measurements of the tank were also performed. In total, nine corrosion pits were identified. Three of the pits were through-wall, three were not through-wall, and the remaining three were nearly through-wall based on comparison of the pit depths against the nominal tank wall thickness. The indications were compared against historical fuel levels. Four were at locations that were always below the lower normal level limit (i.e., always under fuel) and five were between the lower and upper normal level limits (i.e., at times exposed to air). The pits were encapsulated with two inch diameter threaded pipe half-couplings.

Based on tank level monitoring data, the location of the defects, and expected flow rate assuming all nine locations propagated through wall, engineering evaluation concluded that the intended function of the standby shutdown facility fuel oil storage tank to provide a source of oil for the standby shutdown facility diesel engines was not adversely affected by the defects identified in the tank. Since six of the corrosion pits did not penetrate the full tank wall, it was determined that the corrosion did not initiate on the outer surface of the tank. Based on the localized, random nature of the corrosion pits, including four pits located below the fuel surface and the aggressive nature of the corrosion, the degradation mechanism was determined to be microbiologically influenced corrosion. The standby shutdown facility fuel oil day tank was also inspected in 2012 and no indications of degradation was identified which indicates that this was a localized issue limited to the standby shutdown facility fuel oil storage tank.

Following the event, a review of previous fuel oil sampling results was performed to determine if programmatic changes were required. This review did not indicate any definitive trend indicating microbial growth in the standby shutdown facility fuel oil storage tank. However, the review noted a positive shift in adenosine triphosphate analysis results between June 2007 and July 2012. This shift was attributed at the time to a change in the laboratory used to perform the testing. A shift in adenosine triphosphate analysis results when the laboratories, analyzers, or even analysts is made due to the nature of the test.

Corrective actions to address the issue included the addition of periodic monitoring for boron to the oil sampling program to ensure adequate biocide concentration to prevent microbiologically influenced corrosion. Boron level serves as a measure of the presence of the Biobor JF biocide. Adenosine triphosphate analysis is also periodically performed to directly monitor potential microbial activity in the fuel. In addition, the chemistry database was updated to allow better trending of additional parameters that could indicate microbial growth including total bacterial count, total fungal count, and boron concentration. A procedure change was implemented to provide instructions for addition of biocide directly to the standby shutdown facility fuel oil storage tank, in addition to biocide addition to new fuel, when required based on operational, chemical, or physical data indicating possible microbial growth (e.g., filter plugging, adverse trends in viscosity, water and sediment, adenosine triphosphate analysis results, or biocide concentration). This issue was also submitted to INPO to ensure the ONS operating experience was shared with the industry.

The standby shutdown facility fuel oil storage tank was re-inspected in 2015, three years after the 2012 inspection and seven years earlier than the normal ten year inspection interval for the tank, as described in OE example 2 below.

OE example 1 provides objective evidence that plant-specific OE that identifies potential aging mechanisms is evaluated and used to adjust the program as necessary. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to monitor and trend the conditions. In this case, a scheduled inspection was moved up seven years.

2. In July 2015 an inspection was completed on the ONS standby shutdown facility fuel oil storage tank. Ultrasonic testing, low frequency electromagnetic testing, and visual inspections were completed on the inside of tank. All welds (shell and support ring welds) and the shell itself were visually inspected.

   Ultrasonic testing readings were taken on the shell, heads, and any suspect areas identified during low frequency electromagnetic testing. The spot ultrasonic testing readings on the shell and the heads were taken as close as reasonably possible to the locations established during the previous inspection in 2012. The low frequency electromagnetic testing system was used to perform a 100% coverage of the shell and heads.

   A visual inspection was performed on the surface and welds of the west head and the east head of the tank. No internal corrosion was found and the heads were judged to be fit for service.

   The shell of the tank was inspected visually, with ultrasonic testing, and with low frequency electromagnetic testing. A band of minor surface corrosion was found along the bottom one inch of the internal surface of the tank but did not require repair. One external corrosion pit was found higher on the tank wall. This demonstrates that the low frequency electromagnetic testing along with the ultrasonic testing inspection is effective in identifying and quantifying external degradation. This pit will be monitored in future inspections.

   All nozzles were found to be in good serviceable condition.

   Following the inspection the tank was judged to be fit for continued service. Based on ultrasonic wall thickness readings and low frequency electromagnetic testing, the tank was determined to be acceptable for continued service for at least 20 years. The site has scheduled the next inspection in 2025 which is within ten years prior to the SPEO. Periodic inspections will continue through the SPEO on a ten year frequency.

   The 2015 inspection confirmed that the corrective actions taken following the 2012 inspection were effective in preventing microbiological induced corrosion

   OE example 2 provides objective evidence that inspections, along with the corrective action program, can effectively ensure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Fuel Oil Chemistry* AMP, with the noted enhancements, will provide reasonable assurance that loss of material will be adequately managed so that the intended functions of components within the scope of LR will be maintained during the SPEO.

B2.1.19 REACTOR VESSEL MATERIAL SURVEILLANCE

Program Description

The *Reactor Vessel Material Surveillance* AMP is an existing condition monitoring program that manages reduction of fracture toughness due to neutron irradiation embrittlement of the ferritic reactor pressure vessel beltline materials in a reactor coolant and neutron fluence environment. The program uses surveillance capsules containing reactor vessel material specimens that are located near the inside reactor pressure vessel wall in the beltline region so that the specimens duplicate, as closely as possible, the neutron spectrum, temperature history, and maximum neutron fluence experienced at the inner surface of the reactor vessel. As described in RIS 2014-11, beltline materials are those ferritic reactor vessel materials with a projected neutron fluence greater than 1.0E+17 n/cm^2 (E > 1 MeV) at the end of the license period (for example, the subsequent period of operation) which are evaluated to identify the extent of neutron radiation embrittlement for the material. Because of the location of the capsules between the reactor core and the reactor vessel wall, the resulting lead factor allows surveillance capsules to achieve a neutron fluence exposure earlier than the reactor pressure vessel. This allows surveillance capsules to be withdrawn and tested prior to the inner surface receiving an equivalent neutron fluence such that the surveillance test results bound the conditions at the end of the subsequent period of operation.

The *Reactor Vessel Material Surveillance* AMP, formerly a portion of the ONS reactor vessel integrity program, is an integrated surveillance program that is based on the BWOG reactor vessel integrity program, which consisted of four B&W plant utilities, five Westinghouse plant utilities with B&W fabricated reactor vessels, and Framatome (formally Babcock & Wilcox) and is now included within the PWROG. This program meets the requirements of 10 CFR Part 50, Appendix H, which requires the implementation of a reactor vessel material surveillance program when the peak neutron fluence at the end of the design life of the vessel exceeds 1.0E+17 n/cm^2 (E > 1 MeV).

This program addresses neutron embrittlement of all ferritic reactor vessel beltline materials as defined by 10 CFR Part 50, Appendix G, as the region of the reactor vessel that directly surrounds the effective height of the active core and the adjacent regions of the reactor vessel that are predicted to experience sufficient neutron damage to be considered in the selection of the limiting material with regard to radiation damage. Materials with projected neutron fluence greater than 1.0E+17 n/cm^2 (E > 1 MeV) at the end of the subsequent period of operation are considered to experience sufficient neutron damage to be included in the beltline. Materials monitored within the ONS license renewal materials surveillance program continue to serve as the basis for this AMP.

The surveillance portion of this AMP adheres to the requirements of 10 CFR Part 50, Appendix H as well as the ASTM standards incorporated by reference in 10 CFR Part 50, Appendix H. The surveillance capsule withdrawal schedule is documented in the *Reactor Material Surveillance* AMP (BAW-1543, Revision 4, Supplement 7-A), which is the implementing document for this AMP.

Through the master integrated reactor vessel program, a large amount of surveillance data are available for many of the Linde 80 weld wire heats that are located in the reactor vessels of the ONS units. For each of the weld wire heats located in the ONS units reactor vessel where surveillance data are available, test data exist from capsules removed between one and two times their projected neutron fluence after the period of subsequent license renewal except for the upper shell to lower shell circumferential weld for ONS Unit 3.

Duke Energy was a member of the BWOG reactor vessel working group. The BWOG designed an irradiation surveillance program (master integrated reactor vessel program) in which member materials are irradiated at host plants. ONS materials were irradiated at Crystal River Unit 3 and in the master integrated reactor vessel program. The master integrated reactor vessel program Charpy values and direct fracture toughness (Master Curve and Linde 80 J-integral resistance) data will be used as supplemental data. To date this program has developed one set of Charpy values, two sets of irradiated “Master Curve” data, and a Linde 80 J-integral resistance model relative to the ONS beltline materials. The PWROG is now the mechanism for the previous BWOG reactor vessel working group activities, and Duke Energy is a member of the PWROG.

The objective of the *Reactor Vessel Material Surveillance* AMP is to provide sufficient material data and dosimetry to (a) monitor irradiation embrittlement to a neutron fluence level which is greater than the projected peak neutron fluence of interest projected to the end of the subsequent period of operation, and (b) provide adequate dosimetry monitoring during the subsequent period of operation. Dosimetry monitoring during the subsequent period of operation is performed by the *Neutron Fluence Monitoring* AMP. The *Reactor Vessel Material Surveillance* AMP provides data on neutron embrittlement of the reactor vessel materials and neutron fluence data. These data are used to evaluate the TLAA on neutron irradiation embrittlement (e.g., upper-shelf energy, pressurized thermal shock, pressure-temperature limits evaluations, etc.) as needed to demonstrate compliance with the requirements of 10 CFR Part 50, Appendix G, and 10 CFR 50.61 and 10 CFR 50.61a for the subsequent period of operation.

This AMP has capsules that have neutron fluences between one and two times the peak reactor vessel wall neutron fluence of interest at the end of the subsequent period of operation (i.e., 72 EFPY). Test results from these capsules are reported, consistent with 10 CFR Part 50, Appendix H.

Select unirradiated archive reactor vessel materials (base metals and weld metals) for the Oconee units continue to be stored and maintained for possible future use. In addition, broken irradiated Linde 80 weld metal specimens from previously removed master integrated reactor vessel program capsules are being stored and available for possible future use.

This *Reactor Vessel Material Surveillance* AMP is a condition monitoring program that measures the increase in Charpy V-notch 30 foot-pound (ft-lb) transition temperature and the drop in the upper-shelf energy as a function of neutron fluence and irradiation temperature. The data from this surveillance program are used to monitor neutron irradiation embrittlement of the reactor vessel, and are inputs to the neutron embrittlement TLAA. The ONS *Reactor Vessel Material Surveillance* AMP is also used in conjunction with the proposed ONS *Neutron Fluence Monitoring* AMP.

All surveillance capsules, including those previously withdrawn from the reactor vessel, must meet the test procedures and reporting requirements of the applicable ASTM standards referenced in 10 CFR Part 50, Appendix H, to the extent practicable, for the configuration of the specimens in the capsule. Any changes to the surveillance capsule withdrawal schedule must be approved by the NRC prior to implementation, in accordance with 10 CFR Part 50, Appendix H, Paragraph III.B.3.

NUREG-2191 Consistency

The ONS *Reactor Vessel Material Surveillance* AMP is an existing program that is consistent with the ten elements of AMP XI.M31, *Reactor Vessel Material Surveillance* AMP specified in NUREG-2191 (GALL-SLR) with the exceptions described below.

Exception 1 to NUREG-2191

1. Oconee Unit 3 only:

    Each plant is to have a plant-specific surveillance program or integrated surveillance program where at least one capsule has attained or will attain neutron fluence between one and two times the peak reactor vessel wall neutron fluence at the location of interest at the end of the subsequent period of extended operation.

    For each of the Linde 80 weld wire heats located in the ONS Unit 1 and Unit 2 reactor vessels where surveillance data are available, test data exist from capsules removed between one and two times their projected neutron fluence after the period of subsequent license renewal (i.e., 72 EFPY). However, the ONS Unit 3 upper shell to lower shell circumferential weld material peak fluence is projected to be 2.01E+19 n/cm^2 (E > 1 MeV) at 72 EFPY and the respective surveillance program material (weld wire heat 72442) that has been tested has a maximum fluence of 1.95E+19 n/cm^2 (E > 1 MeV).

    Justification for Exception 1

    The original ONS Unit 3 plant-specific *Reactor Vessel Material Surveillance* AMP was designed in accordance with ASTM E185-66 and updated to meet the intent of ASTM E185-70. ASTM E185-66 required the capsule test specimens be taken from the base metal with the highest transition temperature, any weld metal, and the associated heat-affected-zone metal. Thus the weld metal included in the ONS Unit 3 plant-specific *Reactor Vessel Material Surveillance* AMP was a Linde 80 weld, but not the controlling weld metal (same heat/flux lot as the beltline region controlling weld) within the ONS Unit 3 reactor vessel. However, with the creation of the integrated reactor vessel material surveillance program and the later master integrated reactor vessel program, test specimens representing the ONS Unit 3 controlling beltline weld were made available.

    To date, tested surveillance data are available for Linde 80 weld wire heat 72442, which is the same wire heat that is used in the controlling ONS Unit 3 reactor vessel upper shell to lower shell circumferential weld. Surveillance data exist from three capsules with fluences ranging from 6.09E+18 to 1.95E+19 n/cm^2 (E > 1 MeV), which are below the projected fluence of the controlling ONS Unit 3 circumferential weld at the end of the subsequent license renewal period (2.01E+19 n/cm^2, E > 1 MeV). However, there are several other Linde 80 weld wire heats where surveillance data are available above this projected fluence, which have compositions similar to Linde 80 weld wire heat 72442. Currently there are thirteen tested surveillance capsules that are available containing Linde 80 weld metals with copper and nickel compositions similar to Linde 80 surveillance weld WF-67 (wire heat 72442). The fluences for these capsules range from 1.96E+18 to 2.14E+19 n/cm^2 (E > 1 MeV), which exceed the ONS Unit 3 end of the SLR period fluence of the upper shell to lower shell circumferential weld (2.01E+19 n/cm^2, E > 1 MeV). Because of the similarities in copper and nickel contents, the embrittlement behavior of these Linde 80 weld wire heats is expected to be nearly identical based on the trend curve prediction methods called out in RG 1.99, Revision 2.

The observed behavior of the measured surveillance test data for these Linde 80 weld metals shows similar trend responses (shift versus fluence) with expected variances based on the small differences in copper and nickel contents and expected scatter common with Charpy impact testing. In addition, the available surveillance test data all lie within the 2-sigma (+56°F) upper bound with all but one datum point falling within the 1-sigma (+28°F) upper bound, and 68.75% of the data falling below the actual predicted trend line. Therefore, in accordance with the RG 1.99, Revision 2 guidelines, the predicted shift (ΔT30) for surveillance weld WF-67 (wire heat 72442) relative to the measured data is expected to remain conservative.

The weld wire heat 72442 best estimate copper content for the ONS Unit 3 reactor vessel upper shell to lower shell circumferential weld WF-67 differs from that of the surveillance weld WF-67 (best estimate Cu = 0.26 wt% vs. surveillance weld Cu = 0.22 wt%), but their nickel contents are the same (Ni = 0.60 wt%). There are several other Linde 80 weld wire heats where surveillance data are available, which have compositions similar to the best estimate copper and nickel contents of Linde 80 weld wire heat 72442. Again because of the similarities in copper and nickel contents, the embrittlement behavior of these Linde 80 weld wire heats is expected to be nearly identical based on the trend curve prediction methods called out in RG 1.99, Revision 2.

Currently there are nine tested surveillance capsules that are available containing Linde 80 weld metals with copper and nickel compositions similar to best estimate copper and nickel contents of Linde 80 weld wire heat 72442. The fluences for these capsules range from 7.27E+17 to 3.04E+19 n/cm^2 (E > 1 MeV), which exceed the ONS Unit 3 end of the subsequent license renewal period fluence of the upper shell to lower shell circumferential weld (2.01E+19 n/cm^2, E > 1 MeV).

The observed behavior of the measured surveillance test data for these Linde 80 weld metals shows similar trend responses (shift versus fluence) with expected variances based on the small differences in copper and nickel contents and expected scatter common with Charpy impact testing. The variances are considered reasonable such that these Linde 80 weld metals can be considered similar with respect to irradiated embrittlement behavior. In addition, the available surveillance test data all lie within the 2-sigma (+56°F) upper bound with all but one datum point falling within the 1-sigma (+28°F) upper bound, and 66.67% of the data falling below the actual predicted trend line. Note that the one data point above the 1-sigma (+28°F) upper bound was at low fluence, which is not the area of interest for this assessment. Therefore, in accordance with the RG 1.99, Revision 2 guidelines, the predicted shift ($\Delta T30$) for the ONS Unit 3 upper shell to lower shell circumferential weld WF-67 (wire heat 72442) relative to the measured data is expected to remain conservative.

Exception 2 to NUREG-2191

2. Oconee Units 1, 2, and 3:

If an existing standby capsule that has been previously withdrawn from the reactor vessel is used for testing to meet the neutron fluence criterion for the subsequent period of extended operation and the capsule does not require additional irradiation, then that (formerly standby) capsule is incorporated into the surveillance capsule withdrawal schedule of the *Reactor Vessel Material Surveillance* AMP upon receipt of the subsequently renewed license, and reporting of the test results is consistent with 10 CFR Part 50, Appendix H, with the “withdrawal date” of the capsule considered to be no later than the date of the subsequently renewed license.

Disposal of irradiated plant-specific specimens in standby capsules has been reviewed by the NRC as reported in BAW-1543, Revision 4, Supplement 7-A. The existing B&W plant-specific standby capsules either do not contain weld materials or are not expected to contribute significantly to the Linde 80-weld metal surveillance database.

Justification for Exception 2

The existing B&W plant-specific standby capsules are not required to support SLR for the Oconee Units. Relevant capsule data has been obtained to support the reactor pressure vessel TLAA have neutron fluences between one and two times the peak reactor vessel wall neutron fluence of interest at the end of the subsequent period of operation (i.e., 72 EFPY), with exception of ONS-3 heat 72442. Justification for ONS-3 heat 72442 is provided above.

Exception 3 to NUREG-2191

3. Oconee Units 1, 2, and 3:

If a plant has ample capsules remaining for future use, all pulled and tested samples placed in storage with reactor vessel neutron fluence less than 37.5% of the projected neutron fluence at the end of the subsequent period of extended operation, may be discarded. All pulled and tested samples with a neutron fluence greater than 37.5% of the projected reactor vessel neutron fluence at the end of the subsequent period of extended operation and all untested capsules are placed in storage (these specimens and capsules are saved for possible future reconstitution and reinsertion use) unless the applicant has gained NRC approval to discard the pulled and tested samples or capsules.

All pulled and tested samples with a neutron fluence greater than 37.5% of the projected reactor vessel neutron fluence at the end of the SPEO and all untested capsules have not been placed in storage.

Justification for Exception 3

The samples are not expected to contribute significantly to the Linde 80-weld metal surveillance database and are not required to support SLR for the Oconee units. Relevant capsule data has been obtained to support the reactor pressure vessel TLAA have neutron fluences between one and two times the peak reactor vessel wall neutron fluence of interest at the end of the subsequent period of operation (i.e., 72 EFPY), with exception of ONS-3 heat 72442. Justification for ONS-3 heat 72442 is provided above.

Enhancements

None

Operating Experience

Based on a broad search of pertinent Oconee operating experience, the following examples provide objective evidence that the *Reactor Vessel Material Surveillance* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2014, an action item was initiated in the corrective action program to identify potential impacts and actions in response to a discovery by Framatome regarding a Charpy specimen orientation issue for B&W-manufactured reactor vessel beltline plates and forgings. Plate and forging materials data with unspecified Charpy specimen orientations were identified that may have been used to establish material values for certain reactor vessels. Framatome prepared a condition report to address this discrepancy. The evaluation addresses the identified condition for the Surry Unit 2 reactor vessel beltline region plate materials where a discrepancy in the initial reference temperature RT_{NDT} values was noted. The deficiency was corrected and the applicable Framatome topical reports were amended. This OE was reviewed by Oconee, and it was determined there was no impact to the reactor vessel analyses.

   OE example 1 provides objective evidence that the existing AMP activities are being effectively implemented to identify and manage aging effects of in-scope components and that the results of inspection activities are used to inform and enhance the program. Deficiencies identified during inspection activities are entered into the corrective action program and appropriate corrective actions are taken to evaluate and correct the deficiencies.

2. The *Reactor Vessel Material Surveillance* AMP continues through the Master Integrated Reactor Vessel Program. The purpose of the Master Integrated Reactor Vessel Program

is to augment the existing reactor vessel surveillance programs and to provide a basis for sharing information between plants. The shared data from the integrated program provides for the continued safe operation of the each ONS unit by managing the reduction of fracture toughness of the reactor vessel materials due to neutron embrittlement. By participating in the Master Integrated Reactor Vessel Program, the ONS units fulfill the intent and scope of 10 CFR 50, Appendix H.

OE example 2 provides objective evidence that the existing AMP activities are being effectively implemented to identify and manage aging effects of in scope components and that the results of inspection activities are used to inform and enhance the program.

3. In 2012, an action item was initiated in the corrective action program to identify actions needed to update reactor vessel integrity Time-Limited Aging Analyses (TLAAs) as a result of planned changes in the ONS fuel cycle, including (a) an increase in capacity factor, (b) Measurement Uncertainty Recapture, (c) implementation of 24-month fuel cycles, and (d) implementation of once-burned high thermal performance (HTP) fuel assemblies on the periphery. Additionally, the TLAAs were updated to account for replacing the ex-vessel dosimetry in Unit 2 (see OE example 5), and to incorporate updated fluence transport calculations to address the described changes. Actions to replace the ex-vessel dosimetry and update fluence calculations to the current end-of-life were completed in 2018.

   OE example 3 provides objective evidence that the program manager for the *Reactor Vessel Material Surveillance* AMP utilizes the corrective action program to self-identify changing plant conditions and to take timely corrective actions to assure that components will continue to perform their intended functions.

4. In 2013, an action item was initiated in the corrective action program to identify potential impacts and actions in response to a discovery by Framatome that 33 EFPY pressure-temperature (P-T) limits in use at the time for ONS Unit 3 may be nonconservative. While performing calculations for 54 EFPY P-T limit curves, it was determined that the copper value for a component in the Unit 3 reactor vessel was higher than the original value used for calculating the adjusted reference temperature (ART), which is used to calculate P-T limit curves. The ART calculated with the higher copper value was significantly higher than the original ART, which resulted in an adverse impact to the existing 33 EFPY P-T limit curves. Actions were taken to (a) require compensatory actions during plant operation until new P-T limit curves were developed and implemented, (b) review operation over the previous three cycles to ensure that the integrity of the reactor vessel had not been challenged, and (c) evaluate the adequacy of operational margins with respect to design limits. No challenges to the integrity of the Unit 3 reactor vessel were identified. The issue was resolved in 2014 when new 54 EFPY P-T limit curves were implemented.

   OE example 4 provides objective evidence that the corrective action program is being used effectively to identify and implement actions in response to newly-identified conditions such that the ability of components to perform their intended functions is maintained.

5. In 2016, an action was initiated in the corrective action program to identify that the ONS existing ex-vessel dosimetry capability should be expanded to include the extended beltline region, which includes the nozzle region and the region below the active core. This work was facilitated through Duke Energy's participation in the PWROG. Measurement data from the ex-vessel dosimetry program provides the basis for justification of neutron fluence. The work also addresses the NRC RG 1.190 requirement that licensees are required to benchmark their fluence calculational methodologies against measured data and addresses recent NRC concerns regarding the qualification basis for neutron fluence calculations outside of the traditional beltline region. This action to install ex-vessel dosimetry to monitor traditional and extended beltline regions in Unit 2 was completed in 2018.

   OE example 5 provides objective evidence that the *Reactor Vessel Material Surveillance* AMP critically self-assesses program performance and self-identifies actions that support continuous improvement and to assure that components will continue to perform their intended functions.

6. In 2020, an aging management program effectiveness review was performed on the *Reactor Vessel Integrity* program. The *Reactor Vessel Integrity* program was evaluated against the performance criteria identified in NEI 14-12 "Aging Management Program Effectiveness." The review concluded that the *Reactor Vessel Integrity* program is meeting the requirements of NEI 14-12. No gaps were identified during the effectiveness review.

   This effectiveness review provides objective evidence that the current *Reactor Vessel Integrity* program is effectively managing aging and meeting all current license renewal commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the subsequent period of operation.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Reactor Vessel Material Surveillance* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Reactor Vessel Material Surveillance* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the ONS *Reactor Vessel Material Surveillance* AMP, with exceptions noted above, provides reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.20 ONE-TIME INSPECTION

Program Description

The *One-Time Inspection* AMP is a new condition monitoring program that will manage loss of material, cracking, and reduction of heat transfer of components exposed to treated borated water, treated water, waste water, raw water, air, condensation, underground, fuel oil, or lubricating oil environments. The program also manages loss of coating integrity for certain components that do not perform a pressure boundary intended function and where loss of coating integrity would not impact the intended functions of downstream components.

The *One-Time Inspection* program will conduct one-time inspections of susceptible locations to verify the effectiveness of the *Water Chemistry* program (B2.1.2), the *Fuel Oil Chemistry* program (B2.1.18), and *Lubricating Oil Analysis* program (B2.1.25). The program will verify either no unacceptable age-related degradation is occurring or require additional actions to ensure the intended function of affected components will be maintained during the SPEO. For steel components exposed to environments that do not include corrosion inhibitors, the *One-Time Inspection* program will verify that long term loss of material will not result in a loss of intended function by performing wall thickness measurements on a representative sample of components in each environment. The program also verifies that fouling is not occurring in heat exchanger tubes exposed to lubricating oil and treated water environments, that loss of material due to erosion of the high pressure safety injection minimum flow orifice is not occurring such that intended functions could be impacted, and that loss of material and/or cracking of aluminum, nickel alloy, and stainless steel in an air or condensation environment is not occurring. Additionally, the program ensures that cracking of stainless steel piping exposed to reactor cooling leakage or air in reactor vessel leakage detection piping and comparable locations in the reactor coolant system is not occurring.

The elements of the program include: (a) determination of the sample size of components to be inspected based on an assessment of materials of fabrication, environment, plausible aging effects, and OE, (b) identification of the inspection locations in the system or component based on the potential for the aging effect to occur, (c) determination of the examination technique, including acceptance criteria that would be effective in managing the aging effect for which the component is examined, and (d) an evaluation of the need for follow-up examinations to monitor the progression of aging if age related degradation is found that could jeopardize an intended function before the end of the SPEO.

The program includes inspections that are focused on locations that are isolated from the flow stream, that are stagnant, or have low flow for extended periods and are susceptible to the gradual accumulation or concentration of agents that promote certain aging effects. The inspections will include a representative sample of the system population and will focus on the bounding or lead components most susceptible to aging due to time in service, and severity of operating conditions. A representative sample size of 20% of the population (up to a maximum of 25 component inspections) will be established for each material, environment, and aging effect combination. The program verifies either that unacceptable degradation is not occurring or requires additional actions be performed that will ensure the intended function of affected components will be maintained during the SPEO.

One time inspections that do not meet acceptance criteria are evaluated in accordance with the corrective action program. If any inspections do not meet the acceptance criteria, additional inspections will be conducted, unless the cause of the aging effect for each applicable material and environment is corrected by repair or replacement. The number of increased inspections is determined in accordance with the corrective action program; however, no fewer than five additional inspections for each inspection that did not meet acceptance criteria, or 20% of each applicable material, environment, and aging effect combination is inspected, whichever is less. If subsequent inspections do not meet acceptance criteria, an extent of condition and extent of cause analysis is conducted to determine the further extent of inspections. The additional inspections will include inspections of components with the same material, environment, and aging effect combination at all three Oconee units.

This program will not be used for components with known age related degradation mechanisms, or when the environment in the SPEO is not expected to be equivalent to that in the prior operating period. Instead, other AMPs, including programs that rely on periodic inspections, are used to manage age-related degradation of these structures and components. Inspections not conducted in accordance with ASME Code Section XI requirements will be conducted in accordance with plant-specific procedures including inspection parameters such as lighting, distance, offset, and surface conditions.

<u>NUREG-2191 Consistency</u>

The ONS *One-Time Inspection* AMP is a new program that, when implemented, will be consistent with the ten elements of AMP XI.M32, *"One-Time Inspection"* specified in NUREG-2191.

<u>Exception to NUREG-2191</u>

None

<u>Enhancements</u>

None

<u>Operating Experience</u>

Based on a search of pertinent Oconee OE, the following discussion provides objective evidence that the *One-Time Inspection* AMP will be effective in managing aging effects for structures, systems, and components within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO.

1. While the *One-Time Inspection* AMP for the SPEO is not an existing or ongoing program, Oconee does have significant OE with the implementation of one time inspections arising with the initial LRA. Oconee one time inspections associated with the initial renewed license included pressurizer examinations, the reactor coolant pump lubricating oil collection system inspection, the treated water stainless steel inspection, and the reactor building spray system inspection. The results of these inspections confirmed no

significant or unacceptable aging that could impact intended functions during the initial PEO was occurring. Oconee one-time inspections addressed a range of materials, and environments, and were performed on both a focused and a sampling basis. Inspection methods included many of the same surface and volumetric examination techniques that will be utilized for SLR inspections.

The NRC performed an inspection of Oconee implementation of LR commitments in an inspection performed during August of 2012. In the inspection, the NRC inspectors reviewed the licensing basis, program basis documents, administrative and implementing procedures to verify that the inspections were performed as described in the LRA and the corresponding NRC SER. The inspectors interviewed licensee personnel to discuss the selection process for the inspection points within the scope of the program and verify consistency with the licensing basis. The inspectors also reviewed a sample of volumetric and visual inspection results to verify that the examination and evaluation of results were performed in accordance with the implementing procedures. The NRC identified no findings during this inspection and concluded that implementation of AMP activities was consistent with the LR commitments and the conditions in the renewed operating license.

OE example 1 provides objective evidence that initial LR program commitments have been properly implemented and one-time inspections provide an effective method of verifying that significant age-related degradation is not occurring in systems with chemistry controlled service environments.

2. An item was entered into the corrective action program in 2013 to document an evaluation of preventive maintenance activities associated with cleaning and inspection of the reactor coolant pump motor lower bearing oil coolers. This evaluation included a detailed inspection and metallurgical analysis, which determined that significant material degradation of these coolers had not occurred after extended time (20 years) in service. It was further noted that fouling of these coolers was minimal and had not resulted in noticeable performance degradation of the cooler manifested in higher lower bearing oil temperatures. The results of this evaluation were used to determine the appropriate interval for periodic maintenance of the coolers.

   OE example 2 provides objective evidence that the effects of aging are appropriately evaluated in systems where significant aging is not expected to ensure reliable long term operation of components within the scope of this program.

The above two examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *One-Time Inspection* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *One-Time Inspection* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *One-Time Inspection* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with Oconee CLB during the SPEO.

B2.1.21 SELECTIVE LEACHING

<u>Program Description</u>

The *Selective Leaching* AMP is a new condition monitoring program that includes a one-time inspection for components exposed to closed cycle cooling water and treated water environments since plant-specific OE has not revealed evidence of significant selective leaching in these environments, as well as opportunistic and periodic inspections for components exposed to raw water, waste water, and soil environments. Visual inspections supplemented by mechanical examination techniques such as chipping or scraping (for ductile and gray cast iron components) will be conducted. Periodic destructive examinations of components for physical properties (i.e., degree of dealloying, depth of dealloying, through wall thickness, and chemical composition) will be conducted for components exposed to raw water, waste water, and soil environments. Inspections and tests will be conducted to determine whether selective leaching is occurring and whether loss of material will affect the ability of the components to perform their intended function for the SPEO.

Components in the scope of the *Selective Leaching* AMP include piping and piping components, valve bodies, pump casings, and other components that are constructed of susceptible materials and exposed to environments conducive to selective leaching. Materials susceptible to selective leaching which are in the scope of this program are gray cast iron, ductile iron, and copper alloys containing greater than fifteen percent zinc, or greater than eight percent aluminum (aluminum bronze). Environments that promote susceptibility to selective leaching include raw water, closed cycle cooling water, treated water, waste water, and soil.

For the one-time and periodic/opportunistic portions of the program, visual inspections supplemented by mechanical examination techniques such as chipping or scraping (for ductile and gray cast iron components) will be conducted on a representative sample of components of each material and environment combination of components. A representative sample consists of three percent of each material and environment population per unit or a maximum of seven components per population per unit for periodic inspections or ten components per population for one-time inspections. When inspections are performed on piping, a one foot axial length section will be considered as one inspection. Additionally, for one time and periodic/opportunistic inspections, one destructive examination will be performed per population. The number of visual/ mechanical inspections may be reduced by two for each destructive inspection performed beyond the minimum recommended number of destructive examinations required to be performed in each ten year interval. Since Oconee is a three-unit site, a reduced periodic visual/ mechanical inspection sample size of seven components and one destructive inspection maximum per population per unit will be adopted for sample populations that are not percentage-based. This sample size reduction is acceptable because design, operating, and environmental conditions between the units are similar enough such that the aging effects are not occurring differently. All three units are of comparable age and changes to water chemistry practices, to plant equipment, and operating conditions have been implemented in a consistent manner across all three units. A measurement uncertainty recapture power uprate license amendment request was approved by the NRC in January 2021 (ADAMS Accession Number ML20335A001). Implementation of the measurement uncertainty recapture power uprate will not substantively change operating conditions such that the rate of aging effects managed by this program would be affected. No other power uprates have been implemented on any of the units. Water chemistry programs monitor various chemistry parameters and require out-of-spec conditions to be corrected under the corrective action program in a timely manner. Raw water systems for all three units draw from the same source, Lake Keowee. Therefore, a reduced sample size will provide a representative sample of the condition of the plant equipment and the existence of the aging effects involved.

Inspections are conducted in accordance with plant-specific procedures including inspection parameters such as lighting, distance, offset and surface conditions as appropriate. Results will be evaluated against acceptance criteria to confirm that the sampling bases (e.g., selection, size, frequency) will maintain the intended functions of components throughout the SPEO based on the projected rate and extent of degradation. The acceptance criteria are: (a) for copper-based alloys, no noticeable change in color from the normal yellow color to the reddish copper color or green copper oxide; (b) for gray cast iron and ductile iron, the absence of a surface layer that can be easily removed by chipping or scraping or identified in the destructive examinations, (c) the presence of no more than a superficial layer of dealloying, as determined by removal of the dealloyed material by mechanical removal, and (d) the components meet system design requirements such as minimum wall thickness, when extended to the end of the SPEO.

When the acceptance criteria are not met such that it is determined that the affected component should be replaced prior to the end of the SPEO, additional inspections will be performed. If subsequent inspections do not meet acceptance criteria, an extent of condition and extent of cause analysis will be conducted to determine the further extent of inspections

This new program will be implemented and initial inspections will be performed within the 10-year period prior to the SPEO.

<u>NUREG-2191 Consistency</u>

The Oconee *Selective Leaching* AMP is a new program that, when implemented, will be consistent with the recommendations in NUREG-2191 XI.M33, Selective Leaching.

<u>Exception to NUREG-2191</u>

None

<u>Enhancements</u>

None

<u>Operating Experience</u>

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Selective Leaching* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. A commitment was made during initial LR to perform a one-time inspection on a representative sample of gray cast iron components exposed to closed-cycle cooling water, treated water, and raw water environments to confirm that selective leaching was not occurring. This one-time inspection was completed in 2012. Inspections were performed on seven cast iron pump casings in the following systems:

   - auxiliary service water system - auxiliary service water system pump
   - chilled water system - chilled water pump
   - low pressure service water system - low pressure service water system pump
   - high pressure service water system - high pressure service water system pump
   - service water system - Keowee fire protection pump
   - condensate system - hotwell pump (two pumps were inspected, one in-situ and one that had been removed for maintenance)

   The inspections consisted of metallurgical replication to confirm the material of the pump was gray cast iron, visual inspection, and hardness testing. Prior to inspection and testing, the surface of the pumps was thoroughly cleaned, including use of mechanical methods such as scrapers, brushes, and abrasive paper, as required. Although mechanical examination (e.g., chipping or scraping) was not explicitly required, any damage to the pump casing while cleaning was considered a failure. A total of approximately 830 hardness measurements were obtained across the seven pumps. The results of the hardness testing and visual inspection detected no evidence of selective leaching and no damage occurred during cleaning of any of the seven pumps.

   OE example 1 provides objective evidence that initial LR program commitments have been properly implemented and that significant loss of material due to selective leaching is not typical for gray cast iron components exposed to closed-cycle cooling water, treated water, and raw water environments at Oconee.

2. For SLR, a ten year review of Oconee OE has been performed to identify occurrences of selective leaching. This review identified no evidence that loss of material due to selective leaching will adversely impact the performance of intended functions during the SPEO other than the example provided below in a raw water environment. No failures due to selective leaching were identified for components constructed of susceptible materials and exposed to closed cycle cooling water or treated water environments.

   OE example 2 provides objective evidence that significant degradation due to selective leaching is not occurring in susceptible materials exposed to closed cycle cooling water or treated water environments at Oconee, and therefore, the use of one-time inspection for selective leaching in these environments is appropriate for the SPEO.

3. In July 2018, field inspection during disassembly of a small, in-line filter assembly identified two chips in the alignment ring of the gray cast iron filter head. This filter is typically in service with low pressure service water (raw water) as the process fluid. The alignment ring consists of a thin protruding wall integral to the filter head that ensures proper alignment between the filter housing and head during re-assembly. The alignment ring is not part of the sealing surface and serves no function in the process flow path. Inspection of the filter head identified general corrosion present across the filter head

which was documented in the station corrective action program. Evaluation of the condition of the filter head concluded it was acceptable for continued service and a work request was issued to replace the filter head in accordance with the normal work scheduling process.

During the reassembly of the filter, the area around a threaded screw hole broke away from the filter head. This issue was documented in the corrective action program and the filter was replaced. The filter head was sent to the metallurgical laboratory for analysis. The metallurgical lab determined the gray cast iron filter head had experienced general corrosion over all areas exposed to raw water as well as areas of graphitic corrosion which significantly weakened the material such that failure occurred during normal maintenance. Three similar filters in the low pressure service water system have been selected for inspection to determine extent of condition. These extent of condition inspections are scheduled to be completed in 2021 and will include removal of the filter head for destructive examination at the metallurgical laboratory to determine if selective leaching is occurring in these components.

OE example 3 provides objective evidence that metallurgical examinations are effective for identifying selective leaching. The brittle failure of this filter indicates that the mechanical examination techniques such as chipping or scraping that will be performed will be effective at detecting selective leaching in gray cast iron components managed by this program.

The above examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *Selective Leaching* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *Selective Leaching* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Selective Leaching* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.22 ASME CODE CLASS 1 SMALL-BORE PIPING

Program Description

The *ASME Code Class 1 Small-Bore Piping* AMP is a new condition monitoring program that will manage cracking in ASME Code Class 1 small-bore piping that is defined as greater than or equal to one-inch nominal pipe size diameter (NPS) and less than four inches NPS. This program augments the existing ASME Code, Section XI requirements and provides for examination of a sample of full penetration (butt) welds and partial penetration (socket) welds in Class 1 piping to manage cracking due to stress corrosion cracking or thermal or vibratory fatigue loading. This program will employ volumetric or destructive examinations to augment inspections performed by the *ASME Code, Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* (B2.1.1) AMP.

The *ASME Code Class 1 Small-Bore Piping* AMP will focus on socket and butt welds for piping that is susceptible to stress corrosion cracking or cracking due to thermal or vibratory fatigue loading. One-time inspections and periodic inspections will be performed for a sample population of welds, in accordance with NUREG-2191, Table XI.M35-1, to determine if cracking is occurring for locations within the scope of the *ASME Code Class 1 Small-Bore Piping* program including full penetration (butt) and partial penetration (socket) welds. Since such cracking can initiate from the inside diameter of the piping, volumetric or destructive examination methods will be employed to detect cracks that may originate from the inside diameter of butt welds, socket welds, and their base metal materials. The extent and schedule for volumetric examination in this program is based on plant-specific OE and whether actions have been implemented that effectively mitigate the cause(s) of any past cracking.

Butt Welded Piping

Age-related cracking has been identified in ONS Class 1 small-bore piping butt weld populations and, therefore, the program will perform periodic examinations to monitor for cracking of butt welds within the scope of the *ASME Code Class 1 Small-Bore Piping* program. Periodic examinations of 10 percent of the butt welds within the scope of this program will be performed every 10 years, up to a maximum of 25 welds per unit. Although ONS has effectively performed corrective actions to address and mitigate the causes of the leaks that have occurred on each unit (either through design changes, improved maintenance outage practices, or increased inspections/replacements for certain locations where corrective action to preclude cracking is not feasible), periodic inspections of small-bore butt welds for Oconee Unit 1, 2, and 3 will be performed in accordance with Category C, as defined by NUREG-2191, Table XI.M35-1. Accordingly, for each unit, periodic volumetric or destructive inspections of susceptible butt welds will be performed with the first examinations completed within the 6-year period prior to the SPEO and subsequent examinations completed every 10 years during the SPEO.

Socket Welded Piping

Age-related cracking has not been identified in Class 1 small-bore socket welded piping on Oconee Unit 1, 2 or 3. As a result, a one-time examination of these welds will be performed in accordance with Category A, as defined by NUREG-2191, Table XI.M35-1. A one-time inspection of 3 percent of the socket welds within the scope of this program, up to a maximum of

10 welds per unit, will be performed for each ONS unit within the 6-year period prior to the SPEO. The examination method will be volumetric or destructive with welds selected for examination from locations determined to be most risk significant and most susceptible to cracking. Because more information can be obtained from a destructive examination than from a nondestructive volumetric examination, as stated in NUREG-2191, Table XI.M35-1, each socket weld subject to destructive examination will be credited as equivalent to having volumetrically examined two welds toward the number of required inspections. If evidence of cracking is identified during the one-time inspections, periodic examinations of ten percent of the socket welds within the scope of this program will be performed every ten years.

The following *ASME Code Class 1 Small Bore Piping Welds* table provides a summary of the inspections required for ONS Units 1, 2 and 3 Class 1 small bore piping:

Table B1-1 ASME Code Class 1 Small Bore-Piping Welds

Unit	Weld Type	Table XI.M35-1 Category	Examination	Total Weld Population	Sample Size[1] (Percent/Number Requiring Inspection
1	Butt	C	Periodic	265	25 (10% up to 25)
1	Socket	A	One-time	91	3 (3% up to 10)
2	Butt	C	Periodic	448	25 (10% up to 25)
2	Socket	A	One-time	108	4 (3% up to 10)
3	Butt	C	Periodic	393	25 (10% up to 25)
3	Socket	A	One-time	86	3 (3% up to 10)

Note 1: Number of inspections required are rounded up to the nearest whole number

Volumetric examinations will employ techniques that have been demonstrated to be capable of detecting flaws and discontinuities in the examination volume of interest. Destructive examination methods may be used in lieu of volumetric examination. If cracking is revealed by an inspection, the condition will be entered into the corrective action program and additional inspections will be performed for the population of welds (butt welds or socket welds) that have experienced cracking in accordance with ASME Section XI, Sub-article IWB-2420; and periodic inspections will continue to be performed in accordance with NUREG-2191, Table XI.M35-1, Category C.

This new ONS *ASME Code Class 1 Small-Bore Piping* AMP will be implemented within the 6 years prior to the SPEO. Initial periodic examinations for the butt weld populations on each ONS unit will be completed within the 6 years prior to the start of the SPEO, and no later than 6 months prior to the SPEO or no later than the last refueling outage prior to the SPEO. Subsequent periodic examination campaigns for butt welds will also be completed every 10 years during the SPEO. One-time inspections will be completed for the socket weld populations for each ONS unit within the 6 years prior to the start of the SPEO, and no later than 6 months prior to the SPEO, or no later than the last refueling outage prior to the SPEO.

Industry and plant-specific OE will be evaluated in the development and implementation of this program.

NUREG-2191 Consistency

The Oconee *ASME Code Class 1 Small-Bore Piping* AMP is a new program that, when implemented, will be consistent with the ten elements of AMP XI.M35, *ASME Code Class 1 Small-Bore Piping* specified in NUREG-2191 (GALL-SLR).

Exception to NUREG-2191

None

Enhancements

None

Operating Experience

Based on a search of pertinent ONS OE, the following examples provide objective evidence that the *ASME Code Class 1 Small-Bore Piping* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. The OE search for this AMP included the corrective action program, metallurgical laboratory reports, and programmatic inspection results.

A comprehensive review of all available plant specific ONS Unit 1, 2 and 3 OE was performed during the development of the ONS SLRA to identify all issues of cracking or leaks in ASME Code Class 1 small-bore piping (less than 4 inch NPS and greater than or equal to 1 inch NPS). As documented below, cracking of small-bore socket welds has not occurred at ONS but has occurred in certain small-bore butt weld locations. These cracking events occurred due to design considerations unique to the specific location where the crack occurred or improper outage practices that have subsequently been corrected and do not indicate that cracking of small-bore butt welds is prevalent at ONS. In instances where corrective actions to preclude cracking were not feasible, additional inspections are performed (i.e., augmented ISI inspections) to monitor for cracking and initiate replacement, as required. Regardless, the *ASME Code Class 1 Small-Bore Piping* AMP will perform periodic examinations of a representative sample of small-bore butt welds in accordance with Category C, as defined in Table XI.M35 of NUREG-2191 to ensure that cracking of these welds is adequately managed during the SPEO.

<u>ONS Unit Specific Plant Operating Experience</u>

Each instance of age-related cracking (i.e., stress corrosion cracking and cracking due to thermal or vibratory fatigue loading) of ASME Code Class 1 small bore piping (less than four inches nominal pipe size and greater than or equal to one inch nominal pipe size) that was identified during the review of ONS OE is summarized below for each ONS unit.

<u>Unit 1</u>

1. In January 1998, a leak was discovered in a butt welded 90-degree elbow on the ONS Unit 1 pressurizer surge line drain line. A crack had developed in a butt weld on the drain line from the pressurizer surge line (Reference: LER 269/98-02).

   The component was removed and sent for metallurgical analysis. Destructive examination determined the failure was caused by a combination of stress corrosion cracking that developed on the external weld surface coupled with a mechanical vibration that drove the crack through- wall. The corrosive environment on the exterior surface of the piping was determined to be caused by regular outage decontamination and wash down practices that may have provided chlorides and moisture needed for stress corrosion cracking to occur. During the investigation of the leak, destructive examination and internal surface examinations showed no evidence of inside diameter-initiated cracking in the drain line. The metallurgical report noted evidence of fatigue striations and scattered ductile rupture away from the crack origins. This suggests mixed-mode (stress corrosion cracking/fatigue) propagation after crack initiation.

   Corrective actions completed included performing penetrant testing at affected weld locations on the pressurizer surge line prior to removal of drain line for replacement. The results of the non-destructive examinations revealed no indications. An extent of condition investigation was completed which included performing additional penetrant testing non-destructive exams for Class 1 butt welds on Unit 1 as well as both Unit 2 and 3 Class 1 butt welds that are not included in the ISI program (pipe diameter 1 inch or less). Penetrant testing surface examination is an appropriate inspection technique since the leak was caused by externally initiated stress corrosion cracking. No evidence of cracking was identified during these examinations.

   A corrective action was completed to perform chemistry analysis on the pressurizer surge line including the removed portions of the pressurizer surge drain line in accordance with the power chemistry materials guide program. This action confirmed that chlorides on the outside diameter of the surge drain line exceeded limits. Additional corrective actions were initiated to document and clean all affected areas.

In addition, entries were made into the corrective action program to further investigate and determine the source of the vibration on the pressurizer surge line drain. The apparent cause analysis confirmed the cause of the pipe leak to be cracking initiation by external chloride induced stress corrosion cracking and propagation by a mixed mode of stress corrosion cracking and fatigue. Corrective actions completed included replacement and reanalysis of the Unit 1 pressurizer surge drain line. Other completed corrective actions included improved procedures with better preventive measures to minimize introduction of corrosives (such as chlorides) into to the plant environment.

Although this chloride contamination event was caused by improper outage practices that have since been corrected and can be considered event-driven rather than age-related, this OE example is conservatively considered evidence that cracking of small-bore butt welds could occur at ONS Unit 1. Mitigation has been completed, including replacement and reanalysis of the pressurizer surge drain line piping and improvement of outage practices to ensure that chloride contamination of stainless-steel piping susceptible to stress corrosion cracking does not occur. Periodic surface inspections of the pressurizer surge drain nozzle are currently performed as augmented inspections in accordance with the *ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD* (B2.1.1) program. Although mitigation of the pressurizer surge line has been completed, small-bore butt welds will conservatively be inspected in accordance with Category C, as defined in Table XI.M35 of NUREG-2191.

2. In November 2013, a reactor coolant system pressure boundary leak was identified at a high-pressure injection line nozzle during a Unit 1 reactor building walkdown. An entry was made into the corrective action program and shutdown was initiated in accordance with Technical Specifications.

   The leak was from a circumferential crack in the safe end to pipe butt weld located between the high-pressure injection nozzle and the reactor coolant system loop injection block valve. A root cause evaluation determined that mechanical vibration induced high cycle fatigue caused a through wall crack. A system design that resulted in higher than desired system vibration on the high-pressure injection line and inadequate administrative guidance for conduct of augmented examinations were identified as contributing causes. During analyses used to support the root cause evaluation for the safe end to pipe leak, the potential for flow cavitation and subsequent erosion of the high-pressure injection piping elbows immediately downstream of the in-line flow orifices was identified. This cavitation degradation is believed to be the result of the high pressure injection full flow tests that are performed at the end of each refueling outage to verify the operation of the high-pressure injection system and confirm it can deliver the required flow rates for various high-pressure injection nozzle configurations. Cavitation is likely with flow rates above 100 gpm through the 0.78” orifices.

Corrective actions were initiated to prevent recurrence including the following:

- Leaking weld replaced
- Increased frequency of high-pressure injection nozzle safe end-to pipe butt weld ultrasonic inspections for lines that have higher vibration potential
- Inspected all high-pressure injection lines using diverse techniques
- Implemented a means, in program governance procedures, to ensure the critical elements of the inspection procedures used to implement augmented inspections are incorporated into revised or new superseding procedures
- Revised all program procedures to incorporate root cause lessons learned

As outlined above, significant program improvements were made including increased rigor and improved basis documentation information for all augmented ISI examinations performed at ONS. These AMP improvements were made to ensure aging effects are properly evaluated and future examinations are scheduled commensurate with the safety significance of the component.

The following two augmented exams were added for Oconee Unit 1, 2 and 3 to manage aging effects and prevent recurrence.

- High pressure injection nozzle volumetric inspections of safe end to pipe butt welds to identify cracking
- High pressure injection system piping elbow ultrasonic testing wall thickness measurements for wall thinning due to cavitation (NOTE: Cavitation erosion of the elbows just downstream of the high-pressure injection flow orifices is managed by the *Flow Accelerated Corrosion* (B2.1.8) AMP).

Although high-cycle fatigue is typically considered a design issue rather than aging, this OE is conservatively considered evidence that cracking of small-bore butt welds could occur at ONS Unit 1 and, therefore, periodic inspections will be performed in accordance with Category C, as defined in Table XI.M35-1 of NUREG-2191. This OE example also provides objective evidence that the corrective action program was used effectively to identify the cause of the weld failure, identify the population of welds within the extent of condition, and implement appropriate comprehensive corrective actions, including increased frequency of ISI augmented examinations and programmatic enhancements.

3. In November 2014, during the Unit 1 outage, ultrasonic examinations were performed on the RCS drain line piping downstream of the RCS connection. ASME Section XI Code rejectable indications were detected on the exterior curve of the first elbow in the drain line off the Unit 1 RCS cold leg. The issue was documented in the corrective action program for evaluation and follow-up actions. The degraded condition was a 17% through-wall leak on the 1.5” drain line elbow due to thermal fatigue failure. The 1.5” RCS Drain Line piping is butt welded out to the first isolation valve.

Corrective actions included replacement of the leaking elbow and adjacent piping prior to restart from the 2014 outage, performance of examinations at other susceptible drain line locations, and revision of program documentation to include more frequent examinations of the drain line elbows. As a result, examinations at this location are performed every other refueling outage in accordance with the ONS Augmented Inservice Inspection Schedule.

This OE example involved thermal fatigue in the base metal of Unit 1 cold leg loop butt welded drain piping. This OE provides objective evidence that the corrective action program is used effectively to identify and evaluate the cause of RCS and connected piping age related cracking occurrences, and to initiate corrective actions to identify the population within the extent of condition and correct adverse conditions.

<u>Unit 2</u>

4. In April 1997, a leak was identified in the ONS Unit 2 butt weld connecting the piping to the nozzle safe end on one of the two normal high pressure injection lines. The cause was a through-wall crack in the butt weld connecting the makeup/high pressure injection pipe and the safe-end of a reactor coolant loop nozzle.

   This leak at an ONS Unit 2 safe end to high pressure injection/makeup line weld prompted re-inspection of all high-pressure injection nozzles, safe ends and thermal sleeves. Further examination found a gap in the contact area between the thermal sleeve and the safe-end, indicative of loss of contact that caused the thermal sleeve in this line to become loose. The thermal sleeve was found to be cracked, with portions missing from the end that extends into the reactor coolant system flow path. Significant wear damage was observed at both the upstream and the downstream end. Cracking was also found in the pipe in the vicinity of the "warming" line nozzle. Examinations of the other thermal sleeves of the high-pressure injection system showed no evidence of damage. Ultrasonic testing and radiographic testing of the welds and the thermal sleeves in the other Unit 2 high pressure injection nozzles showed no indications of cracking or loosening, or other signs of degradation. The thermal sleeve in the Unit 2 high pressure injection/makeup line was replaced with a new safe end and new thermal sleeve design.

   Metallurgical examination determined the crack consisted of an inside surface flaw. The metallurgical analysis also indicated that crack initiation and propagation in the pipe to safe-end weld was caused by high-cycle fatigue due to a combination of thermal cycling and flow induced vibration. This phenomenon was identified as the probable cause for similar safe-end cracking observed at other industry pressurized water reactors (including ONS) in the early 1980's (Reference: Information Notices IN 97-46 and 82-09, and Generic Letter 85-20).

   Although high-cycle fatigue is typically considered a design issue rather than aging, this OE example is conservatively considered evidence that inside diameter cracking of small-bore butt welds could occur at ONS Unit 2 on the thermal sleeves and, therefore, periodic inspections will be performed in accordance with Category C, as defined in Table XI.M35-1 of NUREG-2191. This example also provides objective evidence that the corrective action program is used effectively to identify and evaluate the cause of RCS and connected piping age related cracking occurrences, and to initiate corrective actions to identify the population within the extent of condition and correct adverse conditions.

Unit 3

5. No age-related failures have occurred in Unit 3 small bore piping butt welds. However, since the design of ONS Unit 3 is similar to ONS Unit 1 and Unit 2, periodic examinations of small-bore butt welds will be performed in accordance with Category C, as defined in Table XI.M35 of NUREG-2191.

Units 1, 2 and 3

6. As a result of interactions between the B&W Owner's Group and the NRC on BAW-2243A, *Demonstration of the Management of Aging Effects for the Reactor Coolant System Piping*, the B&W Owner's group utilities committed to perform an additional sample inspection of Class 1 small-bore piping (piping less than 4-inch size) to provide assurance that potential cracking of small bore reactor coolant system piping is adequately managed such that the small bore piping can perform its intended function during the period of extended operation. As described in NUREG-1723, *Safety Evaluation Report related to the License Renewal of Oconee Nuclear Station, Units 1, 2, and 3*, ONS committed to a small-bore piping inspection program that would verify that service induced weld cracking is not occurring in small-bore RCS piping. The purpose of the one-time inspections was to gain confidence in the current condition of the small bore reactor coolant system piping at ONS which does not receive a volumetric examination and to gain insights into the acceptability of the current ASME Section XI actions to manage the aging of these lines.

   A total of 59 one-time inspections were completed on ONS butt welds and butt welded components across all three units by the fall of 2010 in support of the ONS commitment for small-bore piping inspections. Specifically, 55 butt welds were subject to in situ ultrasonic testing and four piping segments containing butt welds were destructively examined, as described further below. No evidence of cracking was identified during these examinations. More than 60% of the examinations were for a component that was in service more than 30 years. More than 80% of the examinations were for a component that was in service more than 20 years.

   - A Unit 1 metallurgy report describes the destructive examination of a 2½ inch x 2½ inch x 1½ inch butt welded, Schedule 160, Type 316 stainless steel tee from the ONS Unit 1 pressurizer spray line that was removed in 2009 and was later submitted to the metallurgy lab for evaluation. This line was selected because it was potentially susceptible to thermal fatigue. No cracking or other damage was detected on the pressurizer main to auxiliary spray tee.
   - A Unit 2 metallurgy report describes the destructive examination of a 2½ inch x 2½ inch x 1½ inch butt welded, Schedule 160, Type 316 stainless steel tee from the ONS Unit 2 pressurizer spray line was removed in 2010. This line was selected because it was potentially susceptible to thermal fatigue. No cracking or other damage was detected on the pressurizer main to auxiliary spray tee.
   - A Unit 3 metallurgy report describes the destructive examination of a one-foot long section of 1- inch Schedule 160 stainless steel pipe that was removed in 2011 from the ONS Unit 3 high pressure injection warming (minimum flow) line between two welds. Past evaluations of the high-pressure injection normal makeup sleeves

damaged by thermal fatigue had concluded that there was a potential for periodic reverse-flow through, and associated thermal fatigue of, the warming line. No cracking or other service-related degradation was observed on the ONS Unit 3 high pressure injection warming line section.

- A Unit 3 metallurgical analysis report describes the destructive examination of the ONS Unit 3 Pressurizer Steam Space Sample Line in 2011. A 4¾ inch long section of ½ inch Schedule 160 stainless steel pipe was removed from the ONS Unit 3 pressurizer steam space sample line. This line was selected because it was potentially susceptible to thermal fatigue and other degradation mechanisms. No cracking or other service-related degradation was observed on the ONS Unit 3 pressurizer steam space sample line segment.

This OE example provides objective evidence that as of 2010, when the initial license renewal small bore piping one-time inspections were performed, age-related cracking of small-bore butt welds was not prevalent. This indicates that the examples provided above where leaks have occurred are discrete issues caused by design factors unique to the specific location where the crack occurred or improper outage practices that resulted in local chloride contamination induced SCC.

Based on the review of OE summarized above, there have been no age-related socket weld failures of ASME Code Class 1 piping that is less than four inches nominal pipe size and greater than or equal to one inch nominal pipe size on any of the three ONS units. Therefore, the *ASME Small Bore Inspection Piping* AMP will perform Category A inspections for socket welds. Since there has been age-related cracking in small bore piping butt welds at ONS, periodic inspections will be performed for all ONS Units 1, 2 and 3, in accordance with Category C, as defined in Table XI.M35-1 of NUREG-2191.

The above examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *ASME Code Class 1 Small Bore Piping* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *ASME Code Class 1 Small Bore Piping* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *ASME Code Class 1 Small Bore Piping* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.23 EXTERNAL SURFACES MONITORING OF MECHANICAL COMPONENTS

Program Description

The *External Surfaces Monitoring of Mechanical Components* AMP is a new condition monitoring program that will manage the following aging effects:

- Loss of material, cracking, and reduction of heat transfer of metallic components;
- Hardening or loss of strength, loss of material, and cracking or blistering of polymeric components;
- Hardening or loss of strength, and loss of material of elastomeric components;
- Loss of material, cracking, and loss of preload for heating, ventilation, and air conditioning closure bolting; and
- Reduced thermal insulation resistance

Visual inspections of accessible external surfaces will be performed during system inspections and walkdowns. The inspection parameters for metallic components will include material condition, which consists of evidence of rust, pitting, crevice, and general corrosion; surface imperfections such as cracking and wastage; coating degradation such as cracking, flaking, or blistering; evidence of insulation damage or wetting; leakage from piping, ducting, or component bolted joints; and accumulation of debris on heat exchanger surfaces exposed to air. Coating degradation will be used as an indicator of possible degradation on underlying component surfaces. Inspection parameters for elastomeric and polymeric components will include blistering, hardening, discoloration, surface cracking, crazing, scuffing, loss of thickness, exposure of internal reinforcement, and dimensional changes. For certain materials, such as elastomers and flexible polymers, physical manipulation to detect hardening or loss of strength will be used to augment the visual inspections conducted under this program.

Periodic visual inspections, not to exceed a refueling outage interval, of accessible surfaces of metallic, polymeric, and elastomeric components, and insulation metallic jacketing (or protective outer layer if metal jacketing is not used) will be conducted. This frequency will accommodate inspections of components in locations that are normally only accessible during refueling outages. Surfaces that are not readily visible during plant operations or refueling outages will be inspected when they are made accessible and at such intervals that will ensure the components intended functions are maintained. There are no cementitious components within the scope of this program.

Surface examinations or ASME Code, Section XI visual examinations (VT-1) will be conducted to detect cracking of copper alloy (>15% zinc or >8% aluminum) components exposed to air or condensation environments. A representative sample will be performed from each of the copper alloy (>15% Zn) and copper alloy (>8% aluminum) component populations every ten years. Examinations will be conducted on 20% of the surface area unless the component is measured in linear feet, such as piping. Alternatively, any combination of a minimum of 25 one-foot axial length sections and components will be inspected.

A sample of outdoor component surfaces that are insulated and a sample of indoor insulated components exposed to condensation (due to the in-scope component being operated below the dew point), will be periodically inspected every ten years during the SPEO. Following removal of insulation, surface examinations or ASME Code, Section XI VT-1 examinations will be conducted to detect loss of material and cracking of the component surfaces. A minimum of 20% of the in-scope piping length, or 20% of the surface area for components whose configuration does not conform to a one-foot axial length determination will be inspected. Alternatively, any combination of a minimum of 25 one-foot axial length sections and components for each material type will be inspected.

If any sampling-based inspections to detect cracking in copper alloy (>15% zinc) or copper alloy (>8% aluminum) do not meet the acceptance criteria, then additional inspections will be conducted, unless the cause of the aging effect for each applicable material and environment is corrected by repair or replacement. There will be no fewer than five additional inspections for each inspection that does not meet acceptance criteria, or 20% of each applicable material, environment, and aging effect combination inspected, whichever is less. If any subsequent inspections do not meet acceptance criteria, then an extent of condition and extent of cause analysis in accordance with the corrective action program will be conducted to determine the further extent of inspections required. The additional inspections will be completed within the same interval (i.e., ten year inspection interval) in which the original inspection was conducted. Additional samples will be inspected for any recurring degradation to ensure corrective actions appropriately address the associated causes. The additional inspections will include inspections of components with the same material, environment, and aging effect combination at each of the Oconee units.

Inspections will be performed by personnel qualified in accordance with site procedures and programs to perform the specified task. Inspections within the scope of the ASME Code will follow site procedures consistent with the ASME Code. Non-ASME Code inspection procedures will include requirements for items such as lighting, distance, offset, surface coverage, and presence of protective coatings.

Acceptance criteria will be such that the component will meet its intended function until the next inspection or until the end of the SPEO, whichever is shorter. Quantitative acceptance criteria, such as required minimum wall thickness, will be used where practical. For qualitative evaluations, applicable parameters such as change in hardness, flexibility, or surface condition will be used to reasonably ensure that a consistent determination is made based on the observed conditions.

The external surfaces of components that are buried or in underground environments are inspected by the *Buried and Underground Piping and Tanks* (B2.1.26) program. The external surfaces of outdoor tanks are inspected by the *Outdoor and Large Atmospheric Metallic Storage Tanks* (B2.1.17) program. Loss of material due to boric acid corrosion is managed by the *Boric Acid Corrosion* (B2.1.4) program. The *One-Time Inspection* (B2.1.20) program will confirm the absence of cracking for external surfaces of aluminum and stainless steel components for which the aging effect is not expected to occur based on plant OE.

NUREG-2191 Consistency

The *External Surfaces Monitoring of Mechanical Components* program is a new program that, when implemented, will be consistent with NUREG-2191, Section XI.M36, External Surfaces Monitoring of Mechanical Components.

Exception to NUREG-2191

None

Enhancements

None

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *External Surfaces Monitoring of Mechanical Components* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO.

1. In the fall of 2009, water was found dripping from insulation installed on service water piping located in the basement of the turbine building. The insulation was removed for inspection and the piping was found to be heavily corroded. Engineering evaluation identified a through-wall leak due to internal corrosion of the steel piping which was the cause of the external corrosion under the insulation. This issue was entered into the corrective action program, and the leak was monitored until the corroded section of piping was replaced during the next available work window.

   OE example 1 provides objective evidence that visual inspection of external insulation surfaces can identify accumulation of moisture underneath the insulation, and that use of the corrective action program is an effective process for correcting identified deficiencies.

2. An oil leak from a breathing air compressor hydraulic hose was identified in October 2012. The issue was entered into the corrective action program. Subsequent inspection identified a black hose that was noted as brittle to the touch and which had a visible bulge on the exterior surface. Inspection of the hose after removal noted interior degradation at the same location where the bulge was located. The degraded hose was replaced with a new hose.

   OE example 2 provides objective evidence that visual inspection and physical manipulation of elastomers is capable of identifying changes in material properties which are indicative of degradation, and that use of the corrective action program is an effective process for correcting identified deficiencies.

3. A plant walkdown was conducted at the Keowee hydroelectric station in August 2013 which identified rust on cooling water strainers and piping in the depressing air gallery. The issue was entered into the corrective action program. The areas of rust were removed from the affected components and the surfaces were repainted with upgraded coating.

OE example 3 provides objective evidence that system inspections and walkdowns are an appropriate method for monitoring the condition of external surfaces, and that use of the corrective action program is an effective process for correcting identified deficiencies.

The above examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *External Surfaces Monitoring of Mechanical Components* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *External Surfaces Monitoring of Mechanical Components* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *External Surfaces Monitoring of Mechanical Components* AMP will provide reasonable assurance that the effects of aging will be managed such that the components within the scope of this program will continue to perform their intended functions consistent with the CLB during the SPEO.

B2.1.24 INSPECTION OF INTERNAL SURFACES IN MISCELLANEOUS PIPING AND DUCTING COMPONENTS

Program Description

The *Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components* AMP is a new condition monitoring program that will manage loss of material and cracking of metallic components, as well as loss of material, cracking, blistering, hardening, and loss of strength of polymeric and elastomeric materials. The program also manages loss of coating integrity for certain components that do not perform a pressure boundary intended function and where loss of coating integrity would not impact the intended functions of downstream components. Reduction of heat transfer and flow blockage will also be managed. This program will consist of visual inspections of internal surfaces of piping, piping components, ducting, heat exchanger components, polymeric and elastomeric components, and other mechanical components. Applicable environments include air, condensation, closed cycle cooling water, diesel exhaust, fuel oil, gas, lubricating oil, raw water, treated water, and waste water. Except for elastomeric and polymeric components, aging effects associated with components within the scope of the *Open Cycle Cooling Water System* (B2.1.11) AMP, *Closed Treated Water Systems* (B2.1.12) AMP, and Fire Water System (B2.1.16) AMP will not be managed by this program.

Steel piping exposed piping exposed to raw water in the high pressure service water system and Keowee fire detection/protection system having only CLB intended functions of leakage boundary (spatial) as defined in the NUREG-2192, Standard Review Plan for Review of Subsequent License Renewal Applications for Nuclear Power Plants Table 2.1-4(b) is managed for loss of material (due to general, pitting, crevice corrosion and microbiologically influenced corrosion) by this program. Steel piping in these systems is susceptible to recurring internal corrosion but this program is not credited to manage recurring internal corrosion. The *Open-Cycle Cooling Water Systems* (B2.1.11) program supplements this program and provides for management of recurring internal corrosion for steel piping exposed to raw water in the high pressure service water system and Keowee fire detection/protection system.

This program relies on internal inspections performed during the periodic system and component surveillances or during the performance of maintenance activities when the surfaces are made accessible for visual inspection. The program includes visual inspections and when appropriate, surface examinations. For certain materials, such as flexible polymers, physical manipulation to detect hardening or loss of strength is used to augment the visual examinations conducted under this program. This program relies on periodic visual (VT-1) or surface examinations to manage cracking due to stress corrosion cracking in stainless steel components exposed to diesel exhaust, potable raw water, and waste water and in copper alloys exposed to waste water. Visual inspections may be conducted in lieu of VT-1 or surface examinations where it has been analytically demonstrated that surface cracks can be detected by leakage prior to a crack challenging the structural integrity or intended function of the component.

At a minimum, in each 10-year period during the SPEO a representative sample of 20 percent of the population (defined as components having the same combination of material, environment, and aging effect) or a maximum of 25 components per population per unit are typically inspected. However, since Oconee is a three-unit site, this maximum number will be reduced to 17 components per population per unit where the sample size is not based on a percentage of the population. This is acceptable because design, operating, and environmental conditions between the units are similar enough such that the aging effects are not occurring differently. All three units are of comparable age, and changes to water chemistry practices, operating conditions, etc., have been implemented in a consistent manner across all three units. A measurement uncertainty recapture power uprate license amendment request was approved by the NRC in January 2021 (ADAMS Accession Number ML20335A001). Implementation of the measurement uncertainty recapture power uprate will not substantively change operating conditions such that the rate of aging effects managed by this program would be affected. No other power uprates have been implemented on any of the Oconee Units. Water chemistry programs monitor various chemistry parameters and require out-of-spec conditions to be corrected under the corrective action program in a timely manner. Raw water systems for all three units draw from the same water sources. Oconee has only one (standby shutdown facility) diesel generator, such that distribution of diesel generator run times is not an issue. Therefore, a reduced maximum sample population size will provide a representative sample of the condition of the plant equipment and the existence of the aging effects involved.

This program does not manage cracking due to stress corrosion cracking or loss of material in aluminum exposed to aqueous solutions and air environments, or to stainless steel components exposed to air environments. A review of plant OE has not identified the existence of these aging effects in aluminum and stainless steel components in these environments. Therefore, one-time inspections will be performed for these material, environment, and aging effect populations under the *One-Time Inspection* (B2.1.20) program to verify that these aging effects are not applicable. If cracking or loss of material is identified during the one-time inspections, periodic inspections will be performed under the appropriate AMP, which may include this program as applicable.

NUREG-2191 Consistency

The *Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components* AMP will be consistent with the ten elements of AMP XI.M38, *“Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”* specified in NUREG-2191.

Exception to NUREG-2191

None

Enhancements

None

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *Inspections of Internal Surfaces of Miscellaneous Piping and Ducting Components* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO.

1. In September 2009, while performing routine preventive maintenance activities on the primary instrument air system, a crack was identified in the strainer body where a threaded nipple is connected. A work request was initiated to repair the strainer, and the item was entered in the corrective action program to document the deficiency and to consider whether a routine preventive maintenance task should be considered to periodically replace the strainer body based on age. The engineering evaluation of this item determined that the existing quarterly preventive maintenance inspections were sufficient to identify degradation, and that the strainer body will continue to be monitored and replaced on condition, as appropriate.

   OE example 1 provides objective evidence that opportunistic visual inspections performed during existing preventive maintenance activities are an effective method for identifying degraded conditions and that the corrective action program is an effective tool for resolving identified issues.

2. Maintenance activities in 2018 identified a crack in the Unit 3 reactor building auxiliary fan ductwork. Work order completion records document that the ductwork has an opening of fourteen inches long and two inches wide. The crack is located at a pocket lock joint and runs partially across the bottom of the duct and turn slightly up the backside of the duct and stops at the duct joint. There is a duct support on either side of the crack. An item was entered into the corrective action program to identify the deficiency, document the engineering evaluation, and address ongoing inspection and monitoring activities. Additional reviews of the inspection documentation, determined that the crack does not pose a safety issue, and would have little effect on system performance. A corrective action was implemented to revise preventive maintenance activities for the reactor building auxiliary fan ducting to ensure that focused monitoring is performed of this location each outage.

   OE example 2 provides objective evidence that the corrective action program is appropriately used to adjust recurring preventive maintenance activities when evidence of degradation is identified to ensure that intended functions are maintained.

3. In October 2010, internal sleeves for the two condenser circulating water expansion joints were found damaged during outage inspections. The inspection discovered a small hole in a seal near the backing plate overlap. In addition, the center band had slipped resting one side on the lower band while the other side was wedged over the backing plate near the top band. Upon disassembly it was found that the backing plate was damaged, and bent out of shape. The offset of the joint measured 2.875 inches. There were also two bulges in backing plate. The larger of the two measured 4 inches long and 2 inches wide. The other bulge measured 2 inches round. An extent of condition evaluation noted that other Unit 3 outlet water box seals were found to be in excellent shape. There were no issues with bands or backing plates, bugles or any other defects noted. Repair was accomplished with the installation of a new seal and backing plate.

   OE example 3 demonstrates the ability of opportunistic inspections to identify degradation well before intended functions are affected. The use of the corrective action program and follow up actions demonstrate that extent of condition is considered, that evaluations are done to ensure intended functions are maintained (including consideration of potential adverse spatial interactions), and that effective measures are put into place to prevent recurrence. In addition, this OE provides objective evidence that the aging management activities provided by this program will effectively identify degradation of elastomers.

4. A review of Oconee OE over a ten year period (January 2011 through January 2021) has revealed recurring internal corrosion in steel piping exposed to raw water within the scope of the *Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components* AMP. Through wall leakage due to localized piping degradation has occurred on several occasions. When leakage has been identified, the issue has been entered into the corrective action program and appropriate corrective actions have been taken including increased inspections, piping repair or replacement, and modifications to install more corrosion resistant piping materials.

   In addition, there have been several occasions over the ten year review period where wall thickness measurements have identified remaining wall thickness less than preestablished screening criteria or less than 50% of nominal wall thickness. General corrosion rates at Oconee are typically on the order of one to two mil per year due to the high quality of raw water from Lake Keowee. Challenges to required minimum wall thickness are normally due to localized corrosion. The specific corrosion mechanism cannot be definitively established through wall-thickness measurements and so are conservatively assumed to be indicative of recurring internal corrosion as defined in Section 3.3.2.2.7 of NUREG-2192. When wall- thickness below conservative screening criteria has been identified, the issue has been entered into the corrective action program and appropriate corrective actions have been taken including reevaluation of required minimum wall thickness, piping repair or replacement, and modifications to install more corrosion resistant piping materials.

   Recurring internal corrosion of water-based fire suppression system piping will be managed by the *Open-Cycle Cooling Water System* (B2.1.11) AMP. The material of construction and service environment are equivalent between the open-cycle cooling water systems and the water-based fire suppression systems and, therefore, managing recurring internal corrosion of these systems as a single population is appropriate. The *Open-Cycle Cooling Water System* (B2.1.11) program will inspect a representative sample of locations with conditions that are characteristic of the conditions found throughout raw water filled systems at Oconee. The results of these inspections are then extrapolated to similar locations throughout all the raw water systems within the scope of SLR. This characteristic-based approach recognizes the commonality among the component materials of construction and the environment to which they are exposed.

   OE example 4 provides objective evidence that plant OE is reviewed and evaluated for indications of recurring internal corrosion and appropriate corrective actions are taken to ensure aging is adequately managed.

The above examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *Internal Surfaces in Miscellaneous Piping and Ducting Components* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *Internal Surfaces in Miscellaneous Piping and Ducting Components* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Internal Surfaces in Miscellaneous Piping and Ducting Components* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.25 LUBRICATING OIL ANALYSIS

Program Description

The *Lubricating Oil Analysis* AMP is an existing preventive program that ensures loss of material and reduction of heat transfer is not occurring in important plant equipment by maintaining the quality of lubricating oil and hydraulic oil. The program ensures that contaminants, particularly water and particulates, are within acceptable limits and are consistent with manufacturer and industry guidelines.

The program directs condition monitoring activities (sampling, analyses, and trending), thereby maintaining an environment that is not conducive to loss of material or reduction of heat transfer.

The lubricating oil testing (sampling and analysis) and condition monitoring activities identify detrimental contaminants such as water, sediments, and specific wear elements. The contaminant levels are trended in the program's database. Corrective actions are initiated when any of the contaminant levels exceed the acceptance criteria limit. Corrective actions typically include evaluating, identifying, and correcting the source of the detrimental contaminants.

In summary, the *Lubricating Oil Analysis* AMP applies monitoring methods that are effective in maintaining the quality of the oil environment in mechanical systems and avoiding significant equipment degradation.

NUREG-2191 Consistency

The *Lubricating Oil Analysis* AMP is an existing program that will be consistent with the ten elements of AMP XI.M39, *"Lubricating Oil Analysis"* specified in NUREG-2191 (GALL-SLR) with the enhancement described below.

Exception to NUREG-2191

None

Enhancements

The following enhancement will be implemented in the following program element: Detection of Aging Effects (Element 4)

1. Update the *Lubricating Oil Analysis* program procedures to specify that in all cases, phase-separated water in any amount is not acceptable (Element 4).

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Lubricating Oil Analysis* program will continue to be effective in managing the aging effects for systems and components within the scope of the program so that intended functions will be maintained consistent with the CLB during the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. A February 2010 lube oil analysis of a Keowee governor bearing oil sample indicated high lead and a high general particle count. The sample indicated 313 ppm lead for Keowee Unit 1 and 223 ppm lead for Keowee Unit 2 compared to the 100 ppm lead standard. A condition report was initiated in the corrective action program and a new preventive maintenance strategy was developed for the governor bearing oil. The following corrective actions were taken to implement the new preventive maintenance strategy:

    - Keowee turbine guide bearing oil operating temperatures were monitored and trended. Engineering evaluation of trending results did not indicate any increase of turbine guide bearing temperatures.
    - Two work orders were created that completely replaced the turbine guide bearing oil for both Keowee Units 1 and 2.
    - System filtration requirements established to be performed per manufacturer's guidelines.
    - The turbine guide bearing sampling frequency was doubled as a result of the high particle count.

    OE example 1 provides objective evidence that the *Lubricating Oil Analysis* program inspections, along with the corrective action program, will effectively monitor in scope lubricating oil to provide reasonable assurance that contaminants are within acceptable limits and that lubrication oil is maintained consistent with manufacturer and industry guidelines during the SPEO.

2. A September 2012 lab analysis of a semi-annual oil sample from the Keowee Unit 1 governor oil indicated that the viscosity was low for the reported oil type/grade. Other test results were reported as satisfactory. A condition report was initiated in the corrective action program, and a recommendation was made to re-sample at the next scheduled interval. Since the next scheduled interval would be in six months, a second sample was taken on 10/18/2012 and a *"Remaining Useful Life Evaluation Routine"* test using linear sweep voltammetry was ordered. A *"Rotating Pressure Vessel Oxidation Test"* was also ordered to evaluate the remaining oxidation life of the oil. The results of the analysis of the second sample indicated that the additive package in the oil was depleted. The oil could no longer withstand oxidation and the oil pH had begun to change. The rise in the acidity of the oil was the cause of the low viscosity found earlier and the acidity in the oil was leaving equipment vulnerable to damage. The recommendation was to replace at least half of the oil. All the governor oil was subsequently replaced on 11/1/2012.

    OE example 2 provides objective evidence that the *Lubricating Oil Analysis* program inspections, along with the corrective action program, will effectively monitor in scope lubricating oil to provide reasonable assurance that contaminants are within acceptable limits and that lubrication oil is maintained consistent with manufacturer and industry guidelines during the SPEO.

3. On April 18, 2017, the results of an oil sample analysis from the 1B motor drive feedwater pump indicated 0.1% water. A decision was made to place the 1B MFDWP back on the

1B lube oil purifier for a week to improve the oil quality and remove the water. A work request was written to perform another oil sample on April 24, 2017 after a week on the lube oil purifier. The analysis of the April 24, 2017 sample tested in high fault in bacterial contamination, but the water content had fallen to 0.0510%. The normal frequency was doubled for placing the 1B motor drive feedwater pump oil tank on the 1B lube oil purifier. After the reduction of water content was established, a subsequent sample lab analysis results indicated that the bacterial intrusion had been eliminated. Additional sampling of the 1B motor drive feedwater pump oil tank confirmed that the lube oil purifier to be effective at reducing the containments and water content. However, analysis of oil samples from the 1B motor drive feedwater pump oil tank taken on November of 2017 once again indicated an increase in both contaminants and water content. A condition report was initiated in the corrective action program, and inspections of the 1B motor drive feedwater pump oil tank for possible in-leakage were performed.

These inspections identified a steam leak from the 1B feedwater pump turbine steam seal header drain pipe as the likely source of the water intrusion into the tank.

OE example 3 provides objective evidence that the *Lubricating Oil Analysis* AMP inspections, along with the corrective action program, will effectively monitor in scope lubricating oil to provide reasonable assurance that contaminants are within acceptable limits and that lubrication oil is maintained consistent with manufacturer and industry guidelines during the SPEO.

4. The current standby shutdown facility diesel generator lubrication oil sample and analysis program began on 2/20/2001. During the 19 years of program implementation, the standby shutdown facility diesel generator lubricating oil has been sampled on over 250 occasions and confirmed to be in acceptable condition by tracking the following parameters:

   - Water content in accordance with ASTM D6304, *Standard Test Method for Determination of Water in Petroleum Products, Lubricating Oils, and Additives by Coulometric Karl Fischer Titration*
   - Viscosity in accordance with ASTM D7279, *Standard Test Method for Kinematic Viscosity of Transparent and Opaque Liquids by Automated Houillon Viscometer*
   - The Titration Acid Number in accordance with ASTM D664, *Standard Test Method for Acid Number of Petroleum Products by Potentiometric Titration*
   - The presence of 21 wear metals, contaminants and additives in the lubrication oil in accordance with ASTM D5185, *Standard Test Method for Multi-element Determination of Used and Unused Lubricating Oils and Base Oils by Inductively Coupled Plasma Atomic Emission Spectrometry*.

   OE example 4 provides objective evidence that the *Lubricating Oil Analysis* program inspections are being performed in accordance with industry guidelines.

The above examples provide objective evidence that the *Lubricating Oil Analysis* program will continue to be effective in managing the aging effects for systems and components within the scope of the program so that intended functions will be maintained consistent with the CLB during the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Lubricating Oil Analysis* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Lubricating Oil Analysis* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.26 BURIED AND UNDERGROUND PIPING AND TANKS

Program Description

The *Buried and Underground Piping and Tanks* AMP is an existing condition monitoring program that manages loss of material and cracking on external surfaces of piping and tanks in soil or underground environments within the scope of SLR through preventive and mitigative actions. The program addresses piping and tanks composed of carbon steel, ductile iron, gray cast iron, stainless steel and copper alloys. There is no buried or underground cementitious or polymeric piping within the scope of SLR at Oconee. Loss of material and cracking of bolting associated with buried and underground piping systems is also managed by this program.

The program manages aging through preventive and mitigative actions (i.e., coatings, backfill quality, and cathodic protection), relies on inspection activities, including visual examination of buried and underground piping and tanks, electrochemical verification of the effectiveness of the cathodic protection system, nondestructive evaluation of pipe or tank wall thicknesses, and performance monitoring of fire mains. The number of inspections is based on the effectiveness of the preventive and mitigative actions.

Annual cathodic protection system surveys are conducted to monitor structure-to-soil potential and cathodic protection current. The program uses the -850 mV relative to copper/copper sulfate reference electrode, instant off criterion specified in NACE SP0169-2007 for acceptance criteria for determination of cathodic protection system effectiveness in performing cathodic protection surveys.

Inspections are conducted by qualified individuals. Where the coatings, backfill, or the condition of exposed piping does not meet acceptance criteria the condition is entered into the corrective action program for evaluation. Degraded conditions such as loss of material, damaged coatings, non-conforming backfill, or improper cathodic protection system voltage are evaluated under the corrective action program to determine appropriate corrective actions.

The program relies on monitoring of system header pressure and annual leak rate testing for aging management of the buried piping in the high pressure service water system, which serves as the fire protection system for Oconee. The program relies on system flow monitoring and annual flow testing for aging management of the buried Keowee fire detection/protection system piping. In addition, opportunistic visual inspections of the external surface of buried high pressure service water system and Keowee fire detection/protection system piping will be performed when the piping is excavated for any reason.

This program does not address loss of material due to selective leaching. The *Selective Leaching* (B2.1.21) program is used to manage loss of material due to selective leaching of susceptible materials.

The *Buried and Underground Piping and Tanks* AMP will be enhanced as described below to provide reasonable assurance that buried and underground piping and tanks and components, constructed of carbon steel, ductile iron, gray cast iron, stainless steel and copper alloys will perform their intended function during the SPEO.

NUREG-2191 Consistency

The *Buried and Underground Piping and Tanks* AMP is an existing program that will be consistent with NUREG-2191, Section XI.M41, *Buried and Underground Piping and Tanks* with exceptions and enhancements, as described below, respectively.

Exception 1 to NUREG-2191

Program Element Affected: Preventive Actions (Element 2)

1. NUREG-2191 recommends that coatings and cathodic protection be provided for buried copper alloy piping. The buried copper alloy instrument air system piping is not coated, and cathodic protection is not provided.

   Justification for Exception 1

   The copper alloy Instrument Air System piping within the scope of the *Buried and Underground Piping and Tanks* AMP supplies compressed air from a dedicated air compressor and air tank to level instrumentation for the elevated water storage tank. A modification will be completed prior to entry into the SPEO to abandon this buried copper alloy piping.

Exception 2 to NUREG-2191

Program Element Affected: Detection of Aging Effects (Element 4)

2. NUREG-2191 recommends the limiting critical potential for cathodic protection systems should not be more negative than -1200 mV. The Oconee *Buried and Underground Piping and Tanks* AMP will maintain the instant-off potential of all test locations between -850 mV and -2000 mV

   Justification for Exception 2

   The cathodic protection system for the standby shutdown facility diesel engine fuel oil tank was installed in 2010 to replace the original passive sacrificial anode system. Due to the location of the tank and space limitations in the area, anodes could not be installed on the south side of the tank that is adjacent to the standby shutdown facility building wall. Also, the design depth for the anodes on the north side of the tank could not be obtained due to a shallow bedrock layer in the area. In order to achieve adequate polarization at test locations for the south side of the tank, an instant-off potential more negative than - 1200 mV was required for test locations for the north side of the tank.

   The -1200 mV limiting critical potential recommendation is designed to minimize damage to the coating of buried structures caused by excessive cathodic protection current (i.e., cathodic disbondment). This criterion is intended to prevent coating damage for all coating systems in common use for buried structures. The coating used for the standby shutdown facility diesel engine fuel oil tank is a two part system consisting of a high build epoxy primer and a high build coal tar epoxy finish coat. Epoxy coating systems are less susceptible to cathodic disbondment than other coating systems such as tape wrap coatings.

Damage to the external coating, should it occur, would not impact the intended function of the standby shutdown facility diesel engine fuel oil tank. However, damage to the external coating would increase the amount of exposed metal surface area and could potentially challenge the ability of the cathodic protection system to provide adequate current to provide effective mitigation of corrosion. The cathodic protection system for the standby shutdown facility diesel engine fuel oil tank is designed with sufficient capacity to provide additional current if coating damage were to occur. The Oconee *Buried and Underground Piping and Tanks* AMP will be enhanced to require trending of cathodic protection current data to identify changes that could indicate coating degradation and to ensure that the cathodic protection current demand remains within the capacity of the system design such that adequate protection of the tank is ensured (i.e., instant-off potential is more negative than -850 mV for all test locations).

In addition to the enhanced monitoring described above, the *Oconee Fuel Oil Chemistry* (B2.1.18) and *Buried and Underground Piping and Tanks* (B2.1.26) AMPs provide for periodic internal inspection and wall thickness monitoring of the buried standby shutdown facility diesel engine fuel oil tank at least once every ten years.

The combination of inspections and cathodic protection system monitoring provide reasonable assurance that age-related degradation of the standby shutdown facility diesel engine fuel oil tank will be managed such that intended functions will be maintained consistent with the current licensing basis through the SPEO.

Exception 3 to NUREG-2191

Program Element Affected: Detection of Aging Effects (Element 4)

3. NUREG-2191 recommends ten linear feet of piping be exposed during each inspection. The Oconee *Buried and Underground Piping and Tanks* AMP exposes a quadrant of ten linear feet of buried steel condenser circulating water system piping during each inspection.

Justification for Exception 3

The buried steel condenser circulating water system piping consists of large diameter (96-inch to 132-inch) low pressure piping that supplies cooling water from the intake to the main condensers. The only other buried steel piping within the scope of the program is the 16-inch supply line and the 12-inch return line for the radwaste equipment cooling system that take suction from and discharge to the 132-inch condenser circulating water system ‘B’ intake pipe. The radwaste equipment cooling system does not perform any SLR intended functions and the supply and return lines are only in scope as part of the pressure boundary of the large diameter condenser circulating water system piping. The intended function of the large diameter piping is to provide a source of water for safety related cooling systems and for water-based fire suppression systems. It is also credited with providing water for decay heat removal through the main condenser during certain non-power operation fire scenarios in accordance with NFPA 805. The flow required to perform the SLR intended functions is significantly less than the design flow during normal operation when this piping provides cooling water to the main condenser to condense steam from the Main Turbine and maintain condenser vacuum. Therefore, pinhole leaks will not impact the SLR intended functions of this piping as long as structural integrity of the piping is maintained.

Given the size of this piping, excavation and visual inspection of 360 degrees of the circumference of the pipe is not feasible. Inspection of a quadrant of ten linear feet of the piping (i.e., 9 to 12 o'clock or 12 to 3 o'clock) will provide a sufficient representative sample to determine the condition of the piping. To supplement the external inspection, low frequency electromagnetic testing will be performed from the internal surface of the entire circumference of the same ten linear foot section of piping that is externally inspected. Follow-up ultrasonic wall thickness measurements will be performed of areas identified as low points during the low frequency electromagnetic testing inspection. The minimum number of external visual inspections and internal nondestructive examinations will be determined based on the effectiveness of preventive actions in accordance with NUREG-2191, Table XI.M41-2. In addition, internal visual inspections of 100% of the buried condenser circulating water system piping are performed on a six-year frequency to detect indications of through-wall leaks. The combination of direct visual inspections, internal nondestructive examination, and internal visual inspection for leakage will provide reasonable assurance that the intended functions of the buried condenser circulating water system piping will be maintained.

<u>Enhancements</u>

The following enhancements shall be implemented in the respective program elements: Preventive Actions (Element 2), Parameters Monitored or Inspected (Element 3), Detection of Aging Effects (Element 4), Monitoring and Trending (Element 5), Acceptance Criteria (Element 6), and Corrective Actions (Element 7)

1. Install a cathodic protection system in accordance with NACE SP0169-2007 for buried carbon steel piping within the scope of the program (Element 2).

2. Complete a modification to abandon the buried copper alloy instrument air system piping within the scope of this program. (Elements 2 and 3)

3. Annual cathodic protection system monitoring will be performed with a maximum grace period of two months. The system will be monitored at least once during each calendar year. (Element 2)

4. Utilize an inspection method that has been demonstrated to be capable of detecting cracking for uncoated stainless steel piping and when visual inspections of coated stainless steel piping detect coating degradation or damage which could potentially result in stress corrosion cracking of the base material. Indications of cracking will be evaluated

in accordance with applicable codes and plant-specific design criteria. (Elements 3, 6 and 7)

5. Perform wall thickness measurement if visual inspections identify evidence of corrosion beyond minor surface rusting for both coated and uncoated metallic piping or tanks. The results of the wall thickness measurement will be used to calculate a corrosion rate and project wall thickness through the end of the SPEO. If the depth or extent of degradation of the base metal could have resulted in a loss of pressure boundary function when the loss of material is extrapolated to the end of the SPEO, then additional inspections will be performed as follows: When measured pipe wall thickness, projected to the end of the SPEO, does not meet the minimum pipe wall thickness requirements due to external corrosion, the number of inspections within the affected piping category will be doubled or increased by five, whichever is smaller. If adverse indications are found in the expanded sample, an extent of condition and extent of cause analysis to determine the further extent of condition and extent of cause. Timing of any additional inspections will be based on the severity of the identified degradation and the consequences of leakage or loss of function. Any additional inspections will be performed within the same 10-year inspection interval in which the original degradation was identified, or within four years after the end of the 10-year interval if the degradation was identified in the latter half of the 10-year interval. Expansion of sample size may be limited by the extent of piping subject to the observed degradation mechanism or if the piping system or portion of the system is replaced or otherwise mitigated within the same 10-year inspection interval in which the original degradation was identified or within four years after the end of the 10-year interval, if the degradation was identified in the latter half of the 10-year interval. (Elements 4, 5, 6, and 7)

6. Perform inspections of buried steel condenser circulating water system piping at least once every ten years. The minimum number of inspections will be determined based on the effectiveness of preventive actions in accordance with NUREG-2191, Table XI.M41-2. Ten linear feet of piping will be exposed for each inspection. Inspections of the large diameter condenser circulating water system intake piping will expose a quadrant (i.e., 9 to 12 o'clock or 12 to 3 o'clock) of the piping. External inspections of the large diameter condenser circulating water system intake piping will be supplemented by low frequency electromagnetic testing performed from the internal surface of the same section of piping that is externally inspected with follow-up ultrasonic wall thickness measurements performed of areas identified as low points during low frequency electromagnetic testing. (Element 4)

7. Perform visual inspections of at least two ten-linear foot sections of buried uncoated stainless steel piping at least once every ten years. Piping inspection locations will be selected based on risk (i.e., susceptibility to degradation and consequences of failure). (Element 4)

8. Perform visual inspections of at least four ten-linear foot sections of underground coated steel piping at least once every ten years. Piping inspection locations will be selected based on risk (i.e., susceptibility to degradation and consequences of failure). (Element 4)

9. Internal volumetric inspections of the standby shutdown facility diesel engine fuel oil tank will cover at least 25% of the surface area of the tank and include at least some of both the top and bottom of the tank. (Element 4)

10. Personnel performing inspections of buried coated piping and tanks will either: 1) possess an Association for Materials Protection and Performance coating inspector program level 2 or level 3 inspector qualification, 2) complete the EPRI *Comprehensive Coatings Course* and complete the EPRI *Buried Pipe Condition Assessment and Repair Training Computed Based Training Course*, or 3) be qualified as a coatings specialist in accordance with ASTM D7108. (Element 6)

11. If significant coating damage is identified during visual inspections, then perform an evaluation to determine if the coating damage was caused by nonconforming backfill. If it is determined that the coating damage was caused by nonconforming backfill, then conduct an extent of condition evaluation to determine the extent of degraded backfill in the vicinity of the observed damage. (Element 7)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Buried and Underground Piping and Tanks* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In September 2019 a self-assessment was performed to verify the regulatory compliance and on-going effectiveness of selected LR AMPs and the overall LR program. The assessment included a review of LR documentation, procedures, completed work orders, corrective action program documents and interviews. Commitments made during the initial LR for Oconee credited the periodic internal inspections of system piping implemented through the condenser circulating water system internal coatings inspection (UFSAR Section 18.3.17.5) program for aging management of buried piping and the standby shutdown facility diesel fuel oil storage tank inspection (UFSAR Section 18.3.17.14) for aging management of the buried tank. This program was evaluated as part of this self-assessment and the review confirmed that aging management activities are being performed in accordance with commitments made during the initial LR process.

   An area for improvement was identified related to the condenser circulating water system internal coatings inspection. The results of internal inspections of the condenser circulating water system piping is intended to serve as representative of other buried piping systems within the scope of LR at Oconee. The self-assessment identified that there was insufficient guidance in program documentation to ensure that appropriate evaluation of extent of condition is performed if unacceptable degradation is identified. This issue was entered into the corrective action program and program documentation has been revised to include guidance to perform extent of condition evaluations if inspection results are unacceptable.

OE example 1 provides objective evidence that aging management activities have been implemented in accordance with initial LR commitments and that self-assessments are used to identify and implement programmatic improvements.

2. An in-line ultrasonic inspection of buried Unit 1 standby shutdown facility auxiliary service water system piping (evaluated with the condenser circulating water system for SLR) was performed during the Fall 2016 refueling outage. This inspection provided wall thickness measurements for approximately 280 feet of six-inch diameter schedule 80 carbon steel piping externally coated with coal tar epoxy. The inspection was performed to address system operating history of previous occurrences of pipe leaks in 2006 and 2009 that resulted in the replacement of portions of the buried steel piping with stainless steel in system piping for all three Oconee units. All average pipe wall thicknesses were greater than the mill tolerance value. However, the inspection identified numerous indications of localized wall loss. An external visual inspection of a portion of this piping was also performed and identified a number of areas of missing coatings with general surface corrosion and some localized pitting. An engineering evaluation was performed and concluded the piping was significantly degraded but remained operable. To ensure the continued reliability of the system, the remaining buried carbon steel piping in the standby shutdown facility auxiliary service water subsystem for all three Oconee units was replaced with externally coated stainless steel with all piping replacements completed by 2018.

   OE example 2 provides objective evidence that the inspection techniques utilized by this program are capable of detecting degradation of buried piping and that appropriate corrective actions are taken when degraded conditions are identified to ensure intended functions are maintained.

3. Inspections of portions of the condenser circulating water system intake and discharge piping were performed in 2009, 2013, and 2014. The 2009 inspection was performed from the external surface when a portion of the eleven foot diameter 0.375 inch thick piping was exposed during construction of the protected service water building. The 2013 and 2014 inspections were performed from the internal surface of the Unit 2 and Unit 3 discharge piping, respectively. The results of these inspections are summarized below.

   The March 2009 inspection was performed on the portion of the Unit 3 intake piping exposed during construction of the protected service water building and included visual inspection of five sections of piping and low frequency electromagnetic testing of three of those sections. Each piping section was defined as the area between reinforcement ribs which is approximately ten linear feet. No evidence of wall loss was identified by low frequency electromagnetic testing. Ultrasonic testing of random locations on the piping was performed to validate the low frequency electromagnetic testing results and all readings were above nominal wall thickness. The visual inspection of the piping identified numerous areas of localized coating degradation with minor surface corrosion and two areas of localized corrosion. The larger pit had a diameter of approximately 0.75 inch and a depth of approximately 0.25 inch. An engineering evaluation was performed and concluded that the piping was acceptable for continued service. Areas of coating degradation were repaired but, since the system was in service during the inspection, a weld repair of the areas exhibiting localized corrosion was not performed.

The October 2013 inspection was performed on a forty foot section of the Unit 2 condenser circulating water system discharge piping. The inspection was performed using a four inch flat-bottomed scanner to inspect a four foot wide strip at the four o'clock and nine o'clock positions. No significant areas of wall loss were detected during the inspection with wall loss less than ten percent for all sections inspected. Ultrasonic testing of the area inspected by low frequency electromagnetic testing was also performed on approximately fourteen-inch centers with results indicating an average wall thickness of 0.355 inch. The lowest reading was 0.339 inch. All readings were above the minimum required wall thickness for the discharge pipe of 0.313 inch. The corrosion rate was calculated to be 0.001 inch per year and the piping was determined to be acceptable for continued service.

The April 2014 inspection was performed around the entire circumference of an approximately eleven-linear foot segment of the Unit 3 condenser circulating water system discharge piping. The low frequency electromagnetic testing scan of this piping identified no evidence of pitting or wall thinning with all areas inspected indicating wall loss less than ten percent. Ultrasonic testing of the area inspected by low frequency electromagnetic testing was also performed on fourteen-inch centers with results indicating an average wall thickness greater than the nominal wall thickness of 0.375 inch. The lowest reading was 0.359 inch. All readings were above the minimum required wall thickness for the discharge pipe of 0.313 inch. The corrosion rate was calculated to be less than 0.001 inch per year and the piping was determined to be acceptable for continued service.

OE example 3 provides objective evidence that appropriate inspections are performed to monitor the condition of buried piping and that the external environment of buried components at Oconee is generally not conducive to aggressive corrosion.

4. The original design of the standby shutdown facility diesel engine fuel oil tank included a passive cathodic protection system that relied on sacrificial anodes to mitigate corrosion. A modification was completed in 2010 to replace the passive system with an impressed current cathodic protection system due to depletion of the original sacrificial anodes. In 2017, a separate modification was completed which installed tornado protection for the standby shutdown facility building cable trench. During this modification, the reference electrode test box for the system was removed which prevented the measurement of tank-to-soil potentials during subsequent annual surveys. A modification was proposed to reinstall the test box but upon further evaluation it was determined that the modification was not required since the connection to the tank is still accessible to perform the test. A revision to the testing procedure has been completed to address the issue and reestablish the annual survey.

   The annual survey was successfully completed in February 2021. The results of testing for one location did not meet the -850 mV relative to copper/copper sulfate reference electrode acceptance criterion. The instant-off potential for this location was -795 mV relative to copper/copper sulfate reference electrode. This issue was documented in the corrective action program and rectifier adjustments were made to achieve instant-off potential more negative than the -850 mV relative to copper/copper sulfate reference electrode for all test locations. Although the 100 mV alternative acceptance criterion is not relied upon by this program, during system design and installation, the native potential for this location was recorded to be -444 mV relative to copper/copper sulfate reference electrode which indicates that the alternative acceptance criterion would have likely been satisfied and provides reasonable assurance that the tank was adequately protected since the last successful performance of the test.

Testing results for the standby shutdown facility diesel engine fuel oil tank cathodic protection system performed to date do not indicate any adverse trend in system performance. Other than the result for one location during the February 2021 test, the results of testing completed to date have confirmed instant off potential more negative than -850 mV relative to copper/copper sulfate reference electrode for each location during each performance of the test.

The standby shutdown facility diesel engine fuel oil tank was inspected in 2012 and 2015. Visual and low frequency electromagnetic testing were performed of 100% of the accessible internal surface area during both inspections. Ultrasonic testing was of areas of concern identified by low frequency electromagnetic testing and as directed by engineering. The 2012 inspection identified and repaired nine indications of internally initiated microbiologically influenced corrosion, as discussed further in the *Fuel Oil Chemistry* (B2.1.18) AMP. No indications of externally initiated degradation were identified in 2012. The 2015 inspection identified one indication of localized external degradation. The measured wall thickness at this location was calculated to remain above the minimum required wall thickness based on a conservative corrosion rate of 0.002 inch per year through the next scheduled inspection. Wall thickness at this location will be measured during the next inspection to confirm that the newly installed impressed current cathodic protection system has arrested active corrosion.

OE example 4 provides objective evidence that Oconee has taken appropriate actions to restore cathodic protection for the standby shutdown facility diesel engine fuel oil tank and that inspections performed to monitor the condition of the tank are effective.

5. In February 2019, a self-assessment was performed of the Duke fleet buried piping program. The objectives of the assessment were to determine if all procedural requirements were being fulfilled (including all requirements to meet NEI 09-14 and initial LR commitments), determine if the program was being implemented consistently across the fleet, and validate the scope of the program. The assessment identified no significant gaps related to the implementation of the existing Oconee program. The assessment identified several potential opportunities for improvement of the Oconee program that required further evaluation but only one was related to equipment within the scope of SLR. The assessment team noted a duplication of planned work with both a one-time work order to clean and inspect the buried standby shutdown facility diesel engine fuel oil tank and an existing periodic maintenance work order that performs the same task. The duplicate work order has been deleted and the tank is scheduled to be inspected in 2025. The performance of the additional inspection was to confirm the effectiveness of corrective actions taken to address a leak from the standby shutdown facility Diesel Fuel Oil Tank, as described further in the *Fuel Oil Chemistry* (B2.1.18) AMP.

OE example 5 provides objective evidence that the *Buried and Underground Piping and Tanks* AMP includes periodic assessments which are effective in ensuring the program objectives are being met and opportunities for improvements are being implemented.

6. In February 2012, a self-assessment was performed in preparation for the NRC TI 2515/182, *"Review of the Implementation of the Industry Initiative to Control Degradation of Underground Piping and Tanks"* inspection. The objectives of the assessment were to evaluate the station's compliance with NEI 09-14 and to determine the efficacy and robustness of the Oconee program. The assessment identified no significant gaps related to the implementation of the Oconee program or compliance with NEI 09-14. The assessment identified the three potential opportunities for improvement of the Oconee program. The program opportunities for improvement and resolutions are summarized below:

- No procedural guidance existed to notify the buried pipe engineer when trenches or vaults containing underground piping were opened. To address this issue, the work order planning guide was revised to alert appropriate organizations when removal of covers from trenches or vaults occurs so that opportunistic inspections can be performed.
- The self-assessment could not confirm that all buried piping leaks had been reported to INPO as required by NEI 09-14. A review of the corrective action program was performed following the completion of the self-assessment and identified three instances where the issue was not reported to INPO or where the report had to be updated to clarify that the reported leak was from a buried component. These three instances are not directly relevant to the Oconee *Buried and Underground Piping and Tanks* AMP since the leaks occurred on equipment that is not subject to aging management review. Two new reports were created to allow the Oconee OE to be shared with the industry and the existing report was revised to specify that the reported leak was from a buried component. Current procedures require any leaks from buried or underground piping or tanks within the scope of the NEI 09-14 program or within the scope of LR to be reported to INPO to ensure Oconee OE is shared with the industry.
- Inadequate assessment of the condition of buried and underground piping that has experienced leaks or has been previously repaired may have been performed. A review of the corrective action program was performed following the completion of the self-assessment and identified three instances of leaks within the scope of the program where inadequate assessment of the remaining piping run was performed. Two of these leaks occurred on piping that is not within the scope of SLR (buried PVC plant drinking water system pipe and underground steel vacuum system pipe). The third leak occurred in 2009 on the Unit 2 standby shutdown facility auxiliary service water system piping. All of the original carbon steel buried piping in this system has since been replaced as described in OE example 2, above. Current procedures include guidance regarding sample expansion to bound and characterize the extent of the condition to ensure that appropriate assessment of the condition of buried and underground piping occurs in the event of leaks or unsatisfactory inspection results.

OE example 6 provides objective evidence that the Oconee program has been implemented in accordance with NEI 09-14 guidance and that self-assessments are effective in ensuring the program objectives are met and opportunities for improvements are implemented.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Buried and Underground Piping and Tanks* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Buried and Underground Piping and Tanks* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Buried and Underground Piping and Tanks* AMP, with enhancements noted above, will provide reasonable assurance that aging effects will be adequately managed such that the components within the scope of this program will continue to perform their intended functions consistent with the CLB during the SPEO.

B2.1.27 INTERNAL COATINGS/LININGS FOR IN-SCOPE PIPING, PIPING COMPONENTS, HEAT EXCHANGERS, AND TANKS

Program Description

The *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* AMP is a new condition monitoring program that includes visual inspections of internal coatings/linings of ductile iron, and carbon steel piping, piping components, tanks, heat exchangers exposed to raw water, treated water, treated borated water, or lubricating oil. There are no internally coated or lined piping, piping components, heat exchangers, or tanks exposed to closed-cycle cooling water, waste water, fuel oil, air, or condensation within the scope of this program. This program is not used to manage the integrity of coatings applied to external surfaces of piping or components.

Other than for buried fire header piping, the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* program will include periodic visual inspections to verify the integrity of internal coatings designed to adhere to and protect the base metal. For tanks and heat exchangers, all accessible surfaces are inspected. Piping inspections are sampling-based. Inspection intervals are established by a coating specialist qualified in accordance with an ASTM International standard endorsed in RG 1.54. However, inspection intervals should not exceed those specified in NUREG-2191, AMP XI.M42, Table XI.M42-1, *"Inspection Intervals for Internal Coatings/Linings for Tanks, Piping, Piping Components, and Heat Exchangers."* Opportunistic inspections will be performed for cement-lined buried water-based fire suppression system piping.

The training and qualification of individuals involved in coating/lining inspections of non-cementitious coatings/linings are conducted in accordance with ASTM International Standards endorsed in RG 1.54, *"Service Level I, II and II Protective Coatings Applied to Nuclear Power Plants,"* including the NRC guidance contained in RG 1.54 associated with a particular standard. For cementitious coatings/linings, inspectors should have a minimum of five years of experience inspecting or testing concrete structures or cementitious coatings/linings or a degree in the civil/structural discipline and a minimum of one year of experience. Inspection results that do not satisfy established acceptance criteria are entered into the Oconee 10 CFR 50, Appendix B corrective action program. The corrective action program ensures that conditions adverse to quality are promptly corrected.

The program will be implemented through various station procedures and work activities. Inspections are performed for signs of coating failures and precursors to coating failures including peeling, delamination, blistering, cracking, flaking, chipping, rusting, and mechanical damage. Peeling and delamination is not acceptable. Blisters are evaluated by a coatings specialist, and should be limited to a few intact small blisters that are completely surrounded by sound material, and with size and frequency not increasing between inspections. Minor cracks in cementitious coatings are acceptable provided there is no evidence of debonding. Coatings/linings that do not meet acceptance criteria are repaired, replaced, or removed. Physical testing is performed where physically possible (i.e., sufficient room to conduct testing) or examination is conducted to ensure that the extent of repaired or replaced coatings/linings encompass sound coating/lining material. These inspections, and subsequent repairs, replacements, or evaluations of internal coatings will provide reasonable assurance that in scope components and downstream components will meet CLB intended functions for the SPEO.

Aging of the internal coating for the elevated water storage tank will be managed as described in the *Fire Water System* (B2.1.16) program.

NUREG-2191 Consistency

The *Oconee Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* AMP is a new program that will be consistent with the ten elements of AMP XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks” specified in NUREG-2191 (GALL-SLR), as modified by SLR-ISG-2021-02-MECHANICAL, “Updated Aging Management Criteria for Mechanical Portions of the Subsequent License Renewal Guidance” with the following exceptions.

Exception 1 to NUREG-2191

Program Element Affected: Detection of Aging Effects (Element 4)

1. NUREG-2191, as modified by SLR-ISG-2021-02-MECHANICAL, states that opportunistic inspections can be performed in lieu of periodic inspections, for buried internally lined/ coated fire water system piping provided that through-wall flaws in the piping can be detected through continuous system pressure monitoring. Opportunistic inspections of the cement lining of the buried Keowee fire detection/protection system piping will be performed in lieu of periodic inspections. System pressure monitoring is not an effective means of detecting through-wall flaws in Keowee fire detection/protection system piping.

   Justification for Exception 1

   The Keowee fire detection/protection system pressure and normal system loads are supplied by the static head between Lake Keowee level and elevation of the fire suppression equipment. A flow switch is installed upstream of the buried cement lined ductile iron piping. This flow switch provides an auto-start signal to the pump if flow greater than ten gallons per minute is detected. Start of the fire protection pump is indicated in the control room such that any significant leak of buried system piping would be immediately detected. In a typical fire protection system, header pressure is maintained by a jockey pump. A leak in excess of jockey pump capacity would result in decreased header pressure which would provide indication of a leak. A typical jockey pump in nuclear station fire protection system has a capacity on the order of 50 gallons per minute. As such, the alternate leak detection method utilized for the Keowee fire detection/protection system is more sensitive than the recommended method. Flow testing and internal piping inspections of the Keowee fire detection/protection system will occur at intervals specified in NFPA 25, or as modified by AMP XI.M27, Table XI.M27-1 and Oconee OE is acceptable (i.e., no leaks due to age-related degradation of cement lining used in buried in-scope fire water system components).

Exception 2 to NUREG-2191

Program Element Affected: Corrective Actions (Element 7)

2. NUREG 2191 recommends that coatings/linings that do not meet acceptance criteria are repaired, replaced, or completely removed. If degradation is identified, the emergency feedwater pump turbine lubricating oil tank internal coating will not be repaired, replaced, or completely removed.

   Justification for Exception 2

   Lessons learned and improved maintenance practices for similar turbines have been communicated at industry meetings facilitated by Nuclear Maintenance Application Center's terry turbine users group and are incorporated in the applicable EPRI maintenance guides. Industry best practice for maintenance of internal coatings applied to turbine oil systems is to remove any damaged coating and not attempt to recoat the surfaces. Defective, damaged, or degraded coating on the emergency feedwater pump turbine lubricating oil tank will be removed but the internal surface will not be repaired or replaced. Removal of the coating will ensure flow blockage will not occur. Periodic inspections of the emergency feedwater pump turbine lubricating oil tanks will continue to be performed to monitor the condition of the internal coating, remove any loose or degraded coating, and monitor the condition of the base metal.

   The NRC approved a GALL exception based on very similar justification as documented in the SER related to the LR of Fermi 2, Docket No. 50-341, July 2016 (ADAMS Accession Number ML16190A241) and in the SER related to the SLR of Peach Bottom Atomic Power Station Units 2 and 3, Docket Nos. DPR 44 and DPR 56, October 2019 (ADAMS Accession Number ML19280D820).

Enhancements

None

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO.

1. In September 2019 a self-assessment was performed to verify the regulatory compliance and on-going effectiveness of selected LR AMPs and the overall LR program. Implementation of the borated water storage tank coatings inspection (UFSAR Section 18.3.17.1) and condenser circulating water system internal coatings inspection (UFSAR Section 18.3.17.5) was evaluated as part of this self-assessment. This review confirmed that internal coating inspection aging management activities are being performed in accordance with commitments made during the initial LR process. Summaries of recent

internal inspections of the condenser circulating water system and borated water storage tanks are provided in OE examples 2 and 3, respectively.

An area for improvement was identified related to the condenser circulating water system internal coatings inspection. The results of internal inspections of the condenser circulating water system piping is intended to serve as representative of other buried piping systems within the scope of LR at Oconee. The self-assessment identified that there was insufficient guidance in program documentation to ensure that appropriate evaluation of extent of condition is performed if unacceptable degradation is identified. This issue was entered into the corrective action program and program documentation has been revised to include guidance to perform extent of condition evaluations if inspection results are unacceptable.

OE example 1 provides objective evidence that aging management activities have been implemented in accordance with initial LR commitments and that self-assessments are used to identify and implement programmatic improvements.

2. The internally coated condenser circulating water system intake piping has been visually inspected at least once every five years. All accessible internal surfaces are assessed during physical walkdowns of the piping. The inspection reports from the previous ten years have been reviewed and each have concluded that no conditions existed that would prevent the piping from performing its intended functions through the next scheduled inspection. The results of the inspections for each unit are summarized below.

Unit 1: Inspections of the internal coating of the Unit 1 condenser circulating water system intake piping were performed during the Spring 2011, Fall 2014, and Fall 2018 refueling outages. Generally, the internal coating was found to be in good overall condition with localized areas of rust blooms and nodules. During the Fall 2014 outage, three small areas of coating delamination were identified. These areas were re-inspected during the Fall 2016 and Fall 2018 refueling outage and determined to be acceptable for continued service. Three additional small areas of delamination were identified during the Fall 2018 refueling outage and are planned for repair during the next opportunity when the condenser circulating water system intake piping is drained.

Unit 2: Inspections of the internal coating of the Unit 2 condenser circulating water system intake piping were performed during the Fall 2013 and 2015 refueling outages. Portions of the intake piping could not be inspected during the Fall 2013 refueling outage due to leak-by of isolation valves preventing complete de-watering of the pipe and due to resource and time restraints. During each of these inspections the coating was found to be in overall good condition with localized areas of rust blooms and nodules. No areas of previously unidentified degradation requiring immediate repair were identified during these inspections. Work orders were created following each inspection to perform repairs of identified coating issues at the next opportunity. These repairs have been completed or are scheduled to be completed during the next outage when the piping is de-watered.

Unit 3: Inspections of the internal coating of the Unit 3 condenser circulating water system intake piping were performed during the Spring 2012, Spring 2016, and Spring 2018 refueling outages. During each of these inspections the coating was found to be in overall good condition with localized areas of rust blooms and nodules. No areas of previously unidentified degradation requiring immediate repair were identified during these inspections. Previously identified coating issues were repaired during the Spring 2016 refueling outage. Three small areas of coating delamination were identified during the Spring 2016 refueling outage and subsequently repaired during the Spring 2018 refueling outage as well as numerous other localized areas of concern. All other previously identified areas of degraded coating were re-inspected during the Spring 2018 refueling outage and determined to be acceptable for service until the next scheduled inspection. New areas of localized coating degradation identified in 2018 have been scheduled for re-inspection or repair during the next refueling outage when the piping is de-watered.

OE example 2 provides objective evidence that visual inspections of the internal coating of the condenser circulating water system have successfully identified indications of coating degradation and that appropriate corrective actions are being taken, including re-inspection and repair of degraded coatings, to ensure system intended functions are maintained.

3. The internally coated borated water storage tanks are visually inspected at least once every six years. All accessible internal surfaces are assessed during physical walkdowns of the tanks. The inspection reports from the previous ten years have been reviewed and each have concluded that no conditions existed that would prevent each tank from performing its intended functions through the next scheduled inspection. The results of the inspections for each unit are summarized below.

   Unit 1 – The internal coating of the Unit 1 borated water storage tank was visually inspected during the Fall 2014 refueling outage. During this evolution, wall thickness measurements of the tank bottom were also planned but were unable to be completed so the tank was entered again during the Fall 2016 outage allowing for a second internal visual inspection. The overall condition of the internal coating was very good. Small blisters were identified in areas that had been previously repaired, but they were intact and there was no indication of a breach in the coating. No change in the condition of the coating was noted between the Fall 2014 and Fall 2016 inspections.

   Unit 2 – The internal coating of the Unit 2 borated water storage tank was visually inspected during the Fall 2011 refueling outage. The overall condition of the internal coating was very good. Small blisters were identified in areas that had been previously repaired, but they were intact and there was no indication of a breach in the coating. Two areas of coating degradation identified during the previous inspection completed during the Spring 2007 refueling outage were repaired. Two other small areas of degraded coating that had not been previously identified were also repaired. The internal coating of the tank was re-inspected during the Fall 2016 refueling outage, including areas of concern previously identified. Six areas of degraded coating were identified by engineering and repaired during the Fall 2016 refueling outage.

   Unit 3 – The internal coating of the Unit 3 borated water storage tank was visually inspected during the Fall 2010 refueling outage. The overall condition of the tank coating was very good. Areas that had previously been repaired were inspected and no issues were identified. The previous inspection report from 2006 identified a small area of exposed metal where slight surface rust was occurring. This area was re-inspected in Fall 2010 and no significant change in condition had occurred from the previous inspection. The surface rust in this area was determined to be very minor in nature and acceptable for continued service. Small areas of rust staining were identified at the bottom of two pipe penetrations and attributed to rust from the penetration itself and not due to corrosion of the tank wall. The internal coating of the tank was re-inspected during the Fall 2016 refueling outage, including areas of concern previously identified and found to be acceptable for continued service. No coating repairs were performed in 2016.

OE example 3 provides objective evidence that visual inspections of the internal coating of the borated water storage tanks have successfully identified indications of coating degradation and that appropriate corrective actions are being taken, including re-inspection and repair of degraded coatings, to ensure system intended functions are maintained.

4. Periodic internal visual inspections of the 36 total main condenser waterboxes for the three Oconee operating units are performed during each refueling outage. These inspections have identified varying degrees of degradation of the original coal tar epoxy coating. The walls inside the waterboxes, including the tubesheet, have been observed to have rust blooms, nodules, and degraded sections of coating. A small amount of material loss from the walls in various forms of pitting, scaling, and flaking has been experienced. Though degradation observed to date has not adversely affected main condenser operation or challenged the intended function of the waterboxes, engineering recommended that the internal coatings in all three units be repaired. A project has been developed to fully re-coat both the inlet and outlet waterboxes, including tubesheets, for all three Oconee operating units. The project involves replacing the original coal tar epoxy coating with a Plastocor epoxy coating system. To date, re-coating activities have been completed for ten of the 36 total waterboxes. The remaining waterboxes are scheduled to be re-coated during upcoming outages with all re-coating activities planned for completion by 2026.

   This OE example provides objective evidence that ongoing periodic visual inspections have been successful in detecting and monitoring coating degradation to allow for the scheduling and performance of coating repairs prior to impact on component intended functions.

5. Inspections of the emergency feedwater pump turbine oil tanks have historically identified peeling and flaking of the manufacturer applied internal coating. This is a generic issue for similar turbine oil reservoirs across the industry. Industry best practice, as documented in EPRI turbine maintenance guides, is to remove any degraded coating to prevent potential performance issues due to the presence of foreign material but not to attempt to recoat the internal surface. The results of inspections from the previous ten years were reviewed during the development of this AMP. No evidence of ongoing coating degradation or significant corrosion were identified during the 15 inspections of the internal surface of the three emergency feedwater pump turbine oil tanks performed over the previous ten years.

> This OE example provides objective evidence that the remaining sound coating is stable and that maintenance activities at Oconee have been successful at mitigating the potential impact on turbine performance from degraded coating in the emergency feedwater pump turbine oil tanks.

The above examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

<u>Conclusion</u>

The implementation of the *Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.28 ASME XI, SUBSECTION IWE

Program Description

The *ASME Section XI, Subsection IWE* AMP is an existing condition monitoring program that manages cracking, loss of material, loss of sealing, loss of preload, and loss of leak tightness by providing aging management of the steel liner of the concrete containment. ASME Code, Section XI, Subsection IWE inspections are performed in order to identify and manage containment liner aging effects that could result in loss of intended function for the SPEO. Included in this inspection program are the containment liner plate and its integral attachments, containment penetrations, containment hatches, airlocks, and pressure retaining bolting.

Surface and volumetric examinations are performed to identify indications of degradation. The primary inspection method is visual examination (general visual, VT-1, VT-3) of surfaces for evidence of cracking, discoloration, wear, pitting, excessive corrosion, arc strikes, gouges, surface discontinuities, dents, and other signs of surface irregularities, including discernible liner plate bulges. Limited volumetric examinations (ultrasonic thickness measurement) and surface examinations (e.g., liquid penetrant) are performed, as required. Plant OE has not identified any discernible bulges requiring further examination. Acceptance criteria, corrective actions, and expansion of the inspection scope when degradation exceeding the acceptance criteria is found are in accordance with ASME Code, Section XI, Subsection IWE, Article IWE 3000.

For the third containment inspection interval, beginning during the third quarter of 2014, IWE Containment inservice inspections are performed in accordance with the 2007 Edition of ASME Code, Section XI, Subsection IWE (through the 2008 addenda), supplemented with the applicable requirements of 10 CFR 50.55a(b)(2)(ix). Prior to the end of each interval, the IWE Program Plan is revised to reflect the appropriate update of ASME Code, Section XI, consistent with the provisions of 10 CFR 50.55a.

Containment seals and gaskets are included in the scope of the *10 CFR Part 50, Appendix J* (B2.1.31) AMP. Service Level 1 coatings are included in the scope of the *Protective Coating Monitoring and Maintenance* (B2.1.35) AMP.

Procedures will include preventive actions to ensure bolting integrity for replacement and maintenance activities by specifying proper selection of bolting material and lubricants, and appropriate installation torque or tension to prevent or minimize loss of bolting preload and cracking of high strength bolting. For structural bolting consisting of ASTM A325, ASTM A490, ASTM F1852 and/or ASTM F2280 bolts, the preventive actions for storage, lubricant selection, and bolting and coating material selection discussed in Section 2 of the Research Council for Structural Connections publication, *"Specification for Structural Joints Using High-Strength Bolts,"* will be used.

There are no stainless steel penetration bellows installed as part of the containment pressure boundary. Stainless steel high energy pipes that penetrate the containment are connected to carbon steel penetration sleeves with dissimilar metal welds. Plant OE has not identified any stress corrosion cracking associated with these welds. The *10 CFR Part 50, Appendix J* AMP manages the aging of these dissimilar metal welds. The containment steel liner and penetrations were analyzed for cyclic fatigue and do not require surface examinations in addition to visual examinations. This evaluation is a TLAA and the projected number of cycles is less than the design cycles for 80 years. Therefore, cracking due to fatigue is managed as a TLAA. A one-time volumetric examination of metal liner surfaces that are inaccessible from one side will be performed if triggered by plant-specific OE. This supplemental volumetric examination consists of a sample of one-foot square locations that include both randomly selected and focused areas most likely to experience degradation based on OE and/or relevant considerations such as environment.

The *ASME Section XI, Subsection IWE* AMP manages aging of the steel liner of the concrete containment building. An evaluation of the acceptability of the inaccessible areas is completed whenever conditions are detected in accessible areas that could indicate the presence of, or result in, degradation to such inaccessible areas.

NUREG-2191 Consistency

The *ASME Section XI, Subsection IWE* AMP will be consistent with the recommendations provided in Section XI.S1 of NUREG-2191 with the enhancements as described below.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented in the following program elements: Preventive Actions (Element 2), Parameters Monitored or Inspected (Element 3), and Detection of Aging Effects (Element 4).

1. The program will be enhanced to specify that for “high strength” structural bolting consisting of ASTM A325, ASTM F1852, and/or ASTM A490 bolts, the preventative actions for storage, lubrication, and stress corrosion cracking potential discussed in Section 2.0 of Research Council for Structural Connections publication *“Specification for Structural Joints Using ASTM A325 or ASTM A490 Bolts,”* will be used. (Element 2)

2. The program will be enhanced to include inspection attributes for the aging mechanisms listed in NUREG-2191. For non-coated surfaces this includes evidence of cracking, discoloration, wear, pitting, excessive corrosion, arc strikes, gouges, surface discontinuities, dents, and other signs of surface irregularities including discernible liner plate bulges. For painted or coated surfaces this includes evidence of flaking, blistering, peeling, discoloration, and other signs of potential distress of the underlying metal shell or liner system, including discernible liner plate bulges. (Element 3)

3. The program will be enhanced to specify a one-time volumetric examination of metal liner surfaces that are inaccessible from one side if triggered by plant-specific OE. The trigger for this supplemental examination is plant-specific occurrence or recurrence of measurable metal liner corrosion (base metal material loss exceeding 10% of nominal plate thickness) initiated on the inaccessible side or areas, identified since the date of

issuance of the first renewed license. This supplemental volumetric examination consists of a sample of one-foot square locations that include both randomly-selected and focused areas most likely to experience degradation based on operating experience and/or other relevant considerations such as environment. The supplemental volumetric examinations for each unit will occur within two refueling outages after identifying the trigger for the examination. Any identified degradation is addressed in accordance with the applicable provisions of the ASME Section XI, Subsection IWE program. The sample size, locations, and any needed scope expansion (based on findings) for this one-time set of volumetric examinations should be determined on a plant-specific basis to demonstrate statistically with 95 percent confidence that 95 percent of the accessible portion of the containment liner is not experiencing corrosion degradation with greater than 10 percent loss of nominal thickness. (Element 4)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *ASME Section XI, Subsection IWE* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2018, the NRC performed a walkdown of the Oconee Unit 3 reactor building and questioned if the containment leak chase channel piping that is embedded in the basement floor is inspected as part of the containment ISI program, specifically ASME Section XI, Article IWE Item E1.30, *Moisture Barriers*. Per the ASME Code, moisture barrier exams shall include moisture barrier materials intended to prevent intrusion of moisture against inaccessible areas of the pressure retaining metal containment shell or liner at concrete to metal interfaces which are not seal-welded. The NRC identified that failure to inspect the leak chase channel piping as a part of IWE Item E1.30 is a potential performance deficiency.

   A corrective action item was generated to perform inspections of piping penetrations and the liner in areas of concern. Tasks were also generated to inspect and repair coatings at the piping penetrations, and to inspect and repair the moisture barrier as needed. Two indications were noted in the liner plate and determined not to require repair. An indication in the moisture barrier was identified and was repaired. Actions were taken to update the containment ISI plan to include these specific areas for visual inspection.

   OE example 1 provides objective evidence that age-related inspection findings or concerns are entered into the corrective action program and appropriate corrective actions are taken to evaluate and correct deficiencies.

2. In 2018, a containment ISI examination of the containment liner plate identified an area of wall loss greater than 10% of the nominal liner plate thickness. This is a relevant condition as defined by Section IWE-3522 of the Section XI Code, and requires engineering evaluation for acceptance for continued service. The exam was initially performed by ultrasonic testing and the lowest thickness found was well within the

acceptable range. However, pit gauge readings in this area found pits with depths that would result in wall thicknesses marginally less than 90% of the nominal thickness. Follow up actions under the corrective action program included evaluation of the liner for continued service, re-coating the liner plate, restoration of the moisture barrier, evaluation of extent of condition, and initiation of augmented examinations of the moisture barrier under the containment ISI Program.

OE example 2 demonstrates that inspections of containment components are being performed in accordance with industry guidelines and that those inspections are effective in identifying aging effects prior to loss of intended function. OE example 2 also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to monitor and trend the conditions.

3. An inspection of the containment moisture barrier was performed in 2020 as required by ASME Section XI, Subsection IWE. The examination identified relevant indications of the moisture barrier such as wear, damage, surface cracks, and lack of adhesion that could permit intrusion of moisture against inaccessible areas of pressure retaining surfaces of the metal containment liner. The evaluation determined that all areas of the moisture barrier should be subject to repair and re-inspection. Follow up corrective actions included the implementation of inspection and repair activities for all accessible areas of the moisture barrier. Several inaccessible areas were identified; each of these were inspected to ensure no signs of corrosion or staining was present. Actions were also taken to update the containment ISI plan to document these inaccessible areas and address in future examinations.

   OE example 3 provides objective evidence that program inspections, along with the corrective action program, will effectively monitor in scope SSCs to assure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO.

4. OE affirms Oconee awareness of the need to evaluate internal and external events for relevance, and to incorporate updates as appropriate to ensure program effectiveness.

   - An item was entered into the corrective action program in 2013 to document a potential issue raised by NRC inspectors while reviewing an engineering change package related to in-service containment liner inspection ports for a US pressurized water reactor facility. NRC inspectors challenged the plant's position on the definition of "inaccessible" as it relates to certain portions of the containment liner that are not inspected. A corrective action was initiated to require a follow up investigation, which determined that Oconee does not have areas that are bolted and glued like those described in the engineering change package for the other facility.
   - An item was entered into the corrective action program in 2014 to document Oconee review of industry OE, where a hole was identified in the containment liner plate at another pressurized water reactor facility. Investigation and laboratory analysis by that utility determined that there were indications of two through wall penetrations with a possible third penetration slightly off-set from the second. After cleaning the area and removal of the corrosion products, a hole initially determined to be approximately 0.40" x 0.28" in size was discovered in the containment steel liner plate. The direct

cause of this industry event was pitting type corrosion, originating from foreign material introduced during the original construction of the containment wall. The Oconee evaluation of this item concluded that Oconee performs liner plate inspections that are capable of detecting degradation of this nature, and that no such degradation had been identified at Oconee.

OE example 4 provides evidence Oconee has recognized the importance of addressing external OE. OE example 4 also demonstrates that Oconee is performing required ISI examinations, consistent with the requirements of ASME Section XI, Subsection IWE. Oconee OE demonstrates that the corrective action program is utilized to document and resolve items that do not meet acceptance criteria, or when unexpected or abnormal conditions are observed. The OE also reflects the involvement of engineering to evaluate and disposition degradation and anomalous conditions to ensure that intended functions are maintained, and that updates to program activities are implemented as necessary to ensure ongoing program effectiveness.

5. In September 2020, an AMP effectiveness review was performed for the *ASME Section XI Containment Inservice Inspection* program. The subject ONS program aging management activities were evaluated against the performance criteria identified in NEI 14-12, "Aging Management Program Effectiveness". The effectiveness reviews included the IWE and IWL aspects of the Containment Inservice Inspection program. The review concluded that both programs are meeting the requirements of NEI 14-12. No gaps were identified during these effectiveness reviews.

   OE example 5 provides objective evidence that the current *ASME Section XI Containment Inservice Inspection* program is effectively managing aging and meeting all current LR commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the SPEO.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *ASME Section XI, Subsection IWE* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *ASME Section XI, Subsection IWE* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

<u>Conclusion</u>

The implementation of the *ASME Section XI, Subsection IWE* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects and mechanisms will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.29 ASME XI, SUBSECTION IWL

Program Description

The *ASME Section XI, Subsection IWL* AMP is an existing condition monitoring program that manages the following aging effects for containment concrete:

- Cracking
- Loss of material and loss of material (spalling, scaling)
- Distortion
- Loss of bond
- Increase in porosity and permeability

For the current ten year inspection interval (starting 7/15/2014 and going through 7/2024), IWL containment inservice inspections are performed consistent with the 2007 Edition of ASME Code, Section XI, Subsection IWL (including 2008 addenda), supplemented with the applicable requirements of 10 CFR 50.55a(b)(2). In conformance with 10 CFR 50.55a(g)(4)(ii), the *Containment Inservice Inspection* program will be updated during each successive 120 month inspection interval to comply with the requirements of the latest edition and addenda of the code specified 12 months before the start of the inspection interval.

The program includes the accessible areas of the concrete dome and cylinder walls. The evaluations of these accessible areas provide the basis for extrapolation to the expected condition of inaccessible areas, and an assessment of potential degradation in such areas. The primary inspection method is visual examination (VT-1C, VT-3C) using the evaluation criteria provided in Chapter 5 of ACI 349.3R-02, *"Evaluation of Existing Nuclear Safety-Related Concrete Structures."* Photography and its variations may be used to trend aging effects such as cracking, spalling, delamination, pop-outs, or other age-related concrete degradation as illustrated in ACI 201.1R-1968, *"Guide for Conducting a Visual Inspection of Concrete in service."*

Tendon wires and tendon anchorage hardware surfaces are inspected for loss of material, cracking, and mechanical damage. The tendon corrosion protection medium is tested for pH, presence of free water, and soluble ion concentration.

The *ASME Section XI, Subsection IWL* AMP tests selected sample tendons for yield strength, ultimate tensile strength, and elongation. The sample includes hoop tendons, vertical tendons and dome tendons. The frequency of tendon inspections is consistent with IWL-2421 for sites with multiple units. The assessment and trending of measured tendon prestressing forces will be managed by the program.

Additionally, inaccessible areas of the Oconee reinforced containment concrete structure, such as the dome, wall, basemat, ring girders and buttresses, are managed by the *ASME Section XI, Subsection IWL* AMP, supplemented by the *Structures Monitoring* (B2.1.33) program. Steel liners for the concrete containments, and their integral attachments, are included within the scope of the *ASME Section XI, Subsection IWE* (B2.1.28) program.

NUREG-2191 Consistency

The *ASME Section XI, Subsection IWL* program is an existing program that will be consistent with the ten elements of AMP XI.S2, *ASME Section XI, Subsection IWL*, specified in NUREG-2191 (GALL-SLR) with enhancements and exceptions described below.

Exception to NUREG-2191

Program Element Affected: Acceptance Criteria (Element 6)

1. The predicted lower limit values were developed based upon the original design criteria and CLB for the tendons. These criteria consider the same factors, but are not in complete accordance with RG 1.35.1 for determining predicted lower limit values. During development of the graphs, prestress losses resulting from elastic shortening were computed for each tendon group and not individually as prescribed in RG 1.35.1. The predicted lower limit curves represent the average values for each tendon group.

   Justification for Exception 1 to NUREG-2191:

   In a safety evaluation dated September 15, 1997, the NRC approved changing the tendon surveillance program by adoption of RG 1.35, Revision 3 methodology which included guidance in RG 1.35.1 for establishing prescribed lower limits and minimum required values for tendon groups. This approach was also approved for LR In NUREG-1723 and will be continued throughout SPEO.

Enhancements

The following enhancements will be implemented in the following program elements: Parameters Monitored or Inspected (Element 3), and Monitoring and Trending (Element 5)

1. The program will be enhanced to incorporate monitoring for changes in material properties of increase in porosity and permeability, and loss of strength and pattern cracking with darkened edges. (Element 3)

2. The program will be enhanced to specify that inspection results are documented and compared to previous results to identify changes from prior inspections. (Element 5)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *ASME Section XI, Subsection IWL* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2011, NRC Information Notice 11-20, *"Concrete Degradation by Alkali-Silica Reaction (ASR)"* was reviewed to determine if additional actions were required. The review identified that the scope of the inspections of concrete structures includes evidence of patterned cracking indicative of alkali-silica reaction. There has been no visual evidence/ patterned cracking indicative of alkali-silica reaction on the exterior of any Oconee concrete structures that are exposed to water, except the Keowee spillway wing walls, which have shown evidence of small amounts of expansion in the past. Since 2005, frequent monitoring of the Keowee spillway wing walls has taken place to document and trend the inward expansion of these walls. It was ultimately concluded by testing of the Keowee spillway wing walls that alkali-silica reaction was the contributing cause of this expansion, however, wall movements were very small and posed no significant risk to the structural integrity of the walls. There was no visual evidence of alkali-silica reaction at the Keowee spillway wing walls. As a result of the experience at Keowee, those at Oconee who perform structures monitoring inspections of concrete are familiar with alkali-silica reaction.

   OE example 1 provides objective evidence that industry OE is reviewed for applicable aging effects, and appropriate actions are included in aging management programs. This example also illustrates how program inspections, effectively monitor in scope SSCs to assure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the subsequent period of extended operation.

2. During the regularly scheduled ASME Code Section XI, Subsection IWL concrete surface examination of the Oconee Unit 1 reactor building in 2012, it was reported that superficial cracks had been observed in the containment dome. The cracks were in a circumferential pattern, following the curvature of the dome, and about 12" apart. The cracks appeared to follow the circumferential rebar placed in the dome during construction, and were determined to exceed the maximum 0.010" width below which no further evaluation is required in accordance with ASME Code Section XI, Subsection IWL, IWL-3221.3(d). Exposed rebar was also discovered and was painted to inhibit rust. The IWL responsible engineer subsequently evaluated the cracking, and concluded that there was no loss of functional capacity associated with this condition. The evaluation recognized that long term effects could include water exposure to the rebar causing rebar expansion and spalling of concrete, and recommended a long-term plan be developed for coating or weatherizing the remaining surface of the dome and protecting the exposed rebar. Follow up actions under the corrective action program included the installation of a protective coating system, as well as a task for subsequent coating inspections.

   OE example 2 demonstrates that inspections of accessible areas of the concrete dome are being performed in accordance with industry guidelines and that those inspections are effective in identifying aging effects prior to loss of intended function. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to monitor and trend the conditions.

3. In December of 2012, while performing temperature readings at the Unit 1 main steam penetration inside of the enclosed penetration area, it was discovered that the maximum inner surface of the concrete around the piping at the penetration was 227^{o}F. The main

steam penetration configuration is shown in UFSAR Figure 3-20. The concrete cylinder at the main steam penetration is 3’-9” thick. The temperature found exceeds the limit set forth in Subsection CC-3440 of ASME Code Section III, Division 2. The issue was entered into the corrective action program. Subsection CC-3440 of ASME Code Section III, Division 2 states higher temperatures than 150°F for general areas and 200°F for local areas may be allowed in the concrete if tests are provided to evaluate the reduction in strength and this reduction in strength is applied to the allowable strength considered in the design. Also, evidence shall be provided which verifies that the increased temperatures do not cause deterioration of the concrete either with or without load.

The concrete temperatures were not uniform around the penetration and were hotter above the penetration than below the penetration, with no values exceeding the 200°F limit being below the penetration and did not exceed the 200°F limit beyond about 4 feet from the edge of the penetration.

Subsequently, nondestructive testing of the exterior Unit 1 reactor building concrete wall, was performed in February of 2013. The testing was performed to evaluate the condition of the concrete immediately around the penetration. The spectral analysis of surface waves nondestructive testing is a volumetric testing method that was utilized during the investigation. The spectral analysis of surface waves test method involves determining the relationships between the wavelength and velocity of different surface vibrations as the vibration frequency is varied and is an indication of concrete condition and strength of the concrete throughout the depth of the structure (as described in ACI 228.2R, “*Nondestructive Test Methods for Evaluation of Concrete in Structures”*, Section 2.2.4). The spectral analysis of surface waves test results indicate that all of the test locations have data within the typical range of sound structural concrete. Additionally, the test areas were visually inspected by the engineering consultant to look for any indications that the concrete had reached damaging temperatures. There were no indications of color changes to the concrete to a light pink or buff color, which is typical in fire damage cases and is a visual indication of degradation. The concrete was also sounded to assess if the surface hardness of the concrete had degraded or become brittle relative to areas away from the penetration. These sounding techniques showed no indication of significant concrete degradation. The investigation concluded that there was no significant damage to the concrete immediately surrounding the penetration. Therefore, there is no reduction in strength to be considered in the design.

OE example 3 provides objective evidence that the existing AMP activities are being effectively implemented to identify and manage aging effects of in scope components and that the results of inspection activities are used to inform and enhance the program. Deficiencies identified during inspection activities are entered into the corrective action program and appropriate corrective actions are taken to evaluate and address deficiencies.

4. During Unit 1 tendon surveillances in 2016, lift-off examinations were performed on either end of a selected tendon. This is an augmented examination associated with repair and replacement activities during steam generator replacement activities, required in accordance with IWL-2521.2. In the lift-off exam for end 1 of the tendon, the maximum

ram pressure was achieved without successful liftoff. The liftoff of end 2 of the tendon was subsequently performed, and liftoff was achieved at a value less than the minimum required value, less than the predicted lower limit, and significantly lower than end 1. The condition was referred to the corrective action program, which directed that lift-off testing be repeated. During the repeat lift-off test, the tendon successfully met the acceptance criteria. Based on the retest, it was concluded there was a discrepancy in the performance and documentation of the initial test.

OE example 4 provides objective evidence that program inspections, along with the corrective action program, will effectively monitor in scope SSCs to assure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO.

5. An item was entered into the corrective action program in 2016 which documents that spalled concrete was observed at the top of each of the 6 hoop tendon buttresses during Unit 1 containment ISI examinations. This noted condition was similar to that which had previously been observed and repaired on the other Oconee units. It was determined that a grout repair should be implemented by the end of the next Unit 1 Containment ISI surveillance, as some locations are not easily accessible at full power operation and the repair is dependent on the power scaffolding being in place with a crane operator present. Corrective actions included the initiation of a work order to accomplish the required repairs which were completed in 2020.

   OE example 5 demonstrates that inspections of accessible areas of containment cylinder walls are being performed in accordance with industry guidelines and that those inspections are effective in identifying aging effects prior to loss of intended function. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to correct deficiencies.

6. In September 2020, an AMP effectiveness review was performed for the *ASME Section XI Containment Inservice Inspection* Program. The subject ONS program aging management activities were evaluated against the performance criteria identified in NEI 14-12, "Aging Management Program Effectiveness". The effectiveness reviews included the IWE and IWL aspects of the *ASME Section XI Containment Inservice Inspection* program. The review concluded that both programs are meeting the requirements of NEI 14-12. No gaps were identified during these effectiveness reviews.

   OE example 6 provides objective evidence that the current Containment Inservice Inspection program is effectively managing aging and meeting all current license renewal commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the subsequent period of operation

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *ASME Section XI, Subsection IWL* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, re-evaluation, repairs, or replacements is provided for locations where aging effects are found.

Periodic assessments of the *ASME Section XI, Subsection IWL* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *ASME Section XI, Subsection IWL* AMP, with the noted enhancements, provides reasonable assurance that the identified aging effects and mechanisms will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.30 ASME XI, SUBSECTION IWF

Program Description

The *ASME Section XI, Subsection IWF* AMP is an existing condition monitoring program that manages loss of material, cracking, loss of preload, and loss of mechanical function for supports of Class 1, 2, and 3 piping components.

During the fifth ISI interval (July 2014 to July 2024), inspections of supports for Class 1, 2, and 3 piping and components are performed consistent with 2007 Edition of the ASME Code Section XI through the 2008 Addenda, as approved in 10 CFR 50.55a. In conformance with 10 CFR 50.55a(g)(4)(ii), the ISI program is updated during each successive 120 month inspection interval to comply with the requirements of the latest edition and addenda of the code specified twelve months before the start of the inspection interval. ASME Code edition will be used consistent with the provisions of 10 CFR 50.55a during the SPEO.

Supports for Class 1, 2, and 3 piping and component supports are selected for examination per the requirements of ASME Code, Section XI, Subsection IWF. Acceptance standards are specified in ASME Code, Section XI, Subsection IWF, Article IWF-3400. If a component support does not meet the acceptance standards of IWF-3400 but is electively repaired to as new condition, the sample is increased or modified to include another support that is representative of the remaining population of supports that were not repaired. The scope of the inspection for supports is based on class and total population as defined in Table IWF-2500-1. The primary inspection method employed is visual examination. Inspections that reveal indications or relevant conditions that are unacceptable are entered in the corrective action program.

The requirements of subsection IWF are supplemented to include monitoring of high-strength bolting (actual measured yield strength greater than or equal to 150 ksi or 1,034 MPa and greater than one inch nominal diameter), with volumetric examination comparable to that of ASME Code, Section XI, Table IWB-2500-1, Examination Category B-G-1 to detect cracking in addition to the VT-3 examination. In each ten year period during the SPEO, a representative sample of bolts will be inspected. The sample will be 20% of the population (for a material/environment combination) up to a maximum of 17 bolts.

Procedures will include preventive actions to ensure bolting integrity for replacement and maintenance activities by specifying proper selection of bolting material and lubricants, and appropriate installation torque or tension to prevent or minimize loss of bolting preload and cracking of high-strength bolting. For structural bolting consisting of ASTM A325, ASTM A490, ASTM F1852 and/or ASTM F2280 bolts, the preventive actions for storage, lubricant selection, and bolting and coating material selection discussed in Section 2 of the Research Council for Structural Connections publication, "*Specification for Structural Joints Using High-Strength Bolts*," will be used.

This program includes a one-time inspection within five years prior to entering the SPEO of an additional 5% of the sample populations for Class 1, 2, and 3 piping supports. The additional supports will be selected from the remaining population of IWF piping supports and will include components that are most susceptible to age related degradation.

NUREG-2191 Consistency

The ONS *ASME Section XI, Subsection IWF* AMP is an existing program that will be consistent with the ten elements of AMP XI.S3, *ASME Section XI, Subsection IWF*, specified in NUREG-2191 (GALL-SLR) with enhancements described below.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented in the following program elements: Scope of Program (Element 1), Preventive Actions (Element 2), Detection of Aging Effects (Element 4), and Monitoring and Trending (Element 5):

1. Perform periodic evaluations of the acceptability of inaccessible areas of supports (e.g., portions of supports encased in concrete, buried underground, or encapsulated by guard pipe), when conditions exist in accessible areas that could indicate the presence of, or result in, degradation to inaccessible areas of supports. Perform these evaluations once every ten years during the SPEO. (Element 1).

2. Procedures will be revised to specify that for structural bolting consisting of ASTM A325, ASTMF1852, and/or ASTM A490, the preventative actions for storage, lubricants, and stress corrosion cracking potential discussed in Section 2 of Research Council for Structural Connections publication, "*Specification for Structural Joints Using ASTM A325 or A490 Bolts*," will be used (Element 2).

3. Procedures will be revised to specify that whenever replacement of bolting is required, bolting material, installation torque or tension, and use of lubricants and sealants will be in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339 (Element 2).

4. Perform a one time inspection within five years prior to entering the SPEO of an additional 5% of the sample populations for Class 1, 2, and 3 piping supports. The additional supports will be selected from the remaining population of IWF piping supports and will include components that are most susceptible to age related degradation (Element 4).

5. Procedures will be revised to specify that, for NSSS component supports, high-strength bolting greater than one-inch nominal diameter, volumetric examination comparable to that of ASME Code, Section XI, Table IWB-2500-1, Examination Category B-G-1 will be performed to detect cracking in addition to the VT-3 examination. In each ten year period during the SPEO, a representative sample of bolts will be inspected. The sample of high-strength bolting greater than one-inch nominal diameter subject to volumetric examination will consist of 17 bolts per unit. The sample shall include the bolting that is

most susceptible to age-related degradation (i.e., based on time in service, aggressive environment, etc.) (Element 4).

6. If a component does not exceed the acceptance standards of IWF-3400 but is repaired to as-new condition, the sample is increased or modified to include another support that is representative of the remaining population of supports that were not repaired (Element 5).

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *ASME Section XI, Subsection IWF* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In November of 2012, during regularly scheduled ISI, it was discovered that the spacer for a pipe clamp bolt next to a load stud was missing. Spacers are provided to maintain required dimensions and to prevent the bending in the ears of the clamp due to over tightening of the nut. A condition report was initiated in the corrective action program and further evaluation determined that the pipe is bearing on the clamp and the required dimension is maintained. Therefore, the missing spacer was not an operational concern and the clamp continued to perform its intended function. Follow up corrective actions included updating the support sketch to reflect the field condition, as evaluated and determined to be acceptable.

2. In April of 2015, during ASME Section XI VT-3 inspections, a pipe support was found out of tolerance. The pipe support sketch indicated a gap above and below the pipe, and the inspection found the pipe was bearing on the support below, with a gap above. The analytical model for this piping problem was subsequently re-analyzed with the support being restricted in the vertical direction. The results of the analysis indicated that, although piping stresses are within the allowable limits and the support is capable of taking the load, support loads on one of the nearby supports exceeded its capability. Further review indicated that some improvements could be made to the analysis model. Subsequent re-analysis concluded that all piping components are qualified for the faulted condition, such that the piping, hangers, and equipment would not fail, and other equipment is not affected. In summary, the analyses showed that all piping components are qualified for the faulted condition, but not in conformance with the UFSAR. A recommendation was made that the support be declared operable but degraded/non-conforming and assigned a corrective action. The condition was resolved when a design change was implemented to remove the support that was found to be discrepant. An analysis was performed as part of the design change to demonstrate that all piping stresses and support loads were satisfactory as modified.

3. In January of 2016, during an ASME Section XI VT-3 inspection, it was noted that the hanger had an approximate gap of 1/8 inch between the base plate and the wall. A work order was written to add a shim to the top north anchor of the baseplate. During craft inspection in preparation to add the shim, it was discovered that a shim between the base

plate and wall was already in place. The gaps were checked and found to be within tolerance per the specification, but the shim did not meet the requirements of the specification. Upon further review, other bill of material discrepancies were noted on the design drawing. A condition report was initiated in the corrective action program. A corrective action was initiated for engineering to evaluate the significance of the discrepancies. An engineering review determined that the discrepancies are acceptable with no changes required to the hanger and no challenges to operability. An engineering change was implemented to revise the design drawing to match the installed configuration.

4. In November of 2017, while performing ASME Section XI VT-3 inspections, a pipe clamp on a rod hanger was found overtightened. Quality control noted that the tolerance of a specified dimension on the pipe clamp exceeded the value referenced on the design drawing. The item was entered into the corrective action program, and an evaluation of the discrepancy was requested. The evaluation determined that the as found condition to be acceptable. Corrective actions included an assignment to revise the drawing to reflect the acceptability of the field condition.

5. In February of 2018, several discrepancies were identified during the pre-outage visual VT-3 examinations of a variable load spring support. The item was entered into the corrective action program, and appropriate notifications of the condition were made. An engineering evaluation of the information from the inspection and addressed each of the indications identified. The evaluation determined that the saddle’s as found condition is acceptable. Corrective actions included revising the hanger sketch to reflect the as-built condition.

These examples reflect that Oconee is performing required support examinations, consistent with the requirements of ASME Section XI, Subsection IWF. Evidence is provided that inspections are performed by qualified personnel and approved methods, and that these methods are capable of detecting nonconforming conditions and degradation. Evidence is provided that examinations are compared to design conditions to determine acceptability. The corrective action program is utilized to resolve instances where field configuration differs from the design condition, with field corrections or design documents updates initiated as appropriate. Oconee OE demonstrates that the corrective action program is utilized to document and resolve items that do not meet acceptance criteria, or when unexpected or abnormal conditions are observed. The OE also reflects the involvement of engineering to evaluate and disposition degradation and anomalous conditions, and to implement corrective actions as needed to ensure that intended functions are maintained.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *ASME Section XI, Subsection IWF* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *ASME Section XI, Subsection IWF* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *ASME Section XI, Subsection IWF* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects and mechanisms will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.31 10 CFR PART 50 APPENDIX J

Program Description

The *10 CFR Part 50, Appendix J* AMP is an existing performance monitoring program that manages the loss of material, loss of leak tightness, cracking, and loss of bolting preload in the containment and various systems penetrating primary containment. The program also detects loss of sealing due to degradation of elastomer gaskets and seals. The program manages steel and stainless steel containment structural elements, concrete embedments, penetration sleeves, hatches, airlocks, and bolting in indoor uncontrolled air and treated water environments.

The program consists of tests performed in accordance with the regulations and guidance provided in 10 CFR 50, Appendix J, *"Primary Reactor Containment Leakage Testing for Water-Cooled Power Reactors,"* Option B; Regulatory Guide 1.163, *"Performance-Based Containment Leak-Test Program,"* and NEI 94-01, *"Industry Guideline for Implementing Performance-Based Options of 10 CFR Part 50, Appendix J,"* and subject to the requirements of 10 CFR Part 54, *"Requirements for Renewal of Operating Licenses for Nuclear Power Plants."*

Containment leak rate tests are performed to ensure that leakage through the containment and systems and components penetrating primary containment does not exceed allowable leakage limits, as specified in the Technical Specifications. An integrated leak rate test and local leak rate tests are performed at intervals that comply with 10 CFR Part 50, Appendix J, Option B.

Visual inspections of the accessible interior and exterior surfaces of the containment structure, performed by the *ASME Section XI, Subsection IWE* (B2.1.28) program and the *ASME Section XI, Subsection IWL* (B2.1.29) program, augment the *10 CFR Part 50, Appendix J* program leakage rate testing and detect evidence of structural degradation that may affect the containment leak rate. These inspections are performed at intervals that comply with 10 CFR Part 50, Appendix J.

Aging effects of containment pressure-retaining boundary components excluded from leak rate testing are managed by the *External Surfaces Monitoring of Mechanical Components* (B2.1.23) program, *One-Time Inspection* (B2.1.20) program, *Water Chemistry* (B2.1.2) program, *Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components* (B2.1.24) program, *Open-Cycle Cooling Water System* (B2.1.11) program and the *Flow-Accelerated Corrosion* (B2.1.8) program.

Monitoring and trending is performed by comparing valve and penetration leakage from test results to administrative leakage limits that are set lower than the regulatory acceptance criteria. Test or inspection results that do not satisfy established criteria are entered into the corrective action program for evaluation.

NUREG-2191 Consistency

The ONS *10 CFR Part 50, Appendix J* AMP is consistent with the ten elements of AMP XI.S4, *10 CFR Part 50, Appendix J* specified in NUREG-2191.

Exception to NUREG-2191

None

Enhancements

None

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *10 CFR Part 50, Appendix J* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. The following two examples, while not age-related issues, do illustrate the types of actions taken under the current *10 CFR Part 50, Appendix J* program. The first example is from November 2013. The Oconee Unit 2 fuel transfer tube and reactor coolant standby shutdown facility makeup secondary penetration failed its Type C local leak rate test. Leakage was attributed to issues with the spent fuel pool to reactor coolant makeup pump block valve. The leak rate measured during the Type C test was 13,200 standard cubic centimeters per minute. This was above the test acceptance criteria of 443 standard cubic centimeters per minute. At the time of the test, all leakage was determined to be valve seat leakage.

   The cumulative leakage for the Oconee Unit 2 containment, including leakage from this block valve was determined to be 25,631 standard cubic centimeters per minute. The total allowable leakage for the Unit 2 containment is 212,402 standard cubic centimeters per minute ($0.6L_a$) and therefore, the requirements of Tech Spec 3.6.1 were met. A work order was generated and repair was completed.

   The second example is from May 2014. The equivalent Unit 3 valve was tested and exhibited a similar high leak rate (28,700 standard cubic centimeters per minute). The cumulative leakage for the Oconee Unit 3 containment, including this valve, was 48,874 standard cubic centimeters per minute. Engineering and operations evaluated the Oconee Unit 3 leakage against the total allowable leakage of 212,402 standard cubic centimeters per minute ($0.6L_a$) and determined the Unit 3 Containment met the requirements of Tech Spec 3.6.1.

   A cause evaluation was performed on the failed leak rate test for the Unit 3 spent fuel pool to reactor coolant makeup pump block valve. The cause evaluation noted the stem and disc for the valve had been replaced as the result of a 10 CFR Part 21 notification from the manufacturer. The valve disc removed from valve was compared to a new disc from the manufacture and a dimensional difference was noted in the “feet on the bottom of the disc wedge” and affected the disc to seat contact.

The cause evaluation also noted that the Unit 2 block valve experienced excessive seat leakage following the same stem/disc/wedge replacement during the fall of 2013 outage and that the issue applies to all three Oconee units. Work orders were issued for this same block valve on all three units to ensure the proper contact between the valve seat and disc sealing surfaces.

OE example 1 demonstrates that actions taken under the current *10 CFR Part 50, Appendix J* program, including use of the corrective action program ensure appropriate corrective actions are taken to evaluate and correct deficiencies.

2. In April of 2020, Oconee Unit 3 electrical penetration WD-7 was leak rate tested and did not meet the acceptance criteria of 16 standard cubic centimeters per minute. The leakage measured during testing was 30 standard cubic centimeters per minute. A condition report was initiated in the corrective action program. The cumulative leakage for the Oconee Unit 3 containment was evaluated by engineering and operations and found to meet the requirement of Tech Spec 3.6.1. Since the measured leakage is a small contributor to the overall containment leakage rate, it was determined acceptable to repair at a later date and a work order was opened to repair during the next refueling outage.

   OE example 2 demonstrates that the actions under the current *10 CFR Part 50, Appendix J* program, including use of the corrective action program ensure appropriate corrective actions are taken to evaluate and correct deficiencies.

3. In August 2020, a Maintenance Rule (a)(1) evaluation was performed due to three recent Unit 3 leak rate tests failing to meet acceptance criteria and being considered maintenance rule functional failures. The three leak rate tests were for the reactor building auxiliary cooler low pressure service water system supply control valve, reactor building auxiliary cooler low pressure service water system supply block valve, and the normal sump drain/hydrogen re-combiner drains secondary penetration.

   The evaluation identified reactor building auxiliary cooler low pressure service water system supply control valve and reactor building auxiliary cooler low pressure service water system supply block valve had failed their respective leak rate tests due to material build up on the valve seats due to solids and debris. These valves did not have preventive maintenance activities to periodically disassemble and inspect/clean the valve internals. The corrective action was to create preventive maintenance activities in the work management system to periodically disassemble and inspect these valves to prevent future leak rate test failures. Preventive maintenance activities were also generated for the respective valves on Unit 1 and Unit 2. All valves were scheduled to be disassembled during their next respective refueling outage.

   The evaluation identified that valve seat leakage was the cause for the leak rate test failure on Oconee Unit 3. Accumulation of debris on the valve seat was determined to be the cause of the valve seating issue and that led to the excessive leakage. A review of the outage activities prior to the leak rate test for this penetration identified several outage related draining activities for multiple systems through this valve prior to testing. Service water system dead legs known to contain silt, sediment, and corrosion products were drained through the valve, leading to the accumulation of debris on the valve seat surfaces causing leakage. The corrective action was to revise the outage schedule for performing leak rate testing on this Unit 3 valve until after all draining and cleaning activities are complete. This change was also applied to the respective leak rate testing schedules for Oconee Unit 1 and Unit 2.

OE example 3 demonstrates that the actions under the current *10 CFR Part 50, Appendix J* program, including use of the corrective action program ensure appropriate corrective actions are taken to evaluate and correct deficiencies.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the*10 CFR Part 50, Appendix J* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO. Adverse conditions identified by the Appendix J program are identified and entered in the corrective action program for resolution.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *10 CFR Part 50, Appendix J* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *10 CFR Part 50, Appendix J* AMP provides reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.32 MASONRY WALLS

Program Description

The *Masonry Walls* AMP is an existing program implemented as part of the current *Structures Monitoring* (B2.1.33) AMP. It is based on the guidance provided in IE Bulletin 80-11, *"Masonry Wall Design"*, and NRC Information Notice 87-67, *"Lessons Learned from Regional Inspections of Licensee Actions in Response to IE Bulletin 80-11"*, and is implemented through station procedures.

The *Masonry Walls* AMP manages inspections of masonry walls for cracks in joints, unsealed penetrations, missing or broken blocks, or separation from supports that could impact the intended function or potentially invalidate its evaluation basis. The program relies on periodic visual inspections, conducted at a nominal five year frequency to monitor and maintain the condition of masonry walls within the scope of SLR so that the established evaluation basis for each masonry wall remains valid during the SPEO. Observed aging effects that could impact masonry wall intended function or potentially invalidate its evaluation basis are entered into the corrective action process for further analysis, repair, or replacement. Masonry walls that are considered fire barriers are also managed by the *Fire Protection* (B2.1.15) program.

Aging effects of masonry wall structural steel support elements that provide technical basis for boundary conditions used in seismic analysis are managed by the *Structures Monitoring* (B2.1.33) AMP.

NUREG-2191 Consistency

The Oconee *Masonry Walls* AMP is an existing program that will be consistent with the ten elements of AMP Section XI.S5, *Masonry Walls* specified in NUREG-2191 (GALL-SLR) with enhancements described below.

Exception to NUREG-2191

None

Enhancements

The following enhancement will be implemented in the following program element: Parameters Monitored or Inspected (Element 3)

1. The masonry wall portion of the *Structures Monitoring* (B2.1.33) AMP will be updated to modify the parameters monitored to identify potential shrinkage and/or separation of masonry walls and include loss of material in addition to the currently managed cracking at joints (Element 3).

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Masonry Walls* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. Inspections of masonry walls are conducted as part of inspections performed under the *Structures Monitoring* (B2.1.33) AMP on a nominal five year interval. Reports from previous outage accessible inspections are reviewed prior to each new civil structure inspection. Items noted in previous inspection reports are revisited. Inspections are performed from the various elevations for the outage accessible locations. Items noted as continue to monitor and items with open work orders are carried forward into updated inspection reports.

   The evaluation criteria is ACI 349.3R, *"Evaluation of Existing Nuclear Safety-Related Structures*", which permits cracks up to 0.015" (0.4mm) (ACI 349.3R 5.1.1) without further evaluation, and cracks up to 0.04" if comparisons can be made to previous observed conditions (ACI 349.3R 5.2.1). Cracks greater than 0.04" noted for the first time during this exam are recorded and dispositioned to monitor during the next five year inspection.

   During recent civil structures inspections of the Oconee auxiliary building, turbine building, and radwaste facility, several small cracks (less than 0.04") were identified. These cracks have been measured, photographed, and documented in the Oconee corrective action program and are being monitored during future civil structures inspections. In addition, a hole was identified in a masonry wall, and a crack around a door frame was identified. Work orders were generated to repair these documented deficiencies.

   Oconee civil structure inspection results demonstrate that inspections of masonry walls are being performed in accordance with industry guidelines and that those inspections are effective in identifying aging effects prior to loss of intended function. OE example 1 demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to monitor and trend the conditions.

2. During the installation of a new duct through a masonry wall in 2014, a crack in the wall was identified. The wall in question is located between Room 343 and the west hallway on the third floor of the auxiliary building near column line 86. Based on a walkdown of the wall by engineering, the crack was observed in the west face of the top course of masonry just on the south edge of the opening where a new duct frame was to be installed through the wall. From an engineering perspective, the cracked face of the block was evaluated and determined to be is acceptable "as is". It was further determined that while not desirable, a small portion of the west face of the block could be removed in the process of drilling the holes and installing the new duct frame would be acceptable. Planning for the installation of the new duct was adjusted to avoid disturbing the area of the cracked block face.

OE example 2 provides objective evidence that the corrective action program was used effectively to identify unanticipated conditions while performing activities in the field and implement corrective actions to evaluate and mitigate age-related aspects of the condition.

3. During an inspection of newly exposed wall surfaces in 2010, an issue with a masonry wall was observed. The top mortar joint for the masonry block walls on the West Side of the Cask Decontamination Room at elevation 796‘ - 809‘ were not fully covered by the underside of the beam at elevation 809‘. Based on the location of the wall near safety significant mechanical equipment and the determination that the wall could potentially fail during a seismic event, compensatory actions were required until seismic restraints were installed to address the condition.

   OE example 3 provides objective evidence that inspections are performed on newly accessible masonry wall surfaces, and that use of the corrective action program is an effective process for correcting identified deficiencies.

4. A seismic and flood walkdown performed in 2012 in response to Fukushima Near-Term Task Force Recommendation 2.3 (SECY-11-0093) identified one discrepancy and one potential issue involving masonry walls:

   a. A seismic evaluation performed in 1996 identified that a seismic strut should be cut at a masonry wall/concrete wall interface but was found to be still connected during the walkdown. Subsequent analysis was performed to document the acceptability of the as found condition and concluded that strut did not need to be cut.
   b. An opening in a masonry wall penetration was observed with unsupported large bore piping penetrating the wall. A concern was identified that the unsupported length of large bore piping could adversely impact the equipment in the area during a seismic event. An assessment was performed to confirm that neither the wall or the piping were required to be seismically qualified. Potential flooding of the auxiliary building from a postulated non-seismic pipe breach was addressed and documented acceptable.

   OE example 4 demonstrates the effective use of industry OE and the corrective action program to identify potential non-conforming conditions, and take timely corrective action to ensure components in the scope of LR are evaluated and maintained consistent with the CLB for the SPEO.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the masonry walls AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the masonry walls AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Masonry Walls* AMP, as a subset of the *Structures Monitoring* (B2.1.33) AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with ONS CLB during the SPEO.

B2.1.33 STRUCTURES MONITORING

Program Description

The *Structures Monitoring* AMP is an existing condition monitoring program that consists of periodic visual inspection and monitoring the condition of concrete and steel structures, structural components, component supports, and structural commodities to ensure that aging degradation (such as those described in ACI 349.3R, ACI 201.1R, SEI/ASCE 11, and other documents) will be detected, the extent of degradation determined and evaluated, and corrective actions taken prior to loss of intended functions. Quantitative results (measurements) and qualitative information from periodic inspections are trended with sufficient detail, such as photographs and surveys for the type, severity, extent, and progression of degradation, to ensure that corrective actions can be taken prior to a loss of intended function. The acceptance criteria are derived from applicable consensus codes and standards. For concrete structures, the program includes personnel qualifications and quantitative evaluation criteria of ACI 349.3R. Structures are monitored on an interval of a nominal five years. The interval may be increased to a nominal 10-year frequency with appropriate justification based on the structure, environment and related inspections. There are provisions for more frequent inspections when conditions are observed that have a potential for impacting an intended function. Unacceptable conditions, when found, are evaluated or corrected in accordance with the corrective action program. The monitoring methods are effective in detecting the applicable aging effects and the frequency of monitoring is adequate to prevent significant age related degradation to ensure there is no loss of intended function.

The *Structures Monitoring* AMP was developed to implement the requirements of 10 CFR 50.65 and is based on NUMARC 93-01, *"Industry Guideline for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants,"* and Regulatory Guide 1.160, *"Monitoring the Effectiveness of Maintenance at Nuclear Power Plants."* The program includes elements of the *Masonry Walls* (B2.1.32) program and *Inspection of Water-Control Structures Associated with Nuclear Power Plants* (B2.1.34) program.

Concrete structures are inspected for indications of deterioration and distress including evidence of leaching, loss of material, cracking, and a loss of bond, as defined in ACI 201.1R. Steel components are inspected for loss of material due to corrosion. Inspections also include seismic joint fillers, elastomeric materials; and fiber reinforced polymers and steel bracings associated with masonry walls. The program also includes provisions for periodic testing and assessment of groundwater chemistry and opportunistic inspections of accessible below grade concrete structures.

Protective coatings are not relied upon to manage the effects of aging for structures included in the scope of this program. A dewatering system is not relied upon to control settlement and porous concrete was not used in the design of foundations.

Applicable components within the scope of this program include, but are not limited to: bolting, concrete anchors and embedments, concrete components, decking and siding, doors and door seals, ductbanks, external surfaces of bus enclosures (metallic ducting) and bus enclosure structural supports, expansion and seismic joints, foundations, hatches, hazard barriers, metal components such as louvers, miscellaneous steel, penetrations seals and sleeves, piles, pipe whip restraints and jet impingement shields, shielding, steel components, steel liners, supports, panels, racks, cabinets, enclosures, cable trays, conduits, wire way gutters, and tubing track.

Applicable metallic materials within the scope of this program include: aluminum, carbon steel, ductile iron, galvanized steel, and stainless steel; applicable bolting materials include: carbon steel, galvanized steel, and stainless steel. Applicable non-metallic materials within the scope of this program include: reinforced concrete, elastomer, fiberglass reinforced polymer, grout, and Lubrite.

Applicable environments within the scope of this program include air-outdoor, air-indoor uncontrolled, air, air with borated water leakage, treated water, raw water, water-flowing, and groundwater/soil and soil.

Applicable aging effects within the scope of this program include change in material properties/ loss of strength, cracking, loss of material, loss of mechanical function, loss of preload/ self-loosening, and loss of sealing.

NUREG-2191 Consistency

The *Structures Monitoring* AMP is an enhanced program that will be consistent with the recommendations provided in Section XI.S6, *Structures Monitoring* program of NUREG-2191 with the enhancements described in below.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented in the following program elements: Scope of Program (Element 1), Preventive Actions (Element 2), Parameters Monitored/Inspected (Element 3), Detection of Aging Effects (Element 4), Monitor and Trending (Element 5), and Acceptance Criteria (Element 6).

1. Add the following structures to the scope of the program (Element 1):

    a) Microwave house structure
    b) Technical support building cable vault
    c) 100kv structure
    d) Protected service water building
    e) Protected service water duct banks
    f) Borated water storage tank superstructure
    g) HP Office Building
    h) Administration Building

2. Procedures will be revised to specify that structural components inspected include structural bolting, anchor bolts and embedments, supports and bracings associated with

masonry walls, pipe whip restraints and jet impingement shields, transmission towers, panels and other enclosures, racks, sliding surfaces, sump and pool liners, electrical cable trays and conduits, tube tracks, electrical duct banks, manholes, doors, penetration seals, and other elastomeric materials (Element 1).

3. Expand the monitoring and evaluation of raw water and ground water chemistry, for pH, chlorides, and sulfates, on a frequency not to exceed five years that accounts for seasonal variations (e.g., quarterly monitoring every fifth year), from locations that are representative of the groundwater in contact with structures within the scope of SLR (Element 1):

    a) Enter adverse results, which exceed water chemistry criteria, into the corrective action program. As part of the corrective actions, if aggressive groundwater is identified that might affect structures in scope for SLR, perform additional water testing at additional locations and perform soil testing in order to confirm the extent, severity, and potential aging mechanisms resulting from the aggressive groundwater/ soil.
    b) Develop engineering evaluations to evaluate the water chemistry results to assess the impact, if any, on below-grade concrete, including the potential for further degradation due to the aggressive groundwater, as well as consideration of current conditions. As part of the engineering evaluations, determine if additional actions are warranted, which might include enhanced inspection techniques and/or increased frequency, destructive testing, and focused inspections of representative accessible (leading indicator) or below grade, inaccessible concrete structural elements exposed to aggressive groundwater/soil.
    c) Develop the initial engineering evaluations prior to the SPEO. Develop follow-up engineering evaluations on an interval not to exceed five years.
    d) If aggressive groundwater and soil is identified, at a minimum, perform focused inspections of representative, accessible (leading indicator) structural elements, or if accessible areas will not be leading indicators for the potential aging mechanisms, excavate and inspect buried concrete elements exposed to aggressive groundwater/ soil.
    e) If degraded concrete is identified, as part of the focused inspections of leading indicators (representative, accessible or exposed inaccessible concrete), enter adverse results that exceed ACI 349.3R second tier criteria into the corrective action program, and expose inaccessible concrete so that the extent of the condition can be determined, baseline conditions documented, and additional actions identified such as repairs, new preventative actions, additional evaluations, and future inspections.

4. For structural bolting consisting of ASTM A325, ASTMF1852, and/or ASTM A490, provide guidance for storage, lubricants, and the steps to minimize stress corrosion cracking potential discussed in Section 2 of Research Council for Structural Connections publication, “Specification for Structural Joints Using ASTM A325 or A490 Bolts”. (Element 2)

5. Provide guidance so that when replacement bolting is required, bolting material, installation torque or tension, and use of lubricants and sealants will be in accordance

with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339. (Element 2)

6. Provide guidance for proper specification of new high strength bolting material and lubricant to prevent or mitigate degradation and failure of structural bolting in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339. (Element 2)

7. Expand the program to include details regarding inspection and evaluation for steel liners. (Element 3)

8. Provide inspection and evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. The program will be enhanced to explicitly mention the changes in material properties of increase in porosity and permeability, and loss of strength and pattern cracking with darkened edges. (Element 3)

9. Develop a new implementing procedure or revise an existing implementing procedure to address aging management of inaccessible areas exposed to potentially aggressive groundwater/soil environment that will include the following (Element 2, 3, and 4):

   a) Monitor raw water and ground water chemistry, for pH, chlorides, and sulfates, on a frequency not to exceed five years that accounts for seasonal variations (e.g., quarterly monitoring every fifth year), from locations that are representative of the groundwater in contact with structures within the scope of SLR.
   b) Enter adverse results, which exceed water chemistry criteria, into the corrective action program. As part of the corrective actions, if aggressive groundwater is identified that might affect structures in scope for SLR, perform additional water testing at additional locations and perform soil testing in order to confirm the extent, severity, and potential aging mechanisms resulting from the aggressive groundwater/soil.
   c) Develop engineering evaluations to evaluate the water chemistry results to assess the impact, if any, on below-grade concrete, including the potential for further degradation due to the aggressive groundwater, as well as consideration of current conditions. As part of the engineering evaluations, determine if additional actions are warranted, which might include enhanced inspection techniques and/or increased frequency, destructive testing, and focused inspections of representative accessible (leading indicator) or below grade, inaccessible concrete structural elements exposed to aggressive groundwater/soil.
   d) Develop the initial engineering evaluations prior to the SPEO. Develop follow-up engineering evaluations on an interval not to exceed five years.
   e) If aggressive groundwater and soil is identified, at a minimum, perform focused inspections of representative, accessible (leading indicator) structural elements, or if accessible areas will not be leading indicators for the potential aging mechanisms, excavate and inspect buried concrete elements exposed to aggressive groundwater/soil.
   f) If degraded concrete is identified, as part of the focused inspections of leading indicators (representative, accessible or exposed inaccessible concrete), enter adverse results that exceed ACI 349.3R second tier criteria into the corrective action

program, and expose inaccessible concrete so that the extent of the condition can be determined, baseline conditions documented, and additional actions identified such as repairs, new preventative actions, additional evaluations, and future inspections.

10. Monitor and trend through-wall groundwater leakage, infiltration volumes, and leakage water chemistry for signs of concrete or steel reinforcement degradation. Develop additional engineering evaluations, which consider more frequent inspections, as well as destructive testing of affected concrete to validate existing concrete properties, and leakage water chemistry results. If leakage volumes allow, consider water chemistry analysis of the leakage pH, along with mineral, chloride, sulfate and iron content in the water. (Element 2, 3, and 4)

11. Expand the program to monitor accessible sliding surfaces for indications of significant loss of material due to wear or corrosion, and for accumulation of debris or dirt. Establish acceptance criteria for sliding surfaces as no significant loss of material due to wear or corrosion, and no debris or dirt that could restrict or prevent sliding of the surfaces, as required by design. (Element 3 and 6)

12. Expand the program to monitor elastomeric vibration isolators and bearing pads, structural sealants, and seismic joint fillers for cracking, loss of material, and hardening. Supplement visual inspection of elastomeric elements with tactile inspection to detect hardening, if the intended function is suspect. Establish acceptance criteria, for elastomeric pads and vibration isolation elements, structural sealants, and seismic joint fillers, as no loss of material, cracking, or hardening that can lead to loss of isolation or support function. (Element 3, 4, and 6)

13. Require that personnel performing inspections and evaluations meet the qualifications specified within ACI 349.3R with respect to knowledge of inservice inspection of concrete and visual acuity requirements. (Element 4)

14. Perform inspections under the enhanced program in order to establish quantitative baseline inspection data to a sufficient detail to allow for trending, prior to the SPEO. (Element 4 and 5)

15. Revise inspection procedures to base inspection acceptance criteria on quantitative requirements derived from industry codes and standards, including but not limited to ACI 349.3R, ACI 318, SEI/ASCE 11, or the relevant AISC specifications and consider industry and plant OE. Use justified quantitative acceptance criteria whenever applicable. (Element 6)

16. Provide evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. Base the acceptance criteria for concrete surfaces on the second tier evaluation criteria provided in Chapter 5 of ACI 349.3R. (Element 6)

17. Clarify that loose bolts and nuts are not acceptable unless accepted by engineering evaluation. (Element 6)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Structures Monitoring* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2011, engineering reviewed NRC Information Notice 11-20, *Concrete Degradation by Alkali-Silica Reaction*, to determine if additional actions were required. The review identified the scope of inspections to be performed on concrete structures looking for evidence of patterned cracking indicative of alkali-silica reaction. There has been no visual evidence of patterned cracking indicative of alkali-silica reaction on the exterior of any concrete structures on sites that are exposed to water, except the Keowee spillway wing walls, which have shown evidence of small amounts of expansion in the past. Since 2005, frequent monitoring of the Keowee spillway wing walls has taken place to document and trend the inward expansion of these walls. It was ultimately concluded by testing of the Keowee spillway wing walls that alkali-silica reaction was the contributing cause of this expansion; however, wall movements were very small and posed no significant risk to the structural integrity of the walls. There was no visual evidence of alkali-silica reaction at the Keowee spillway wing walls. As a result of the experience at Keowee, site personnel at Oconee who perform structures monitoring inspections of concrete are familiar with alkali-silica reaction.

   OE example 1 provides objective evidence that industry OE is reviewed for applicable aging effects, and appropriate actions are included in AMPs. This example also illustrates how program inspections, effectively monitor in scope SSCs to assure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO.

2. In February 2018, it was identified that the Unit 2 and Unit 3 tendon gallery inspections were not completed in 2017. Even though portions of the tendon galleries are inspected as part of the *ASME Section XI, Subsection IWL* (B2.1.29) AMP, the entire tendon gallery was not inspected. The tendon gallery inspections were subsequently completed, the results recorded, and conditions determined to be acceptable. The model work order describing inspection activities to be performed was updated to add tasks to ensure that the tendon gallery inspections would be acceptably completed going forward.

   OE example 2 provides objective evidence that identified programmatic deficiencies involving inspection planning and implementation are entered into the corrective action program and appropriate corrective actions are taken to evaluate and correct deficiencies.

3. In March 2018, it was identified that structures inspections of the independent spent fuel storage facility were not completed on the specified frequency in 2017. In 2017, the external surfaces of the independent spent fuel storage facility were visually inspected. After further review of the independent spent fuel storage facility commitment information,

it was determined that the inspection that was completed in 2017 was not sufficient. An internal inspection of at least one horizontal storage module was due in 2016 but had not been completed. The internal inspection was subsequently completed, and the conditions were acceptable. Changes were developed to the implementing work order instructions to prevent recurrence. To address concerns involving the potential extent of missed commitments associated with structural inspections, other reviews were performed to ensure commitment compliance, including the inspections at the intake structure and of fiber-reinforced polymer exterior reinforcement of masonry walls, which is described in OE example 7 below.

Although independent spent fuel storage facility structures inspections are outside the scope of the Structures Monitoring AMP, OE example 3 provides objective evidence that identified programmatic deficiencies involving inspection planning and implementation are entered into the corrective action program and appropriate corrective actions are taken to evaluate and correct deficiencies.

4. Condition monitoring inspections of structures included in the scope of the LR Rule are required to be performed on a nominal five year interval. Results of ongoing civil structures inspections are documented and represent Oconee plant specific operating experience.

   The inspection results for the different inspections in the same structures and areas are collated into a calculation so that current inspection results can be compared to previous inspection results. The structures monitoring inspection results in these calculations were reviewed. Degradation of structures and structural elements was identified in different areas included under the structures monitoring inspections. The degradation is recorded, compared to previous results, reviewed and evaluated by qualified personnel, and significant degradation is entered into the corrective action program to initiate corrective actions such as repairs or replacements, more frequent inspections, more detailed evaluations, or design changes. The review of the inspection results and issues in the corrective action program determined that: 1) degradation was identified and documented; 2) structural repairs are performed under the corrective action program; 3) accessible areas are inspected nominally every five years; and 4) inaccessible areas are evaluated. Ongoing inspections and evaluations have not revealed results that would challenge an intended function. The performance of inspections and evaluation of issues in the corrective action program have resulted in the effective implementation of the AMP.

   Oconee civil structure inspection results demonstrate that inspections are being performed in accordance with industry guidelines and that those inspections are effective in identifying aging effects prior to loss of intended function. Pertinent examples of ONS civil structure inspection results are included in OE examples 5 through 7 below. These OE examples demonstrate that continued implementation of the *Structures Monitoring* AMP will assure that the structures and components within the scope of the program will continue to perform their intended functions during the SPEO.

5. The structures monitoring implementing procedures and currently documented inspection results were reviewed to assess compliance with the level of detail recommended in the SLR-GALL. Enhancements to the implementing procedures have been developed to

meet the level of detail in the SLR-GALL. It was found that the documented inspection results, especially in later years, frequently meet the SLR-GALL recommendations. The following are examples:

In 2017, an inspection of the standby shutdown facility diesel exhaust chimney and roof was performed. Concrete crack widths, lengths and orientation were recorded and compared to previous inspections. No significant changes to the concrete degradation were identified. All previously identified cracks are assessed as unchanged, inactive and stable and likely formed shortly after construction. Many additional cracks were observed in floors and walls but not recorded in this report because they do not pose a structural concern. Cracks observed during this exam greater than 0.015” were recorded for future monitoring. The cracks in the curb above the diesel exhaust chimney were significantly larger as compared to the size reported in the 2012 report. A large portion of the curb was repaired following the 2017 inspection in 2018. Because of the curb cracking, condition reports were initiated in the corrective action program and a more detailed inspection of the inside of the diesel exhaust chimney was performed using a borescope, camera, and flashlight. It was determined that the chimney is structurally sound and is capable of performing it’s intended function. The concrete damage was attributed to diesel exhaust coming off the deflector plate and hitting the concrete directly north of the deflector plate. The degraded concrete was identified for monitoring during subsequent inspections.

In 2020, the reactor building for Unit 3 was found to be structurally in very good condition. A condition report was written to document all findings. Items listed in the previous condition monitoring inspection report from spring of 2016 were reviewed and located during the 2020 inspection. Cracks that were previously noted as 0.010” wide or smaller were not monitored. Cracks 0.015” wide or larger are monitored with reference made to ACI 349.3R. Some findings are the following: 1) missing anchor bolts at a hanger support plate were evaluated and it was determined that the support plate had previously been found to be adequate; 2) cracks in a grout pad under a base plate were photographed and a work request was initiated for a repair; and 3) a concrete crack in a wall was measured with a crack comparator for width, the crack length documented, and the crack photographed to allow for trending.

OE example 5 provides objective evidence that the existing *Structures Monitoring* AMP effectively monitors and manages the condition of structures, more detailed inspections are performed when needed, and inspection records will allow for the recommended trending of inspection results in conjunction with implementation of enhancements. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to monitor and trend the conditions.

6. Plant OE was reviewed to identify instances of water infiltration into plant structures, and to assess any impact on the functions of in scope structures. Water infiltration into the plant is addressed through inspections and corrective actions, and monitoring is in place to ensure that the effects are insignificant. Several examples are provided below.

   Roofing is included within the scope of the inspections. Inspection results are recorded, and repairs initiated. As an example, the roof replacements on the turbine buildings were completed in 2019. Completion of this project ensured that the turbine buildings and equipment are protected.

In 2010 in the east penetration room of the Unit 2 auxiliary building and in 2013, in the Unit 3 spent fuel cooler room in the auxiliary building, plant walkdowns and inspections identified deficient penetration seals caused by mechanical damage, not aging. The potential consequences of the seal failures under design conditions were evaluated and it was determined that there would not have been a loss of intended function for potentially impacted equipment due to the small size of the defects with respect to the margin. The deficient seals were repaired. The inspections were expanded to include other seals. Preventative maintenance inspections were initiated.

In 2012, the standby shutdown facility inspection results for annual groundwater in-seepage inspection revealed concrete cracks in exterior walls. an engineering evaluation found that the cracks were deemed acceptable. Cracks in exterior, basement walls with groundwater seepage had previously been identified in 1997 and repairs initiated. In 2002, the inspection report documents that the groundwater seepage through hairline cracks in basement concrete walls had been satisfactorily corrected.

The Unit 2 auxiliary building, low pressure injection pump room had a larger amount of water than other locations. Numerous plans have been completed to try to stop the water in leakage. Sealant has been placed along the joint for the floor and the wall, an attempt was made to stop the water by seal injecting the cracks in the wall, and a water diversion was installed in the tendon gallery to allow the water to drain down into the tendon gallery instead of going into the low pressure injection pump room through an engineering change in 2011. The amount of water coming in now has significantly decreased since the engineering change was completed. Currently the water intrusion is now a housekeeping issue rather than a structural concern.

The structures monitoring inspection results in the various calculations were reviewed. Significant structural effects due to water leakage or water infiltration were not identified. Generally, the leakage was a housekeeping concern that could be addressed by generating corrective maintenance activities to minimize the housekeeping impacts when the leakage was significant. The *Structures Monitoring* program inspections identified and evaluated minor losses of material on steel components exposed to water leakage. No indications of significant concrete degradation due to groundwater infiltration have been identified.

In accordance with plant procedures the spent fuel pool leak detection valves are opened and inspected for visible leakage during weekly operator rounds. Significant spent fuel pool leakage was not identified through corrective action program condition report searches.

OE example 6 provides objective evidence that water infiltration into plant structures is addressed through inspections, the scope of inspections are expanded to identify the extent of the condition, potential consequences of degradation are evaluated, conditions are monitored and evaluated, and corrective actions are taken, including preventative maintenance as well as repairs and replacement, to identify the leakage source, reduce the potential for degradation due to exposure to water infiltration, and to ensure functional requirements are met.

7. The inspection of fiber-reinforced polymer external reinforcement of exterior masonry walls is within the scope of the *Structures Monitoring* AMP.

The fiber reinforced polymer is installed on the exterior masonry walls of each unit's auxiliary building. The fiber reinforced polymer is required to ensure the structural integrity of these masonry walls when subjected to design-basis tornado differential pressure loading. The fiber reinforced polymers are covered by siding installed as part of the natural phenomena barrier applied to safety related SSC structures so as to provide tornado/wind protection to the underlying structure. The installation of the fiber reinforced polymer was approved through a license change approved by the NRC in 2011. The inspections include a visual inspection of the mortar joints at the bottom of the walls and portions of the in-service walls for degradation. The adhesion (pull-off) testing of the fiber reinforced polymer is documented in accordance with implementing work instructions.

The inspections were completed every outage for the first six years after installation (2012-2017). Then, based on no observed fiber reinforced polymer degradation, the inspection frequency transitioned to every other outage for the next four years (2018-2021). Then, if justified, based on continued no observed fiber reinforced polymer degradation, the inspection frequency will transition to every third outage thereafter (2022-2034). At this time the inspections are being completed every other outage. This inspection frequency was approved by the NRC as part of the SER for the license change.

Visual inspections of test walls and portions (both random and controlled locations) include changes in color, debonding, peeling, blistering, cracking, crazing, deflections and other anomalies. No fiber reinforced polymer degradation has been observed. Inspection results are documented with photos at each inspection, used for comparison of new results with previous inspection results and post installation photos. Quantitative acceptance criteria using industry guidance is provided. Provisions included describing further inspections and tests to be considered if degradation is identified.

In 2018, because of recent OE concerning other inspection commitments (as previously mentioned), engineering decided to complete a thorough review of fiber reinforced polymer inspection commitments. While reviewing Unit 3 fiber reinforced polymer inspection results from the 29th refueling outage, engineering discovered a portion of the fiber reinforced polymer inspection was not completed as required. It was found that the required visual inspections of mortar joints located along the bottom edge of fiber reinforced polymer-strengthened masonry walls were not performed. The commitment to perform visual inspection of the mortar joints along the bottom edge of fiber reinforced polymer-strengthened masonry walls would identify any sliding of the walls when exposed to tornado-induced differential pressure (walls would slide outward). During original installation of the fiber reinforced polymer, model work instructions were generated to perform visual inspections of the walls where fiber reinforced polymer is applied and for the adhesion testing of the fiber reinforced polymer on test walls. A model work instruction was not generated for visual inspections of the mortar joints along the bottom edge of fiber reinforced polymer-strengthened walls. Because of the siding and girt system installed over the fiber reinforced polymer walls, many of the mortar joints are inaccessible from the exterior side of the walls. Interior inspections of the walls were completed per the structures monitoring inspection procedure in 2012 and 2017. Additionally, a walk down was performed by engineering in April 2018 to re-inspect the interior side of fiber reinforced polymer-strengthened walls, specifically focusing on the mortar joints around the perimeter of the walls. No significant degradation was observed. Any sliding of the wall due to pressure would be visible. Previous visual inspections, including the one performed in 2018, did not find any evidence to suggest any sliding has occurred. A model work instruction was created to ensure the interior side of the fiber reinforced polymer-strengthened walls are inspected, specifically the mortar joint along the bottom of the walls.

In 2018, as a result of the incomplete fiber reinforced polymer inspections, an extent of condition review of other structures/features was performed to ensure that the licensing committed inspection scope had been properly translated into model work instruction scope. Included in the scope of review were the following structures/features: 1) protected service water building and ductbank; 2) trench 3; 3) standby shutdown facility fuel oil storage tank; 4) external flood walls and east slope protection; 5) Keowee underground trench; 6) borated water storage tank superstructure; and 7) FLEX building. The extent of condition review was completed, and it was determined that the other commitments were adequately addressed in associated model work instructions.

OE example 7 provides objective evidence that inspection results are recorded using photographs so that quantitative comparisons can be made to previous test results that allows for trending, and quantitative acceptance criteria are used that are based upon industry standards for the component type, material, and environment combination. This OE also provides objective evidence that self-assessments are performed to verify compliance with commitments, plant OE is considered, the scope is expanded to identify the extent of deficient conditions, and corrective actions are taken if deficiencies are identified.

8. In September 2019, a self assessment of the Oconee civil structures inspection program was performed to verify that the existing aging management activities to identify and correct age-related degradation of structures and structural elements within the scope of the program, is being effectively implemented. The program self assessment was comprised of a review of previous self assessments, structures monitoring implementing procedures, inspections results, and programmatic issues addressed in the corrective action program for age-related degradation of structures and structural elements. The self assessment found that aging management activities were being performed in accordance with commitments, but identified several opportunities for improvement applicable to the civil structures inspection program documentation. As a result of the self assessment, license renewal documentation was evaluated for consistency and accuracy. In addition, implementing procedures and work orders were reviewed to verify license renewal programmatic standards are met.

OE example 8 provides objective evidence that aging management activities have been implemented in accordance with initial license renewal commitments and that self-assessments are used to identify and implement programmatic improvements.

Overall, the above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Structures Monitoring* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO. Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided when significant aging effects are found. Assessments of the *Structures Monitoring* AMP have been performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

<u>Conclusion</u>

The implementation of the *Structures Monitoring* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.34 INSPECTION OF WATER-CONTROL STRUCTURES ASSOCIATED WITH NUCLEAR POWER PLANTS

Program Description

The *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP is an existing inservice inspection and surveillance program for dams, slopes, canals, and other raw water-control structures associate with emergency cooling water systems or flood protection at Oconee. The program addresses age-related deterioration, degradation due to environmental conditions, and the effects of natural phenomena that may affect water-control structures. The program provides for periodic monitoring and maintenance of water-control structures so that the consequences of age-related deterioration and degradation can be prevented or mitigated in a timely manner, in order to prevent a loss of intended function.

Structural components and commodities monitored under this program include steel bolting, concrete anchors; concrete elements; concrete and steel elements of the condenser circulating water discharge pipe, penstock, power tunnels, spillway, and intakes; steel members; as well as steel piles, sluice gates, and trash racks; and equipment supports and foundations. Because of the plant design, there are no stand alone, external flood protection features that are in scope for SLR. The flood protection features are part of a structure, such as an exterior wall or earthen dam, which are in scope for SLR.

The program manages loss of material, loss of preload, cracking, loss of bond, loss of form, increase in porosity and permeability, and reduction of strength. Environments include outdoor air, groundwater/soil, and water flowing or standing.

RG 1.127 describes a basis acceptable to the NRC staff for developing an appropriate inservice inspection and surveillance program for dams, slopes, canals, and other water-control structures associated with emergency cooling water systems or flood protection of nuclear power plants. Instead of committing to RG 1.127, at Oconee, these types of structures are managed in accordance with the requirements of the FERC five year inspection requirements. The inspections of dams and dikes, within the scope of this program, include inspections of the Keowee river dam; Keowee spillway and left abutment, Keowee intake and powerhouse; little river dam; little river dikes A, B, C, and D; and the Oconee intake canal dike. These inspections are performed in accordance with the requirements contained in *Title 18 of the Code of Federal Regulations, Conservation of Power and Water Resources, Part 12, Safety of Water Power Projects and Project Works, Subpart D* (Inspection by Independent Consultant). The SLR-GALL has determined that for dam inspection and maintenance, programs under the regulatory jurisdiction of the FERC or the U.S. Army Corps of Engineers, continued through the SPEO, are adequate for the purpose of aging management.

The *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP addresses age-related deterioration, degradation due to extreme environmental conditions, and the effects of natural phenomena that may affect the intended functions of the water-control structures and components in the scope of this program. The monitoring methods are effective in detecting the applicable aging effects and the frequency of monitoring is adequate to prevent the loss of intended function due to significant age-related degradation. Elements of the program are designed to provide records of periodic inspections and evaluations of structural conditions to detect age-related deterioration and degradation and to initiate maintenance activities and corrective actions so that the consequences of age-related deterioration and degradation can be prevented or mitigated in a timely manner.

In general, parameters monitored are in accordance with FERC requirements for dams and dikes and those in Section C.2 of RG 1.127, *"Inspection of Water Control Structures Associated with Nuclear Power Plants",* for the remaining structures within the scope of this program. Oconee is not currently committed to the requirements in NRC RG 1.127, but RG 1.127 has been considered in the site procedure for inspections of structures in scope for SLR. The site aging management procedure refers to the guidance provided in NRC RG 1.127 and American Concrete Institute 349.3R-02. Structures exposed to aggressive water require additional plant-specific investigation.

Inspections of the Keowee river dam; little river dam; little river dikes a, b, c, and d; Oconee intake canal dike; Keowee spillway and left abutment, Keowee intake and powerhouse are performed in accordance with the requirements contained in 18 CFR Part 12, *Safety Of Water Power Projects And Project Works*. Specific corrective actions and confirmation are implemented in accordance with the corrective action program.

The inspections performed under the FERC five year inspection program have been approved by FERC and are the CLB for Oconee regarding aging management of the dams. Oconee will continue to comply with these FERC requirements during the SPEO.

The *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP is implemented through the *Structures Monitoring* (B2.1.33) AMP for the associated in scope structures.

NUREG-2191 Consistency

The *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP is an existing program that will be consistent with the recommendations provided in Section XI.S7, *Inspection of Water-Control Structures Associated with Nuclear Power Plants* program of NUREG-2191 (GALL-SLR) with enhancements described below.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented in the following program elements: Preventive Actions (Element 2), Parameters Monitored/Inspected (Element 3), Detection of Aging Effects (Element 4), Monitoring and Trending (Element 5), and Acceptance Criteria (Element 6).

1. For structural bolting consisting of ASTM A325, ASTMF1852, and/or ASTM A490, provide guidance for storage, lubricants, and the steps to minimize stress corrosion cracking potential discussed in Section 2 of Research Council for Structural Connections

publication, *“Specification for Structural Joints Using ASTM A325 or A490 Bolts”*. (Element 2)

2. Provide guidance so that when replacement bolting is required, bolting material, installation torque or tension, and use of lubricants and sealants will be in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339. (Element 2)

3. Provide guidance for proper specification of new high strength bolting material and lubricant to prevent or mitigate degradation and failure of structural bolting in accordance with the guidelines of EPRI NP-5769, EPRI TR-104213, and the additional recommendations of NUREG-1339. (Element 2)

4. Provide inspection and evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. The program will be enhanced to incorporate monitoring for movements (e.g., settlement, heaving, and deflection), conditions at junctions with abutments and embankments, pattern cracking with darkened edges, the changes in material properties of increase in porosity and permeability, and loss of strength. (Element 3)

5. Expand the program to monitor accessible sliding surfaces for indications of significant loss of material due to wear or corrosion, and for accumulation of debris or dirt. Establish acceptance criteria for sliding surfaces as no significant loss of material due to wear or corrosion, and no debris or dirt that could restrict or prevent sliding of the surfaces, as required by design. (Element 3)

6. Require that personnel performing inspections and evaluations meet the qualifications specified within ACI 349.3R with respect to knowledge of inservice inspection of concrete and visual acuity requirements. (Element 4)

7. Create provisions for special inspections immediately following the occurrence of significant natural phenomena, such as large floods, earthquakes, hurricanes, tornadoes, or intense local rainfalls. (Element 4)

8. Require the evaluation of raw water and groundwater chemistry that is sampled from a location that is representative of the water in contact with structures within the scope of SLR by the responsible engineer. This will be done on an interval not to exceed five years and account for seasonal variations (e.g., quarterly monitoring every fifth year). (Element 4)

9. Develop a new implementing procedure or revise an existing implementing procedure to enhance the aging management of inaccessible areas exposed to potentially aggressive groundwater/soil environment that will include the following (Element 4):

    a. Monitor raw water and ground water chemistry, for pH, chlorides, and sulfates, on a frequency not to exceed five years that accounts for seasonal variations (e.g., quarterly monitoring every fifth year), from locations that are representative of the groundwater in contact with structures within the scope of SLR.

b. Enter adverse results, which exceed water chemistry criteria, into the corrective action program. As part of the corrective actions, if aggressive groundwater is identified that might affect structures in scope for SLR, perform additional water testing at additional locations and perform soil testing in order to confirm the extent, severity, and potential aging mechanisms resulting from the aggressive groundwater/ soil.

c. Develop engineering evaluations to evaluate the water chemistry results to assess the impact, if any, on below-grade concrete, including the potential for further degradation due to the aggressive groundwater, as well as consideration of current conditions. As part of the engineering evaluations, determine if additional actions are warranted, which might include enhanced inspection techniques and/or increased frequency, destructive testing, and focused inspections of representative accessible (leading indicator) or below grade, inaccessible concrete structural elements exposed to aggressive groundwater/soil.

d. Develop the initial engineering evaluations prior to the SPEO. Develop follow-up engineering evaluations on an interval not to exceed five years.

e. If aggressive groundwater and soil is identified, at a minimum, perform focused inspections of representative, accessible (leading indicator) structural elements, or if accessible areas will not be leading indicators for the potential aging mechanisms, excavate and inspect buried concrete elements exposed to aggressive groundwater/ soil.

f. If degraded concrete is identified, as part of the focused inspections of leading indicators (representative, accessible or exposed inaccessible concrete), enter adverse results that exceed ACI 349.3R second tier criteria into the corrective action program, and expose inaccessible concrete so that the extent of the condition can be determined, baseline conditions documented, and additional actions identified such as repairs, new preventative actions, additional evaluations, and future inspections.

10. Monitor and trend through-wall groundwater leakage, infiltration volumes, and leakage water chemistry for signs of concrete or steel reinforcement degradation. Develop additional engineering evaluations, which consider more frequent inspections, as well as destructive testing of affected concrete to validate existing concrete properties, and leakage water chemistry results. If leakage volumes allow, consider water chemistry analysis of the leakage pH, along with mineral, chloride, sulfate and iron content in the water. (Element 4)

11. Perform inspections under the enhanced program in order to establish quantitative baseline inspection data to a sufficient detail to allow for trending, prior to the SPEO. (Element 5)

12. Provide evaluation criteria for structural concrete using quantitative second tier criteria of Chapter 5 in ACI 349.3R. Base the acceptance criteria for concrete surfaces on the “second-tier” evaluation criteria provided in Chapter 5 of ACI 349.3R. (Element 6)

13. Clarify that loose bolts and nuts are not acceptable unless accepted by engineering evaluation. (Element 6)

14. Degradation of piles and sheeting are accepted by engineering evaluation or subject to corrective actions. (Element 6)

15. Revise inspection procedures to base inspection acceptance criteria on quantitative requirements derived from industry codes and standards, including but not limited to ACI 349.3R, ACI 318, SEI/ASCE 11, or the relevant AISC specifications and consider industry and plant OE. Use justified quantitative acceptance criteria whenever applicable. (Element 6)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In September 2019, a self-assessment of the Oconee civil structures inspection program, including water controlled structures, was performed to verify that the existing aging management activities to identify and correct age-related degradation of structures and structural elements within the scope of the program, are being effectively implemented in the first period of extended operation. The program self assessment was comprised of a review of previous self assessments, structures monitoring implementing procedures, inspections results, and programmatic issues addressed in the corrective action program for age-related degradation of structures and structural elements. The self assessment identified several opportunities for improvement applicable to the water-control structures inspection program. As a result of the self assessment, license renewal documentation was evaluated for consistency and accuracy. In addition, implementing procedures and work orders were reviewed to verify license renewal programmatic standards are met.

   This operating experience example provides objective evidence that aging management activities have been implemented in accordance with initial LR commitments and that self-assessments are used to identify and implement programmatic improvements.

2. In March 2018, it was identified that structural inspections of the independent spent fuel storage facility were not completed on the specified frequency in 2017. In 2017, the external surfaces of the independent spent fuel storage facility were visually inspected. After further review of the independent spent fuel storage facility commitment information, it was determined that the inspection that was completed in 2017 was not sufficient. An internal inspection of at least one horizontal storage module was due in 2016 but had not been completed. The internal inspection was subsequently completed, and the conditions were acceptable. Changes were developed to the implementing work order instructions to prevent recurrence. To address concerns involving the potential extent of missed commitments associated with structural inspections, other reviews were performed to ensure commitment compliance, including the inspections at the intake structure and of the fiber-reinforced polymer exterior reinforcement of masonry walls.

The extent of condition review for the intake structure determined that the 2017 inspection of the Unit 1 intake structure was not complete as well. Divers completed the inspection of the skimmer wall, underwater weir, and other easily accessible areas. Other parts of the Unit 1 intake structure are more difficult to access because they cannot be accessed by boat. The remaining inspection activities were to be bundled with additional inspections on the Unit 2 intake structure, but the work order was closed without additional action. This was entered into the corrective action program. Engineering performed a review of the previous inspection results as well as the results of what was identified during the 2017 work. No significant degradation was noted that would cause the intake to not be able to perform its intended function. The remaining Unit 1 intake structure inspection was subsequently scheduled and completed in 2018.

Although independent spent fuel storage facility structures inspections are outside the scope of the *Structures Monitoring* AMP, this example provides objective evidence that identified programmatic deficiencies involving inspection planning and implementation are entered into the corrective action program and appropriate corrective actions are taken to evaluate and correct deficiencies.

3. Condition monitoring inspections of structures included in the scope of the License Renewal Rule are required to be performed on a nominal five year interval. Results of ongoing civil structures inspections are documented and represent Oconee plant specific operating experience.

   The inspection results for the different inspections in the same structures and areas are collated so that current inspection results can be compared to previous inspection results. It was confirmed that the site structures monitoring and FERC inspections were completed on at least a nominal 5 year frequency. Degradation of structures and structural elements was identified in different areas included under the structures monitoring and FERC inspections. The degradation is recorded, compared to previous results, reviewed and evaluated by qualified personnel, and significant degradation is entered into the corrective action program to initiate corrective actions such as repairs or replacements, more frequent inspections, more detailed evaluations, or design changes. Inspections of structural elements were performed using divers and by dewatering the structures. The review of the inspection results and issues in the corrective action program determined that: 1) degradation was identified and documented; 2) structural repairs are performed under the corrective action program; 3) accessible areas are inspected nominally every five years; and 4) inaccessible areas are evaluated. Ongoing inspections and evaluations have not revealed results that would challenge an intended function. The performance of inspections and evaluation of issues in the corrective action program have resulted in the effective implementation of the aging management program.

   Oconee water-control structure inspection results demonstrate that inspections are being performed in accordance with industry guidelines and that those inspections are effective in identifying aging effects prior to loss of intended function. Pertinent examples of ONS civil structure inspection results are included in OE examples 4 through 6 below. These OE examples demonstrate that continued implementation of the *Inspection of Water-Control Structures Associated With Nuclear Power Plants AMP* will assure that the structures and components within the scope of the program will continue to perform their intended functions during the SPEO.

4. In 1998, a spall was identified during the diver inspection in the Unit 2 condenser circulating water intake structure pump pit. A temporary steel plate was installed during the inspection until permanent repairs could be performed. In 2001, the concrete was repaired with an underwater grout repair. The structural calculation was updated to reflect the repair and it was determined that repair did not result in a loss of capacity. Subsequent inspections cover this same area provide for continuing inspection to allow for identification of any future degradation of the repair or of the structural elements in the same areas. Degradation of the grout repair was not identified.

   OE example 4 provides objective evidence that below water inspections are performed using divers, degraded areas are identified, the degraded conditions are evaluated, corrective actions selected, corrective actions are taken to correct degraded conditions, and follow-up inspections are performed to continue monitoring the structure after a repair.

5. The sheet piles at the exterior of the condenser circulating water intake structure are within the scope of the inspections performed under this AMP. The sheet piles were previously coated with coal tar epoxy. The coating on the sheet piles on the north side of the road is mostly intact with minimal corrosion. Very little coating remains on the sheet piles on the south side of the access road. Visual inspections first documented localized corrosion of the sheet piles in 1997 and recorded the approximate percentage of the degraded surface. In 2006, ultrasonic test measurements were taken of the 0.375” thick material and smallest thickness found was 0.370”. The loss of 0.005” of the material thickness was assessed and it was determined to be not a concern. In 2016, additional ultrasonic test measurements were taken on the south sheet piles. The thicknesses were variable due to the localized nature of the corrosion with the smallest value being 0.348”. A nominal rate of loss was determined based upon the smallest localized thickness that was identified. The nominal rate of loss was used to estimate the minimum expected reading at the time of the next inspection, performed five years later in 2021. The minimum expected remaining thickness of the sheet pile was determined to be acceptable.

   OE example 5 provides objective evidence that the existing AMP effectively monitors and manages the condition of structures, more detailed inspections are performed when needed, and inspection records allow for the recommended trending of inspection results, and that conclusions are made regarding the ability of the structure to perform its intended function considering on-going degradation.

6. Alkali-silica reaction issues at Keowee dam have been identified and their impacts evaluated, with corrective actions taken to ensure to the safe and reliable operation of the spillway gates. The alkali-silica reaction investigations have characterized the alkali-silica reaction induced change in volume of the concrete, evaluating their impacts on operation of the spillway gates, and planning and implementing monitoring and mitigation measures.

There is documented movement of the spillway abutment walls and piers attributed to alkali-silica reaction. Monitoring points, bridge monuments and tell-tale gages are used to monitor movement. These points indicate continued vertical and horizontal movement. The piers and walls have some pattern cracking and efflorescence; however, the concrete looks to be structurally sound and serviceable.

Tainter gate guide rollers were removed in 1987 due to gates binding during operation. A gate experienced binding problems during full opening tests in 1993 and 1997. As a result of this binding, Duke initiated a survey of the spillway. The results of this survey confirmed that at several elevations, the gate was slightly wider than the bay width, which was attributed to alkali-silica reaction induced expansion of the concrete. In 2000, the embedded gate guides of the same gate were machined to remove areas that were causing the binding.

During the 2001 gate operating tests, contact between the gate and the embedded guide plates caused gate binding. Similar binding problems had been experienced with another gate, which is located at the right end of the spillway structure. Further investigation of the binding problem determined that the two end walls have moved inward. A survey monitoring program was established in 2002, to evaluate the rate of movement. The spillway abutment walls and piers had been included in the deformation surveying program since 1991.

In 2003, gate binding problems were again experienced. Inspection of the hoist shaft indicated movement of the right wall, which required the shaft to be removed and shortened. The binding of this gate was resolved in 2004 by removing and reinstalling the guide plates, increasing the clearance by recessing the guide plates into the pier and end wall, and replacing the gate seals.

Issues associated with gate operations were discussed during the seventh FERC Part 12D safety inspection and the potential failure modes analysis performed in 2006. A threshold of 0.75” of additional spillway end wall movement was established as part of the potential failure modes analysis. If exceeded, the threshold would trigger the need for further assessment and possible remediation. Ten monuments (five on each abutment wall) were added to the spillway monitoring network to enhance the existing system. These monuments were added as a result of the alkali-silica reaction investigations and recommendations from the Part 12 and potential failure modes analysis reports completed in 2006.

In 2008, the movement threshold on the spillway abutment walls was exceeded. A four-phase plan was established to further investigate and evaluate the abutment wall movements. The phases of the plan are:

- Phase I – Scope
- Phase II – Testing and Evaluation
- Phase III – Design of Remedial Actions
- Phase IV – Implementation

Phase I provided the scoping for performing 17 investigative tasks.

Phase II was the execution included drilling, sampling, borehole imaging, compression testing, petrographic testing, in-situ stress testing by overcoring, biaxial modulus testing, and stress calculation. This phase provided an understanding of the movements of the end walls, concluding that the alkali-silica reaction expansion of the mass concrete was the cause. The investigations found that no significant deterioration of the spillway concrete had occurred. The principal concern is the long-term reliability of the gates. Results of the testing indicated that the alkali-silica reaction could continue for the foreseeable future.

Phase III of the plan encompasses the design of remedial actions. The most viable solution was determined to be providing additional operating/travel clearance. There are no reliable methods to stop or retard the alkali-silica reaction process, so accommodating the movements is the most practical solution. Phase II provided information on anticipated rates of movement, so planning for future mitigation measures is feasible. The earlier side seal modifications involved resetting the seal plates deeper into the piers and end walls. Because of the heavy reinforcing steel, it is not feasible to further recess these plates. As a result, modifications to the gates themselves is the likely remediation for continued wall movement. For now, monitoring data and visual inspections are being used to guide the implementation schedule for phases III and IV.

The spillway has factors of safety that exceed the FERC criteria and has demonstrated its stable behavior for many years. The only factor that might change with time is the effects of alkali-silica reaction concrete growth; however, the impacts of alkali-silica reaction are more of an operational concern related to the radial gates, not a stability concern. No structural deterioration of the spillway concrete, such as loss of strength or significant cracking, has been noted during the alkali-silica reaction investigations.

OE example 6 provides objective evidence that the existing AMP effectively monitors and manages the condition of structures, degradation is identified and evaluated, degradation mechanisms are determined, more detailed inspections and monitoring are performed when needed, material testing is used to determine the impact of aging effects on materials, inspection records allow for the recommended trending of inspection results, numerical acceptance criteria are developed, and that conclusions are made regarding the ability of the structure to perform its intended function considering on-going degradation.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, re-evaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Inspection of Water-Control Structures Associated with Nuclear Power Plants* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Inspection of Water-Control Structures Associated With Nuclear Power Plants* AMP as a subset of the *Structures Monitoring* (B2.1.33) AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.35 PROTECTIVE COATING MONITORING & MAINTENANCE

Program Description

The *Protective Coating Monitoring and Maintenance* AMP is an existing mitigative and condition monitoring program which manages loss of coating integrity of service level I coatings inside the primary containment (as defined in NRC RG 1.54) in air-indoor uncontrolled and treated water environments. The failure of the service level I coatings could adversely affect the operation of the emergency core cooling systems by clogging the emergency core cooling systems suction strainers. Proper maintenance of the service level I coatings ensures that coating degradation will not impact the operability of the emergency core cooling systems. The *Protective Coating Monitoring and Maintenance* program includes coating system selection, application, inspection, assessment, maintenance, and repair for any condition that adversely affects the ability of service level I coatings to function as intended. Evaluations are performed for test or inspection results that do not satisfy established criteria and the conditions are entered into the corrective action program.

Service level I coatings prevent or minimize the loss of material due to corrosion, but these coatings are not credited for managing the effects of corrosion for the carbon steel containment shells and components. This program ensures only that the service level I coatings maintain adhesion so as to not affect the intended function of the emergency core cooling systems suction strainers.

The program also provides controls over the amount of unqualified coatings. Unqualified coating may fail in a way to affect the intended function of the emergency core cooling systems suction strainers. Therefore, the quantity of unqualified coating is controlled to ensure that the amount of unqualified coating in the primary containment is kept within acceptable design limits.

NUREG-2191 Consistency

The *Protective Coating Monitoring and Maintenance* program is an existing program that will be consistent with NUREG-2191, Section XI.S8, *Protective Coating Monitoring and Maintenance*, as modified by SLR-ISG-Structures-2021-03-STRUCTURES, *“Updated Aging Management Criteria for Structures Portions of the Subsequent License Renewal Guidance”* with the enhancement described below.

Exception to NUREG-2191

None

Enhancements

The following enhancement will be implemented in the following program elements: Parameters Monitored or Inspected (Element 3), Detection of Aging Effects (Element 4), Monitoring and Trending (Element 5), and Acceptance Criteria (Element 6).

1. Procedures will be enhanced to explicitly state peeling and physical damage are considered in the condition assessment. (Element 3)

2. Procedures will be enhanced to reference ASTM D5163-08. (Element 3, 4, 5 and 6)

<u>Operating Experience</u>

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Protective Coating Monitoring and Maintenance* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In August 2018 the Oconee nuclear coatings program was audited and several documentation issues were identified related to the program that warranted corrective actions to ensure compliance with procedure requirements.

   The audit identified that a coating deviation request form related to a component installed in the Oconee Unit 2 containment was not in permanent records as required. The hard copy of the coating deviation request form was located and was submitted to the station QA document repository for retention. Additionally, an extent of condition was performed to ensure all coating deviation records were being stored in accordance with requirements. All required records were accounted for.

   Additionally, the audit identified the Oconee Unit 1 primary containment coatings conditions assessment form had been completed and the hard copy of the document was available, but was not correctly filed with the initiating work order package documentation for retention.

   The calculation tracking containment debris inventory was identified as not being updated after each refueling outage based on the containment coatings condition assessments performed, which identify degraded qualified coatings, the quantity of non-qualified coatings in containment, and coating repairs and replacement. Significant margins for quantity of degraded and non-qualified coatings in all containments were maintained and tracked, however, the tracking calculation was not updated after each refueling outage as required. A cause evaluation identified misinterpretation of documentation requirements by the responsible engineer and organizational changes that shifted responsibility for some documentation aspects of the inspections from a fleet organization to the site as contributing causes. The calculation was updated to incorporate the missing information and documentation requirements discussed with responsible individuals to ensure understanding.

   OE example 1 provides objective evidence that age-related inspection findings are entered into the corrective action program and appropriate corrective actions are taken to evaluate and correct deficiencies. The audit corrective actions ensured the program documentation was brought up to date, and procedures and model work order instructions were updated to eliminate confusion related to documentation requirements.

The program corrective actions have been effective and demonstrated in subsequent outages. The inspections have been carried out in accordance with station procedures and the documentation has been submitted for retention.

2. Recent reactor building coating assessments performed on Oconee Units 1, 2, and 3 demonstrate the effectiveness of the *Protective Coating Monitoring and Maintenance* program.

   The scheduled Oconee Unit 1 reactor building coatings assessment was performed during the October 2018 outage in accordance with the primary containment coatings condition assessment procedure. The assessment identified 76 square feet of new degraded coating and documented 91 square feet of coating that was remediated. The total amount of degraded coated remaining in the Oconee Unit 1 containment was 1410 square feet, with significant margin to the calculated limit for the performance of emergency core cooling sump. The coating assessment documentation was submitted for retention with the work order document package and work requests were initiated in the work management system to plan the remediation of the newly identified degraded coatings.

   The scheduled Oconee 2 reactor building coating assessment was performed during the October 2019 outage in accordance with the primary containment coatings condition assessment procedure. The assessment identified 152 square feet of new degraded coating and documented 54 square feet of coating that was remediated. The total amount of degraded coated remaining in the Oconee 2 containment was 3654 square feet, with significant margin to the calculated limit for the performance of emergency core cooling sump. The coating assessment documentation was submitted for retention with the work order document package and work requests were initiated in the work management system to plan the remediation of the newly identified degraded coatings.

   The scheduled Oconee 3 reactor building coating assessment was performed during the April 2020 outage in accordance with the primary containment coatings condition assessment procedure. The assessment identified 20 square feet of new degraded coating and documented 28 square feet of coating that was remediated. The total amount of degraded coated remaining in the Oconee 3 containment was 3135 square feet, with significant margin to the calculated limit for the performance of emergency core cooling sump. The coating assessment documentation was submitted for retention with the work order document package and work requests were initiated in the work management system to plan the remediation of newly identified degraded coatings.

   OE example 2 demonstrates that inspections of service level I coatings inside the primary containment are being performed in accordance with requirements and that those inspections are effective in managing loss of coating integrity. The actions from the audit performed in 2018 were implemented and have incorporated into the program demonstrating the effectiveness of the Oconee corrective action program to effect change on AMPs.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Protective Coating Monitoring and Maintenance* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Protective Coating Monitoring and Maintenance* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

<u>Conclusion</u>

The implementation of the *Protective Coating Monitoring and Maintenance* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.36 ELECTRICAL INSULATION FOR ELECTRICAL CABLES AND CONNECTIONS NOT SUBJECT TO 10 CFR 50.49 ENVIRONMENTAL QUALIFICATION REQUIREMENTS

Program Description

The *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is an existing condition monitoring program that will continue to manage the aging effect of reduced insulation resistance of accessible electrical cable and connection insulation in adverse localized environments. This AMP is the portion of the existing Oconee UFSAR 18.3.14 *Insulated Cables And Connections* AMP for initial LR that includes accessible insulated cables and connections within the LR scope that are installed in adverse localized environments within in-scope structures and which could be subject to the environments' applicable aging effects from heat, radiation, and moisture. An adverse localized environment is defined as a condition in a limited plant area that is significantly more severe than the specified service condition for the cable or connection. This program does not include insulated cables and connections that are in the *Environmental Qualification* (B3.3) program.

At least once every ten years, accessible insulated cables and connections installed in adverse localized environments are visually inspected for jacket surface anomalies such as embrittlement, discoloration, cracking, melting, swelling, or surface contamination. Surface anomalies are indications that can be visually monitored to preclude the conductor insulation applicable aging effect. The inspections acceptance criteria is no unacceptable, visual indications of jacket surface anomalies which suggest that a conductor insulation applicable aging effect may exist that could lead to a loss of the LR intended function, as determined by engineering evaluation. As part of the periodic inspections, previously identified and mitigated adverse localized environments' cumulative aging effects applicable to in-scope cable and connection insulation will be reviewed to confirm that the insulation's intended functions continue to be supported during the SPEO.

If testing is evaluated to be necessary after visual inspections identify degraded or damaged conditions (e.g. unacceptable surface anomalies) that may adversely affect the performance of cable or connection insulation intended functions, then proven tests applicable to condition monitoring of the insulation are performed (e.g., thermography may be included). For a large number of cables identified as degraded, a sample population will be tested. Testing as part of an existing maintenance, calibration, or surveillance program may be credited. Test results are to be within the acceptance criteria, as identified in Oconee procedures.

Further investigation will be performed on cables and connections per the corrective action program when the acceptance criteria is not met. Corrective actions may include, but are not limited to, testing, shielding or otherwise changing the environment, relocating or replacement. When an unacceptable condition is identified, a determination will be made as to whether this same condition could be applicable to other cables and connections.

NUREG-2191 Consistency

The *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is an existing program that will be consistent with the ten elements of AMP XI.E1, "*Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements*" specified in NUREG-2191 (GALL-SLR) with enhancements described below.

Exception to NUREG-2191

None

Enhancements

The following enhancements shall be implemented in the respective program elements: Parameters Monitored or Inspected (Element 3), and Detection of Aging Effects (Element 4), and Acceptance Criteria (Element 6)

1. As part of the periodic inspections, add review of previously identified and mitigated adverse localized environments' cumulative aging effects applicable to in-scope cable and connection insulation to confirm that the insulation's intended functions continue to be supported during the SPEO. (Elements 3 and 4)

2. Add a description of potential testing and its sampling: If testing is evaluated to be necessary after visual inspections identify degraded or damaged conditions (e.g. unacceptable surface anomalies) that may adversely affect the performance of cable or connection insulation intended functions, then proven tests applicable to condition monitoring of the insulation are performed (e.g., thermography may be included). For a large number of cables identified as degraded, a sample population will be tested. The sample size will be 20% of each affected cable and connection type with a maximum sample size of 25. Among the factors to consider for developing the test sample population are cable or connection type, environment, voltage level, circuit loading, and insulation material which is the most important factor per EPRI guidance. Testing as part of an existing maintenance, calibration, or surveillance program may be credited. The basis for the sample selection shall be documented. (Element 4)

3. Add acceptance criteria for potential testing of accessible cables and connections with unacceptable visual inspection results to the Oconee AMP description: Test results are to be within the acceptance criteria, as identified in the Oconee procedures. (Element 6)

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the Oconee *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In September 2019, a self-assessment was performed for the existing *Insulated Cables and Connections* AMP (UFSAR 18.3.14), as part of a *"License Renewal Aging Management Programs"* self-assessment. The existing AMP includes elements of the *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* program and the *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* program. No areas for improvement findings were identified for the *Insulated Cables and Connections* AMP. One relatively less significant opportunity for improvement on AMP documentation that was generic to all the assessed AMPs was applicable to the *Insulated Cables and Connections* AMP in that model work orders were found to include outdated standards and engineering owner names. The opportunity for improvement was entered into and addressed in the corrective action program.

   OE example 1 provides objective evidence that the program critically assesses program performance to ensure all current LR commitments are being satisfied, and that the program self-identifies actions to support continuous improvement.

2. From September 2009 to April 2012, initial baseline visual inspections of accessible cables and connections were performed as required by the initial renewed operating license. Included in the inspections scope was the identification of surface anomalies in cable jackets and connector coverings that are accessible, i.e. can be viewed from floor level without ladders or scaffolding and without opening enclosures. The areas inspected were based on a 100% walk-down of Oconee Units 1, 2, and 3 plant areas and structures, e.g. in reactor buildings, auxiliary buildings, turbine buildings, standby shutdown facility, Keowee hydroelectric station, among other areas. Such total-of-area approach is conservative versus acceptable limitation of inspections to predetermined bounding adverse localized areas. Although more housekeeping and configuration issues were discovered, the following two conditions were identified, prior to a loss of circuit function, as being linked to aging-related degradation within the scope of the existing *Insulated Cables and Connections* AMP:

   a) A jacketed (liquid-tight) flexible conduit to a heater drain limit switch was found touching a non-insulated portion of steam pipe. The heat-degraded flex conduit was replaced and rerouted away from the pipe heat source to prevent future heat degradation. The internal wiring insulation was not identified as being similarly degraded.
   b) Heat shrink tubing and rubber insulation covering the interface between some pressurizer heater cables and connectors was found to be cracking at the (adverse localized environment) location closest to the pressurizer heater. In some cases, the tubing was no longer shrunk securely around the cable. The degradation did not immediately threaten functionality, as the cables and connections themselves did not show evidence of heat deterioration. The tubing was replaced, precluding a potential loss of intended function.

   OE example 2 demonstrates the effective use of the existing AMPs periodic visual inspections of accessible cables and connections exposed to adverse localized environments caused by heat, radiation, or moisture to identify insulation aging-related degradation prior to loss of intended function.

3. From May 2018 to November 2019, portions of the ten year walkdown visual inspections were performed in the Units 1, 2, and 3 reactor buildings and in the standby shutdown facility. Although more housekeeping and configuration issues were discovered (e.g. trash in tray, interlocked armor separated or pulled loose from a cable armor terminator outside an enclosure), there were no instances of identified cable or connection jacket or insulation aging-related degradation. At a Unit 1 electrical penetration, a group of small diameter non-SLR-scope instrumentation cables were found with corrosion (rust) on the exterior braided metallic armor; but no polymer jacket or insulation degradation was identified. One Unit 2 non-safety related cable's jacket was found with a few small apparently partial melt spots that did not expose the underlying steel armor, that did not require repair or challenge functionality, and that indicated discrete, minor installation or maintenance damage versus aging from an adverse localized environment.

   OE example 3 demonstrates the ongoing effective use of the existing AMP's periodic visual inspections of accessible cables and connections exposed to adverse localized environments caused by heat, radiation, or moisture to identify insulation aging related degradation prior to loss of intended function.

4. In June 2012, a focused self-assessment was performed for Oconee LR phase 2 readiness. The assessment team reviewed the existing *Insulated Cables And Connections* AMP, which includes elements of the *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP and the *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP. Accessible cable and connections walkdown inspections in the reactor buildings, auxiliary buildings, turbine buildings, standby shutdown facility, Keowee hydroelectric station, and other areas had all been performed and well documented in sufficient detail (e.g. typed notes, action requests, work requests, and work orders). Engineering calculations to further formalize the results, commitments, and other documentation were still being quality-verified at the time of assessment but were completed shortly thereafter.

   OE example 4 demonstrates the use of self-assessments to evaluate existing AMP related inspections and documentation for identifying and resolving cable jacket and insulation aging-related degradation that could lead to a loss of intended function.

5. In November 2012, neoprene jackets on two safety related low-voltage cables were found deteriorated to the point of some jacket material broken away from the underlying armor due to exposure to a suspected nearby heat source. Such loss of outermost jacket material does not and did not prevent the cables from being able to perform their intended functions. However, the jacket aging can indicate the potential aging of the internal conductors' ethylene-propylene rubber insulation which has superior temperature aging resistance and is also not nearly as exposed to adverse localized environments versus the neoprene jacket. Therefore, electrical insulation resistance tests (at over 4 times nominal operating voltage) were performed on both cables, leading to only a jacket repair covering on one cable and a spliced-in new cable section (without the obsolete neoprene material) on the other.

OE example 5 demonstrates good maintenance behavior and awareness during non-AMP activities to identify aging-related cable jacket deterioration that could lead to electrical insulation aging related degradation. OE example 5 also provides objective evidence that existing Oconee maintenance practices and the corrective action program are effective to identify and resolve aging-related degradation prior to a loss of intended function.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

<u>Conclusion</u>

The implementation of the *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.37 ELECTRICAL INSULATION FOR ELECTRICAL CABLES AND CONNECTIONS NOT SUBJECT TO 10 CFR 50.49 ENVIRONMENTAL QUALIFICATION REQUIREMENTS USED IN INSTRUMENTATION CIRCUITS

Program Description

The *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements Used in Instrumentation Circuits* AMP is a new performance monitoring program that will manage the effects of reduced insulation resistance of non-EQ cable and connection insulation in instrumentation circuits with sensitive, high voltage, low level current signals and that are subjected to adverse localized environments caused by temperature, radiation, or moisture. The AMP will apply to the in scope non-EQ portions of circuits in the area radiation monitoring system (e.g. high range containment area radiation monitors) and the neutron flux monitoring nuclear instrumentation system.

Exposure of electrical cables to adverse localized environments can result in reduced insulation resistance, which increases leakage current between insulated conductors or from insulated conductors to ground. Reduced insulation resistance is a concern for circuits with sensitive, high voltage, low level current signals because reduced insulation resistance may contribute to signal inaccuracies.

Reduced insulation resistance caused by severe degradation in the cable insulation can be detected by periodically reviewing past calibration or surveillance results before losing the cable or connection intended function. Regular calibration or surveillance testing is already performed for in scope instrumentation circuits. When the non-EQ cables and connections are included as part of the calibration or surveillance circuit, this AMP will periodically review and evaluate the past calibration or surveillance results (since the last review) to identify the existence of cable and connection insulation aging related degradation. The reviews will be completed before the SPEO and at least once every ten years, thereafter.

As an alternative to reviewing calibration or surveillance results, or when the non-EQ cables and connections (cable systems) are not included as part of the calibration or surveillance, a proven cable system test will be performed for the in-scope circuits. Such test will be judged effective in detecting deterioration in the cable system insulation. If credited for this AMP’s implementation, the cable system tests will be performed before the SPEO and thereafter at a frequency based on engineering evaluation but at least once every ten years.

NUREG-2191 Consistency

The Oconee *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements Used in Instrumentation Circuits* AMP is a new program that, when implemented, will be consistent with NUREG-2191, Section XI.E2, Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements Used in Instrumentation Circuits.

Exception to NUREG-2191

None

Enhancements

None

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements Used in Instrumentation Circuits* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO.

1. In September 2013, an action request was initiated in the corrective action program identifying the unavailability of a Keithley Electrometer required to perform power range neutron detector leakage resistance and voltage response testing. ONS decided not to directly replace the obsolete Keithley Electrometer, but instead use a contracted service for an industry best practice of CHAR testing; a combination of time domain reflectometry and current/voltage curve results testing, which detects circuit capacitance and series and shunt impedances, including insulation resistance.

   OE example 1 demonstrates Oconee use of OE from the corrective action and preventive maintenance programs and industry involvement to apply new or improved test techniques applicable to this AMP that are effective in detecting age related degradation of sensitive, high voltage, low level current signal instrumentation cable and connection insulation.

2. In November 2013, an action request was initiated in the corrective action program identifying an issue in the Unit 3 nuclear instrumentation power range (3NI-5) channel measurements. Power range indications were swinging between 99.6% and 96.6% reactor power per neutron flux detection. CHAR tests (time domain reflectometry and current/voltage curve) were performed on all three triaxial cables for this detector (two signal cables and one high voltage power supply cable). The tests found a high impedance location (unspecified whether series or shunt such as insulation resistance) at either the triaxial connector of the ‘top’ signal cable or the E4 penetration feed-through on the inside containment end. A subsequent CHAR test on the isolated signal cable verified that the 3NI-5 measurements stabilized after a replacement triaxial connector was installed and the connection location was moved within the penetration enclosure.

   OE example 2 demonstrates the effectiveness of the corrective action program and this AMP’s test techniques for detecting degradation in sensitive, high voltage, low level current signal instrumentation cables and connections.

3. In December 2013, an action request was initiated in the corrective action program identifying an issue in the Unit 2 nuclear instrumentation (2NI-6) channel measurements. The 2NI-6 channel measurements were found not tracking with the other three reactor power range channels. Losing operation of one channel does not lose the nuclear instrumentation function. CHAR testing (time domain reflectometry and current/voltage curve) identified and located an open connection between the power supply triaxial cable and the detector connector underneath the canal seal plate. In the subsequent refueling outage, the cause was determined to be a poor solder contact on the center conductor in the connector at the detector end of the power supply triaxial field cable in the reactor building. Along with the replacement connector installation, CHAR testing of all three 2NI-6 cables in that outage verified no extent of condition in the two signal triaxial cables. Other similar channel circuits had been operating reliably for much longer periods than 2NI-6.

   Although not finding age-related degradation of insulation, OE example 3 demonstrates the effectiveness of the corrective action program and this AMP's techniques for detecting high voltage, low level current instrumentation cable and connection degradation that could lead to a loss of intended function.

4. In July 2014, an action request was initiated in the corrective action program identifying an issue in the Unit 3 nuclear instrumentation (3NI-7) channel measurements. The 3NI-7 channel measurements were found to be 'drifting' from the other three power range channels. Although the drift was in the conservative direction and was still within surveillance requirements, calibration was requested. Historical data through approximately three fuel cycles (six years) was reviewed to find that 3NI-7 had shown a pattern of faster drift compared to the other three channels. The relative drift was more prominent in the beginning of the fuel cycles; and the 3NI-7 readings became more precise with the other channels as the cycle continued. The data review found that the drift had been questioned and investigated previously in other action requests, in one case with operability confirmed by the drift again being in the conservative direction (higher than actual value) and by calibration being successfully completed within procedure tolerance with no other issues besides increased calibration frequency. The history also indicated that the 3NI-7 conservative drift occurred both before and after associated reactor protection system cabinet electronics were replaced. It was ultimately concluded that the drift was due to this particular channel's neutron detector response characteristics.

   OE example 4 demonstrates the effectiveness of the corrective action program and the use of historical calibration or other measurements data review to determine the condition of sensitive, high voltage, low level current signal instrumentation circuits. Such historical calibration or surveillance review will be similarly applied in this AMP (when the cable is included) to detect cable and connection insulation age related degradation that may lead to the loss of intended function.

5. In March 2019, an action request was initiated in the corrective action program documenting a Unit 3 Control Room operator aid computer alarm received for the high range containment area radiation monitor (3RIA-57). Recent and historical review of operator aid computer data showed that this detector had periodically spiked and returned to normal. The

response of 3RIA-57 was indicative of an invalid reading during source check because the indication quickly rose (spiked) and then decayed away. Further, investigation, testing and troubleshooting determined that the problem was caused by faulty connection assemblies, which were repaired to correct the issue.

Although not directly attributed to the cable or connection insulation aging (especially since the cables are not routed in the reactor building beyond the penetrations), OE example 5 demonstrates that the existing corrective action program and maintenance testing and inspections applicable to this AMP effectively identify and resolve degradation of sensitive, high voltage, low level current signal instrumentation cable that could lead to a loss of intended function.

The above OE examples provide objective evidence that the aging management activities and methods to be implemented by the *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements Used in Instrumentation Circuits* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements Used in Instrumentation Circuits* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the ONS *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements Used in Instrumentation Circuits* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.38 ELECTRICAL INSULATION FOR INACCESSIBLE MEDIUM-VOLTAGE POWER CABLES NOT SUBJECT TO 10 CFR 50.49 ENVIRONMENTAL QUALIFICATION REQUIREMENTS

Program Description

The *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is an existing condition monitoring program that will continue to manage the aging effect of reduced electrical insulation resistance due to exposure to significant moisture. The program is comprised of the inaccessible medium-voltage cable portion of the existing condition monitoring program, *Insulated Cables And Connections* program.

This AMP applies to the electrical insulation for inaccessible (e.g., underground in buried conduit, embedded ducts or conduits (e.g. duct banks), trenches, vaults, manholes, or direct buried) non-EQ medium-voltage power cables (operating voltage of 2kV to 35kV) within the scope of SLR that are potentially exposed to significant moisture. For this program, significant moisture is defined as exposure to moisture that lasts more than three days (i.e., long-term wetting or submergence over a continuous period) that if left unmanaged, could potentially lead to a loss of intended function.

Periodic actions are taken to prevent in-scope inaccessible medium-voltage power cables from being exposed to significant moisture. Water collection in accessible trenches (e.g. low points) and conduit manholes containing in-scope medium-voltage cables and conduit ends is monitored via documented inspections, and the water removed as needed. The inspection frequencies have been established based on Oconee OE over time and do not exceed a one year interval. Inspections and dewatering will also be performed after event-driven occurrences such as heavy rain, rapid thawing of heavy ice and snow, or flooding. The inspections are performed to confirm that in-scope medium-voltage power cables are not submerged, cable/splices and cable support structures are intact, and de-watering systems (e.g., sump pumps and drains) and associated alarms operate properly.

The issued NRC SLR-ISG-2021-04-ELECTRICAL revises NUREG-2191 XI.E3A to allow for less frequent (five year) periodic manhole inspection. This relaxation is not applicable unless or until the SLR-ISG described self-monitored manhole water level indication and alarms are installed and implemented at Oconee.

In-scope non-EQ inaccessible medium-voltage cables found to be exposed to significant moisture are tested to detect reduced electrical insulation resistance, an indicator of insulation age-related degradation. The cable testing includes one or more proven methods, such as dissipation factor (‘tangent-delta’) or similar power factor, AC voltage withstand, partial discharge, step voltage, time-domain reflectometry, frequency-domain reflectometry, insulation resistance with or without polarization index, or other applicable and effective testing. Cables are tested at least once every six years. More frequent testing may occur based on test results and OE.

There are no submarine cables or other cables designed for continuous wetting or submergence currently in the scope of this program. Future installed cables of these potential designs would be considered for inclusion in this program, at least for a one-time test.

NUREG-2191 Consistency

The *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is an existing program that, following enhancement, will be consistent with the ten elements of AMP XI.E3A, *"Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements"* specified in NUREG-2191 (GALL-SLR), as modified by SLR-ISG-2021-04-ELECTRICAL, *Updated Aging Management Criteria for Electrical Portions of Subsequent License Renewal Guidance*.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented in the following program elements: Preventive Actions (Element 2), Parameters Monitored or Inspected (Element 3), Detection of Aging Effects (Element 4) and Acceptance Criteria (Element 6).

1. Add inspections for water accumulation performed after event driven occurrences, such as heavy rain, rapid thawing of heavy ice and snow, or flooding (Element 2).

2. For the periodic water accumulation inspections, add documented verification that either automatic or passive drainage systems or manual pumping are effective in preventing medium-voltage cable exposure to significant moisture (Elements 2 and 6).

3. Remove from program descriptions the original 'significant voltage' portion of exposures to determine the inaccessible medium-voltage cables for testing (Element 3).

4. Revise the inaccessible medium-voltage cable testing and water accumulation inspection matrix to include inspection methods, test methods, and acceptance criteria (Element 4).

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions are maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. A plant-specific OE search that was performed for 2009 through 2019 yielded one result indicating an in-service insulation failure of an in-scope inaccessible medium-voltage power cable due to aging from significant moisture. (See OE example #4 below.) Thus, the corresponding Oconee in-service failure rate is 1 failure per 3 reactors or 0.333 failures per reactor. This OE search result is fairly consistent with the previous searches for GL 2007-01 covering a broader history but focused on inaccessible power cables, for which Oconee reported one prior applicable inaccessible or underground power cable failure under test (i.e., none in-service) over Oconee's three unit history up to the GL. For the totality of the industry's response, GL 2007-01 Summary Report - Figure 24 indicates that 46 medium-voltage power cable failures with "water / moisture" as a definitive, probable, or possible causal factor were identified for the 104 applicable reactors, or an average of 0.442 failures per reactor. This industry failure rate could be further reduced since the summary report data included cables and failures beyond the scope of this AMP (e.g., not in SLR scope, test/non-service failures, or failures not attributed to insulation aging degradation).

   The above results demonstrate the low prevalence of applicable Oconee lost intended functions related to the *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP.

2. In July 2009, after discovery that two trench sump pumps had power inadvertently eliminated during a building demolition, it was recommended to perform quarterly inspections and water pumping (if needed) unless or until the sump pumps system could be permanently restored or replaced. The trench contains cables within the scope of the program. Preventive maintenance was enhanced to require inspections and as-needed pumping on a quarterly frequency.

   In April 2011, the water accumulation challenge in this trench was again noted as part of LR cable aging management walkdown inspections. That documentation indicated that the worst case water level remained below the medium-voltage cables suspended on wall supports well off the trench floor but that the underlaying low-voltage cables were exposed to submergence. Based on this OE, the preventive maintenance frequency was changed to monthly unless or until a permanent power restoration to sump pumps is implemented.

   OE example 2 provides objective evidence that the AMP manager critically self-assesses program performance and self-identifies actions that support continuous improvement.

3. In April 2020, Oconee received a green 10 CFR 50 non-cited violation for failure to identify and correct repeated cable submergence including two QA-1/safety related medium-voltage cables supplying normal power to the standby shutdown facility switchgear. Although the two cables of interest are not credited for standby shutdown facility event mitigation, they are designated as safety related. Corrective actions were initiated to evaluate the need to include the two standby shutdown facility medium-voltage cables in the cable AMP, to divert water from entering the common trench with standby shutdown facility cables, to promptly remove water from the common trench, to remove trash, dirt, and mud from the common trench, and to review operator rounds for the common trench to improve the prevention and monitoring of cable submergence therein.

OE example 3 provides objective evidence that deficiencies identified are entered into the corrective action program. The corrective action program is effective in evaluating and correcting degraded conditions. Continued implementation of the program will assure degraded conditions will be identified and corrected during the SPEO.

4. In December 2011, the Y-phase conductor faulted to ground in 1 of 7 parallel 4.16kV inaccessible cables in a trench between a transformer and switchgear for the standby buses. As part of an alternate station blackout recovery path, the faulted cable is within the scope of SLR. Per the existing *Insulated Cables And Connections* AMP, a Very-Low-Frequency Tangent-Delta test had been performed in June 2010 separately on each of the 3 phases of this circuit but with the conductors from the same phase of all 7 parallel cables connected together. The Y-phase test results indicated potential degradation and that ‘Further Study’ was needed. Therefore, a follow-up test was planned while contingency replacement components (e.g. cable and splices) were being obtained. However, the cable failure occurred before the re-test would have been performed.

   Oconee replaced the inaccessible section of cable using a splice at an indoor accessible location. Likely caused by installation damage, a cut was found through the faulted cable jacket to the armor near the fault exit hole location. An independent external lab determined that the insulation was locally degraded in a ten foot section by water-treeing, which is caused by long-term water ingress in the presence of an electric field. A lightning-strike voltage surge was the likely final stressor breaking down the degraded insulation to create the ground fault. Since the Tangent-Delta test is a global or average-condition test, localized age-related degradation can potentially be masked in varying degrees if testing very long or paralleled insulated and shielded conductors. The original 2010 Tangent-Delta test was remarkably effective in identifying the localized degradation in one cable, even though tested in parallel with six other ~1,500-foot cables. However, the re-test responses were not timely enough to prevent the fault.

   This OE contributed directly to the subsequent development of the fleet cable AMP implementation procedure by requiring, for paralleled conductors tested with unsatisfactory diagnostic results, that a withstand test should also be performed and that additional diagnostic tests must be on isolated individual insulated conductors. This OE also validates the effective sensitivity of the Tangent-Delta testing to detect insulation age-related degradation.

   OE example 4 provides objective evidence that plant-specific OE that potentially involves aging is evaluated and used to adjust the program as necessary. OE example 4 also demonstrates the use of the corrective action program to identify degraded conditions and take corrective action to ensure aging effects are identified.

5. In July 2012, a self-assessment for the LR phase 2 NRC inspection determined that the *Insulated Cable And Connections* AMP had exempted manholes in the turbine building basement since these manholes were not directly being exposed to rain water and surface runoff. Although that lack of direct outdoor exposure is true, these manholes can occasionally backfill from turbine building trenches. The assessment identified a history of water collection in some of these manholes and recommended that they be added to the AMP inspections. Corresponding inspections found over two feet of water in one of the

four manholes (which was found to have no drain), one inch in another of the manholes, and no standing water or cable submergence in the remaining two manholes. The manholes with standing water were initially added to the quarterly periodic inspections and pumping as needed until OE could establish a more permanent frequency; while the other two manholes were added to annual inspections. The permanent inspection frequency for the manhole that had experienced significant moisture and cable submersion was established to be a monthly basis.

OE example 5 demonstrates the use of self-assessment and the corrective action program to clarify and improve existing AMP related inspection scopes to prevent an environmental aging stressor (standing water for medium-voltage cables) that could lead to loss of an intended function.

6. In April 2014, Oconee successfully applied borescope technology to extend visual inspection capability as much as 130 feet beyond the ground surface collection points to a trench itself to improve verification of the trench drainage effectiveness. The trench contains in-scope Keowee emergency underground medium-voltage power and low-voltage instrument and control cables. The trench drainage verification inspection procedure was previously limited to visual examination of drain outlets, inspection ports, and drywell collections; and it lacked a means to inspect inside the trench itself. The results of the extended inspections showed no standing water and no evidence of degrading cables or structural supports. The Oconee maintenance procedure for the inspections was revised to regularly include use of a borescope camera to perform enhanced periodic trench drainage visual inspections.

   OE example 6 provides objective evidence that the program critically assesses program performance and identifies actions that support continuous improvement.

7. In June 2017, Oconee conducted a self-assessment on its implementation of the fleet Cable AMP to evaluate its inaccessible medium-voltage cable testing practices, some of which includes cables within the SLR scope per the existing Oconee *Insulated Cables And Connections* AMP. The self-assessment revealed that the periodic testing scope has nearly doubled from an initial 12 circuits largely due to the addition of protected service water major-project circuits. A second round of testing had already been completed for 10 circuits. A few tests identified degraded splices which prompted more frequent subsequent tests and eventual splice abandonment or replacements. One circuit's test detected significant age-related degradation within cable insulation itself (OE example 4 above). The self-assessment also confirmed that the preventive maintenance frequency for the periodic cable testing had been updated to at least once every six years versus original LR committed ten year frequency for both the original and added scope of medium-voltage circuits. The six year inspection frequency is consistent with NUREG-2191 guidance.

   OE example 7 demonstrates the use of self-assessment and provides objective evidence that industry OE involving aging is evaluated and used to adjust the program as necessary.

8. In September 2019, a self-assessment was performed for the existing *Insulated Cables And Connections* AMP (UFSAR 18.3.14), as part of a “LR AMPs” self-assessment. The existing program includes elements of the *Electrical Insulation for Electrical Cables and Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* program and the *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* program. No areas for improvement findings were identified for the *Insulated Cables And Connections* AMP. One relatively less significant opportunity for improvement on documentation that was generic to all the assessed programs was applicable to the *Insulated Cables And Connections* AMP in that model work orders were found to include outdated standards and program owner names. The generic opportunity for improvement was initiated and addressed in the corrective action program.

   OE example 8 provides objective evidence that the program critically assesses program performance to ensure all current LR commitments are being satisfied, and that the program self-identifies actions to support continuous improvement.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Electrical Insulation for Inaccessible Medium-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.39 ELECTRICAL INSULATION FOR INACCESSIBLE INSTRUMENT AND CONTROL CABLES NOT SUBJECT TO 10 CFR 50.49 ENVIRONMENTAL QUALIFICATION REQUIREMENTS

Program Description

The *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is a new condition monitoring program that will manage the aging effect of reduced electrical insulation resistance due to exposure to significant moisture. The AMP will apply to the electrical insulation for inaccessible (e.g., installed underground, in buried conduit, cable trenches, cable troughs, duct banks, vaults, manholes, or direct buried) non-EQ instrument and control cables and splices within program scope that are potentially exposed to significant moisture, including instrument and control cables designed for continuous wetting or submergence. For this program, significant moisture is defined as exposure to moisture that lasts more than three days (i.e., long term wetting or submergence over a continuous period) that if left unmanaged, could potentially lead to a loss of intended function. Cable wetting or submergence resulting from event driven occurrences and mitigated by either automatic or passive drains is not considered significant moisture for this AMP.

Periodic actions will be taken to prevent in scope inaccessible instrument and control cables from being exposed to significant moisture. Water accumulation in accessible conduit ends, manholes, and trenches (e.g. low points) containing in-scope instrument and control cables will be periodically monitored via documented inspections, and the water removed as needed. The inspection frequencies will be based on Oconee OE with cable wetting or submergence and with water accumulation over time. Inspections and dewatering will be performed at least once annually and after event driven occurrences such as heavy rain, rapid thawing of heavy ice and snow, or flooding. The first inspection for SLR will be completed prior to the SPEO. The inspections will be performed to confirm that in-scope instrument and control cables are not submerged, cable/splices and cable support structures are intact, and de-watering systems (e.g., sump pumps and drains) and associated alarms operate properly.

The issued NRC SLR-ISG-2021-04-ELECTRICAL revises NUREG-2191 XI.E3B to allow for less frequent (5-year) periodic manhole inspection. This relaxation is not applicable unless or until SLR-ISG described self-monitored manhole water level indication and alarms are installed and implemented at Oconee.

Accessible portions (e.g. in manholes) of in-scope inaccessible instrument and control cables will be visually inspected at least once every six years, coordinated with the water accumulation inspections, to assess observable jacket age-related degradation that may be indicative of electrical insulation age-related degradation. The inaccessible instrument and control cables that are found to be exposed to significant moisture will be evaluated to determine if testing is required. If testing is needed, then based on cable application and insulation material, one or more types of one-time testing of in-service samples is performed to assess the insulation condition. One-time test(s) will be performed on significant-moisture-exposed instrument and control cables whose insulation type is known from Oconee or industry OE to degrade with continuous exposure to moisture (e.g. Vulkene or Raychem cross-linked polyethylene). If testing is required, the specific type of test(s) will be a proven technique capable of detecting reduced insulation resistance of the cable’s insulation system due to wetting or submergence. Required one-time tests and the first visual inspections for SLR will be completed before the SPEO. The need for additional tests or inspections will be determined by the test or inspection results as well as Oconee and industry OE.

Testing of installed in-service inaccessible instrument and control cables as part of an existing maintenance, calibration or surveillance program, testing of coupons, abandoned or removed cables, or inaccessible medium or low voltage power cables subjected to the same or bounding environment, service application, cable routing, manufacturing and electrical insulation material may be credited in lieu of or in combination with direct testing of installed in-service inaccessible instrument and control cables when testing is required. A sampling methodology will be used when many inaccessible instrument and control cables exposed to significant moisture are evaluated as requiring testing.

NUREG-2191 Consistency

The *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is a new program that, when implemented, will be consistent with NUREG-2191, Section XI.E3B, *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements*, as modified by SLR-ISG-2021-04-ELECTRICAL, *Updated Aging Management Criteria for Electrical Portions of Subsequent License Renewal Guidance.*

Exception to NUREG-2191

None

Enhancements

None

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be effective in managing aging effects for components within the scope of the program so that the intended functions are maintained consistent with the CLB for the SPEO.

1. A plant-specific OE search that was performed for 2009 through 2019 yielded no examples of degraded in-scope inaccessible instrument and control cable insulation that lost SLR intended function due to aging from significant moisture. This OE search result is consistent with the previous searches for GL 2007-01 covering a broader history but focused on inaccessible power cables, for which Oconee reported no applicable inaccessible or underground low-voltage power cable failures. For the totality of the industry's response, the GL 2007-01 summary report - figure 23 indicates that fourteen low-voltage power cable failures with "water/moisture" as a causal factor were identified for the 104 applicable reactors, or an average of 0.135 failures per reactor. The failure

rate could be further reduced since the Summary Report data includes cables and failures beyond the scope of this AMP (e.g., not in scope, test/non-service failures, or failures not attributed to insulation degradation).

The above results demonstrate the low prevalence of applicable Oconee lost intended functions related to the *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP.

2. In July 2009, after discovery that two trench sump pumps had power inadvertently eliminated during a building demolition, it was recommended to perform quarterly inspections and water pumping (if needed) unless or until the sump pumps system could be permanently restored or replaced. The trench contains cables within the scope of the program. Preventive maintenance was enhanced to require inspections and as-needed pumping on a quarterly frequency.

   In April 2011, the water accumulation challenge in this trench was again noted as part of LR cable aging management walkdown inspections. That documentation indicated that the worst case water level remained below the medium-voltage cables suspended on wall supports well off the trench floor but that the underlaying low-voltage cables were exposed to submergence. Based on this OE, the preventive maintenance frequency was changed to monthly unless or until a permanent power restoration to sump pumps is implemented.

   OE example 2 provides objective evidence that the AMP manager critically self-assesses program performance and self-identifies actions that support continuous improvement.

3. In July 2012, a self-assessment for the LR phase 2 NRC inspection determined that the *Insulated Cable And Connections* AMP had exempted manholes in the turbine building basement since these manholes were not directly being exposed to rain water and surface runoff. Although that lack of direct outdoor exposure is true, these manholes can occasionally backfill from turbine building trenches. The assessment identified a history of water collection in some of these manholes and recommended that they be added to the AMP inspections. Corresponding inspections found over two feet of water in one of the four manholes (which was found to have no drain), one inch in another of the manholes, and no standing water or cable submergence in the remaining two manholes. The manholes with standing water were initially added to the quarterly periodic inspections and pumping as needed until OE could establish a more permanent frequency; while the other two manholes were added to annual inspections. The permanent inspection frequency for the manhole that had experienced significant moisture and cable submersion was established to be a monthly basis.

   OE example 3 demonstrates the use of self-assessment and the corrective action program to clarify and improve existing AMP related inspection scope to prevent an environmental aging stressor (standing water for medium-voltage cables) that could lead to loss of an intended function.

4. In September 2012, during preparations to move underground cables to construct a new maintenance building, a concrete manhole was observed with water covering non-safety

related low-voltage cables. While the *Insulated Cables and Connections* AMP for the initial PEO required no action for inaccessible low-voltage cables, Oconee took the conservative position that the low-voltage cables should also be kept as dry as possible. Aware of broadening industry attention to inaccessible cables exposed to significant moisture, Oconee added periodic inspections and water removal, as needed, for this low-point manhole as a scheduled work activity in the work management system.

OE example 4 provides objective evidence that plant-specific and industry OE that potentially involves aging is evaluated and used to proactively adjust inspection and preventive maintenance practices as necessary.

5. In April 2014, Oconee successfully applied borescope technology to extend visual inspection capability as much as 130 feet beyond the ground surface collection points to a trench to improve verification of the trench drainage effectiveness. The trench contains in-scope Keowee emergency underground medium-voltage power cables and low-voltage instrument and control cables. The trench drainage verification inspection procedure was previously limited to visual examination of drain outlets, inspection ports, and drywell collections, and it lacked a means to inspect inside the trench itself. The results of the extended inspections showed no standing water and no evidence of degrading cables or structural supports. The Oconee maintenance procedure for the inspections was revised to regularly include use of a borescope camera to perform enhanced periodic trench drainage visual inspections.

   OE example 5 provides objective evidence that the program critically assesses program performance and identifies actions that support continuous improvement.

The above examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Electrical Insulation for Inaccessible Instrument and Control Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.40 ELECTRICAL INSULATION FOR INACCESSIBLE LOW-VOLTAGE POWER CABLES NOT SUBJECT TO 10 CFR 50.49 ENVIRONMENTAL QUALIFICATION REQUIREMENTS

Program Description

The *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is a new condition monitoring program that will manage the aging effect of reduced electrical insulation resistance due to exposure to significant moisture. The AMP will apply to the electrical insulation for inaccessible (e.g., installed underground in buried conduit, cable trenches, cable troughs, duct banks, vaults, manholes, or direct buried) non-EQ low-voltage power cables and splices (operating voltage less than 2 kV) within the scope of SLR that are potentially exposed to significant moisture, including low-voltage power cables designed for continuous wetting or submergence. For this program, significant moisture is defined as exposure to moisture that lasts more than three days (i.e., long-term wetting or submergence over a continuous period) that if left unmanaged, could potentially lead to a loss of intended function. Cable wetting or submergence resulting from event driven occurrences and mitigated by either automatic or passive drains is not considered significant moisture for this AMP.

Periodic actions will be taken to prevent in-scope inaccessible low-voltage power cables from being exposed to significant moisture. Water accumulation in accessible conduit ends, manholes, and trenches (e.g., low-points) containing in-scope low-voltage power cables will be periodically monitored via documented inspections, and the water removed as needed. The inspection frequencies will be based on Oconee OE with cable wetting or submergence and with water accumulation over time. Inspections and de-watering will be performed at least once annually and after event driven occurrences such as heavy rain, rapid thawing of heavy ice and snow, or flooding. The first inspection for SLR will be completed prior to the SPEO. The inspections will be performed to confirm that in-scope low-voltage power cables are not submerged, cable/splices and cable support structures are intact, and de-watering systems (e.g., sump pumps and drains) and associated alarms operate properly.

The issued NRC SLR-ISG-2021-04-ELECTRICAL revises NUREG-2191 XI.E3C to allow for less frequent (five year) periodic manhole inspection. This relaxation is not applicable unless or until SLR-ISG described self-monitored manhole water level indication and alarms are installed and implemented at Oconee.

Accessible portions (e.g., in manholes) of in-scope inaccessible low-voltage power cables will be visually inspected at least once every six years, coordinated with the water accumulation inspections, to assess observable jacket age-related degradation that may be indicative of electrical insulation age-related degradation. The inaccessible low-voltage power cables that are found to be exposed to significant moisture will be evaluated to determine if testing is required. If testing is needed, then based on cable application and insulation material, one or more type(s) of one-time testing of in-service samples is performed to assess the insulation condition. One-time test(s) will be performed on significant moisture exposed low-voltage power cables whose insulation type is known from Oconee or industry OE to degrade with continuous exposure to moisture (e.g., Vulkene or Raychem cross-linked polyethylene). If testing is required, the specific type of test(s) will be a proven technique capable of detecting reduced insulation resistance of the cable's insulation system due to wetting or submergence. Required one-time tests and the first visual inspections for SLR will be completed before the SPEO. The need for additional tests or inspections will be determined by the test or inspection results as well as Oconee and industry OE.

Testing of installed in-service inaccessible low-voltage power cables as part of an existing maintenance, calibration or surveillance program, testing of coupons, abandoned or removed cables, or inaccessible medium-voltage power cables or instrument and control cables subjected to the same or bounding environment, service application, cable routing, manufacturing and electrical insulation material may be credited in lieu of or in combination with direct testing of installed in-service inaccessible low-voltage power cables when testing is required. A sampling methodology will be used when many inaccessible low-voltage power cables exposed to significant moisture are evaluated as requiring testing.

NUREG-2191 Consistency

The *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is a new program that, when implemented with exceptions below, will be consistent with NUREG-2191, Section XI.E3C, *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements*, as modified by SLR-ISG-2021-04-ELECTRICAL, *Updated Aging Management Criteria for Electrical Portions of Subsequent License Renewal Guidance*.

Exception 1 to NUREG-2191

The following program element(s) have exceptions:

Program Element Affected: Detection of Aging Effects (Element 4)

1. The fourth paragraph for Element 4 – Detection of Aging Effects in NUREG-2191 Section XI.E3C, as modified by SLR-ISG-2021-04-ELECTRICAL-Appendix C, states the following:

   *"Testing of installed inservice low-voltage power cables as part of an existing maintenance, calibration or surveillance program, testing of coupons, abandoned or removed cables, **or inaccessible low-voltage power cables*** [emphasis added] *subjected to the same or bounding environment, inservice application, cable routing, manufacturing and insulation material may be credited in lieu of or in combination with testing of installed inservice inaccessible low-voltage power cables when testing is required in this AMP."*

   The above highlighted phrase; *"…or inaccessible low-voltage power cables…"* will be replaced by *"...or inaccessible medium-voltage power cables or instrument and control cables…"* for the ONS *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP.

Justification for Exception 1 to NUREG-2191:

The fourth paragraph for Element 4 – Detection of Aging Effects in NUREG-2191 Section XI.E3C states the following:

> *"Testing of installed inservice low-voltage power cables as part of an existing maintenance, calibration or surveillance program, testing of coupons, abandoned or removed cables,* ***or inaccessible medium voltage power cables or instrumentation and control cables*** [emphasis added] *subjected to the same or bounding environment, inservice application, cable routing, manufacturing and insulation material may be credited in lieu of or in combination with testing of installed inservice inaccessible low-voltage power cables when testing is required in this AMP."*

This exception to NUREG-2191 Section XI.E3C, as modified by SLR-ISG-2021-04-ELECTRICAL-Appendix C will align the Detection of Aging Effects Element for this ONS AMP with the Detection of Aging Effects Element provided in NUREG-2191 Section XI.E3C [Reference 1.7-3]. This change will also align the Detection of Aging Effects Element for this ONS AMP to be consistent with Element 4 of NUREG-2191 Section XI.E3B, as modified by SLR-ISG-2021-04-ELECTRICAL. This change will continue to provide reasonable assurance that insulation material for electrical cables will perform its intended function for the SPEO.

Exception 2 to NUREG-2191

Program Element Affected: Corrective Actions (Element 7)

2. The second paragraph for Element 7 – Corrective Actions in NUREG-2191 Section XI.E3C, as modified by SLR-ISG-2021-04-ELECTRICAL-Appendix C, will not apply to the ONS *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP. Specifically, the following will not apply for Appendix B2.1.40 AMP (GALL-SLR XI.E3C):

> *"Additional inspections are conducted if one of the inspections does not meet the acceptance criteria due to current or projected degradation (i.e., trending). The number of increased inspections is determined in accordance with the site's corrective action process; however, there are no fewer than two additional inspections for each inspection that did not meet the acceptance criteria. The additional inspections are completed within the interval (e.g., refueling outage interval, 10-year inspection interval) in which the original inspection was conducted. Additional samples are inspected for any recurring degradation to ensure corrective actions appropriately address the associated causes. At multi-unit sites, the additional inspections include inspections at all of the units with the same material, environment, and aging effect combination."*

Justification for Exception 2 to NUREG-2191:

As discussed in the summary of proposed revisions in the ISG, the proposed revisions to GALL-SLR XI.E3C add, at least every 5 years, inspection of manholes with water level monitoring and alarms that result in consistent and subsequent pump out of accumulated water prior to wetting or submergence of cable. Also for such equipped manholes, the proposed revisions add inspection of manholes following event-driven occurrences such as heavy rain, rapid thawing of ice and snow, or flooding, only when water level monitoring indicates water is accumulating. The proposed changes to Element 7, Corrective Actions were not discussed nor was the basis for the revision discussed.

The proposed change to Element 7 provides specific corrective actions regarding additional inspections if acceptance criteria is not met. The details provided by the proposed change are greater than those provided for other similar AMPs, including GALL-SLR XI.E3A and XI.E3B. This addition imposes an undue burden with no safety benefit.

To align corrective actions for this AMP with GALL-SLR XI.E3A and XI.E3B inaccessible cable insulation AMPs, Element 7 – Corrective Actions will be consistent with Element 7 of NUREG-2191 Sections XI.E3A and XI.E3B. As such, this AMP will address only the first paragraph for AMP Element 7 of NUREG-2191 Section XI.E3C, as modified by SLR-ISG-2021-04-ELECTRICAL-Appendix C.

Enhancements

None

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO.

1. A plant-specific OE search that was performed for 2009 through 2019 yielded no examples of an in-scope inaccessible low-voltage power cable insulation failure due to aging from significant moisture. Such search result is consistent with the previous searches for GL 2007-01 covering a broader history but focused on inaccessible power cables, for which Oconee reported no applicable inaccessible or underground low-voltage power cable failures. For the totality of the industry's response, the NRC GL 2007-01 summary report - figure 23 indicates that fourteen low-voltage power cable failures with "water/moisture" as a causal factor were identified for the 104 applicable reactors, or an average of 0.135 failures per reactor. This industry failure rate could be further reduced since the summary report data includes cables and failures beyond the scope of this SLR AMP (e.g., not in scope, test/non-service failures, or failures not attributed to insulation degradation).

OE example 1 demonstrates the low prevalence of applicable Oconee lost intended function events related to the *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP.

2. In July 2009, after discovery that two trench sump pumps had power inadvertently eliminated during a building demolition, it was recommended to perform quarterly inspections and water pumping (if needed) unless or until the sump pumps system could be permanently restored or replaced. The trench contains cables within the scope of the program. Preventive maintenance was enhanced to require inspections and as needed pumping on a quarterly frequency.

   In April 2011, the water accumulation in this trench was again noted as part of LR cable aging management walkdown inspections. That documentation indicated that the worst case water level remained below the medium-voltage cables suspended on wall supports well off the trench floor but that the underlaying low-voltage cables were exposed to submergence. Based on this OE, the preventive maintenance frequency was changed to monthly unless or until a permanent power restoration to sump pumps is implemented.

   OE example 2 provides objective evidence that the AMP manager critically self-assesses program performance and self-identifies actions that support continuous improvement.

3. In July 2012, a self-assessment for the LR phase 2 NRC inspection determined that the *Insulated Cable And Connections* AMP had exempted manholes in the turbine building basement since these manholes were not directly being exposed to rain water and surface runoff. Although that lack of direct outdoor exposure is true, these manholes can occasionally backfill from turbine building trenches. The assessment identified a history of water collection in some of these manholes and recommended that they be added to the AMP inspections. Corresponding inspections found over two feet of water in one of the four manholes (which was found to have no drain), one inch in another of the manholes, and no standing water or cable submergence in the remaining two manholes. The manholes with standing water were initially added to the quarterly periodic inspections and pumping as needed until OE could establish a more permanent frequency; while the other two manholes were added to annual inspections. The permanent inspection frequency for the manhole that had experienced significant moisture and cable submersion was established to be a monthly basis.

   OE example 3 demonstrates the use of self-assessment and the corrective action program to improve existing AMP related inspection scopes to prevent an environmental aging stressor (standing water for medium-voltage cables per existing Oconee program) that could lead to loss of an intended function.

4. In September 2012, during preparations to move underground cables to construct a new maintenance building, a concrete manhole was observed with water covering non-safety related low-voltage cables. While the initial LR's *Insulated Cables And Connections* AMP requires no action for inaccessible low-voltage cables, Oconee took the conservative position that the low-voltage cables should also be kept as dry as possible. Aware of broadening industry attention to inaccessible cables exposed to significant moisture,

Oconee added periodic inspections and water removal, as needed, for this low-point manhole.

OE example 4 provides objective evidence that plant-specific and industry OE that potentially involves aging is evaluated and used to proactively adjust inspection and preventive maintenance practices as necessary.

5. In April 2014, Oconee successfully applied borescope technology to extend visual inspection capability as much as 130 feet beyond the ground surface collection points to a trench to improve verification of trench drainage effectiveness. The trench contains in-scope Keowee emergency underground medium-voltage power cables and low-voltage instrument and control cables. The trench drainage verification was previously limited to visual examination of drain outlets, inspection ports, and drywell collections; and it lacked a means to inspect inside the trench itself. The results of the extended inspections showed no standing water and no evidence of degrading cables or structural supports. The Oconee maintenance procedure for the inspections was revised to regularly include use of a borescope camera to perform enhanced periodic trench drainage visual inspections.

   OE example 5 provides objective evidence that the program critically assesses program performance and identifies actions that support continuous improvement.

The above examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

<u>Conclusion</u>

The implementation of the *Electrical Insulation for Inaccessible Low-Voltage Power Cables Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.41 METAL ENCLOSED BUS

Program Description

The *Metal Enclosed Bus* AMP is a new condition monitoring program that will manage the identified aging effects of in-scope metal enclosed bus. The internal portions of accessible bus enclosure assemblies will be visually inspected for age-related degradation, including cracks, corrosion, foreign debris, excessive dust buildup, and evidence of water intrusion. The accessible bus insulation will be visually inspected for signs of reduced insulation resistance, such as embrittlement, cracking, chipping, melting, discoloration, swelling, or surface contamination which may indicate overheating or aging degradation. The accessible internal bus insulating supports will be visually inspected for structural integrity and signs of cracks.

Metal enclosed bus external surfaces and external structural supports are managed by the *Structures Monitoring* (B2.1.33) AMP.

Accessible elastomers (e.g., gaskets, boots, O-rings and sealants) will be inspected for degradation including surface cracking, crazing, scuffing, dimensional change (e.g., “ballooning” and “necking”), shrinkage, discoloration, hardening or loss of strength.

A sample of accessible bolted connections will be inspected for increased resistance of connection by either performing thermography or measuring the connection resistance using a micro-ohmmeter. In addition to thermography or resistance measurement, accessible bolted connections not covered with heat shrink tape or boots are visually inspected for increased resistance of connection (e.g., loose or corroded bolted connections and hardware including cracked or split washers). The sample will be of 20% of the accessible metal enclosed bus bolted connection population with a maximum sample size of 25.

As an alternative to thermography or measuring connection resistance of bolted connections, for accessible bolted connections covered with heat shrink tape, sleeving, insulating boots, etc., insulating material may be visually inspected to detect surface anomalies, such as embrittlement, cracking, chipping, melting, discoloration, swelling, or surface contamination. When an alternative visual inspection is used to check accessible metal enclosed bus bolted connections, the first inspection will be completed prior to the SPEO and every five years thereafter.

The inspections and resistance measurements will be performed prior to the SPEO and at least once every ten years during the SPEO.

NUREG-2191 Consistency

The *Metal Enclosed Bus* AMP is a new program that, when implemented, will be consistent with NUREG-2191, Section XI.E4, *Metal Enclosed Bus*.

Exception to NUREG-2191

Enhancements

None

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *Metal Enclosed Bus* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO.

1. In 2009, INPO Significant Event Report 5-09 was issued for a 6.9 kV non-segregated bus fault at another plant. The overheating was attributed to the combination of heating and bus bolt torque relaxation from repeated thermal cycles over time. This condition was not detected due to repeated deferrals of preventive maintenance over an eight year period that would have inspected the torque of the flexible link bolts.

   The review of this industry OE was entered into the corrective action program for evaluation of applicability to Oconee. Since Oconee had previous plant-specific experience with detensioning and overheating of bolted bus connections, Oconee was found to be up to date on performing scheduled inspections for flex link bolt tightness.

   OE example 1 demonstrates that inspections of metal enclosed bus components are being performed in accordance with industry guidelines and that those inspections are effective in identifying aging effects prior to loss of intended function. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to monitor and trend the conditions.

2. In 2014, thermography performed during a loaded run on Keowee Unit 2 detected a hot spot on a generator isolated-phase bus duct grounding strap. Subsequent investigation of the hot spot revealed that the grounding strap had paint on the mating surfaces. The grounding strap mating surfaces were cleaned and re-torqued. A post maintenance loaded run was performed and thermography of the subject grounding strap indicated that operating temperatures had returned to normal levels compared to adjacent bus duct components.

   OE example 2 demonstrates that existing maintenance practice using thermography is an effective method in detecting and correcting hot spots on metal enclosed bus prior to loss of intended function. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality and to monitor and trend the conditions.

3. In 2019, INPO reported industry OE regarding an automatic reactor scram due to a ground on the isolated-phase bus duct at another nuclear station. The ground was caused by water entry through a deteriorated gasket resulting in a low resistance ground fault. The Oconee bus inspection procedure was reviewed for applicability to this industry OE and it was determined that while the procedure included gasket inspection for

deterioration, procedure revision was needed to ensure that all access covers are checked for degraded gaskets.

OE example 3 provides objective evidence that industry OE that involves aging is evaluated and used to adjust the program as necessary.

The above examples of OE provide objective evidence that the aging management activities and methods to be implemented by the *Metal Enclosed Bus* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *Metal Enclosed Bus* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Metal Enclosed Bus* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.42 FUSE HOLDERS

Program Description

The *Fuse Holders* AMP is a new condition monitoring program. The program will apply to fuse holders outside of active devices susceptible to the following aging effects: increased resistance of connection due to chemical contamination, corrosion, and oxidation or fatigue caused by ohmic heating, thermal cycling, electrical transients, frequent removal and replacement, or vibration. It will also manage degradation of electrical insulation for the fuse holders with metallic clamps susceptible to the aging effects identified. Fuse holders inside an active device (e.g. switchgears, power supplies, inverters, battery chargers, and circuit boards) and not subject to the aging effects identified, are not within the scope of this program.

The metallic portion of fuse holders outside of active devices will be tested at least once every 10 years to assess the impact of any aging stressors. The specific type of test is determined prior to the initial test and detects increased resistance of fuse holder metallic clamp connections. Tests may include thermography, contact resistance testing, or other appropriately justified testing. The condition of the electrical insulation portion of the fuse holders outside of active devices will be visually inspected at least once every 10 years to provide an indication of the condition of the electrical insulation.

NUREG-2191 Consistency

The *Fuse Holders* AMP is a new program that, when implemented, will be consistent with NUREG-2191, Section XI.E5, Fuse Holders.

Exception to NUREG-2191

None

Enhancements

None

Operating Experience

Based on a search of pertinent Oconee OE, the following examples provide objective evidence that the *Fuse Holders* AMP will be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO.

1. In 2015, during a transformer phase rotation test, a loose fuse holder was discovered by observation of an electric arc between the fuse and fuse holder. The condition was entered into the corrective action program, the fuse holder was repaired and an investigation into possible causes was performed. The investigation determined this was a reoccurring issue. The installation procedures for this type of fuse contain notes regarding the orientation of the fuse during installation. Incorrect orientation during

installation was stated to be a cause for damaging the fuse clips. To prevent damage to additional fuse holders, a note in the installation procedure was changed to a caution statement to place more emphasis on the orientation of the fuse during installation. All applicable procedures were reviewed and updated. This example provides objective evidence that current maintenance practices are effective in identifying and correcting fuse holder deficiencies.

2. In 2015, while removing a fuse to perform testing associated with a MOV, the fuse holder tang fell off and the fuse holder was replaced. This example provides objective evidence that current maintenance practices are effective in identifying and correcting fuse holder deficiencies.

3. In 2016, during post-maintenance restoration of Keowee transformer CX, loose fuse holders were discovered in a 600 volt load center compartment. The fuse holder tension was adjusted to ensure good electrical contact and the other fuse holders in the compartment were checked.

   Although this equipment is not in the scope of SLR, OE example 3 provides objective evidence that existing maintenance practices, detection methods and the corrective action program effectively identify and correct deficiencies with the metallic portions of fuse holders prior to the loss of intended function.

The above three examples provide objective evidence that the aging management activities and methods being implemented by the *Fuse Holders* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

<u>Conclusion</u>

The implementation of the *Fuse Holder*s AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B2.1.43 ELECTRICAL CABLE CONNECTIONS NOT SUBJECT TO 10 CFR 50.49 ENVIRONMENTAL QUALIFICATION REQUIREMENTS

Program Description

The *Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is a new condition monitoring program that will manage the aging effects of increased electrical resistance of electrical cable connections (metallic parts).

This program will perform a one-time test, on a representative sampling basis, to confirm the absence of loosening of connections due to thermal cycling, ohmic heating, electrical transients, vibration, chemical contamination, corrosion and oxidation. Sample selection will be based on voltage level (medium and low-voltage), circuit loading (high current load), connection type, and location (high temperature, high humidity, vibration, etc.).

Non-EQ electrical cable connections (metallic parts) associated with cables within the scope of the program will be tested prior to the SPEO to assess the integrity of the cable connections. The specific type of test to be performed will be determined based on the type of connection and will be a proven method for detecting loose connections, such as thermography, contact resistance testing, or other appropriate testing methods without removing the connection insulation such as heat shrink tape, sleeving, insulating boots, etc.

Twenty percent of each connector type with a maximum sample size of 25 constitutes a representative connector sample size. Otherwise, a technical justification of the methodology and sample size used for selecting components under test will be included as part of the program documentation.

A representative sample of cable connections within the scope of SLR will be tested on a one time test basis or at least once every five years if only visual inspection is used to provide an indication of the integrity of the cable connections. Depending on the one time test results, subsequent testing may have to be performed within ten years of initial testing. The first visual inspections or tests for SLR are to be completed prior to the SPEO.

As an alternative to testing for accessible cable connections that are covered with heat shrink tape, sleeving, insulating boots, etc., a visual inspection of insulation materials to detect surface anomalies, such as embrittlement, cracking, chipping, melting, discoloration, swelling or surface contamination may be performed. When the alternative visual inspection is used to check cable connections, the first inspection will be completed prior to the SPEO and repeated at least every five years, thereafter. The basis for performing only the alternative visual inspection to monitor age-related degradation of cable connections will be documented.

NUREG-2191 Consistency

The ONS *Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP is a new program that, when implemented, will be consistent with NUREG-2191, Section XI.E6, *Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements*.

Exception to NUREG-2191

None

Enhancements

None

Operating Experience

Based on a search of pertinent ONS OE, the following examples provide objective evidence that the *Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be effective in managing aging effects for systems and components within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO.

1. In 2011, during routine thermography a main step-up transformer cooling fan cable connection was observed to have elevated temperature and the condition documented in the corrective action program. Periodic temperature monitoring was performed until the cooling fan could be taken out of service and a connection tightened. Post-maintenance thermography confirmed that the connection temperature had returned to normal and no additional actions were required.

   OE example 1 provides objective evidence that current maintenance thermography practices and the corrective action program effectively identify and correct cable connection issues prior to loss of intended function.

2. In 2013, a valve was found to have a boron leak and the leak was documented in the corrective action program. Leak targets identified included electrical cable connectors. The leak was repaired and boron cleaned from the valve components.

   OE example 2 demonstrates that visual inspections are effective in detecting the absence or presence of aging effects for electrical cable connections prior to the loss of an intended function.

3. In 2013, an action request was initiated in the corrective action program to document various alarms were received due to erratic nuclear instrumentation indication. Troubleshooting and electrical testing revealed that a cable connector associated with the reactor protection system was dirty. The connector was cleaned and indications returned to normal. During inspection and repair, the cable termination O-ring was not found installed as shown on the cable termination drawing and a condition report was initiated in the corrective action program. Subsequent engineering evaluation and review of the cable termination drawing determined that the O-ring was optional for the application. The drawing was updated to clarify cable termination sealing requirements.

   OE example 3 provides objective evidence that maintenance practices effectively maintain the condition of electrical cable connections to assure that these components will be able to continue to perform their intended functions during the SPEO. This example also demonstrates the effective use of the corrective action program to confirm and maintain configuration control between in-service equipment and design documentation.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, re-evaluation, repairs, or replacements will be provided for locations where aging effects are found. Periodic assessments of the *Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will be performed to identify the areas that need improvement to maintain effective performance of the program. The program will be informed and enhanced, when necessary, through the systematic and ongoing review of both plant specific and industry OE.

Conclusion

The implementation of the *Electrical Cable Connections Not Subject to 10 CFR 50.49 Environmental Qualification Requirements* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B3.0 TIME-LIMITED AGING MANAGEMENT PROGRAMS

B3.1 Fatigue Monitoring

Program Description

The F*atigue Monitoring* AMP is an existing preventative program that manages fatigue or other types of cyclic loading time limited aging analyses (TLAAs) of the reactor pressure vessel components, reactor coolant pressure boundary piping components, and other components per the acceptance criterion in 10 CFR 54.21(c)(1)(iii). The program monitors and tracks the number of occurrences and severity of design basis transients assessed in the applicable fatigue or cyclic loading analyses, including those in applicable cumulative usage factor (CUF) analyses, environmentally-assisted cumulative usage fatigue (CUF_{en}) analyses, ASME Section III fatigue waiver analyses, and cycle-based flaw growth, flaw tolerance, or fracture mechanics analyses.

The *Fatigue Monitoring* AMP monitors and tracks the number of critical thermal, pressure, and seismic transients to ensure the cumulative usage factor (CUF) and environmentally-assisted fatigue (CUF_{en}) for each analyzed component does not exceed the applicable limit through the SPEO. The program monitors and tracks the number and severity of thermal and pressure transients for Oconee Units 1, 2, and 3 as specified in UFSAR Tables 5-2 and 5-23, which is mentioned in UFSAR Section 5.2.1.4 that is referenced in Technical Specification Section 5.5.6. For fatigue waiver analyses, the program follows the exemption rules outlined in ASME Section III, NB-3630 which uses enveloping design and normal service temperature and pressure values. These analyses only utilize Level A & B (Normal and Upset) cycles. For Oconee, piping systems designed per USAS B31.7 Class II and Class III and USAS B31.1 are to assume a stress range reduction factor to provide conservatism in the piping design to account for thermal fatigue due to cyclic operations. These analyses are not dispositioned in accordance with 10 CFR 54.21(c)(1)(iii), as shown in Section 4.3.3, and are not monitored by this program. The program will continue to monitor transient cycles to ensure that LBB analyses remain valid. No HELB analyses exclude break locations based on fatigue, therefore the program does not apply to HELB.

Design Basis Management

The program verifies the continued acceptability of existing design analyses through cycle counting. The program records, monitors, and tracks the overall cumulative number of plant transients. The program assures that the number of occurrences of each critical transient remains within the limits of the fatigue analyses, which in turn ensures that the analyses remain valid. Oconee UFSAR Table 5-2 and Table 5-23 provide a listing of design transients and associated design cycles. The program monitors actual operating conditions to ensure that fatigue analyses remain valid for the SPEO. The program requires that when a cumulative usage factor or environmentally-assisted cumulative usage fatigue value exceeds 80 percent of the applicable allowable limit or if the minimum time for any transient event total occurrence projection to reach the allowable is less than three years, then the issue shall be entered into the corrective action program.

Environmentally-Assisted Fatigue

Environmentally-adjusted cumulative usage factors are the design cumulative usage factors adjusted to account for the effects of the reactor water environment on component fatigue life. For a plant, the effects of reactor water environment on fatigue are evaluated by assessing a set of sample critical components for the plant. Examples of critical components are identified in NUREG/CR-6260, "*Application of NUREG/CR-5999 Interim Fatigue Curves to Selected Nuclear Power Plant Components;*" however, plant-specific component locations in the reactor coolant pressure boundary may be more limiting than those considered in NUREG/CR-6260, and thus should also be considered. Environmental effects on fatigue for these critical components may be evaluated using the guidance in RG 1.207, Revision 1, *"Guidelines for Evaluating the Effects of Light Water Reactor Coolant Environments in Fatigue Analyses of Metal Components;"* alternatively, the bases in NUREG/CR-6909, *"Effect of LWR Coolant Environments on the Fatigue Life of Reactor Materials,"* (with "average temperature" used consistent with the clarification that was added to NUREG/CR-6909, Revision 1); or other subsequent NRC endorsed alternatives.

The *Fatigue Monitoring* program relies on the *Water Chemistry* (B2.1.2) program to provide monitoring of appropriate environmental parameters for calculating environmental fatigue multipliers (F_{en} values).

The *Fatigue Monitoring* program monitors and tracks the number of occurrences of each of the critical thermal and pressure transients for the established sentinel locations in order to maintain the environmentally-assisted cumulative usage factor below 1.0. For the majority of the sentinel locations, the program documents the severity of operational parameters.

For the pressurizer surge line and high pressure injection system piping subject to environmentally assisted fatigue, the program manages the effects of aging due to fatigue through the *ASME Section XI, Inservice Inspection, Subsections IWB, IWC, and IWD* program by conducting inspections in accordance with ASME Code, Section XI, Non-mandatory Appendix L.

Establish Inspection Frequency by Analysis: Flaw Tolerance

A special aspect of the *Fatigue Monitoring* AMP is the use of flaw tolerance analysis to establish specific inspection frequencies that may be greater than the ASME Section XI requirements. In some cases, flaw tolerance evaluations are used to establish inspection frequencies for components that, for example, exceed cumulative usage factors or environmentally-assisted cumulative usage fatigue limits. As an example, ASME Code, Section XI, Non-mandatory Appendix L provides guidance on the performance of fatigue flaw tolerance evaluations to determine acceptability for continued service of reactor coolant system branch line piping subjected to cyclic loadings. In flaw tolerance evaluations, the predicted size of a postulated fatigue flaw, whose initial size is typically based on the resolution of the inspection method, is a computed parameter that is used to determine the appropriate inspection frequency. The program monitors and tracks the number of occurrences of fatigue sensitive thermal and pressure transients for the selected components that are used in the fatigue flaw tolerance evaluations to verify that the inspection frequencies remain appropriate.

NUREG-2191 Consistency

The Oconee *Fatigue Monitoring* AMP is an existing program that will be consistent with the ten elements of Section X.M1 of NUREG-2191 with the enhancements described below.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented in the following program elements: Scope of Program (Element 1), Parameters Monitored/Inspected (Element 3), Detection of Aging Effects (Element 4), Monitoring and Trending (Element 5), Acceptance Criteria (Element 6), and Corrective Actions (Element 7)

1. The program will be enhanced to require monitoring and tracking of transient cycles associated with the ASME Code, Section XI, Appendix L analysis be performed between the inspections for each ASME Code, Section XI, Appendix L locations. Consistent with existing program cycle counting, a surveillance limit will be established to initiate corrective action prior to exceeding transient cycle assumptions in the ASME Code, Section XI, Appendix L analysis. (Elements 1, 3, 4, 5, 6, and 7)

2. The program will be enhanced to require periodic validation of chemistry parameters used to determine F_{en} factors used. (Elements 3, 4, 5, 6, and 7)

3. The program will be enhanced to expand existing corrective action guidance associated with exceeding a cycle counting surveillance limit to recommend consideration of component repair, component replacement, performance of a more rigorous analysis, performance of an ASME Code, Section XI, Appendix L flaw tolerance analysis, or scope expansion to consider other locations with the highest expected CUF_{en} values. (Element 7)

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Fatigue Monitoring* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2008, a corrective action entry was initiated to evaluate OE contained in NRC issued RIS 2008-30, *Fatigue Analysis of Nuclear Power Plant Components*. This resulted in action items being created for nuclear generation facilities to document the results of implementation of RIS 2008-30.

For Oconee, two different action items were written. The first action item completed addressed recording the implementation of NRC issued RIS 2008-30 as a LR commitment. This was dispositioned by documenting this issue in the associated program specific guide. The second action item completed was written to track the documentation of the RIS. The conclusion of this assignment was to review the calculations performed for LR to address the potential for increased thermal fatigue effects associated with reactor water, or “GSI-190” concerns. In particular, the review included a review to ensure that all aspects of RIS 2008-30 were addressed.

Additional actions included a vendor review of the supporting GSI-190 environmentally assisted fatigue calculations to confirm that the methods used for these environmentally assisted fatigue analyses appropriately considered a full six component tensor, as discussed in RIS 2008-30.

The conclusion of the review showed that the full six tensor approach or specific ASME Code equations were used for all of the environmentally-assisted fatigue analyses. The program documentation was updated to include the requirements of GSI-190. This OE shows that the program effectively considers regulatory guidance.

2. In 2010, a corrective action program entry was initiated by engineering to document and track actions required to update the *Thermal Fatigue Management* program based on modifications to the Oconee Unit 1 pressurizer seal weld. In 2010, the *Thermal Fatigue Management* program supporting documentation for the most recent allowed cycles for the Oconee Unit 1 pressurizer heater bundle seal Weld required updating. AREVA provided the updated fatigue analysis of the Oconee Unit 1 pressurizer heater bundle seal weld. The Oconee Unit 1 pressurizer heater bundle seal weld fatigue analysis was updated to add sufficient margin to the operating cycles. This pressurizer heater bundle seal weld developed a leak in 1989 that was repaired at that time. Supporting analysis for this repair concluded that a revised number of heatup and cooldown cycles (from initial plant operation) would be allowed for continued operation of this component.

   As Oconee Unit 1 has operated since then, the unit has continued to accumulate heatup and cooldown cycles. In 2009, Oconee asked the nuclear steam supply system vendor to update and refine the original analysis to support additional allowed cycles to increase the Oconee Unit 1 cycle margin. This latest nuclear steam supply system vendor fatigue analysis results in a higher number of allowed heatup and cooldown cycles. This additional margin was sufficient for Oconee Unit 1 operation until the pressurizer heater bundles were replaced in the fall of 2014. This new set of allowed cycles is currently documented in the Duke Energy document management system and is reflected in the *Thermal Fatigue Management* program basis.

   This resulted in a corrective action to update the program documentation to include the revised heatup and cooldowns for the Oconee Unit 1 pressurizer heater bundle seal weld.

   OE example 2 provides objective evidence that the *Thermal Fatigue Management* program is being effectively implemented to monitor components for fatigue usage during the first PEO, and continued implementation of the *Fatigue Monitoring* AMP will assure that the monitored components will continue to perform their intended functions during the SPEO.

3. In 2011, a corrective action was initiated to request engineering evaluation of possible thermal cycling effects on the Oconee Unit 2 high pressure injection system thermal sleeves from an October 2011 letdown flow reduction event. The data for the Oconee Unit 2 letdown flow reduction event was reviewed. The reduction of letdown flow resulted in a reduction of HPI normal make up flow for around 9 hours. When letdown was restored, normal make up flow recovered as expected.

   Since the normal make up flow did not go below the threshold and there was no additional significant cycling of the normal make up flow for this event, no significant thermal sleeve thermal cycling occurred. This event did not produce an excessive number of flow cycles nor a significant thermal cycle for the thermal sleeves. This high pressure injection flow event was logged during the monthly high pressure injection flow cycling data review at the end of the month and entered into the high pressure injection thermal sleeve cycling table for Oconee Unit 2.

   According to plant procedures, if letdown flow is less than 75 gpm with reactor coolant system temperature greater than 250°F, then a corrective action should be initiated to evaluate possible thermal cycling effects of high pressure injection thermal sleeves. This was completed and it was determined that no further evaluation was needed.

   OE example 3 provides objective evidence that the *Thermal Fatigue Management* program implementing procedures, along with the corrective action program, will effectively monitor in scope SSCs to assure that these components continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO.

4. In 2011, a corrective action was initiated due to the allowable operating transient cycle manual cycle counting update not being performed in a timely manner. This issue was identified during a License Renewal IP-71003 readiness review. For the manual cycle counting, the plant computer data is reviewed and the individual transient events that each of the Oconee Units has experienced since the last counting period are identified. This information is logged, and a summary of the information is utilized to update the AOTC program documentation.

   This corrective action documented that the manual cycle counting summary reviews were not being completed on the specified due date. This was a documentation issue only, but did require attention, since it impacts the completeness of the overall cycle counting effort within the Oconee *Thermal Fatigue Management* AMP. The allowable operating transient cycle update was completed and the action item was closed.

   OE example 4 demonstrates that the *Thermal Fatigue Management* AMP calculations are tracked and effectively updated, as required, by the program. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality.

5. In 2013, a corrective action was initiated to document an error in the valve closure design load cycles used for the replacement once through steam generators. During the evaluation of the reactor building main steam penetrations, concerns arose about the design loads and the design cycles used in the analysis. A review of the replacement once through steam generators design calculations was performed to provide a comparison of the design loads and cycles for the main steam penetrations. The replacement once through steam generators review showed that one of the event cycles was evaluated correctly, but another was not. This corrective action documented the discrepancy and referenced the replacement once through steam generators supplier corrective action that was used to address the concern.

   A review of the supporting replacement once through steam generators analysis calculations shows that the stresses associated with the valve closure were included in the analysis and the resultant stresses met all code limits. This conclusion was confirmed with the replacement once through steam generator supplier. In addition, the fatigue contribution for the load set pairs from the valve closure loadings were so small that even if increased by a factor of ten, would still result in a total cumulative usage factor less than the Code allowable value.

   Therefore, the added cycles do not have a significant impact on the replacement once through steam generators design analysis results and are of concern only in they have not been formally included into the replacement once through steam generator design documentation. The design load set combinations were summarized and have been sent to Oconee for the main steam penetrations.

   OE example 5 provides objective evidence that the *Thermal Fatigue Management* program documentation is reviewed and evaluated to ensure that it remains valid. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality.

6. In 2014, a corrective action program entry was initiated to evaluate industry OE of rejectable weld indications identified on the cold leg injection lines at a pressurized water reactor facility. The evaluation would determine if additional non-destructive examination inspections should be performed in the upcoming Unit 2 and Unit 1 outages. The industry OE report was reviewed, which documented that the cause of the cracks was high cycle thermal fatigue, most likely produced by turbulent penetration of hot reactor coolant cold leg fluid into stagnant injection lines and mixing with cooler water.

   The flaws were identified with the same non-destructive examination method as used at Oconee at the time for all the high pressure injection nozzles that are subject to these phenomena. There was nothing documented in the industry OE report that would result in any additional corrective actions that haven’t already been implemented due to plant-specific OE. The industry OE report supported the conclusion that additional examinations for Oconee Unit 2 during the forced outage, or the during the Oconee Unit 1 refueling outage in the fall of 2014 were not warranted. No additional corrective actions were required.

OE example 6 provides objective evidence that industry OE that involves aging is evaluated and used to adjust the program as necessary. This example also demonstrates that the corrective action program is used effectively to identify and evaluate conditions adverse to quality.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Fatigue Monitoring* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Fatigue Monitoring* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Fatigue Monitoring* AMP, with the noted enhancements, will provide reasonable assurance that the aging effects are adequately managed so that the intended functions of components within the scope of LR are maintained consistent with the CLB during the SPEO.

B3.2 Neutron Fluence Monitoring

Program Description

The *Neutron Fluence Monitoring* AMP is an existing condition monitoring program that manages loss of fracture toughness due to neutron fluence of the reactor pressure vessel regions for which neutron fluence is projected to exceed 1.0E+17 n/cm^2 (E>1MeV) during the SPEO to ensure continued validity of neutron fluence analyses and that applicable reactor pressure vessel neutron irradiation embrittlement analysis (i.e., TLAAs) will remain within their applicable limits. Neutron fluence is a time-dependent input parameter for evaluating reduction of fracture toughness due to neutron irradiation embrittlement. This program monitors the reactor pressure vessel and reactor vessel internals neutron fluence to verify the continued acceptability of existing irradiation embrittlement and related analyses during the SPEO. The components evaluated by these analyses are the reactor pressure vessel shell and welds and reactor vessel internal components subject to reactor coolant and neutron flux environment which are fabricated from carbon or low alloy steel with stainless steel cladding, stainless steel, and nickel alloy materials.

The program has two aspects, one to verify the continued acceptability of existing analyses through neutron fluence monitoring, and the other to provide periodically updated evaluations of the analyses involving neutron fluence inputs to demonstrate that they continue to meet the appropriate limits defined in the CLB.

This program is used in conjunction with the Generic Aging Lessons Learned for Subsequent License Renewal (GALL-SLR) Report AMP XI.M31, “Reactor Vessel Material Surveillance” (Reference: SLR-ONS-AMPR-XI.M31). Accurate neutron fluence values are also necessary to identify the reactor pressure vessel beltline region, for which neutron fluence is projected to exceed 1.0E+17 n/cm^2 (E > 1 MeV) during the subsequent period of extended operation.

Monitoring is performed to verify the adequacy of neutron fluence projection methods that are defined for the CLB in NRC approved reports. Cavity dosimetry measurements are used to verify the accuracy of fluence calculations and to determine fluence uncertainty values in accordance with NRC Regulatory Guide 1.190, *“Calculational and Dosimetry Methods for Determining Pressure Vessel Neutron Fluence.”* These calculations, and related uncertainties, determine when the neutron fluence is projected to exceed 1.0E+17 n/cm^2 (E > 1 MeV) for specific reactor vessel items during the subsequent period of extended operation and thus, require monitoring to ensure their embrittlement analyses remain below applicable limits.

For neutron fluence monitoring activities that apply to components located in the beltline region of the reactor pressure vessels, the monitoring methods are performed in a manner consistent with the monitoring methodology guidelines in RG 1.190, *“Calculational and Dosimetry Methods for Determining Pressure Vessel Neutron Fluence.”* Neutron fluence monitoring methods that are applied to reactor pressure vessel locations outside of the beltline region of the reactor pressure vessels are justified and are consistent with NRC approved methodology. These methods have been benchmarked with both in-vessel and ex-vessel cavity dosimetry for the beltline region.

Neutron Fluence Monitoring AMP results are compared to the neutron fluence parameter inputs used in the neutron embrittlement analyses for reactor pressure vessel components that are required by specific regulations in 10 CFR Part 50. The neutron irradiation embrittlement TLAAs that are within the scope of this Oconee AMP include, but are not limited to: (a) neutron fluence, (b) pressurized thermal shock analyses for pressurized water reactors, as required by 10 CFR 50.61 or alternatively [if applicable for the current licensing basis (CLB)] by 10 CFR 50.61a; (c) reactor pressure vessel upper-shelf energy analyses, as required by Section IV.A.1 of 10 CFR Part 50, Appendix G, and (d) pressure-temperature limit analyses that are required by Section IV.A.2 of 10 CFR Part 50, Appendix G and controlled by plant technical specifications (TS) update and reporting requirements i.e., the 10 CFR 50.90 license amendment process for updates of pressure-temperature limit curves located in the TS limiting conditions of operation, or TS administrative control section requirements for updates of pressure-temperature limit curves that have been relocated into a pressure-temperature limits report.

Reactor vessel surveillance capsule dosimetry data obtained in accordance with 10 CFR Part 50, Appendix H requirements and through implementation of the *Reactor Vessel Material Surveillance* AMP (Reference A2.19) provides inputs to and have impacts on the neutron fluence monitoring results that are tracked by this program. In addition, regulatory requirements in the plant technical specifications or in specific regulations of 10 CFR Part 50 apply, including those in 10 CFR Part 50, Appendix G; 10 CFR 50.55a; and the PTS requirements in 10 CFR 50.61, as applicable for the CLB.

Verification of the uncertainty in assumed reactor vessel fluence values is performed on a cycle-by-cycle basis to ensure neutron fluence projections remain bounding with respect to actual plant operating conditions. The verification is accomplished by performing a review of key reactor vessel fluence input parameters to ensure that any significant changes would be evaluated.

The Oconee calculations of neutron fluence also factor into other analyses or technical report methodologies that assess irradiation-related aging effects. Examples include, but are not limited to: (a) determination of the reactor pressure vessel beltline as defined in Regulatory Issue Summary 2014-11, *"Information on Licensing Applications for Fracture Toughness Requirements for Ferritic Reactor Coolant Pressure Boundary Components,"* (b) evaluation of the susceptibility of reactor vessel internals components to neutron radiation damage mechanisms, including irradiation embrittlement, irradiation-assisted stress corrosion cracking, irradiation-enhanced stress relaxation or irradiation creep and void swelling or neutron induced component distortion; and (c) evaluating the dosimetry data obtained from an reactor pressure vessel surveillance program.

The Oconee program methods and assumptions for determining reactor pressure vessel neutron fluence for the beltline region are consistent with NRC Regulatory Guide (RG) 1.190, "Calculational and Dosimetry Methods for Determining Pressure Vessel Neutron Fluence." These methods have been benchmarked with both in-vessel and ex-vessel cavity dosimetry for the beltline region as reported in BAW-2241P-A, Revision 2.

While no additional in-vessel dosimetry is planned, ONS utilizes ex-vessel (cavity) dosimetry for Unit 2 as a continuous fluence monitoring device. Cavity dosimetry measurements provide continued experimental data to verify the accuracy of fluence calculations and to determine fluence uncertainty values.

Plant-specific fluence analyses were performed for the reactor pressure vessel and reactor vessel internals to support the Oconee SLRA. These plant-specific fluence analyses followed Framatome's NRC approved methodology described in BAW-2241P-A, Revision 2, "Fluence and Uncertainty Methodologies." Although this methodology has not been approved for use outside of the traditional beltline, it was shown in ANP-10348, "Fluence Methodologies for SLR" that Framatome's discrete ordinates methodology is conservative in the nozzle (extended beltline) region. This is due to the conservative modeling of the upper internals, which are modeled as "hot water" and the conservative modeling of the reactor cavity, where all structural components are neglected.

For reactor vessel internals, the Electric Power Research Institute Materials Reliability Program (MRP) conducted an expert panel to evaluate the neutron fluence impacts on the susceptibility of reactor vessel internals items to neutron radiation damage mechanisms (including irradiation embrittlement, irradiated-assisted stress corrosion cracking, irradiation-enhanced stress relaxation or creep and void swelling or neutron induced component distortion), during the development of reactor vessel internals aging management guidance. A gap analysis based on MRP-227, Revision 1-A, "Materials Reliability Program: Pressurized Water Reactor Internals Inspection and Evaluation Guidelines," identified enhancements to the reactor vessel internals inspection recommendations for the subsequent period of extended operation. In support of the gap analysis, detailed deterministic (discrete ordinate transport 2-D) and Monte Carlo ONS reactor vessel internals calculations were performed to justify that MRP-189, Revision 3 is applicable to ONS during the subsequent period of extended operation, and to justify that 72 EFPY neutron exposure used to update the reactor vessel internals TLAA reported in BAW-10008 for the SPEO is in compliance with NUREG-2191, X.M2. The reactor vessel internals will be monitored along with the reactor pressure vessel as part of the *Neutron Fluence Monitoring* AMP.

Ex-vessel cavity dosimetry is used to monitor neutron fluence because the Oconee units do not currently have in-vessel surveillance capsules. Only the ONS Unit 2 reactor vessel has installed cavity dosimetry. However, the ONS Unit 1 and ONS Unit 3 reactor vessel fluence uncertainty values are based on Oconee Unit 2 cavity dosimetry results due to similar design, fabrication, operation, and fuel loading patterns.

The use of the ONS Unit 2 cavity dosimetry for Oconee Unit 1 and Oconee Unit 3 was approved by the NRC in a letter to Duke Power Company dated December 5, 1988 [Reference D. B. Matthews (NRC) letter dated December 5, 1988 to H.B.Tucker (Duke), Subject: "Cavity Dosimetry Program", Oconee Nuclear Station Units 1, 2, and 3 (TAC 65759, 65760, 65761), Docket Nos. 50-269, 50-270, 50-287].

Oconee utilizes cavity dosimetry as a continuous fluence monitoring device for the reactor pressure vessel beltline region. Cavity dosimetry measurements are used to verify the accuracy of reactor pressure vessel fluence calculations and to determine fluence uncertainty values. These calculations and related uncertainties determine when the neutron fluence is projected to exceed 1.0E+17 n/cm^2 (E > 1 MeV) for specific reactor vessel items during the subsequent period of extended operation and thus, require monitoring to ensure their embrittlement analyses remain below applicable limits.

Through the program, cavity dosimetry measurements are used to verify the accuracy of fluence calculations and to determine fluence uncertainty values in accordance with Regulatory Guide 1.190. This program will continue during the period of subsequent license renewal as part of the AMP for reactor pressure vessel and reactor vessel internals neutron embrittlement.

NUREG-2191 Consistency

The *Neutron Fluence Monitoring* AMP is an existing program that is consistent with NUREG-2191, Chapter X.M2, *Neutron Fluence Monitoring*, as modified by SLR-ISG-MECHANICAL-2021-02, *Updated Aging Management Criteria for Mechanical Portions of Subsequent License Renewal Guidance* (ADAMS Accession Number ML20181A434).

Exception to NUREG-2191

None

Enhancements

None

Operating Experience

Based on a broad search of pertinent Oconee operating experience, the following examples provide objective evidence that the *Neutron Fluence Monitoring* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the subsequent period of extended operation. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. ONS has utilized cavity dosimetry to support neutron fluence monitoring since the 1980s. Since all three units have a similar design, fabrication, operation, and fuel loading patterns, only the ONS Unit 2 reactor vessel has installed cavity dosimetry to support neutron fluence monitoring. The use of the ONS Unit 2 cavity dosimetry for Unit 1 and Unit 3 was approved by the NRC in a letter to Duke Power Company dated December 5, 1988. Cavity dosimetry has been irradiated at ONS Unit 2 since cycle 9. The cavity dosimeters are measured to determine the activity resulting from the fast fluence irradiation. In addition, calculations of the dosimetry activities are performed using operational data. The calculation activities are compared to the measurement activities to verify the accuracy and the uncertainty in the calculated fluence. The cavity dosimeters are measured within a frequency such that the fluence uncertainty is kept within the guidance of Regulatory Guide 1.190.

   Dosimetry was last removed during the Oconee Unit 2, cycle 28 outage (November 2017). A reactor vessel fluence analysis was performed in accordance with the requirements of RG 1.190, and the fluences reconciled to account for changes associated with the Oconee measurement uncertainty recapture power uprate license amendment request (ADAMS Accession Number ML20050D379 and ML20335A001).

OE example 1 provides objective evidence that the existing AMP activities are being effectively implemented to identify and manage aging effects of in-scope components, and that the results of these activities are used to inform and enhance the program.

2. In 2011 and 2012, action items were initiated in the corrective action program that identified improvements in the fluence projection process required to meet ONS license renewal reactor vessel integrity program commitments. The action consisted of revising a core design procedure to evaluate the impact of core design changes for their effect on reactor vessel fluence. The procedure was revised to include actions to evaluate changes in fuel cycle length, cycle operating history, and fuel assembly cross section. If fluence impacts due to core design changes are identified, the revised procedure requires entry into the corrective action program for determination of the necessary analyses and corrective actions.

   OE example 2 provides objective evidence that first license renewal program commitments have been properly implemented and that identified deficiencies are entered into the corrective action program. The corrective action program is effective in evaluating and correcting programmatic deficiencies.

3. In 2012, an action item was initiated in the corrective action program that identified actions needed to update reactor vessel integrity Time-Limited Aging Analyses (TLAAs) as a result of planned changes in the ONS fuel cycle, including (a) an increase in capacity factor, (b) Measurement Uncertainty Recapture, (c) implementation of 24-month fuel cycles, and (d) implementation of once-burned high thermal performance (HTP) fuel assemblies on the periphery. Additionally, the TLAAs were updated to account for replacing the ex-vessel dosimetry in Unit 2 (see OE example 4), and to incorporate updated fluence transport calculations to address the described changes. Actions to replace the ex-vessel dosimetry and update fluence calculations to the current end-of-life were completed in 2018.

   OE example 3 provides objective evidence that the program manager for the *Neutron Fluence Monitoring* AMP utilizes the corrective action program to self-identify changing plant conditions and to take timely corrective actions to assure that components will continue to perform their intended functions.

4. In 2016, an action item was initiated in the corrective action program to identify that the ONS existing ex-vessel dosimetry capability should be expanded to include the extended beltline region, which includes the nozzle region and the region below the active core. This work was facilitated through Duke Energy’s participation in the Pressurized Water Reactor Owners Group. Measurement data from the ex-vessel dosimetry program provides the basis for justification of neutron fluence. The work also addresses the NRC RG 1.190 requirement that licensees are required to benchmark their fluence calculational methodologies against measured data and addresses recent NRC concerns regarding the qualification basis for neutron fluence calculations outside of the traditional beltline region. This action to install ex-vessel dosimetry to monitor traditional and extended beltline regions in Unit 2 was completed in 2018.

OE example 4 provides objective evidence that the program manager for the *Neutron Fluence Monitoring* AMP critically self-assesses program performance and self-identifies actions that support continuous improvement and to assure that components will continue to perform their intended functions.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Neutron Fluence Monitoring* AMP will be effective in managing aging effects prior to loss of intended function for the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Neutron Fluence Monitoring* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry operating experience.

Conclusion

The implementation of the *Neutron Fluence Monitoring* AMP will provide reasonable assurance that reactor pressure vessel and reactor vessel internals neutron fluence input to applicable TLAA will be adequately managed so that the reactor vessel and reactor vessel internals intended functions will be maintained consistent with the current licensing basis during the SPEO.

B3.3 Environmental Qualification of Electric Equipment

Program Description

The *Environmental Qualification of Electric Equipment* AMP is an existing program that manages the aging of electrical equipment within the scope of 10 CFR 50.49, *Environmental Qualification of Electrical Equipment Important to Safety for Nuclear Power Plants*. The program includes electric equipment composed of various polymeric and metallic materials that is important to safety. This electric equipment could be subject to the harsh environment effects of a LOCA, HELB, or post-LOCA environment. The electrical equipment could be subject to an adverse localized environment due to temperature or radiation. The program establishes, demonstrates, and documents the TLAA analysis, qualification level, qualified configurations, maintenance, surveillance and periodic replacements necessary to meet 10 CFR 50.49.

Equipment qualified life is specified for equipment within the program scope and appropriate actions such as replacement, refurbishment, or reanalysis are performed prior to the end of qualified life. Changes to material activation energy values as part of a reanalysis are justified. Activities to visually inspect accessible, passive EQ electric equipment located in adverse localized environments at least once every ten years will be added to the program prior to the SPEO.

If an EQ component is determined to be outside the bounds of its qualification basis or when an unexpected adverse localized environment or condition is identified during operational or maintenance activities, the qualification of the affected EQ equipment is evaluated in the corrective action program and appropriate corrective actions are taken to resolve the condition.

The various aging effects addressed by this program are adequately managed so that the intended functions of components within the scope of 10 CFR 50.49 are maintained consistent with the CLB during the SPEO.

NUREG-2191 Consistency

The *Environmental Qualification of Electric Equipment* AMP, after enhancement, will be consistent with the ten elements of AMP NUREG-2191, Section X.E1, *Environmental Qualification of Electric Equipment*.

Exception to NUREG-2191

None

Enhancements

The following enhancements will be implemented for the following program elements: Detection of Aging Affects (Element 4) and Acceptance Criteria (Element 6)

1. Add activities to perform visual inspections of accessible, passive EQ electric equipment located in adverse localized environments at least once every 10 years. The first periodic visual inspection will be performed prior to the SPEO. (Element 4)

2. Establish acceptance criteria for the visual inspection of accessible passive EQ electric equipment located in adverse localized environments. (Element 6)

<u>Operating Experience</u>

Based on a broad search of pertinent ONS OE, the following examples provide objective evidence that the *Environmental Qualification of Electric Equipment* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In 2011, cracked terminal block barriers on an electrical penetration were found while performing an inspection procedure. The purpose of the procedure was to inspect the material condition, clean the exterior and interior of the electrical penetration enclosures as necessary, and perform other corrective actions as identified during the inspection. The inspection procedure scope included terminal blocks and cables.

   The terminal block barrier provides electrical insulation between adjacent terminals. Based on an inspection, the portions of the barriers remaining in place were sufficient to perform the electrical insulation function. The damaged terminal blocks were replaced.

   OE example 1 provides objective evidence that visual inspections, along with the corrective action program, will effectively monitor in scope SSCs to assure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO.

2. In 2012 while performing an extent of condition as a result of a condition identified at another United States power reactor facility where motor operated valve actuator operating cycle limits were exceeded, it was discovered that an ONS containment isolation motor operated valve actuator had also exceeded the EQ program replacement interval of 2000 operating cycles. With no testing to support operation beyond 2000 cycles, the valve was declared inoperable, closed and administratively deactivated.

   Subsequent investigation and evaluations determined that due to lower than postulated thermal aging, accident temperatures, radiation exposure and mechanical stresses, there was reasonable assurance the valve would have performed its intended containment isolation function, notwithstanding exceeding the 2000 cycle limit.

   A cause analysis determined that the motor operated valve program had been using an informal spreadsheet and process to track operating cycles and predict and plan for actuator replacement before the 2000 cycle limit was reached. The cycle limit was a new design requirement for this valve type; however, the *Environmental Qualification Maintenance Manual* was never appropriately revised to reflect this limit.

Corrective actions included replacing the subject motor operated valve actuator, further extent of condition to determine if other actuators had exceeded or approaching the operating cycle limit, revising the *Environmental Qualification Maintenance Manual* to include the 2000 cycle limit and establishing an automated means of collecting motor operated valve actuator cycles.

OE example 2 objectively demonstrates the effective use of systematic and ongoing review of industry OE and the corrective action program to identify degraded conditions, perform extent of condition reviews, and take timely corrective action to ensure that intended functions are maintained during the SPEO.

3. In 2013, it was determined that due to routing of reactor coolant system chemical sample lines the analyzed radiation dose had increased both normal and accident radiation levels for limited areas inside the Unit 3 electrical equipment rooms. The postulated increased radiation resulted in these areas changing from a mild to a harsh environment as defined by the Oconee *Environmental Qualification Criteria Manual* and 10 CFR 50.49 for electrical equipment. An operability determination concluded that the affected electrical equipment, while not qualified for a harsh environment, was considered operable but required corrective actions.

   The corrective actions to resolve the concern included adding the electrical equipment to the EQ program, equipment replacement, and shielding. The option selected was to replace selected radiation sensitive electrical components at a frequency that would preclude exceeding their respective total integrated dose limits.

   OE example 3 provides objective evidence that plant modifications resulting in environmental changes affecting equipment aging are entered into the corrective action program. Appropriate corrective actions are implemented to evaluate and resolve the deficiencies using fleet EQ procedures and analytical methods.

4. In 2014, it was determined that the cable entrance sealing guidance in the solenoid valve *Environmental Qualification Maintenance Manual* required clarification. The *Environmental Qualification Maintenance Manual* cable sealing requirements state that outside containment solenoid valves do not require cable entrance sealing based on a previous operability evaluation. The operability evaluation took credit for the valve failure mode (fail close) while performing its event mitigation required function; however, this evaluation was only performed on a subset of outside containment solenoid valves.

   It was subsequently recognized that there were additional outside containment solenoid valves in the EQ program which were not previously evaluated for proper sealing with respect to event mitigation failure mode and a condition report was initiated in the corrective action program.

Corrective actions included an operability evaluation and extent of condition for the rest of the outside containment solenoid valves in the EQ program and revising the solenoid valve *Environmental Qualification Maintenance Manual*. The *Environmental Qualification Maintenance Manual* revision provided additional guidance on cable sealing requirements with respect to valve failure modes and position (energized/deenergized and fail open/fail close) for the event mitigation intended function.

OE example 4 demonstrates that the ONS EQ program is informed through the systematic and ongoing review of plant-specific OE and programmatic changes are made as necessary.

5. In 2017, a NRC component design basis inspection at another United States power reactor facility identified discrepancies between the plant-specific maintenance requirements for NAMCO EA-180 limit switches and the requirements established by the qualified equipment supplier EQ test report. The supplier documentation required whenever the switch is opened, inspections of the cover gaskets, o-rings, and other items must be performed in order to maintain the switch EQ.

   As a result, ONS performed a review to determine if similar EQ documentation discrepancies for NAMCO switches existed and it was found that ONS had the same issue. ONS actions resulting from this condition included an operability determination for the affected switches, revision of maintenance procedures and associated *Environmental Qualification Maintenance Manual* documentation to reflect vendor requirements when the switch is opened.

   OE example 5 demonstrates that the ONS EQ program is informed through the systematic and ongoing review of industry OE where evaluations are performed to improve the EQ program as necessary.

6. In 2016, a Duke General Office, Catawba, McGuire and Oconee EQ program focused self-assessment was performed in accordance with internal requirements for periodic EQ program reviews. An additional Oconee-specific EQ program 2018 self-assessment was performed as part of the readiness review for an NRC design basis assurance inspection of the Oconee EQ program.

   The objective of the 2016 and 2018 self-assessments was to compare the existing implementation of the Oconee EQ program with internal Duke EQ program procedures, 10 CFR 50.49 requirements, and NRC EQ program specific inspection procedures. The results of the 2016 and 2018 inspections identified various items for Oconee EQ program improvement that were entered into the corrective action program for resolution.

   This OE example provides objective evidence that the Oconee EQ program critically self-assesses program performance on a periodic basis and adjusts the EQ program as necessary to support continuous improvement. The corrective action program is appropriately used to identify, evaluate, and address conditions adverse to quality.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Environmental Qualification of Electric Equipment* AMP will be effective in managing aging effects prior to loss of intended function during the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for conditions where aging effects are found. Periodic assessments of the *Environmental Qualification of Electric Equipment* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Environmental Qualification of Electric Equipment* AMP, with the noted enhancements, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B3.4 Concrete Containment Unbonded Tendon Prestress

Program Description

The *Concrete Containment Unbonded Tendon Prestress* AMP is an existing program that is predicated on the ASME Section XI, Subsection IWL requirements. The program consists of an assessment of measured tendon prestress forces obtained during examinations currently performed in accordance with Subsection IWL of the ASME Code, Section XI, as incorporated by reference in 10 CFR 50.55a. This AMP includes confirmatory actions that monitor loss of containment tendon prestressing forces during the current term and will continue through the SPEO.

The program requires measurement of prestressing forces on an initial sample of each tendon group based on type (dome, hoop, vertical) and subgroups as a result of repair/replacement activities. The measurements are performed every five years, as specified in IWL-2400 and the alternate provision of IWL-2421. In addition to the random sampling used for tendon lift-off force measurement, one tendon in each group and subgroup is selected as a common tendon. The initial sample size, which may be expanded if unacceptable conditions are found such as prestressing force values less than 95% of the predicted lower limit value, is established as specified in Table IWL-2521-1.

Assessments of the results of the tendon prestressing force measurements are performed in accordance with *ASME Section XI, Subsection IWL* (B2.1.29) program to confirm adequacy of the prestressing forces. The assessment consists of a comparison of predicted lower limit values to corresponding minimum required prestressing values, and includes the development of trend lines. The acceptance criteria consist of predicted values on the forces in individual tendons and the corresponding tendon group minimum required prestressing values. The predicted lower limit value for individual tendons is developed based upon the original design criteria and CLB for the tendons. These criteria consider the same factors that are described in RG 1.35.1. The UFSAR, in Section 3.8.1.4, when describing the containment design, notes that any three adjacent tendons in any of these groups can be lost without significantly affecting the strength of the structure due to the load redistribution capabilities of the shell structure.

Trend lines, one for each tendon group, are developed using the measured tendon forces and represent the changes in mean vertical, hoop and dome prestressing forces with time. Trend line regression analysis is performed consistent with NRC Information Notice 99-10. The trend line for each tendon group and subgroup is constructed by regression analysis of all individual, measured prestressing forces in individual tendons of that group and subgroup obtained from all previous representative examinations. If the trend lines do not fall below the minimum required prestressing values prior to the next scheduled surveillance, the tendon prestress force is considered to be acceptable. In accordance with the requirements of 10 CFR 50.55a(b)(2)(viii)(B), an evaluation would be performed and reported in the engineering evaluation report as prescribed in IWL–3300, if the trend lines predict the prestressing forces in the containment to be below the minimum required prestressing value before the next scheduled inspection. The evaluation would include identification of corrective action, if required, prior to tendon forces falling below the minimum required prestressing value established in the design. Corrective actions may include retensioning of tendons, replacement of selected tendons with new tendons, or reanalysis of the concrete containment in order to restore the containment to the required level of structural integrity, prior to a loss of intended function.

The program requires measurement of prestressing forces on an initial sample of each tendon group based on type (dome, hoop, vertical) and subgroups that have resulted from previous Oconee tendon surveillance practice and repair/replacement activities. The measurements of the prestressing force at randomly selected tendons are performed every five years, as specified in IWL-2400. The measurements of the prestressing force at common tendons are performed on a nominal 5 year interval that considers the alternative provisions of IWL-2421. The initial sample size is established as specified in Table IWL-2521-1. The initial sample size may be expanded as the measured force values are compared to the acceptance criteria described in IWL-3221.1, if the measured forces are less than 95% of the predicted forces.

The original Oconee tendon surveillance requirements were established in the original plant Technical Specifications and Subsection IWL of the ASME Code, Section XI, as incorporated by reference in 10 CFR 50.55a. A fixed population of tendons were preselected, and the same tendons were inspected by lift-off testing for all surveillances. The surveillance program consisted of periodic inspections of nine predesignated tendons; three horizontal, three vertical, and three dome tendons on each unit. One of the three tendons in each group was detensioned and retensioned for wire sample removal on a rotational basis. As a result of repeated detensioning and retensioning, tendons were determined to be damaged to the extent that they no longer represent the tendon forces in the group as common tendons. A Technical Specification change was subsequently submitted and approved that requires 11 representative tendons (five hoop, three vertical, and three dome) to be selected randomly with one tendon in each group to be kept unchanged for the subsequent inspection. Original Oconee tendon prestressing force examination results are not included in the trend lines for the common group maintained by the *Containment Tendon Surveillance* program, except for the test results from the first year since the later results do not truly represent the tendon forces in the group as common tendons. Later results are not considered representative due to the wire removal and retensioning performed of the tendons.

Tendon prestressing force examination results for hoop and vertical tendons that were retensioned or replaced as part of the steam generator replacement project are not included in the trend lines for the hoop and vertical tendons maintained for the common group by the *Containment Tendon Surveillance* program. These tendons constitute a subgroup of hoop and vertical tendons due to the different maintenance history. There are too few examination results for these tendons to create a trend line for these subgroups and the measured tendon prestress values are significantly higher than the original tendons so that if included, the trend line would become unconservative. The examination results for these subgroups currently exceed the minimum required prestressing value and the predicted lower limit.

The plotted trend line results provide reliable, reasonable, and adequate data regarding the amount of tendon prestress force losses experienced during the early years of plant operation. The plotted data is adequate to define the recent trend in prestress tendon force losses to ensure that, for continuity of containment structural integrity, tendon prestress forces remain above the minimum required prestressing value during the SPEO.

NUREG-2191 Consistency

The Oconee *Concrete Containment Unbonded Tendon Prestress* AMP is an existing program that is consistent with the ten elements of AMP X.S1, *Concrete Containment Unbonded Tendon Prestress* specified in NUREG-2191 (GALL-SLR) with exceptions as described below.

Exception 1 to NUREG-2191

The following program element(s) have exceptions:

Program Element Affected: Parameters Monitored or Inspected (Element 3)

1. The initial common tendon prestress lift-off force data in the TLAA figures in Section 4.5 were obtained from the first year sampled tendons, which were then detensioned and retensioned, as well as subject to wire removals, which is not in accordance with IWL-2521(b) requirements for common tendons, and is considered to be an exception for this element

   Justification for Exception 1

   1. The original dome, horizontal, and vertical surveillance tendons were not random but were uniquely defined, and although re-tensioned during each surveillance subsequent to the first year surveillance, the plotted results can still provide reliable, reasonable, and adequate data on the amount of losses experienced during the early years of plant operation.

   2. The initial program, although different from that required by *ASME Section XI, Subsection IWL* (B2.1.29), provided a continuous monitoring of containment tendon prestress forces by targeting specific segments of the containment to ensure that, for continuity of containment structural integrity, tendon prestress forces remain above the minimum required prestressing during the SPEO.

   3. The dome, horizontal, and vertical historical tendon lift-off force datapoints in conjunction with those obtained from beyond 1997 are adequate to define the recent trend in prestress tendon forces losses.

   4. The average of the dome, horizontal, and vertical historical tendon lift-off force datapoints for each group for each examination exceed the minimum required prestressing with significant margin.

Exception 2 to NUREG-2191

Program Element Affected: Monitoring and Trending (Element 5)

2. All measured prestressing forces up to the current examination are not plotted against time. The original Oconee tendon prestressing force examination results are not included in the current trend lines, except for the test results from the first year since the results do

not truly represent the tendon forces in the group as common tendons and can result in misleading trend lines if included, due to the wire removal and retensioning of the tendons. In addition, the tendon prestressing force examination results for those hoop and vertical tendons that were retensioned or replaced as part of the steam generator replacement project are not included in the current trend lines. This is considered to be an exception for this element.

Justification for Exception 2

1. The original dome, horizontal, and vertical surveillance tendons were not random but were uniquely defined, and although re-tensioned during each surveillance subsequent to the first year surveillance, the plotted results can still provide reliable, reasonable, and adequate data on the amount of losses experienced during the early years of plant operation.

2. The initial program, although different from that required by *ASME Section XI, Subsection IWL* (B2.1.29), provided a continuous monitoring of containment tendon prestress forces by targeting specific segments of the containment to ensure that, for continuity of containment structural integrity, tendon prestress forces remain above the minimum required prestressing during the SPEO.

3. The dome, horizontal, and vertical historical tendon lift-off force datapoints in conjunction with those obtained from beyond 1997 are adequate to define the recent trend in prestress tendon forces losses.

4. The average of the dome, horizontal, and vertical historical tendon lift-off force datapoints for each group and subgroup for each examination exceed the minimum required prestressing with significant margin.

5. The number of tendon examination results that are not included in the trend lines is small with respect to the total number of tendons as a result of the different maintenance histories for the original common tendons or those tendons affected by the steam generator replacement project. This limits the potential impact on the containment intended function to what be expected to be a small value.

Enhancements

None

Operating Experience

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Concrete Containment Unbonded Tendon Prestress* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the CLB for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In September 2020, an AMP effectiveness review was performed on the containment inservice inspection program. The containment inservice inspection program was evaluated against the performance criteria identified in NEI 14-12 "Aging Management Program Effectiveness." The review concluded that the containment inservice inspection program is meeting the requirements of NEI 14-12. No gaps were identified during the effectiveness review.

   In 2008, a self-assessment was completed by Duke Energy corporate engineering personnel to identify and evaluate risks to the integrity of post-tensioned containments across the fleet, and to identify programs used to monitor or prevent conditions that could lead to a failure of containment integrity. For those risks not managed effectively by one or more of these programs, this assessment developed recommendations that would help to better manage or reduce these risks. This assessment focused on the following site programs and sources of information: 1. ASME Code, Section XI Inservice Inspection Program (*Containment Inservice Inspection* Program); 2. *Boric Acid Corrosion* Program; 3. *10 CFR 50, Appendix J* Program; 4. *Coatings* Program; 5. OE data. Each of the programs are intended to either prevent unacceptable degradation or help to identify degradation before it has progressed to a state that threatens the leak-tight or structural integrity of the containment. The assessments were based upon a review of the Duke Energy fleet as well as industry OE, which included loss of tendon prestressing forces. It was concluded that these programs help to manage risks that can challenge containment integrity and that overall, these programs at Oconee are satisfying their established purposes. Risks that might result in containment tendon degradation were evaluated that result in an excessive, unexpected loss of tendon prestress, which has not been identified at Oconee. These risks fall within the scope of the *ASME Section XI, Subsection IWL* AMP and generally involve material condition issues or containment concrete temperatures not adequately addressed during original containment design and construction. No recommended improvements to the trending of the tendon prestress forces were identified as part of this assessment. In addition, degradation mechanisms and conditions described in NUREG/CR-7111 with respect to a loss of tendon prestress forces have subsequently been reviewed and found to have been adequately addressed by the 2008 assessment.

   OE example 1 provides objective evidence that self-assessments are performed to verify compliance with requirements, plant and industry OE is considered, and corrective actions are taken if deficiencies are identified.

2. In 2012, a calculation was developed to provide information related to *Concrete Containment Unbonded Tendon Prestress* AMP as it related to the tendon prestress TLAA. The calculation was performed as part of Oconee LR implementation. The tendon prestress TLAA calculation provided evidence that the loss of containment tendon prestress is adequately managed consistent with 10 CFR 54.21 (c)(1)(iii) during the PEO.

   Acceptance criteria for tendon surveillance were identified as given in terms of prescribed lower limits and minimum required values and shown in Oconee implementing documents. It was documented that each prescribed lower limit line was extended to 60 years of plant operation and remain above the minimum required values for all three tendon groups. The calculation also provides a comprehensive basis for any further activities that may be required for this program.

The calculation documented that the surveillance requirements include examinations of post-tensioning system and trending of prestressing forces in tendons in accordance with Section XI*, Subsection IWL* of the ASME Boiler and Pressure Vessel Code. In addition to the random sampling used for tendon examination, one tendon of each type is selected from the first-year inspection sample and designated as a common tendon. The common tendons are examined every ten years (+/-12 months). Any condition which fails to meet the acceptance standards of Section XI, *Subsection IWL* is considered an indication of abnormal degradation requiring corrective actions. It was concluded that the testing and trending requirements within the AMP will maintain prestressing forces above minimum levels required, through the first PEO.

The calculation documented that the tendon surveillances done to date have not identified any adverse trends in the tendon prestress forces. The TLAA calculation provided the basis to conclude that the continuation of the *Containment Tendon Surveillance* Program, in accordance with Section XI, *Subsection IWL* of the ASME Boiler and Pressure Vessel Code, and the testing and trending required by this AMP will ensure prestressing forces remain above minimum levels, through the PEO.

OE example 2 provides objective evidence of programmatic aspects of the existing *Concrete Containment Unbonded Tendon Prestress* AMP that contribute to effectively monitor and manage the containment tendon prestress forces. This example provides objective evidence that plant-specific and industry OE that potentially involves aging is evaluated and used to adjust the program as necessary.

3. During the Oconee Unit 3 40th year surveillance in 2015, a small increase in the prestress force in two common tendons was observed. The measured increase in the tendon prestress forces was less than 1% of the total tendon prestress force. The evaluation of the examination results identified that an increase in the tendon prestress force for two common tendons had been measured and compared the magnitude of the accuracy of the measurements. In accordance with IWL-2522(b), the accuracy of the calibration shall be within 1.5% of the specified minimum ultimate strength of the tendon. It was determined that the that the magnitude of the small increase was within the allowable margin in the accuracy of the tendon lift-off force measurements.

   OE example 3 provides objective evidence that upward trending tendon measurements are further assessed as part of the development of the Section XI, *Subsection IWL* examination reports. This OE provides objective evidence that program inspection methods effectively monitor tendon prestress values, and that appropriate aging management will be performed during the SPEO.

4. During tendon surveillances conducted on Unit 1 during 2016, lift-off examinations were performed on either end of a tendon located adjacent to the top of the steam generator replacement opening and is located in existing concrete. This is an augmented examination associated with repair and replacement activities during the steam generator replacement, required in accordance with IWL-2521.2. This work was performed per work

management processes. The liftoff exam for End 1 of the subject tendon was performed and the maximum ram pressure was achieved without successful liftoff. The liftoff of End 2 of the subject tendon was performed and liftoff was achieved at an average ram pressure that equates to approximately 440 kips. The minimum required value tendon force is 565 kips. The predicted lower limit is 634.7 kips, which accounts for tendon relaxation after original tensioning. The recorded liftoff of End 2 was less than the minimum required value, less than the predicted lower limit, and significantly lower than End 1. The condition was entered into the corrective action program, which directed that lift-off testing be repeated and witnessed by engineering. During the repeat lift-off test, the subject tendon successfully met the acceptance criteria. Based on the retest, it was concluded there was a discrepancy in the performance and documentation of the initial test.

OE example 4 provides objective evidence that program inspections, along with the corrective action program, will effectively monitor in scope SSCs to assure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO.

5. In 2017, a calculation was developed to consolidate the documentation of tendon prestress forces from original construction and subsequent inservice inspections that are used to determine tendon force trends, which are used in the evaluation of tendon forces in accordance with IWL-3221.1(c). The consolidated data documented in this calculation provides the means for trending of tendon forces to be used in evaluation of inservice inspection surveillance results in order to meet the code requirements presented in ASME Section XI, *Subsection IWL*. It was found that the current trends indicate tendon prestress losses consistent with predicted values and that some tendon groups have a higher probability of being lower than predicted values. No tested values were found lower than minimum required values. No changes to the AMP were recommended.

   OE example 5 provides objective evidence of programmatic aspects of the existing *Concrete Containment Unbonded Tendon Prestress* AMP that contribute to effectively monitoring and managing the containment tendon prestress forces. This operating experience provides objective evidence that the corrective action program is used to resolve discrepancies in test results, and drives additional actions to resolve the discrepancies.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Concrete Containment Unbonded Tendon Prestress* AMP will be effective in managing aging effects prior to loss of intended function during the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Concrete Containment Unbonded Tendon Prestress* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

Conclusion

The implementation of the *Concrete Containment Unbonded Tendon Prestress* AMP will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

B4.0 Plant-Specific Aging Management Programs

B4.1 Secondary Shield Wall Tendon Surveillance

Program Description

The *Secondary Shield Wall Tendon Surveillance* AMP is an existing condition monitoring program that manages aging effects associated with the tendons and tendon anchorage in the reactor building secondary shield wall. The secondary shield wall tendon system assures the structural adequacy of the secondary concrete shield wall, which provides structural support, shelter and protection to safety related systems, structures, and components. There are no preventive or mitigative actions associated with this program. The program manages for loss of material, cracking, and loss of tendon prestress by conducting visual inspections and tendon lift-off tests in accordance with station procedures. These are performed on three randomly selected horizontal tendons every other outage. Acceptance criteria outlined in station specifications and procedures ensures appropriate corrective actions are taken based on the observed and/or measured conditions. If an inspection identifies a degraded condition associated with a tendon or the tendon anchorage, the corrective action program is utilized to facilitate repair or replacement activities.

Aging Management Program Elements

The results of an evaluation of each element against the 10 elements described in Appendix A of NUREG-2192, *Standard Review Plan for Review of Subsequent License Renewal Applications for Nuclear Power Plants*, are provided below.

Scope of Program – Element 1

The plant-specific *Secondary Shield Wall Tendon Surveillance* AMP includes the tendon wires and tendon anchorage hardware, including bearing plates, anchor-heads, bushing, button-heads, and shims of the Units 1, 2, and 3 secondary shield wall tendons.

The primary purpose of the secondary shield wall is to resist the pressure and jet loads resulting from a design postulated pipe rupture. The secondary shield walls are designed so that sections can be removed. The structural adequacy of the removable sections is assured by the associated post-tensioned tendon assemblies. The primary strength of the removable sections of the wall is provided by horizontal tendons as well as conventional reinforcing bars in each panel. Vertical tendons provide continuity through the horizontal joints. The remaining portions of the secondary shield walls are of conventional concrete design. The steam generator lateral supports attach to the inner face of the secondary shield wall. The tendon system is designed in accordance with ACI 318-63. Each tendon is comprised of ninety (90) 0.25” diameter wires.

Preventive Actions – Element 2

The existing AMP is a condition monitoring activity. There are no preventative or mitigative actions associated with this AMP.

Parameters Monitored or Inspected – Element 3

The *Secondary Shield Wall Tendon Surveillance* program utilizes visual inspections to inspect for loss of material and cracking of tendon anchorage, bearing plates, and shims. Tendon wires are inspected for loss of material and breakage, and button-heads are inspected for cracks, splits or broken button-heads. The program also monitors for loss of preload (prestress) by comparing measured lift-off forces to the established minimum required force for each tendon group, as described in station procedures.

Oconee performs visual inspections and lift-off tests on three randomly selected horizontal tendons every other refueling outage.

Detection of Aging Effects – Element 4

The *Secondary Shield Wall Tendon Surveillance* AMP detects aging effects prior to the loss of the secondary shield wall tendon intended function. This AMP is based on performing secondary shield wall tendon surveillances in accordance with site specific procedures.

Visual inspections and lift-off tests are performed on three randomly selected horizontal tendons every other refueling outage. Visual inspections include looking for moisture, discoloration, foreign matter, rust, corrosion, splits or cracks in the button-heads, broken or missing wires, and other obvious damage.

Lift-off testing is performed on a selected number of tendons every other refueling outage. Lift-off forces are measured and compared to established acceptance criteria.

Monitoring and Trending – Element 5

Condition monitoring for degradation of tendon wires and anchorage is performed by periodic visual inspections, looking for loss of material and cracking. The program also requires monitoring loss of prestress by comparing the measured lift-off forces to the established minimum required force for each tendon group, as specified in station procedures. Station procedures will be enhanced to include reviewing previous visual inspection results for tendon wires and anchorages condition, and lift-off results for the tendons selected for inspection.

Acceptance Criteria – Element 6

The acceptance criteria includes no unacceptable visual indication of moisture, discoloration, foreign matter, rust, corrosion, splits or cracks in the button-heads, broken or missing wires, and other obvious damage. Station procedures define limits of acceptability. Areas that do not meet the acceptance criteria are evaluated for continued service or corrected by repair or replacement.

Lift-off forces are measured and compared to established acceptance criteria described in station procedures. The minimum required forces for the tendon groups range from 390 kips to 560 kips depending on the location of the group. Tendons that do not meet the required lift-off forces are subject to remedial actions such as retensioning or replacement.

Corrective Actions – Element 7

Results that do not meet acceptance criteria are addressed as conditions adverse to quality or significant conditions adverse to quality in the Duke Energy corrective action program. The corrective action program is implemented in accordance with the requirements of 10 CFR 50, Appendix B, Criterion XVI and *Duke Energy Topical Report*. *Duke Energy Topical Report* is incorporated by reference into the Oconee UFSAR. A single program is used regardless of the safety classification of the structure or component. Conditions adverse to quality, such as failures, malfunctions, deviations, defective material and equipment, and non-conformances, are promptly identified and corrected. Corrective actions are implemented through the initiation of a nuclear condition report for actual or potential problems, correction of an equipment deficiency, or the need for corrective maintenance. Site documents that implement AMPs for LR direct that a nuclear condition report be prepared in accordance with those procedures whenever non-conforming conditions are found (i.e., the acceptance criteria are not met). The corrective action procedures specify steps for promptly reporting, evaluating, and correcting conditions adverse to quality and significant conditions adverse to quality commensurate with the significance of the SSC or activity.

The QA program is described in the *Duke Energy Corporation Topical Report,* which implements the requirements of 10 CFR 50, Appendix B, *"Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants."* The Duke Energy QA program includes the three elements of corrective actions, confirmation process, and administrative controls, which are applicable to the safety related and non-safety related structures, components and commodity groups that are subject to aging management review.

Inspections are performed in accordance with station procedures. The results of the inspection determine if the tendon is acceptable as is or in need of repairs such as re-tensioning with re-inspection during the subsequent inspection or replacement. This process ensures that the tendon intended function will be maintained consistent with the CLB through the SPEO.

Confirmation Process – Element 8

The Duke Energy corrective action program contains confirmation process measures for assuring that conditions adverse to quality are promptly identified and corrected. The focus of the confirmation process is on the follow-up actions that must be taken to verify effective implementation of corrective actions. The measure of effectiveness is in terms of correcting and precluding repetition of adverse conditions. The corrective action program stresses that verification of implementation and close-out of corrective action documentation take place and contains measures to monitor these activities by facility and oversight personnel.

Plant procedures, including procedures related to AMPs required for SLR, include provisions for timely evaluation of adverse conditions and implementation of corrective actions required, including root cause evaluations and prevention of repetition where appropriate (e.g., significant conditions adverse to quality).

The corrective action program procedures provide for tracking, coordinating, monitoring, reviewing, verifying, validating and approving corrective actions, and ensure that corrective actions have been effectively implemented. The corrective action process is also monitored for potentially adverse trends. Identification of a potentially adverse trend due to recurring or repetitive unacceptable conditions will result in the initiation of a nuclear condition report.

The QA program is described in the *Duke Energy Corporation Topical Report*, which implements the requirements of 10 CFR 50, Appendix B, *"Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants."* As noted in the QA program topical report, the Duke Energy QA program includes the three elements of corrective actions, confirmation process, and administrative controls, which are applicable to the safety related and non-safety related structures, components and commodity groups that are subject to aging management review.

The *Secondary Shield Wall Tendon Surveillance* program does not rely on NRC endorsed technical or topical reports.

Administrative Controls – Element 9

Administrative controls apply to both safety related and non-safety related structures, components and commodity groups within the scope of this program which are subject to aging management review.

The QA program is described in the *Duke Energy Corporation Topical Report*, which implements the requirements of 10 CFR 50, Appendix B, *"Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants."* As noted in the QA program topical report, the Duke Energy QA program includes the three elements of corrective actions, confirmation process, and administrative controls, which are applicable to the safety related and non-safety related structures, components and commodity groups that are subject to aging management review.

Administrative controls apply to applicable activities, documents, procedures, and instructions regardless of the safety classification of the associated system, structure, component, or commodity group. Administrative controls also provide for formal review and approval of corrective actions.

Operating Experience – Element 10

Based on a broad search of pertinent Oconee OE, the following examples provide objective evidence that the *Secondary Shield Wall Tendon Surveillance* AMP will continue to be effective in managing aging effects for SSCs within the scope of the program so that intended functions will be maintained consistent with the current licensing basis for the SPEO. This broad search included the corrective action program, metallurgical laboratory reports, programmatic inspection results and effectiveness reviews for existing AMPs.

1. In September 2020, an AMP effectiveness review was performed on the *Secondary Shield Wall Tendon Surveillance* program. The *Secondary Shield Wall Tendon Surveillance* program was evaluated against the performance criteria identified in NEI 14-12 "Aging Management Program Effectiveness." The review concluded that the program is meeting the requirements of NEI 14-12. No gaps were identified during the effectiveness review, however one enhancement was identified. The review assessed multiple aspects of the *Secondary Shield Wall Tendon Surveillance* AMP, including

commitment management, implementing activity completion and results documentation, corrective actions, and OE.

The enhancement identified is associated with tendon prestress losses. While tendon prestress losses remain above the minimum required value, they are decaying at a quicker rate than expected. Corrective actions are in place for engineering to continue monitoring and evaluating the decay rate to determine the appropriate next steps such as additional analysis on the minimum required value or re-tensioning tendons per stations procedures.

This effectiveness review provides objective evidence that the current *Secondary Shield Wall Tendon Surveillance* program is effectively managing aging and meeting all current LR commitments. This provides reasonable assurance that ongoing program effectiveness will continue in the SPEO.

2. Condition reports entered in the corrective action program identified Unit 1 (2011) and Unit 3 (2010) tendon lift-off forces that were less than 50 kips above the minimum required value (per station procedure on acceptance criteria). Station procedures state acceptance criteria requires tendon lift-off forces being greater than the minimum required force, but if the forces are less than the minimum required value plus 50 kips, results are acceptable but are subject to remedial actions like re-tensioning. Engineering evaluated each of these instances and decided not to re-tension the tendons. This was based on ASME Section XI acceptance criteria (only requires minimum required value be met), testing experience which has shown aggressive re-tensioning of secondary shield wall tendons causes loss of prestress in adjacent tendons, and engineering judgment that additional tendon force relaxation is not expected.

   Additional actions stemming from these tendon lift-off observations included re-analysis of the minimum required prestress forces for the secondary shield wall tendons, and procedural changes that may be required based on the results of the re-analysis.

   OE example 2 provides objective evidence that program inspections, along with the corrective action program, will effectively monitor in scope SSCs to assure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO.

3. In November 2018, while performing Unit 1 secondary shield wall tendon surveillance, indications were identified on the stressing washer and bushing for SW5. The bushing showed slight rust. Photos of the indications were taken and an evaluation was performed. The evaluation determined that the indications were acceptable and no repairs were required. The remaining parts of the anchorage (button-head, bearing plate, shims) were acceptable. A lift-off was also performed with acceptable results.

   OE example 3 provides objective evidence that program inspections, along with the corrective action program, will effectively monitor in scope SSCs to assure that these components will continue to perform their intended functions, and that appropriate aging management will be performed during the SPEO.

The above examples of OE provide objective evidence that the aging management activities and methods being implemented by the *Secondary Shield Wall Tendon Surveillance* AMP will be effective in managing aging effects prior to loss of intended function during the SPEO.

Appropriate guidance for evaluation or corrective actions for additional inspections, reevaluation, repairs, or replacements is provided for locations where aging effects are found. Periodic assessments of the *Secondary Shield Wall Tendon Surveillance* AMP are performed to identify the areas that need improvement to maintain effective performance of the program. The program is informed and enhanced, when necessary, through the systematic and ongoing review of both plant-specific and industry OE.

<u>NUREG-2191 Consistency</u>

The *Secondary Shield Wall Tendon Surveillance* AMP is not described in NUREG-2191. The *Secondary Shield Wall Tendon Surveillance* AMP is an existing Oconee plant-specific AMP that will be consistent with the ten elements of an AMP described in NUREG-2192, *"Standard Review Plan for Review of Subsequent License Renewal Applications for Nuclear Power Plants"* with the enhancement noted below.

<u>Exception to NUREG-2191</u>

Plant-Specific Program

<u>Enhancements</u>

The following enhancements will be implemented in the following program element: Monitoring and Trending (Element 5)

1. Enhance station procedures to include a review of previous visual inspection and lift-off data results for the tendons selected for inspection. (Element 5)

<u>Conclusion</u>

The implementation of the *Secondary Shield Wall Tendon Surveillance* AMP, with the noted enhancement, will provide reasonable assurance that the identified aging effects will be adequately managed so that the intended functions of components within the scope of this program will be maintained consistent with the CLB during the SPEO.

Technical Specification Changes

APPENDIX D

TECHNICAL SPECIFICATION CHANGES

10 CFR 54.22 requires that an application for LR include any Technical Specification changes or additions necessary to manage the effects of aging during the PEO.

No Technical Specification changes or additions were identified as necessary to manage the effects of aging during the SPEO and as such no Technical Specification changes or additions are included with this SLRA.
