10 CFR 54

ATTN: Document Control Desk
U.S. Nuclear Regulatory Commission
Washington, DC 20555-0001

Perry Nuclear Power Plant, Unit No. 1
Docket No. 50-440, License No. NPF-58
License Renewal Application for the Perry Nuclear Power Plant

Pursuant to 10 CFR Part 54, Energy Harbor Nuclear Corp. hereby submits an operating license (OL) renewal application (LRA) for the Perry Nuclear Power Plant (PNPP), Unit 1, to extend the current operating licenses an additional 20 years beyond the current expiration date.

Energy Harbor also requests renewal of the source, special nuclear material, and by-product licenses under 10 CFR Parts 30, 40, and 70 that are subsumed in or combined with the current PNPP OL.

On October 8, 2020, the NRC issued Amendment 191 to the PNPP OL (ML20216A354), which extended the PNPP OL expiration date approximately 7.7 months, such that it expires 40 years from the date of issuance of the full power operating license (FPOL) as opposed to the issuance date of the low power testing license (NPF-45). Therefore, with the requested approval of the enclosed renewal application, the expiration of the PNPP OL (NPF-58) would be extended from midnight, November 7, 2026, to midnight, November 7,2046.

On July 13, 2020, the NRC approved an exemption for PNPP from 10 CFR 54.17(a) and 10 CFR 2.109(b) Section 2 (ML20171A277) requirements that provide timely renewal protection to licensees that submit sufficient license renewal applications at least 5 years before the expiration of the existing license. The approved exemption allows Energy Harbor to submit an LRA for PNPP at least 3 years prior to the expiration of its existing license, and, if the application is sufficient, still receive timely renewal protection.

On April 14, 2023 (ML23110A788), Vistra Operations Company, on behalf of Energy Harbor Nuclear Corp. and Energy Harbor Nuclear Generation LLC, applied for an order consenting to transfer of the PNPP operating license (OL) from Energy Harbor Nuclear Corp. to Vistra Operations Company LLC (VistraOps). NRC approval of the license transfer is requested no later than October 2023. Therefore, it is anticipated that the license transfer from Energy Harbor Nuclear Generation LLC to VistraOps will be approved within the early review period of the enclosed LRA, and the PNPP license transfer change will be reflected in a supplement, if required, or the next annual update to this application, whichever comes first.

The enclosed LRA contains the information required by 10 CFR Part 54. The application contains technical information required by 10 CFR 54.21 and includes an environmental report prepared in accordance with 10 CFR 54.23 and Subpart A of 10 CFR 51.

In accordance with 10 CFR 54.21(b), each year following submittal of the LRA and at least three months before the scheduled completion of the staff's review, Energy Harbor will submit an LRA amendment identifying any current licensing basis changes that materially affect the contents of the LRA, including the Updated Final Safety Analysis Report (UFSAR) supplement.

PNPP LRA Appendix A, Table A.3, "License Renewal Commitments", provides a summary of the commitments made in the application. This summary will be updated as required throughout the LRA review process.

If there are any questions, or if additional information is required, please contact Mr. Mark Bensi, PNPP License Renewal Project Manager (440) 280-6179 or via email at mjbensi@energyharbor.com.

I declare under penalty of perjury that the foregoing is true and correct. Executed on July 3, 2023.

Sincerely,

Rod L. Penfield

PERRY NUCLEAR POWER PLANT

July 2023

LICENSE RENEWAL APPLICATION

PREFACE

The following describes the location, layout, and editorial conventions in the Perry Nuclear Power Plant (PNPP) License Renewal Application (hereinafter referred to as "this application" or "the application"). Abbreviated names and acronyms used throughout the application are defined at the end of this preface. Commonly understood terms (such as U.S.) and terms used only in referenced document numbers may not be identified in this table. Regulatory documents such as NUREG-1801, *Generic Aging Lessons Learned (GALL) Report*, and 10 CFR Part 54, *Requirements for Renewal of Operating Licenses for Nuclear Power Plants* (the license renewal rule), are referred to by the document number, i.e., NUREG-1801 and 10 CFR 54, respectively. References to the UFSAR are to the Perry Updated Final Safety Analysis Report.

Section 1 provides administrative information required by 10 CFR 54.17 and 10 CFR 54.19.

Section 2 describes and justifies the methods used to determine the systems and structures within the scope of license renewal and the structures and components subject to aging management review. The results of the system and structure scoping are provided in Tables 2.2-1 through 2.2-6. Tables 2.2-1, 2.2-2, 2.2-3 and 2.2-4 list mechanical systems, structures, and electrical systems within the scope of license renewal. Tables 2.2-5 and 2.2-6 list the mechanical systems and structures, respectively, not in the scope of license renewal. Section 2 also provides descriptions of in-scope systems and structures and their intended functions with tables identifying components and commodities requiring aging management review and their component intended functions. References are provided to the results of the aging management reviews in Section 3. The descriptions of systems in Section 2 identify license renewal drawings that depict the components subject to aging management review for mechanical systems, some structures, and for electrical station blackout. These license renewal drawings will be made available for NRC review.

Section 3 describes the results of aging management reviews of mechanical, electrical and structural components requiring aging management review. Section 3 is divided into sections that address (1) the Reactor Vessel, Internals, and Reactor Coolant System, (2) Engineered Safety Features, (3) Auxiliary Systems, (4) Steam and Power Conversion Systems, (5) Containments, Structures, and Component Supports, and (6) Electrical and Instrumentation and Controls. The tables in Section 3 provide a summary of information concerning aging effects requiring management and applicable aging management programs for component and commodity groups subject to aging management review. The information presented in the tables is based on industry guidance on the format and content of NUREG-1800, *Standard Review Plan for the Review of License Renewal Applications for Nuclear Power Plants*. The tables include comparisons with the evaluations documented in NUREG-1801, *Generic Aging Lessons Learned (GALL) Report* as modified by applicable NRC Interim Staff Guidance (ISG) documents for license renewal.

Section 4 addresses time-limited aging analyses (TLAAs), as defined by 10 CFR 54.3. It includes identification of the component or subject and an explanation of the time-dependent aspects of the calculation or analysis. Section 4 demonstrates whether (1) the analyses remain valid for the period of extended operation, (2) the analyses have been projected to the end of the period of extended operation, or (3) the effects of aging on the intended function(s) will be adequately managed for the period of extended operation. Section 4 also confirms that no 10 CFR 50.12 exemption based on time-limited aging analyses as defined in 10 CFR 54.3 is required during the period of extended operation. The information in Section 4 fulfills the requirements for an evaluation of TLAAs in 10 CFR 54.21(c).

Appendix A, Updated Safety Analysis Report Supplement, provides a summary description of programs and activities for managing the effects of aging for the period of extended operation. A summary description of the evaluation of time-limited aging analyses for the period of extended operation is included. A listing of the license renewal commitments related to aging management programs and time-limited aging analyses for the period of extended operation is also included. Following issuance of the renewed license, the material contained in this appendix will be incorporated into the UFSAR. The information in Appendix A fulfills the requirements in 10 CFR 54.21(d).

Appendix B, Aging Management Programs and Activities, describes aging management programs and activities that will manage aging effects on components and structures within the scope of license renewal such that they will continue to perform their intended functions consistent with the current licensing basis for the period of extended operation. Appendix B contains a comparison of the PNPP programs to the programs evaluated in NUREG-1801. The information in Section 2, Section 3, and Appendix B fulfills the requirements of 10 CFR 54.21(a).

Appendix C is the site response to Boiling Water Reactor Vessel and Internals Project (BWRVIP) Applicant Action Items. License renewal applicant action items identified in the corresponding NRC safety evaluation for each of the reports listed are addressed in this appendix.

Appendix D, Technical Specification Changes, concludes that no technical specification changes are necessary to manage the effects of aging during the period of extended operation. The information in Appendix D fulfills the requirements in 10 CFR 54.22 to identify changes to Technical Specifications.

Appendix E, Applicant's Environmental Report – Operating License Renewal Stage, contains the environmental information which fulfills the requirements of 10 CFR 54.23 and 10 CFR 51.53(c).

ABBREVIATIONS AND ACRONYMS

The acronyms that are defined in this application are listed below, with their definitions:

Acronym	Definition
¼T	one-fourth of the way through the vessel wall measured from the internal surface of the vessel
ABN	absorb neutrons
ABVS	auxiliary building ventilation system
AC	alternating current
ACI	American Concrete Institute
ACSR	aluminum conductor steel reinforced
ADHR	alternate decay heat removal
ADS	automatic depressurization system
AEGTS	annulus exhaust gas treatment system
AEM	aging effect/mechanism
AFP	auditable file packages
AHU	air handling unit
ALARA	as low as (is) reasonably achievable
AMP	aging management program
AMR	aging management review
ANSI	American National Standards Institute
APRM	average power range monitor
ART	adjusted reference temperature
ASME	American Society of Mechanical Engineers
ASTM	American Society for Testing and Materials
ATWS	anticipated transient without scram
B&PV	boiler and pressure vessel
BOP	balance of plant
BTP	Branch Technical Position
BWR	boiling water reactor
BWRVIP	Boiling Water Reactor Vessel and Internals Program
CAS	central alarm station
CASS	cast austenitic stainless steel
CB&I	Chicago Bridge & Iron
CBF	cycle based fatigue

Acronym	Definition
CCGCS	containment combustible gas control system
CCW	component cooling water
CE	Conducts electricity
CEI	Cleveland Electric Illuminating (company)
CF	chemistry factor
CFR	Code of Federal Regulations
CLB	current licensing basis
CMAA	Crane Manufacturers Association of America
CMTR	certified material test report
CO2	carbon dioxide
Corp.	corporation
CRD	control rod drive
CRDA	control rod drop accident
CRDRL	control rod drive return line
CSS	core support structure
CST	condensate storage tank
CTS	condensate transfer and storage
Cu	copper
CUF	cumulative usage factor
DC	direct current
DF	direct flow
DGBVS	diesel generator building ventilation system
DO	dissolved oxygen
DPA	displacement per atom
E&IC	electrical and instrumentation and controls
EAF	environmentally-assisted fatigue
ECC	emergency closed cooling
ECCS	emergency core cooling system
ECP	electrochemical corrosion potential
ECPCS	emergency closed cooling pump area cooling system
EFDS	equipment and floor drainage system
EFPY	effective full power years

Acronym	Definition
EN	enclosure (shelter or protection)
EOC	end of cycle
EOF	emergency operations facility
EPRI	Electric Power Research Institute
EQ	environmental qualification
ESF	engineered safety feature
ESW	emergency service water
ESWVS	emergency service water ventilation system
EXP	expansion (thermal, or seismic separation)
F (°F)	degrees Fahrenheit
FAC	flow-accelerated corrosion
FB	fire barrier
FCV	flow control valve
F_{en}	environmentally assisted fatigue correction factor
FENOC	FirstEnergy Nuclear Operating Company
FERC	Federal Energy Regulatory Commission
FHAES	fuel handing area exhaust subsystem
FHAR	fire hazards analysis report
FHASS	fuel handling area supply subsystem
FHAVS	fuel handling area ventilation system
FLB	flood barrier
FME	foreign material exclusion
FP	fire protection
FPCC	fuel pool cooling and cleanup
FPCCS	fuel pool cooling and cleanup system
ft-lb	foot-pound
FW	feedwater
FWLC	feedwater leakage control
GALL	Generic Aging Lessons Learned
GDC	general design criterion
GE	General Electric
GL	Generic Letter
GSI	generic safety issue

Acronym	Definition
H2	hydrogen
HAZ	heat-affected zone
HCU	hydraulic control unit
HDPE	high density polyethylene
HELB	high-energy line break
HEPA	high-efficiency particulate air
HPCS	high pressure core spray
HS	heat sink
HVAC	heating, ventilation, and air conditioning
HWC	hydrogen water chemistry
HWC with NMCA	hydrogen water chemistry with noble metal chemical application
HX	heat exchanger
Hz	hertz
I&C	Instrumentation and Controls
IASCC	irradiation-assisted stress corrosion cracking
ICM	integrated containment management
ID or I.D.	inside diameter
IEEE	Institute of Electronic and Electrical Engineers
IGSCC	inter-granular stress corrosion cracking
ILRT	integrated leak rate test
IN	Information Notice
INPO	Institute of Nuclear Power Operations
IPA	integrated plant assessment
IRM	intermediate range monitor
ISA	International Society of Automation
ISFSI	independent spent fuel storage installation
ISG	Interim Staff Guidance
ISI	inservice inspection
ISP	Integrated Surveillance Program
ksi	kilo-pounds per square inch
kV or KV	kilo-volt
LAS	low alloy steel

Acronym	Definition
LIP	local intense precipitation
LLC	limited liability company
LLRWSPF	low level radwaste storage and processing facility (one designation for the low level radwaste building)
LOCA	loss of coolant accident
LOOP	loss of offsite power
LPCI	low pressure coolant injection
LPCS	low pressure core spray
LPRM	local power range monitors
LR	license renewal
LRA	license renewal application
LR-ISG	Interim Staff Guidance Associated with License Renewal
LRW	liquid radioactive waste
LTOP	low-temperature overpressure protection
LWR	light water reactor
MB	missile barrier
MCC	motor control center
MgKOH	milligrams of potassium hydroxide
MeV	million electron-volts
MIC	microbiologically-influenced corrosion
MMS	mitigation monitoring system
MOV	motor operated valve
MSIP	Mechanical Stress Improvement Process
MSIV	main steam isolation valve
MSL	main steam line
MSR	moisture separator-reheater
mV	millivolt
MWe	megawatts-electrical
MWt	megawatts-thermal
N/A	not applicable
n/cm2	neutrons per square centimeter
NCC	nuclear closed cooling
NEI	Nuclear Energy Institute

Acronym	**Definition**
NEPA	National Environmental Policy Act
NESC	National Electrical Safety Code
NFPA	National Fire Protection Association
Ni	nickel
NMCA	noble metal chemical application
NPDES	National Pollution Discharge Elimination System
NPS	nominal pipe size
NRC	U.S. Nuclear Regulatory Commission
NSAC	National Safety Analysis Center
NSSS	nuclear steam supply system
NUMARC	Nuclear Utility Management and Resources Council
NWC	no water chemistry
O2	oxygen
OCCWS	open cycle cooling water system
OD or O.D.	outside diameter
OE	operating experience
OLNC	on-line noble chemistry
OSSC	on-site storage container
p., pp.	page, pages
P&ID	piping and instrumentation diagram
PA	prompt alert / public address
PAF	primary access facility
PASS	post-accident sampling system
PB	pressure boundary
PEO	period of extended operation
pH	potential of hydrogen
PNPP	Perry Nuclear Power Plant
POF	probability of failure
ppb	parts per billion
ppm	parts per million
psig	pounds per square inch gauge
P-T	pressure-temperature
PTS	pressurized thermal shock

Acronym	Definition
PVC	polyvinyl chloride
PW	pipe whip (restraint)
PWR	pressurized water reactor
PWSCC	primary water stress corrosion cracking
Q	Quality
QAPM	Quality Assurance Program Manual
RAMA	Radiation Analysis Modeling Application
RCA	radiologically controlled area
RCIC	reactor core isolation cooling
RCPB	reactor coolant pressure boundary
RCS	reactor coolant system
RG	Regulatory Guide
RHR	residual heat removal
RI-ISI	risk-informed inservice inspection
RP	release path
RPS	reactor protection system
RPV	reactor pressure vessel
RTNDT	reference temperature (nil-ductility transition)
RVI	Reactor Vessel Internals
RWCU	reactor water cleanup
Rx	reactor
RXV	reactor vessel
SAMA	severe accident mitigation alternatives
SAP	Systeme, Anwendungen und Produkte in der Datenverarbeitung [Systems, Applications and Products in Data Processing] – the plant component database
SBO	station blackout
SCBA	self-contained breathing apparatus
SCC	stress corrosion cracking
SCR	silicon controlled rectifier
SDV	scram discharge volume
SER	Safety Evaluation Report
SFDS	spent fuel dry storage
SHD	provide shielding against radiation

Acronym	Definition
SLC	standby liquid control
SLCS	standby liquid control system
SLO	single loop operation
SNS	support for non-safety affecting safety – Criterion (a)(2) equipment
SO2	sulfur dioxide
SOER	Significant Operating Experience Report
SPB	Structural pressure boundary
SPCU	suppression pool cleanup
SRE	support for regulated events – Criterion (a)(3) equipment
SRM	source range monitor
SRP	Standard Review Plan [NUREG-1800, License Renewal]
SRV	safety relief valve
SSC	system, structure, or component
SSE	safe shutdown earthquake
SSR	support for safety-related – Criterion (a)(1) equipment
STCS	steam tunnel cooling system
TAN	total acid number
TBCCW	turbine building closed cooling water
TBVS	turbine building ventilation system
TIP	traversing incore probe
TLAA	Time-Limited Aging Analysis
TMI	Three Mile Island
TPC	turbine power complex
TSC	technical support center
UFSAR	Updated Final Safety Analysis Report (same as USAR)
UPS	uninterruptible power source
USAR	Updated Safety Analysis Report (same as UFSAR)
USE	upper-shelf energy
USI	Unresolved Safety Issue
UT	Ultrasonic Testing
UTT	Ultrasonic thickness testing
VLI	valve lineup instruction
WANO	World Association of Nuclear Operators

Acronym	Definition
WARF RISB	waste abatement and reclamation facility/radwaste interim storage building (another designation for the low level radwaste building)
WLIN	water level instrumentation nozzle
Zn	zinc
ΔP	differential pressure
ΔRTNDT	shift in reference temperature for nil-ductility transition

1.0 ADMINISTRATIVE INFORMATION

Pursuant to Part 54 of Title 10 of the Code of Federal Regulations (10 CFR 54) [Reference 1.3-1], this application seeks renewal for an additional 20-year term of the facility operating license for Perry Nuclear Power Plant, Unit 1 (PNPP). The current facility operating license (Docket No. 50-440, License Number NPF-58) expires at midnight on November 7, 2026. This application also seeks renewal of the source material, special nuclear material, and by-product material licenses under 10 CFR Parts 30, 40, and 70 that are subsumed in or combined with the facility operating license.

This application is organized in accordance with U.S. Nuclear Regulatory Commission Regulatory Guide 1.188, *Standard Format and Content for Applications to Renew Nuclear Power Plant Operating Licenses*, Revision 2 [Reference 1.3-2], and is consistent with guidance provided by Nuclear Energy Institute (NEI) 95-10, *Industry Guideline for Implementing the Requirements of 10 CFR Part 54 – The License Renewal Rule*, Revision 6 [Reference 1.3-3]. In addition, a summary of those Nuclear Regulatory Commission (NRC) License Renewal Interim Staff Guidance (LR-ISG) documents that remain open is presented in the application.

This application is intended to provide sufficient information for the NRC to complete its technical and environmental reviews pursuant to 10 CFR 54, *Requirements for Renewal of Operating Licenses for Nuclear Power Plants* [Reference 1.3-1], and 10 CFR 51, *Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions* [Reference 1.3-4], respectively.

This application is designed to allow the NRC to make the findings required by 10 CFR 54.29, *Standards for Issuance of a Renewed License*, in support of the issuance of a renewed facility operating license for PNPP.

1.1 GENERAL INFORMATION

The following is the general information required by 10 CFR 54.17 and 10 CFR 54.19 [Reference 1.3-1].

Name of Applicant

Energy Harbor Nuclear Corp. (operator) is acting on its own behalf and for Energy Harbor Nuclear Generation LLC (Energy Harbor Corp.) (owner) by submitting this application. Energy Harbor Nuclear Corp. hereby applies for a renewed operating license for PNPP, Unit 1.

Address of Applicant

Energy Harbor Nuclear Corp. (operator)
168 E. Market Street
Akron, Ohio 44308

Energy Harbor Corp. (owner)
168 E. Market Street
Akron, Ohio 44308

1.1.1 NAMES OF APPLICANTS AND OWNER LICENSEES

Energy Harbor Nuclear Corp., acting on its own behalf and as agent for the owner licensee, submits this application to renew the operating license for PNPP.

Energy Harbor Nuclear Corp. is the operator-licensee for PNPP and has exclusive responsibility and control over the physical construction, operation, and maintenance of the facility. The owner is Energy Harbor Nuclear Generation LLC. Energy Harbor Nuclear Corp. and Energy Harbor Nuclear Generation LLC are owned by Energy Harbor Corp.

The PNPP operating license was transferred from FirstEnergy Nuclear Operating Company (FENOC) and FirstEnergy Nuclear Generation, LLC to Energy Harbor Nuclear Corp. and Energy Harbor Nuclear Generation LLC, respectively, in February 2020. Accordingly, this license renewal application includes reference documents that are directed to, or sourced from, FENOC. [1]

[1] Via Transmittal Letter L-23-095 dated April 14, 2023, Vistra Operations Company, on behalf of Energy Harbor Nuclear Corp. and Energy Harbor Nuclear Generation LLC, submitted an application for an order consenting to transfer of the PNPP operating license. Following approval of the Vistra request, the information in this section will be updated as part of the next annual update to this application.

1.1.2 ADDRESSES OF APPLICANTS AND OWNER LICENSEES

Energy Harbor Corp.
168 E. Market Street
Akron, OH 44308

Energy Harbor Nuclear Corp.
168 E. Market Street
Akron, OH 44308

Energy Harbor Nuclear Generation LLC
168 E. Market Street
Akron, OH 44308

Perry Nuclear Power Plant
10 Center Road
Perry, OH 44081

1.1.3 DESCRIPTION OF BUSINESS OF APPLICANT AND OWNER LICENSEES

Energy Harbor Nuclear Corp. is engaged in the business of operating nuclear generation facilities under the supervision and direction of the owners of the facilities.

Energy Harbor Nuclear Generation LLC owns nuclear generation assets and sells the output of those assets, including from PNPP, to Energy Harbor Corp. Energy Harbor Nuclear Corp. and Energy Harbor Nuclear Generation LLC are subsidiaries of Energy Harbor Corp.

1.1.4 ORGANIZATION AND MANAGEMENT OF APPLICANT AND OWNER LICENSEES

Energy Harbor Corp.

Energy Harbor Corp. is a Delaware Corporation public utility holding company. Energy Harbor Corp. is a privately-held entity. The principal office for Energy Harbor Corp. is in Akron, Ohio.

Energy Harbor Nuclear Corp.

Energy Harbor Nuclear Corp. is a wholly owned direct subsidiary of Energy Harbor Corp., a Delaware Corporation public utility holding company. The principal offices for Energy Harbor Nuclear Corp. are in Akron, Ohio. Energy Harbor Nuclear Corp. is qualified to do business in the states of Ohio and Pennsylvania.

Energy Harbor Nuclear Generation LLC

Energy Harbor Nuclear Generation LLC is a Delaware limited liability company, wholly owned by Energy Harbor Corp., and qualified to do business in the states of Ohio and

Pennsylvania. The Energy Harbor Nuclear Generation LLC principal offices are in Akron, Ohio.

Energy Harbor Corp., Energy Harbor Nuclear Corp. and Energy Harbor Nuclear Generation LLC, are not owned, controlled, or dominated by an alien, a foreign corporation, or a foreign government.

The names and business addresses of the directors and principal officers of Energy Harbor Corp., Energy Harbor Nuclear Corp. and Energy Harbor Nuclear Generation LLC, are listed in the following tables. All persons are citizens of the United States.

Energy Harbor Corp.

1.1.5 CLASS AND PERIOD OF LICENSE SOUGHT

Energy Harbor Nuclear Corp. requests renewal of the Class 103 facility operating license for PNPP, Unit 1 (facility operating license NPF-58) for a period of 20 years beyond the expiration of the current license term. License renewal would extend the facility operating license from midnight, November 7, 2026, to midnight, November 7, 2046. The facility would continue to be known as Perry Nuclear Power Plant, Unit 1, and would continue to generate electric power during the period of extended operation.

This application also includes a request for renewal of the source material, special nuclear material, and by-product material licenses under 10 CFR Parts 30, 40, and 70 that are subsumed in or combined with the current facility operating license.

1.1.6 ALTERATION SCHEDULE

Energy Harbor Nuclear Corp. does not propose to construct or alter any production or utilization facility in connection with this renewal application. No physical plant alterations or modifications have been identified as necessary in order to implement the provisions of the LRA. The current licensing basis (CLB) will be continued and maintained throughout the period of extended operation (PEO).

1.1.7 REGULATORY AGENCIES HAVING JURISDICTION

Regulatory agencies with jurisdiction over PNPP rates and services are as follows:

Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, DC 20426

Public Utilities Commission of Ohio
180 East Broad Street
Columbus, OH 43215

1.1.8 LOCAL NEWS PUBLICATIONS

The news and trade publications which circulate in the area surrounding PNPP, and which are considered appropriate to give reasonable notice of the renewal application to those municipalities, private utilities, public bodies, and cooperatives that might have a potential interest in the facility, are listed below.

Newsroom
The Plain Dealer
4800 Tiedeman Road
Brooklyn, OH 44144

1.1.9 CONFORMING CHANGES TO THE STANDARD INDEMNITY AGREEMENT

10 CFR 54.19(b) [Reference 1.3-1] requires that license renewal applications include "…conforming changes to the standard indemnity agreement, 10 CFR 140.92, Appendix B [Reference 1.3-5], to account for the expiration term of the proposed renewed license." The current Indemnity Agreement (No. B-98) for Perry Nuclear Power Plant, Unit 1, in Article VII, states that the agreement shall terminate at the time of expiration of the license specified in Item 3 of the Attachment (to the agreement). Item 3 of the Attachment to the indemnity agreement, as revised by Amendment Nos. 1 and 2, lists PNPP facility operating license number NPF-58. Energy Harbor has reviewed the original indemnity agreement and Amendments 1 through 7. Neither Article VII nor Item 3 of the attachment specifies an expiration date for license number NPF-58. Therefore, no changes to the indemnity agreement are deemed necessary as part of this application. Should the license number be changed by NRC upon issuance of the renewed license, Energy Harbor requests that NRC amend the indemnity agreement to include conforming changes to Item 3 of the attachment and other affected sections of the agreement.

1.1.10 RESTRICTED DATA AGREEMENT

This application does not contain restricted data or national security information, and Energy Harbor does not expect that any activity under the renewed license for PNPP will involve such information. However, if such information were to become involved, Energy Harbor agrees that it will appropriately safeguard such information and not permit any individual to have access to, or any facility to possess, such information until the individual or facility has been approved under the provisions of 10 CFR 25, *Access Authorization*, or 10 CFR 95, *Facility Security Clearance and Safeguarding of National Security Information and Restricted Data*.

1.1.11 REFERENCED INFORMATION

Under the provision of 10 CFR 54.17(e) [Reference 1.3-1] this application incorporates by reference information contained in previous applications for licenses or license amendments, statements, correspondence, or reports filed with the Commission, based on clear and specific references.

1.2 DESCRIPTION OF PERRY NUCLEAR POWER PLANT

The plant site is located along the southeastern shoreline of Lake Erie on an ancient lake plain approximately 50 feet above lake low water datum. It is approximately 1,030 acres in size and relatively flat. The land has a very gentle slope toward the lake and is incised by small streams which drain into the lake. Located in a rural area of Lake County, Ohio, the site is approximately seven miles northeast of Painesville, the county seat, and 35 miles northeast of Cleveland, the nearest large principal city. The eastern two thirds of the site are within the boundaries of North Perry Village while the western third is within Perry Township. Lake Erie borders the site to the north.

Two nuclear units were planned for the site. Unit 1 construction was completed, and the unit received its full power operating license in November 1986. Unit 2 construction had achieved substantial progress when, in August 1994, the Cleveland Electric Illuminating Company notified the NRC of the intent to permanently terminate construction activities for PNPP Unit 2. Some of the systems and structures that were originally to be shared by both units or intended for Unit 2 are now used to support the operation of Unit 1 (see discussion in LRA Section 2.1.1.4).

The plant has a boiling water reactor nuclear steam supply system as designed and supplied by the General Electric Company and designated BWR/6, with a Mark III containment. The rated core thermal power of the unit is 3,758 MWt. The net electrical output is 1,277 MWe and the gross electrical output is 1,327.6 MWe. These values reflect implementation of one five-percent power uprate, implemented in 2000 following NRC approval of License Amendment 112 to Operating License NPF-58. License Amendment 112 increased rated thermal power from 3,579 MWt to 3,758 MWt. The plant, including the reactor containment, was designed by Gilbert Associates, Inc., Reading, Pennsylvania, as architect-engineer and agent for the applicant.

As identified in the Updated Final Safety Analysis Report (UFSAR) [Reference 1.3-6], the Unit 1 power generation complex (power block) includes the following structures: Reactor Building, Service Building, Turbine Building, Turbine Power Complex, Auxiliary Building, Water Treatment Building, Diesel Generator Building, Radwaste Building, Fuel Handling Building, Auxiliary Boiler Building, Control Complex, Intermediate Building, and Offgas Building. Beyond the power block other structures include the Cooling Tower, Service Water Pumphouse, Emergency Service Water Pumphouse, Circulating Water Pumphouse, Independent Spent Fuel Storage Installation (ISFSI), Meteorological Tower, Low Level Radwaste Building, Fuel Oil Storage Tank and Pumphouse, Condensate Storage Tank, Hydrogen Storage Tanks, Station Switchyard, Primary Access Facility, and Training Center.

Descriptions of many of the PNPP systems and structures can be found in the USAR. Additional descriptive information about the PNPP systems and structures is provided in Section 2 of this application.

2.0 SCOPING AND SCREENING METHODOLOGY FOR IDENTIFYING STRUCTURES AND COMPONENTS SUBJECT TO AGING MANAGEMENT REVIEW AND IMPLEMENTATION RESULTS

This section describes the process for identification of structures and components subject to aging management review (AMR) in the PNPP integrated plant assessment (IPA). For the systems, structures, and components (SSCs) within the scope of license renewal, 10 CFR 54.21(a)(1) [Reference 1.3-1] requires the license renewal applicant to identify and list structures and components subject to AMR. Furthermore, 10 CFR 54.21(a)(2) requires that the methods used to identify these structures and components be described and justified. Information in this section satisfies these requirements.

The scoping and screening method is described in Section 2.1. This method is implemented in accordance with NEI 95-10, *Industry Guidelines for Implementing the Requirements of 10 CFR 54 - The License Renewal Rule*, Revision 6, June 2005 [Reference 1.3-3]. The results of the assessment to identify the systems and structures within the scope of license renewal (plant level scoping) are in Section 2.2. The results of the identification of the long-lived, passive mechanical, structural and electrical components subject to AMR (screening) are in Section 2.3 for mechanical systems, Section 2.4 for structures, and Section 2.5 for electrical and I&C systems.

Table 2.3-1 provides the definitions of component intended functions used in this application for mechanical components.

Table 2.4-1 provides a list of the abbreviations and definitions for the intended functions used in this application for structural components.

Table 2.5-1 provides the definitions of component intended functions used in this application for electrical components.

2.1 SCOPING AND SCREENING METHODOLOGY

The PNPP systems, structures and components (SSCs) scoping and screening approach, process, documents reviewed, and conclusions are described in the following sections:

- Scoping Methodology (Section 2.1.1)
- Screening Methodology (Section 2.1.2)
- Interim Staff Guidance Discussion (Section 2.1.3)
- Generic Safety Issues (Section 2.1.4)
- Conclusion (Section 2.1.5)

2.1.1 SCOPING METHODOLOGY

The License Renewal Rule (10 CFR 54), *Requirements for Renewal of Operating Licenses for Nuclear Power Plants* [Reference 1.3-1], defines the scope of License Renewal.

10 CFR 54.4(a) requires systems, structures, and components (SSCs) to be included in the license renewal process if they are:

(1) Safety-related systems, structures, and components which are those relied upon to remain functional during and following design-basis events (as defined in 10 CFR 50.49 (b)(1)) to ensure the following functions:

(i) The integrity of the reactor coolant pressure boundary;

(ii) The capability to shutdown the reactor and maintain it in a safe shutdown condition; or,

(iii) The capability to prevent or mitigate the consequences of accidents which could result in potential offsite exposures comparable to those referred to in §50.34(a)(1), §50.67(b)(2), or §100.11 of this chapter, as applicable.

(2) All nonsafety-related systems, structures, and components whose failure could prevent satisfactory accomplishment of any of the functions identified in paragraphs (a)(1)(i), (ii), or (iii) of this Section (i.e., §54.4).

(3) All systems, structures, and components relied on in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for fire protection (10 CFR 50.48), environmental qualification (10 CFR 50.49), pressurized thermal shock (10 CFR 50.61), anticipated transients without scram (10 CFR 50.62), and station blackout (10 CFR 50.63).

NEI 95-10, *Industry Guideline for Implementing the Requirements of 10 CFR Part 54 – The License Renewal Rule, Revision 6* [Reference 1.3-3], provides industry guidance for determining which SSCs are within the scope of license renewal. Regulatory Guide 1.188, *Standard Format and Content for Applications to Renew Nuclear Power Plant Operating Licenses*, Revision 2 [Reference 1.3-2], continues to endorse Revision 6 of NEI 95-10 as acceptable for complying with the requirements of 10 CFR Part 54 for preparing an initial LRA. PNPP followed the process and recommendations of NEI 95-10, Revision 6, to determine which SSCs are within the scope of license renewal.

Structural components included in mechanical systems, such as pipe supports and insulation, are evaluated as structural elements and bulk commodities. If a component or parts of it carry electrical current, it is electrical; if it supports, protects or restrains the movement of a component, it is civil/structural; everything else is considered to be mechanical.

A more detailed description of the evaluation process using the criteria of 10 CFR 54.4 [Reference 1.3-1] is described in the following sections. Section 2.1.1.1 discusses the evaluation against the safety-related criterion in 10 CFR 54.4(a)(1). Section 2.1.1.2 discusses the evaluation of nonsafety-related SSCs against the criterion of 10 CFR 54.4(a)(2). Section 2.1.1.3 discusses the evaluation against the regulated events criterion, 10 CFR 54.4(a)(3). The results of these evaluations for plant systems are presented in Section 2.2.

Mechanical

Consistent with NEI 95-10, the PNPP scoping process developed a list of plant mechanical systems and their functions, and then determined which of those functions met any of the three criteria of 10 CFR 54.4(a). Intended functions are the basis for including a system within the scope of license renewal and are identified by comparing the system function with the criteria in 10 CFR 54.4(a).

Systems-Applications-Products (SAP) is the software platform for the PNPP configuration management database. Within that database, component data is organized according to functional locations, hereafter referred to as the SAP functional location database. Components in the database have unique identifiers that include a system label. Thus, the database is used as a starting point to develop a list of plant systems. The database system list was then compared to other current licensing basis (CLB) documentation, including the UFSAR [Reference 1.3-6], Maintenance Rule System Basis Documents and plant drawings. Systems which contain mechanical components were evaluated as mechanical systems. In some cases, closely related systems were combined in this LRA for ease of review.

Structural

Consistent with NEI 95-10, the PNPP scoping process developed a list of plant structures and their functions, and then determines which of those functions meet any of the three criteria of 10 CFR 54.4(a). Intended functions are the basis for including a structure within the scope of license renewal and are identified by comparing the structure function with the criteria in 10 CFR 54.4(a).

Structural components included in mechanical systems, such as pipe supports and insulation, are evaluated as structural elements and bulk commodities.

Structural scoping is performed based on identification of functions for structures and structural commodities. That approach bounds components grouped as structural systems and obviates the need for system-level structural scoping.

Functions for structures were identified based on reviews of applicable plant licensing and design documentation. Documents used in the reviews included the UFSAR, quality categorization within the SAP functional location database, Technical Specifications, the Appendix R Safe Shutdown Capability Report, the Fire Protection Evaluation Report (UFSAR Chapter 9 Appendix A), Maintenance Rule basis documents, engineering calculations, operating procedures, various station drawings, and other license basis documentation such as licensing letters and Safety Evaluation Reports, as necessary. A list of structures within the scope of license renewal is found in Table 2.2-2. The list includes structures that potentially support plant operations or that could adversely impact structures that support plant operations (e.g., seismic II over I). In addition to buildings and facilities, the list of structures includes other structures that support plant operation (e.g., electrical manholes and foundations for freestanding tanks).

Electrical

Three scoping methodologies are described in the EPRI License Renewal Electrical Handbook (EPRI Report 1013475) [Reference 1.3-13]; each methodology describes an approach to determining which electrical and I&C components and commodities at the plant meets the criteria of 10 CFR 54.4. PNPP has chosen Method A, the System Level or In-Scope Bounding Approach.

Using Method A, all plant electrical and I&C (EIC) systems are included in the scope of license renewal. All EIC components in mechanical systems are also included but these systems are not listed separately. Including systems and components beyond those actually required by 10 CFR 54.4 is referred to as an encompassing or bounding review. In addition to the plant EIC systems, certain offsite power systems and components are included in scope based on NRC guidance.

The SAP functional location database includes systems that are categorized as EIC instead of mechanical, based on their predominant function. Those EIC systems are listed in Table 2.2-3. Because of the method used to perform EIC scoping for license renewal, EIC system intended functions were not evaluated for each system during the scoping process.

When used with the plant spaces approach, this scoping method eliminates the need for unique identification of each EIC component and its specific location. The method allows commodity groups, systems or spaces to be eliminated during further review as their intended functions are examined.

Additional details on electrical and I&C system scoping are provided in Section 2.2.

2.1.1.1 Application of Safety-Related Scoping Criteria

A system, structure, component, or bulk commodity is within the scope of license renewal if it is relied upon to remain functional during and following a design basis event as stated in 10 CFR 54.4(a)(1) [Reference 1.3-1]. Design basis events are defined in 10 CFR 50.49(b)(1)(ii) [Reference 1.3-7], as conditions of normal operation, including anticipated operational occurrences, design basis accidents, external events, and natural phenomena for which the plant must be designed to ensure functions identified in 10 CFR 54.4(a)(1)(i) through (iii). The design basis events include the design basis accidents described in Chapter 15 of the UFSAR and events described in other parts of the licensing basis documentation, such as floods, fires, tornados, seismic events, and moderate and high energy line breaks.

The PNPP UFSAR [Reference 1.3-6], Section 3.2.1, specifies:

Plant structures, systems and components important to safety are designed to withstand the effects of a Safe Shutdown Earthquake (SSE) and remain functional if they are necessary to assure:

a. The integrity of the reactor coolant pressure boundary,
b. The capability to shut down the reactor and maintain it in a safe condition, or
c. The capability to prevent or mitigate the consequences of accidents that could result in potential offsite exposures comparable to the guideline exposures of <10 CFR 100> or <10 CFR 50.67> (future revisions to design basis analyses that compare consequences to 10 CFR 100 will be updated to <10 CFR 50.67>) [References 1.3-7 and 1.3-15].

This definition is similar to that used for safety-related SSCs in 10 CFR 54.4(a)(1) but excludes reference to offsite exposures referenced in 10 CFR 50.34(a)(1). Section 10 CFR 50.34(a)(1) is applicable to facilities seeking a construction permit and is therefore not applicable to renewal of the existing Facility Operating License at PNPP.

Component quality (safety) classification is maintained as a controlled field in the SAP functional location database.

Systems that rely on mechanical components to perform a safety function, and structures and structural components that perform a safety function are included in the scope of license renewal. Mechanical system and structural safety functions were determined by review of the following plant-specific references:

- UFSAR
- Quality classification (Q-list – contained within the SAP functional location database)
- Technical Specifications
- Maintenance Rule basis documents
- Engineering calculations
- Operating procedures
- Station drawings
- Other license basis documentation such as licensing letters and Safety Evaluation Reports

2.1.1.2 APPLICATION OF CRITERION FOR NONSAFETY-RELATED SSCS WHOSE FAILURE COULD PREVENT THE ACCOMPLISHMENT OF SAFETY FUNCTIONS

PNPP contains nonsafety-related mechanical systems (and portions of systems) and structures (and parts of structures) whose failure could prevent satisfactory accomplishment of a safety function. The method used to identify these components is consistent with Appendix F of NEI 95-10, *Industry Guideline for Implementing the Requirements of 10 CFR Part 54 – The License Renewal Rule*, [Reference 1.3-3]. Consideration of hypothetical failures that could result from system or structure interdependencies that are not part of the current licensing basis and that have not been previously experienced is not required.

The impact of nonsafety-related SSC failures on safety functions can be either functional or spatial. In a functional failure, the failure of a nonsafety-related SSC to perform its normal function impacts a safety function. In a spatial failure, the loss of structural or mechanical integrity of a nonsafety-related SSC attached to, or in physical proximity to a safety-related component impacts a safety function of the safety-related component.

2.1.1.2.1 Functional Failures of Nonsafety-Related SSCs

At PNPP, systems and structures required to perform a function to support a safety function are generally classified as safety-related and are included in the scope of license renewal per Section 2.1.1.1. For the exceptions where nonsafety-related equipment and structures are required to remain functional to support a safety function, the function is listed as an intended function for 10 CFR 54.4(a)(2) [Reference 1.3-1], and the system or part of the structure containing the equipment is included in scope.

Systems that rely on nonsafety-related mechanical components to support a safety function are included in the scope of license renewal. Mechanical systems with nonsafety-related components that support safety-related functions were determined by review of the following PNPP documents:

- UFSAR [Reference 1.3-6]
- Q list (contained within the SAP functional location database)
- Maintenance Rule basis documents
- Engineering calculations
- Operating procedures
- Station drawings
- Other license basis documentation such as licensing letters and Safety Evaluation Reports

2.1.1.2.2 Spatial Failures of Nonsafety-Related SSCs

Systems, structures and components meeting the scoping criterion of 10 CFR 54.4(a)(2) [Reference 1.3-1] due to spatial failures fit into one of the following categories:

- Nonsafety-related SSCs directly connected to safety-related SSCs; or,
- Nonsafety-related SSCs that are not directly connected to safety-related SSCs but have the potential for spatial interaction (such as Seismic II over I).

Nonsafety-Related SSCs Directly Connected to Safety-Related SSCs

For nonsafety-related SSCs directly connected to safety-related SSCs the connected piping and supports up to and including the first seismic or equivalent anchor beyond the safety-nonsafety interface are within the scope of license renewal if the nonsafety-related piping may provide structural support to the safety-related piping. For the purposes of License Renewal scoping, an equivalent anchor is defined as a seismic anchor or group of supports that provide lateral and torsional restraint in three orthogonal directions. An alternative to specifically identifying a seismic or equivalent anchor is to include enough of the nonsafety-related piping run to ensure that these anchors are included and thereby ensure the piping and anchor intended functions are maintained. NEI 95-10, *Industry Guideline for Implementing the Requirements of 10 CFR Part 54 – The License Renewal Rule* [Reference 1.3-3], Appendix F, Part 4, describes acceptable alternative methods of establishing the scope of nonsafety-related SSCs directly connected to safety-related SSCs. Additionally, nonsafety-related portions of safety-related piping systems downstream of the first anchor are in scope if they have the potential for spatial interaction with safety-related SSCs, as described below.

Systems containing components that perform this function were identified by review of station drawings. Other documents referenced included piping seismic/stress analyses. All piping system transitions from safety-related to nonsafety-related were evaluated to ensure that scoping for this criterion is consistent with the guidance of NEI 95-10 [Reference 1.3-3].

For nonsafety-related structures directly connected to safety-related structures or components, the entire connected structure, or a part of the connected structure up to a designated boundary, will be included within the scope of license renewal. NEI 95-10, Appendix F [Reference 1.3-3], describes acceptable methods of establishing the scope of nonsafety-related structures directly connected to safety-related structures or components.

Nonsafety-Related SSCs Not Directly Connected to Safety-Related SSCs with the Potential for Spatial Interaction

Protective features (whip restraints, spray shields, supports, barriers, temporary flood barriers, etc.) may be installed to protect safety-related SSCs from spatial interaction with nonsafety-related SSCs. Such protective features credited in the plant design are within the scope of license renewal per 10 CFR 54.4(a)(2) [Reference 1.3-1]. Where those features provide adequate protection, the nonsafety-related SSC itself is excluded from the scope of license renewal. The protective features are typically associated with a structural element such as a wall and are included in structural scoping.

The following sections address the different modes of spatial interaction with nonsafety-related SSCs that were considered. Interactions can occur in the following ways:

- Physical impact such as in a seismic event;
- Damage due to leakage, spray, or flooding; and,
- Pipe whip, jet impingement, or harsh environment resulting from a piping rupture.

Physical Impact

This category concerns the potential spatial interaction of nonsafety-related SSCs falling on or otherwise physically impacting safety-related SSCs such that safety functions may not be accomplished.

Nonsafety-related cable trays and conduits are examples of structural commodities that could potentially impact safety-related SSCs.

All nonsafety supports for piping, or supports for long term shielding or scaffolding, with a potential for spatial interaction with safety-related SSCs are within the scope of license renewal per 10 CFR 54.4(a)(2).

NEI 95-10, Appendix F [Reference 1.3-3], confirms that, if the effects of aging on the supports for these piping systems are managed, falling of piping sections is not considered credible, and does not need to be considered. The affected piping section itself is not in scope for 10 CFR 54.4(a)(2) due to the physical impact hazard. The effects of spray and leakage were also considered, as discussed below.

Missiles can be generated from internal or external events, such as failure of rotating equipment. Structures or structural features (e.g., missile barriers) that protect safety-related equipment from missiles are within the scope of license renewal per 10 CFR 54.4(a)(2) [Reference 1.3-1].

Overhead load-handling systems from which a dropped load could result in damage to any system that could prevent the accomplishment of a safety-related function are within the scope of license renewal per 10 CFR 54.4(a)(2) [Reference 1.3-1].

Leakage, Spray, or Flooding

Moderate- and low-energy systems, as well as high-energy systems, have the potential for spatial interactions of spray and leakage. Nonsafety-related systems, and nonsafety-related portions of safety-related systems with the potential for spray or leakage that could prevent safety-related SSCs from performing their required safety function are within the scope of license renewal per 10 CFR 54.4(a)(2) [Reference 1.3-1].

Air and gas (nonliquid, non-steam) systems are not a hazard to other plant equipment. Components that do not contain liquids or steam cannot adversely affect safety-related SSCs due to leakage or spray. Operating experience indicates that nonsafety-related systems containing only air or gas have experienced no failures due to aging that could impact the ability of safety-related equipment to perform required safety functions.

There are no credible aging effects for these systems when the environment is a dry gas. Therefore, these systems are not within the scope of license renewal per 10 CFR 54.4(a)(2) based on the potential for spray or leakage.

Nonsafety-related systems and nonsafety-related portions of safety-related systems containing steam or liquid that are near safety-related equipment are within the scope of license renewal per 10 CFR 54.4(a)(2) (including oil within components that have an oil system that includes an oil pump and piping). Failures of nonsafety-related components may result in spray or leakage onto safety-related equipment.

The review utilized a spaces approach for scoping of nonsafety-related systems (or portions of systems) that have a potential for spatial interaction with safety-related SSCs. A “space” is defined as a room or cubicle that is separated from other spaces by substantial objects (such as wall, floors, and ceilings). The space is defined such that any potential interaction between nonsafety-related and safety-related SSCs, including flooding and harsh environments, is limited to the space. This normally results in the entire safety-related structure being considered as a single space, with all nonsafety-related steam- or liquid-retaining components in the structure being within scope.

Structures and structural elements and commodities have potential for leakage or flooding including earthen structures (major stream, remnant minor stream and the diversion stream) that could prevent safety-related SSCs from performing their required safety function are within the scope of license renewal per 10 CFR 54.4(a)(2). Nonsafety-related walls, curbs, dikes, doors, temporary flood barriers, storm drains, etc., that provide flood barriers for safety-related SSCs are within the scope of license renewal per 10 CFR 54.4(a)(2).

The following structures (spaces) contain safety-related components with the potential for spatial interactions with nonsafety-related components:

- Auxiliary Building
- Condensate Storage Tank Dike
- Control Complex
- Diesel Generator Building
- Emergency Service Water Pump House
- Fuel Handling Building
- Intermediate Building
- Offgas Building
- Reactor Building
- Service Water Valve Pit

Note that the RadWaste Building is classified as safety-related but contains no safety-related mechanical components. However, there are three safety-related conduits at elevation 621 feet (approximately) in the Radwaste Building. The conduits support and protect electrical cables between the Control Complex on the south and an underground duct bank at the north wall of the Radwaste Building. These conduits provide protection of the enclosed cables from spatial interactions with moderate energy piping such as spray or leakage. There are no high energy lines whose failure could result in adverse spatial interactions in the Radwaste Building. Because these safety-related cables are protected by conduit, mechanical components in the Radwaste Building do not have the potential for spatial interactions that could result in the loss of a function identified in 10 CFR 54.4(a)(1).

The Unit 2 Reactor Building forms part of the south wall of the safety-related Intermediate and Fuel Handling Buildings. The Unit 2 Containment Vessel acts as a piping anchor for several in-scope piping systems.

Additionally, some components are conservatively classified as “Q” in the SAP functional location database but are not located within the structures listed above. Evaluations conclude that failure of these components will not result in a loss of a safety-related function, and as such, nonsafety-related components in the same structures are not included within scope for spatial considerations. The scope of these components (including associated panels, supports and cabling) is:

- Reactor protection, rod control and information system instrumentation associated with the turbine and condenser;
- Main steam leak detection temperature instrumentation; and,
- Post-accident high range radiation monitors.

Systems containing nonsafety-related components within safety-related structures were primarily identified by review of station drawings (P&IDs and isometric/piping location drawings). For cases in which component building locations could not be determined by drawing review, other documentation was reviewed to establish component location, or walkdowns were performed. Plant operating procedure valve lineup instructions (VLIs) identify valve locations.

Pipe Whip, Jet Impingement, or Harsh Environments

Pipe whip, jet impingement, and harsh environment effects on safety-related equipment are addressed in site-specific analyses of high- and moderate-energy line breaks. Spatial interactions of pipe whip, jet impingement, and harsh environment are credible only for high-energy systems. The effects of spray, leakage and flooding were also considered, as discussed above, such that high energy lines within safety-related structures are included within scope. As such, scoping of nonsafety-related systems and components due to the potential for high- and moderate-energy line breaks can be limited to those systems (or portions of systems) that are not already in scope due to the spray and leakage consideration. Categorically, scoping of nonsafety-related structures and commodities due to the potential for high- and moderate-energy line breaks can be limited to those structures (or portions of structures) that are not already in scope due to leakage or flooding considerations.

If a high-energy line break (HELB) analysis assumes that a nonsafety-related piping system does not fail, or assumes failure only at specific locations, then that piping system is within the scope of license renewal per 10 CFR 54.4(a)(2) and is subject to aging management review to provide reasonable assurance that those assumptions remain valid throughout the period of extended operation.

2.1.1.3 Application of Criterion for Regulated Events

The scope of license renewal includes SSCs relied on in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for any of the following regulated events:

- Fire protection (FP) (10 CFR 50.48),
- Environmental qualification (EQ) (10 CFR 50.49),
- Pressurized thermal shock (PTS) (10 CFR 50.61),
- Anticipated transient without scram (ATWS) (10 CFR 50.62), and
- Station blackout (SBO) (10 CFR 50.63).

This Section discusses the approach used to identify the systems and structures within the scope of license renewal based on this criterion.

2.1.1.3.1 Fire Protection (10 CFR 50.48)

Systems and structures in the scope of license renewal for fire protection include those required for compliance with 10 CFR 50.48 [Reference 1.3-7]. The fire protection program has been developed to satisfy the requirements of 10 CFR 50 and Branch Technical Position BTP APCSB 9.5-1, Appendix A, and to meet the intent of 10 CFR 50 Appendix R. Equipment relied on for fire protection includes SSCs credited with fire prevention, detection, and mitigation in areas containing equipment important to safe operation of the plant as well as systems that contain plant components credited for safe shutdown following a fire. To identify this equipment, PNPP fire protection licensing basis documents were reviewed. The primary reference for this scoping criterion is the Appendix R Safe Shutdown Capability Report. Other documents reviewed included:

- UFSAR [Reference 1.3-6] Section 9.5.1 (Fire Protection description);
- UFSAR Appendix 9A (Fire Protection Evaluation Report);
- Fire Protection Program procedure;
- Quality classification, Notes and Comments fields of the SAP functional location database; and,
- Station drawings.

The Appendix R Safe Shutdown Capabilities Report describes the PNPP strategy and analysis that assures safe shutdown of the plant in the event of a fire, in accordance with 10 CFR 50, Appendix R.

UFSAR 9.5.1 describes the prevention, detection and suppression design features of plant SSCs.

UFSAR Appendix 9A includes the fire hazards analysis and description of systems for safe shutdown.

The Fire Protection Program procedure provides the administrative guidance for functional requirements of fire rated assemblies and barriers, and for detection and suppression subsystems.

The SAP functional location database quality classification field is a controlled field that can be used to aid in the identification of nonsafety-related components credited with a fire protection function. Most of these components are listed with an augmented ("A") quality field assignment. The database also contains amplifying information in a Notes and Comments section on whether specific components support Fire Protection Program requirements.

Station drawings provide information identifying the scope of fire suppression piping components credited for fire protection.

Based on the PNPP current licensing bases for fire protection, system and structure intended functions performed in support of 10 CFR 50.48 requirements were determined. The results of this determination are provided for mechanical systems in Section 2.3, and in Section 2.4 for structures and structural elements.

2.1.1.3.2 Environmental Qualification (10 CFR 50.49)

10 CFR 50.49 [Reference 1.3-7], defines electric equipment important to safety that is required to be environmentally qualified to mitigate certain accidents that would result in harsh environmental conditions in the plant. The PNPP Environmental Qualification (EQ) Program, which satisfies these requirements, controls the maintenance of the list of EQ components. The SAP functional location database contains a controlled field that identifies components within the EQ program.

The scope of 10 CFR 50.49 does not include electric equipment important to safety located in a mild environment. A mild environment is an environment that would at no time be significantly more severe than the environment that would occur during normal plant operation, including anticipated operational occurrences. This regulation does not apply to structures because structures are not electric equipment.

2.1.1.3.3 Pressurized Thermal Shock (10 CFR 50.61)

10 CFR 50.61 [Reference 1.3-7], requires that licensees of pressurized water reactors (PWRs) evaluate the reactor vessel beltline materials against specific criteria to ensure protection from brittle fracture. As a boiling water reactor (BWR), PNPP is not subject to this regulation.

2.1.1.3.4 Anticipated Transients without Scram (10 CFR 50.62)

An anticipated transient without scram (ATWS) is an anticipated operational occurrence that is accompanied by a failure of the reactor trip function to shut down the reactor.

The ATWS rule, 10 CFR 50.62 [Reference 1.3-7], requires specific improvements in the design and operation of commercial nuclear power facilities to mitigate the consequences of an ATWS event. The licensing bases for the ATWS rule for PNPP is described in UFSAR Appendix 15C.

Based on the PNPP current licensing bases for ATWS, structure and system intended functions performed in support of 10 CFR 50.62 requirements were determined. The results of this determination are provided for mechanical systems in Section 2.3, Section 2.4 for structures and structural elements, and in Section 2.5 for electrical and instrument and controls systems

2.1.1.3.5 Station Blackout (10 CFR 50.63)

10 CFR 50.63 [Reference 1.3-7], requires that each light-water-cooled nuclear power plant be able to withstand, for a specified duration, and recover from a station blackout (SBO). An SBO is the loss of offsite and onsite AC electric power to the essential and nonessential switchgear buses in a nuclear power plant. It does not include the loss of AC power fed from inverters powered by station batteries or by alternate AC sources. The objective of this requirement is to assure that nuclear power plants can withstand an SBO while maintaining adequate reactor core cooling and containment integrity for the specified duration.

Appendix 15H of the UFSAR describes the licensing bases for SBO at PNPP. PNPP has developed a four-hour coping analysis to address the requirements of 10 CFR 50.63.

Based on the PNPP current licensing bases for SBO, structure and system intended functions performed in support of 10 CFR 50.63 requirements were determined. The results of this determination are provided for mechanical systems in Section 2.3, for structures in Section 2.4, and electrical commodities in Section 2.5.

The boundary for SBO is the step-up station transformer for Unit 1 and Unit 2. For Station Blackout Recovery, the boundary is extended to the first interconnection device that would restore offsite power to the main switchyard busses and then to the step-up station transformer. At PNPP, the boundary with the offsite transmission system has been defined at the 345kV switchyard circuit breakers: breakers S-612, S-620, S-621, S-650, S-652, S-660 and S-661. Refer to scoping boundary drawing 206-0010 LR. This boundary definition is consistent with NUREG-1800 [Reference 1.3-9], Section 2.1.3.1.

The Transmission Yard Control House (and associated EIC components) is not credited for offsite power supply reliability or station blackout recovery and is not in the scope of license renewal.

2.1.1.3.6 Cascading Systems in Regulated Events

NUREG-1800 [Reference 1.3-9], Table 2.1-2, “Specific Staff Guidance on Scoping,” under the discussion of “cascading,” identifies that any support system (identified by its CLB, actual plant-specific experience, industrywide experience, as applicable, or existing engineering evaluations) that is specifically relied upon for compliance with, or operation within, the applicable NRC regulation shall not be excluded from scoping. However, second-, third-, or fourth-level support systems are not required to be included. Consistent with this guidance, cascading first-level support systems were included for scoping for regulated events.

2.1.1.4 Scoping of Retired/Abandoned Mechanical Components

A small number of PNPP Unit 1 mechanical fluid components have been retired or abandoned since operation began. Additionally, in August 1994, the Cleveland Electric Illuminating Company formally notified the NRC of the intent to permanently terminate construction activities for PNPP Unit 2. PNPP Units 1 and 2 were originally designed to share some structures and systems.

During Unit 2 construction, a substantial amount of Unit 2 system piping and equipment had been installed in the plant. Subsequently, design changes have been implemented that have retired/abandoned Unit 2 systems, structures and components. Some of the retired/abandoned Unit 2 piping systems are located within structures containing safety-related components and have connections to Unit 1 systems that could represent a source of water to the retired/abandoned piping, or may be configured to retain trapped water. Additionally, some retired/abandoned piping components continue to provide structural/seismic support to attached safety-related Unit 1 piping. In these cases, the retired/abandoned piping performs a 10 CFR 54.4(a)(2) [Reference 1.3-1] function for license renewal.

Documentation (drawings, calcs, etc.) was reviewed for each interface with the retired/abandoned components and/or the components were walked down to determine their status. Piping components (including retired/abandoned piping) that provide structural/seismic support for safety-related piping, or that may contain fluid (water, steam, or oil) in structures that contain safety-related components are within scope of license renewal and are highlighted on license renewal drawings. Retired/abandoned piping components within structures containing safety-related components were only excluded from scope when all the following conditions were met:

- The piping components do not provide structural/seismic support to attached safety-related piping.
- The piping is separated from sources of water by blanks or flanges. Closed valves are not credited to keep fluid from retired/abandoned components.
- The piping is known to be empty of fluid. Empty status was established by configuration (such as the piping being open-ended at the low point), or by ultrasonic testing (UT) or other method that can confirm the absence of trapped fluid.

The review included consideration of abandoned components within structures containing safety-related components whose source of water is via a system connection outside of the safety-related structure, or that have no connection to an in-service system, but may contain trapped water. Retired/abandoned piping components that are located entirely outside of structures containing safety-related components do not perform a function corresponding to 10 CFR 54.4(a)(2) and are not within scope of license renewal.

The results of the scoping evaluations for Unit 2 and abandoned systems structures and components are provided for mechanical systems in Section 2.3, for structures in Section 2.4, and electrical commodities in Section 2.5.

2.1.2 SCREENING METHODOLOGY

Screening is the process for determining which in-scope structures and components require aging management review. Screening is governed by 10 CFR 54.21(a) [Reference 1.3-1], which states:

(1) For those systems, structures, and components within the scope of this part, as delineated in § 54.4, identify and list those structures and components subject to an aging management review. Structures and components subject to an aging management review shall encompass those structures and components—

(i) That perform an intended function, as described in §54.4, without moving parts or without a change in configuration or properties. These structures and components include, but are not limited to, the reactor vessel, the reactor coolant system pressure boundary, steam generators, the pressurizer, piping, pump casings, valve bodies, the core shroud, component supports, pressure retaining boundaries, heat exchangers, ventilation ducts, the containment, the containment liner, electrical and mechanical penetrations, equipment hatches, seismic Category I structures, electrical cables and connections, cable trays, and electrical cabinets, excluding, but not limited to, pumps (except casing), valves (except body), motors, diesel generators, air compressors, snubbers, the control rod drive, ventilation dampers, pressure transmitters, pressure indicators, water level indicators, switchgears, cooling fans, transistors, batteries, breakers, relays, switches, power inverters, circuit boards, battery chargers, and power supplies; and

(ii) That are not subject to replacement based on a qualified life or specified time period.

(2) Describe and justify the methods used in paragraph (a)(1) of this section.

(3) For each structure and component identified in paragraph (a)(1) of this section, demonstrate that the effects of aging will be adequately managed so that the intended function(s) will be maintained consistent with the CLB for the period of extended operation.

For a structure, system component, structural element, or commodity that is within the scope of license renewal, the screening process determines:

- Whether it performs a component intended function without moving parts and without a change in configuration or properties (i.e., it is passive); and,
- Whether it is not subject to replacement based on a qualified life or specified time period (i.e., it is long-lived).

NEI 95-10 [Reference 1.3-3] provides industry guidance for screening structures and components to identify the passive, long-lived structures and components that support an intended function. The screening process for PNPP followed the recommendations of NEI 95-10.

10 CFR 54.21(a)(2) requires that the IPA include a description and justification of the methods used to determine the "passive, long-lived" structural elements and components. Although the requirements for the IPA are the same for each system and structure, the screening process differs for mechanical systems, electrical systems, and structures. The three separate screening processes are described below.

2.1.2.1 Screening of Mechanical Systems and Drawing Preparation

Within the group of systems that are within the scope of license renewal, the passive, long-lived components require aging management review. Components that are either active or subject to replacement based on a qualified life or specified time period do not require an aging management review.

The identification of components subject to aging management review began with the determination of the system evaluation boundary. The system evaluation boundary includes those portions of the system that are necessary to ensure that the intended functions of the system will be performed. Components needed to support each of the system-level intended functions identified in the scoping process are included within the system evaluation boundary.

Within the system evaluation boundary, long-lived passive components that perform or support an intended function without moving parts or a change in configuration or properties are subject to aging management review.

In making the determination that a component is passive (i.e., its intended function is performed without moving parts or a change in configuration or properties), it is not necessary to consider the component parts. However, in the case of valves, pumps, fans, and dampers, the valve bodies, pump casings, and housings for fans and dampers perform an intended function by maintaining the pressure boundary and are therefore subject to an aging management review. If the component is not subject to replacement based on a qualified life or specified time period, then it is considered long-lived. Some components are subject to replacement based on vendor recommendations, plant experience, or any means that establishes a specific service life, qualified life or replacement frequency. Components that are periodically replaced under an administratively controlled process are not included in the aging management review.

License renewal drawings are created by highlighting mechanical flow diagrams to indicate those components that are within the system evaluation boundaries (i.e., that support system intended functions and are thus within scope) and are passive. Components that are periodically replaced may be highlighted and may also be identified as short-lived (and therefore not subject to aging management review) with a drawing note or textually within scoping reports.

Scoping and screening of components within each in-scope mechanical system began with a list of all system components and associated data downloaded from the SAP functional location database, along with applicable system flow diagrams. First, components that support one of the system functional scoping criteria (i.e., those that were not added to scope to address spatial interactions per 10 CFR 54.4(a)(2) [Reference 1.3-1] are highlighted in red. Next, nonsafety-related components within safety-related structures that contain steam, water or other liquid (such as oil) were highlighted in blue. Then, an evaluation of all safety-related to nonsafety-related transitions was conducted as described in Section 2.1.1.2.2 to ensure all components that provide structural support to safety-related components were included within scope. Green highlighting was used to identify components that perform only this structural support function. As these components were identified on the drawing, component data was downloaded from the SAP functional location database and annotated to identify component-level scoping results. The component data was also annotated to screen out active and short-lived components. This process ensured that all mechanical components downloaded from the SAP functional location database were evaluated for in-scope systems. Component types that appear on the drawing and perform an intended function but do not exist in the SAP functional location database (such as piping and bolting) were manually added to the downloaded component list.

Safety-related instrument air solenoid valves (and their associated air tubing) that open to relieve pressure and fail to a safe position upon loss of pressure boundary were not highlighted on drawings, and do not require aging management review because their only intended function is active; maintaining a passive pressure boundary is not an intended function for these components.

Some mechanical components, when combined, are considered a complex assembly. A complex assembly is a predominately active component where the performance of its components is closely linked to that of the intended function of the entire assembly, such that testing and monitoring of the assembly is sufficient to identify degradation of these components. Examples of complex assemblies include diesel engines, instrument air compressors, and chiller units. Complex assemblies are considered active and can be excluded from the requirements of AMR. However, to the extent that complex assemblies include piping or components that interface with external equipment, or components that cannot be adequately tested or monitored as part of the complex assembly, those components are identified and subject to AMR. This approach follows the screening methodology for complex assemblies as described in Table 2.1-2 of NUREG-1800. The components subject to AMR on the complex assembly are highlighted on drawings, but the complex assemblies (i.e., active sub-components, e.g., diesel engines or Control Complex chillers) may not be highlighted.

2.1.2.2 Screening of Structures

10 CFR 54.21(a)(2) requires that the IPA include a description and justification of the methods used to determine the “passive, long-lived” structural elements and commodities. Within the group of structures that are within the scope of license renewal, the passive, long-lived structural elements, and commodities that perform intended functions require aging management review. Components that are either active or subject to replacement based on a qualified life or specified time period do not require an aging management review.

The identification of components subject to AMR begins with the determination of the structure evaluation boundary. The structure evaluation boundary generally includes the entire structure. Structural elements and commodities needed to support each of the structure-level intended functions identified in the scoping process are included within the structure evaluation boundary.

Within the structure evaluation boundary, long-lived passive components that perform or support an intended function without moving parts or a change in configuration or properties are subject to aging management review. In accordance with 10 CFR 54, *Requirements for Renewal of Operating Licenses for Nuclear Power Plants*, [Reference 1.3-1], an in-scope structure (e.g., Auxiliary Building) contains inherently passive long-lived structural elements and commodities. Those structural elements and commodities that perform an intended function are identified in the AMR report.

The evaluation boundaries for mechanical component supports were established in accordance with the rules governing inspection of component supports (i.e., ASME Section XI, Subsection IWF). Component support examination boundaries for integral and non-integral (i.e., mechanically attached) supports are defined in article IWF-1300, Figure IWF-1300-1. In general, the support boundary extends to the surface of the building structure but does not include the building structure. Furthermore, the support boundary extends to include non-integral attachments to piping and equipment but does not include integral attachments to the same. Component support examination boundaries for non-ASME in-scope components included the structural component and the associated attachment to the building structure (e.g., structural component supports for heating, ventilation, and air-conditioning ducts include duct support members, baseplates, and anchorages).

Supports for electrical components include cable trays, conduit, cable tray and conduit supports, electrical panels, racks, cabinets and other enclosures. The evaluation boundary for these items includes supporting elements, including mechanical or integral attachment to the building structure.

Evaluation boundaries for other structural members whose function is to carry dynamic loads caused by postulated design basis events were determined consistent with the method for establishing boundaries for supports described above. That is, the boundary was evaluated including the structural component and the associated attachment to the building structure. The portion of the attachment embedded in the building structure was considered part of the structure.

The screening process for structural elements and commodities involves review of design and licensing basis documents (UFSAR, drawings, etc.) to identify specific structural elements and commodities that make up the structure. Structural elements and commodities typically have no unique functional location identifiers like those assigned to mechanical components. Therefore, grouping structural elements and commodities based on materials of construction first and then subdividing them based on structural elements or commodity design and functions provides a practical means of categorizing them for AMR.

Section 2.4 presents the results of the screening process for structures and structural commodities.

2.1.2.3 Screening of Electrical Systems

Electrical and I&C systems, and electrical components within mechanical systems, did not require further system evaluations to determine which components were required to perform or support the identified intended functions. A bounding scoping approach is used for electrical equipment. All electrical components within in-scope systems were included within the scope of license renewal. In-scope electrical components were placed into commodity groups and were evaluated as commodities during the screening process.

The screening phase for electrical components starts by comparing in-scope commodity types to the commodity types listed in Appendix B of NEI 95-10 [Reference 1.3-3]. NEI 95-10 provides guidance for determining whether the commodities are active or passive. Active commodities are screened out.

Short-lived components or commodities do not require aging management review, so the short-lived components are screened out. 10 CFR 54.21 (a)(1)(ii) [Reference 1.3-1] allows the exclusion of those commodities that are subject to replacement based on a qualified life or specified time period. Electrical commodities included in the Environmental Qualification (EQ) Program meet that exclusion criterion. This is because those components and commodities have defined qualified lives and are replaced prior to the expiration of their qualified lives.

Section 2.5 presents the results of the screening process for electrical and I&C systems.

2.1.2.4 Stored Equipment

Stored equipment that has an SAP functional location database entry is evaluated with the applicable system. Some equipment not in the SAP functional location database is staged for use by the fire brigade, such as smoke ejectors and ventilation trunks, but is not relied upon for fire protection or safe shutdown. Other fire-fighting equipment, such as extinguishers, air packs and fire hoses are addressed as consumables. Additional equipment is staged for beyond-design-basis events. No stored equipment (i.e., without an SAP functional location database entry) is subject to aging management review per 10 CFR 54.21(a) [Reference 1.3-1].

2.1.2.5 Consumables

Consumables include such items as packing, gaskets, component seals, O-rings, structural sealants, oil, grease, component filters, system filters, fire extinguishers, fire hoses, and air packs. Consumables have been evaluated consistent with the information presented in Table 2.1-3 of NUREG-1800 [Reference 1.3-9]. Consumables have been divided into the following four categories for the purpose of license renewal: (a) packing, gaskets, component seals, and O-rings; (b) structural sealants; (c) oil, grease, and component filters; and (d) system filters, fire extinguishers, fire hoses, and air packs.

- Group (a) subcomponents (packing, gaskets, component seals, and o-rings) – These items are commonly found in components such as valves, pumps, heat exchangers, ventilation units or ducts, and piping segments. Based on ANSI B31.1 and the ASME Boiler and Pressure Vessel Code Section III, these subcomponents of pressure-retaining components are not pressure-retaining parts. Therefore, these subcomponents are not relied on to perform a pressure-retaining function and are not subject to aging management review.

- Group (b) structural sealants - structural sealants perform an intended function without moving parts or change in configuration and are not typically replaced. Therefore, structural sealants were determined to be subject to AMR based on their application and are evaluated as bulk commodities in Section 2.4.4.

- Group (c) subcomponents (oil, grease, and component filters) – these items have been treated as consumables because they are either periodically replaced, or they are monitored and replaced based on condition. Therefore, these subcomponents are not subject to aging management review.

- Group (d) consumables (system filters, fire extinguishers, fire hoses, and air packs) – these items are considered to be consumables and are routinely tested, inspected, and replaced when necessary. System filters are monitored during testing and operation and are either replaced periodically or on condition. Fire hoses and fire extinguishers are inspected and pressure tested periodically and must be replaced if they do not pass the test or inspection. Breathing air apparatus and air cylinders are inspected and tested periodically and must be replaced if they do not pass the test or inspection. Fire protection procedures specify the replacement criterion of these components that are routinely checked by tests or inspections to assure operability. Criteria for inspection and replacement are based on accepted industry standards (e.g., Branch Technical Position BTP-APCSB 9.5.1, NFPA-10 for fire extinguishers, NFPA-1962 for fire hoses, 29 CFR 1910.134 for air packs). Therefore, while these consumables are within the scope of license renewal, they do not require an aging management review.

2.1.3 INTERIM STAFF GUIDANCE DISCUSSION

As discussed in NEI 95-10 [Reference 1.3-3], the NRC has encouraged applicants for license renewal to address interim staff guidance (ISGs) in the LRA. The following LR-ISGs are currently active on the NRC website:

LR-ISG-2011-01: AGING MANAGEMENT OF STAINLESS STEEL STRUCTURES AND COMPONENTS IN TREATED BORATED WATER, Revision 1: This ISG recommends the use of the One-Time Inspection program in addition to Water Chemistry to manage aging in oxygenated treated borated water environments. PNPP is a BWR and does not have a treated borated water environment that corresponds to the environment of concern in this ISG.

LR-ISG-2011-02: AGING MANAGEMENT PROGRAM FOR STEAM GENERATORS: This ISG recommends that applicants for license renewal follow the guidance provided in

Revision 3 of NEI 97-06 when implementing their steam generator aging management program. PNPP is a BWR and does not have steam generators.

LR-ISG-2011-03: GENERIC AGING LESSONS LEARNED (GALL) REPORT REVISION 2, AMP XI.M41, “BURIED AND UNDERGROUND PIPING AND TANKS:” LR-ISG-2011-03 program description in Appendices A and B have been replaced by LR-ISG-2015-01, and no further action in this regard is required by this LR-ISG. This ISG also includes associated revisions to the tabular recommendations of NUREG-1801 and NUREG-1800 pertaining to AMR line items. This LRA is consistent with the recommendations of LR-ISG-2011-03 in the AMR tables of Section 3.

LR-ISG-2011-04: UPDATED AGING MANAGEMENT CRITERIA FOR REACTOR VESSEL INTERNAL COMPONENTS OF PRESSURIZED WATER REACTORS: This ISG addresses aging management of PWR components. PNPP is a BWR, for which these recommendations are not applicable.

LR-ISG-2011-05: ONGOING REVIEW OF OPERATING EXPERIENCE: This ISG addresses the evaluation of site and industry operating experience that may be age-related. PNPP will continue to implement operating experience reviews consistent with LR-ISG-2011-05. LRA Appendix A, section A-1 and Appendix B, section B.1.4, describe the operating experience program to maintain aging management programs.

LR-ISG-2012-01: WALL THINNING DUE TO EROSION MECHANISMS: This ISG provides recommendations for management of wall thinning due to various erosion mechanisms and revises the NUREG-1801 [Reference 1.3-8], XI.M17 Flow-Accelerated Corrosion (FAC) program recommendations. This LRA is consistent with the recommendations of LR-ISG-2012-01 in the AMR tables in Section 3, and in the program evaluation in Appendix B, section B.2.22.

LR-ISG-2012-02: AGING MANAGEMENT OF INTERNAL SURFACES, FIRE WATER SYSTEMS, ATMOSPHERIC STORAGE TANKS, AND CORROSION UNDER INSULATION: This ISG revises the recommendations of six programs in NUREG-1801. This LRA is consistent with the recommendations of LR-ISG-2012-02 in the AMR tables in Section 3, and in the program evaluations in Appendix B, sections B.2.2, B.2.15, B.2.18, B.2.21, B.2.25 and B.2.37.

LR-ISG-2013-01: AGING MANAGEMENT OF LOSS OF COATING OR LINING INTEGRITY FOR INTERNAL COATINGS/LININGS ON IN-SCOPE PIPING, PIPING COMPONENTS, HEAT EXCHANGERS, AND TANKS: This ISG provides recommendations for management of loss of coating or lining integrity on in-scope components and adds a new program to address these recommendations in NUREG-1801. This LRA is consistent with the recommendations of LR-ISG-2013-01 in the AMR tables in Section 3, and in the program evaluation in Appendix B, section B.2.27.

LR-ISG-2015-01: CHANGES TO BURIED AND UNDERGROUND PIPING AND TANKS RECOMMENDATIONS: This ISG replaces aging management program (AMP) XI.M41, “Buried and Underground Piping and Tanks,” and the associated Updated Final Safety Analysis Report Summary Description in LR-ISG-2011-03, “Changes to the Generic Aging Lessons Learned (GALL) Report, Revision 2 Aging Management Program (AMP) XI.M41, 'Buried and Underground Piping and Tanks'." In addition, recommendations contained within AMP XI.M41 related to reductions in the extent of inspections to manage selective leaching in buried components were relocated to AMP XI.M33, "Selective Leaching." This LRA is consistent with the recommendations of LR-ISG-2015-01 in the AMR tables in Section 3, and in the program evaluation in Appendix B, section B.2.8 and section B.2.42.

LR-ISG-2016-01: CHANGES TO AGING MANAGEMENT GUIDANCE FOR VARIOUS STEAM GENERATOR COMPONENTS: This ISG addresses aging management of PWR components. PNPP is a BWR, for which these recommendations are not applicable.

SLR-ISG-2021-01-PWRVI: UPDATED AGING MANAGEMENT CRITERIA FOR REACTOR VESSEL INTERNAL COMPONENTS FOR PRESSURIZED-WATER REACTORS: This ISG addresses aging management of PWR components for Subsequent License Renewal. PNPP is a BWR, for which these recommendations are not applicable.

SLR-ISG-2021-02-MECHANICAL: UPDATED AGING MANAGEMENT CRITERIA FOR MECHANICAL PORTIONS OF SUBSEQUENT LICENSE RENEWAL GUIDANCE: This ISG addresses aging management criteria applicable to Subsequent License Renewal and is not applicable for PNPP's initial license renewal. However, the ISG updates to aging management programs were considered as part of operating experience to optimize aging management program effectiveness.

SLR-ISG-2021-03-STRUCTURES: UPDATED AGING MANAGEMENT CRITERIA FOR STRUCTURES PORTIONS OF SUBSEQUENT LICENSE RENEWAL GUIDANCE: This ISG addresses aging management criteria applicable to Subsequent License Renewal and is not applicable for PNPP's initial license renewal. However, the ISG updates to aging management programs were considered as part of operating experience to optimize aging management program effectiveness.

SLR-ISG-2021-04-ELECTRICAL: Updated Aging Management Criteria for Electrical Portions of Subsequent License Renewal Guidance: This ISG addresses aging management criteria applicable to Subsequent License Renewal and is not applicable for PNPP's initial license renewal. However, the ISG updates to aging management programs were considered as part of operating experience to optimize aging management program effectiveness.

Other Subsequent License Renewal (i.e., 60 to 80 years of operation) guidance documents are not applicable to Perry's initial license renewal. However, these documents are treated as operating experience that may be relevant. This operating experience has been considered in the PNPP IPA and applied as appropriate, on a limited basis. The AMR results in Section 3 may include a plant-specific note for line items that include clarification from SLR operating experience. Similarly, AMP descriptions in Appendix B indicate when an element(s) of the program is clarified by SLR operating experience. The other SLR guidance documents that contain potential operating experience applicable to PNPP include:

NUREG-2191 Generic Aging Lessons Learned for Subsequent License Renewal (GALL-SLR) Report (Reference 1-16); and,

NUREG-2192 Standard Review Plan for Review of Subsequent License Renewal Applications for Nuclear Power Plants (Reference 1-17).

2.1.4 GENERIC SAFETY ISSUES

In accordance with the guidance in NEI 95-10 (Reference 1.3-3) and Appendix A.3 of NUREG-1800 (Reference 1.3-9), review of NRC generic safety issues (GSIs) as a part of the license renewal process is required to satisfy the finding required by 10 CFR 54.29. GSIs designated as unresolved safety issues (USIs) and High - and Medium - priority issues in NUREG-0933, Appendix B (Reference 1.3-14), that involve aging effects for structures and components subject to an aging management review or time-limited aging analysis evaluations are to be addressed in the LRA. A review of NUREG-0933 dated 2021, Supplement 35 (current six months prior to the license renewal application submittal), determined that there were no outstanding USIs or High- or Medium-priority GSIs. Two GSIs (199 and 204) are identified as, "Currently open in Regulatory Office Implementation," in NUREG-0933, Appendix B. These were reviewed for aging effects for structures and components subject to an aging management review or TLAAs relevant to the license renewal application.

GSI-199 'Implications of Updated Probabilistic Seismic Hazard Estimates in Central and Eastern United States on Existing Plants,' addresses how current estimates of the seismic hazard level at some nuclear sites in the central and eastern United States might be higher than the values used in their original designs and previous evaluations. The issue does not involve TLAA evaluations or aging effects.

GSI-204 'Flooding of Nuclear Power Plant Sites Following Upstream Dam Failure,' relates to potential flooding effects from upstream dam failure on nuclear power plant sites, spent fuel pools, (SFPs), and sites undergoing decommissioning with spent fuel stored in SFPs. The issue does not involve TLAA evaluations. The PNPP is not situated downstream of any dams that might fail. However, barriers to external and internal flooding are in the scope of LR and subject to AMR, as described in Section 2.4.

2.1.5 CONCLUSION

The methods described in Sections 2.1.1 and 2.1.2 were used at PNPP to identify the systems and structures that are within the scope of license renewal and to identify those structures and components requiring aging management review. The methods are consistent with and satisfy the requirements of 10 CFR 54.4 and 10 CFR 54.21(a)(1).

2.2 PLANT LEVEL SCOPING RESULTS

Tables 2.2-1 and 2.2-2 list the mechanical systems and structures which are within the scope of license renewal for PNPP. The tables reflect a reference to the sections of this LRA which describes the system or structure.

Tables 2.2-3 and 2.2-4 list the EIC and structural systems. For each item on these lists, the tables also provide a reference (if applicable) to the section(s) of the UFSAR that describes the system or structure. For systems with no applicable UFSAR reference, a brief description is provided. As noted in Section 2.1.1, neither EIC nor structural scoping was performed based on system functional grouping. As such, the EIC and structural systems were not evaluated for scoping for EIC components and structures. However, the SAP functional location database includes systems that perform exclusive EIC or structural functions. As a result, Tables 2.2-3 and 2.2-4 are provided for a complete listing of the system functional locations.

Tables 2.2-5 and 2.2-6 list mechanical systems and structures that do not meet the criteria specified in 10 CFR 54.4(a) and are therefore excluded from the scope of license renewal. For each item on these lists, the table also provides a reference (if applicable) to the section of the UFSAR that describes the system or structure. For systems with no applicable UFSAR reference, a brief description is provided.

The list of systems used in these tables and determination of system boundaries is based on the PNPP SAP functional location database. The SAP functional location database is a controlled list of plant systems and components, with each component assigned to one plant system. Mechanical system intended functions are identified in the sections referenced in Table 2.2-1. Intended functions for in-scope structures are identified in the sections referenced in Table 2.2-2.

The list of plant structures was developed from a review of the UFSAR, plant layout drawings, Fire Hazards Analysis Report, design criteria documents, and maintenance rule basis documents. Structure intended functions are identified in the section referenced in Table 2.2-2. Structural commodities associated with mechanical systems, such as pipe supports and insulation, are evaluated with the structural bulk commodities.

As needed, system components are grouped functionally for the aging management review. For example, ASME Class 1 components in various systems are evaluated as the Reactor Coolant Pressure Boundary System in Section 2.3.1.3. For each system, the discussion under “System Boundary” provides further information.

Table 2.2-1
Mechanical Systems within the Scope of License Renewal

System Label	System Name	LRA Section Describing System
B13a	Reactor Vessel (RXV)	2.3.1.5

P98	Suppression Pool Corrosion Monitoring	Thermocouples/electrodes intended for monitoring of corrosion of the drywell wall suppression pool liner
P99	Post Fuel Load Vibrational and Thermal Testing	Temperature and vibration sensors used for plant start-up testing
R10	Plant Electrical	Chapter 8
R11	Station Transformers	Unit 1 and 2 Inter-bus transformers

Table 2.2-3
Electrical and I&C Systems

System Label	System Name	System Function or UFSAR Reference
R14	120 Vac Vital (Inverters and Distribution)	Vital Balance-of-Plant (BOP) uninterruptable power supply (UPS), providing 120 Vac for the Control Room and the Computer Room, and the ATWS UPS for the APRMs, LPRMs and flow instruments used in the Nuclear Instrumentation System (C51)
R15	480 Vac Vital TSC (Inverters and Distribution)	TSC UPS, providing 480Vac for the Emergency Response Information System Computer (C95) and the Site Security Computer
R22	Metal Clad Switchgear (15kv and 5kv)	15kV and 5kV breakers can be manually operated (close and trip) locally at the breaker and operated remotely with control power
R23	Unit Load Centers (480v)	Provides a distribution point for major 480V electrical loads and is the source of 480V power to the Motor Control Centers (R24) and Distribution Panels (R25) throughout the plant
R24	Motor Control Centers (MCCs)	MCCs provide a means of controlling and servicing electrical loads, including Division 1, 2 and 3 Class 1E MCCs and Non-Class 1E MCCs
R25	Distribution Panels	Non-Class 1E distribution Panels provide a means of controlling and servicing smaller, diversified loads
R34	Grounding System	8.3.1.1.4.4
R35	Cathodic Protection System	9.5.4.3
R36	Heat Tracing and Freezing Protection	A nonsafety-related electric heat tracing system provides heating to various system piping runs

R63	Loose Parts Monitoring System	(Abandoned/removed)
R71	Lighting system	9.5.3
R74	Local Starters and Controls	Miscellaneous motor starters
S11	Power Transformers	Main transformers phase A, B, C; auxiliary transformer; Unit 1 and 2 start-up transformers
S41	Step Up Station	Disconnect switches for the main and startup transformers
S42	Transmission Station	8.2.1.2.1, 8.2.2.1

Table 2.2-4
Structural Systems

System Label	System Name	System Function or UFSAR Reference
F17	Under Reactor Vessel Servicing Equipment	Equipment used during outages for maintenance under the RPV, including control rod drive mechanism handling equipment.
H13	Control Room Panels	Panels/cabinets in the control room that house and support control room instrumentation.
H22	Local Panels and Racks (GE)	Control panels and instrument racks that house and support instrumentation throughout the plant.
H51	Local Panels and Racks (Non GE)	Control panels and instrument racks that house and support instrumentation throughout the plant.
L51	Cranes Hoists and Elevators	Plant building elevators and load handling equipment ranging from the reactor building polar crane to portable maintenance trollies.
L54	Rolling Steel Door Operators	Rolling steel doors, including roll-up fire doors, and operators in safety- and nonsafety-related structures.
P80	Seismic Clearance Violation Supports	Pipe and equipment supports in safety-related structures evaluated for adequacy of seismic clearance.
R33	Conduit and Tray Systems	Structural commodities that support and protect EIC cables.
T23	Containment	This system refers to the containment design. The only component with an SAP functional location is the drywell head. Note: structures comprising containment/drywell are evaluated as structures and not systems.

Table 2.2-5
Mechanical Systems Not within the Scope of License Renewal

System Label	System Name	System Function or UFSAR Reference
C51	Neutron Monitoring	The dry tubes for the probes and for the neutron detectors perform a reactor coolant pressure boundary function and are evaluated with the reactor vessel internals. The mechanical portions of the system include drive units, guide tubes, and indexing mechanisms, along with the purge air piping and valves to each indexing mechanism and drive unit. These components are not safety-related, and do not perform a license renewal intended function. Electrical components in the system are in the scope of license renewal. 1.2.2.6.2.3; 7.6.1.4.
C85	Steam Bypass and Pressure Regulator	1.2.2.5.6; 7.7.1.5; 10.4.4.2
E32	Main Steam Isolation Valves Leakage Control	The system is abandoned in place. The abandoned piping includes Shield Building and Auxiliary Building steam tunnel piping penetrations that have been capped to maintain Shield Building annulus and Auxiliary Building pressure boundary and fire barrier integrity. These capped penetrations are evaluated for License Renewal as part of Civil/Structural commodities. 1.2.2.4.21
F11	Fuel Handling and Vessel Service Equipment	Safety-related F11 fuel handling components are used for movement of fuel (fuel prep machines, general purpose grapple, new fuel inspection stand, fuel handling platform) are evaluated as civil/structural components. 1.2.2.7.2; 9.1.4.2.3.1; 9.1.4.2.3.2; 9.1.4.2.7.3; Table 9.1-3
F12	Service Aids	9.1.4.2.4

Table 2.2-5
Mechanical Systems Not within the Scope of License Renewal

System Label	System Name	System Function or UFSAR Reference
F14	In Vessel Servicing Equipment	9.1.4.2.6; Table 9.1-5; Table 9.1-7
F15	Refueling Equipment	The system is composed of the refueling and auxiliary platforms and their associated winches and supporting equipment. The refueling bellows that provides a seal to separate the drywell from the upper pool is evaluated with the Suppression Pool (T21). Safety-Related and Augmented Quality F15 Refueling Equipment (Refueling Platform, 360 Degree Auxiliary Platform) are evaluated as civil/structural components 9.1.4.2.7
G51	Solid Radwaste Disposal	1.2.2.9.3; 11.4
G52	Dry Active Waste	Equipment located in the Waste Abatement Reclamation Facility and addressed under the W99 system.
G58	Spent Fuel Dry Storage	10 CFR 54 is not applicable to spent fuel dry storage, as interim dry fuel storage licensing is regulated by 10 CFR 72, and renewal of dry fuel storage licenses is described in 10 CFR 72.42.
L52	Service Building Machine Shop Equipment	The system consists of Machine Shop tooling and a hoist used to support maintenance activities.
L53	Motor-Operated Louver Operators	The system consists of nonsafety ventilation air inlet and outlet louvers and associated motor operators installed in nonsafety-related structures, except for louvers in the elevator machinery rooms for the Intermediate and Radwaste Buildings. Failure of louvers in those rooms cannot adversely affect safety-related functions.
L55	Miscellaneous Architectural and Facility	The system consists of nonsafety door stops, range hoods and kitchen equipment for the Control Complex,

Table 2.2-5
Mechanical Systems Not within the Scope of License Renewal

System Label	System Name	System Function or UFSAR Reference
		Service Building, Water Treatment Building, and Training Center.
L60	Small Tool Decon Equipment	The system provides for cleaning and decontamination of small tools and components.
L70	Calibrated Test Equipment	The Calibrated Test Equipment system includes miscellaneous equipment and test instrumentation subject to periodic calibration. The system also monitors the WARF ventilation for airborne radioactivity and includes equipment to shred and compact dry waste in the WARF. 12.3.4.2; 12.5.2.3.3
M11	Containment Vessel Cooling	9.4.6.2.2; 9.4.6.3.2
M13	Drywell Cooling	9.4.6.2.1; 9.4.6.3.1
M37	Water Treatment Building Ventilation	9.4.12.2.1
M41	Heater Bay Ventilation	9.4.4.2.2
M42	Turbine Power Complex Ventilation	9.4.8.1; 9.4.8.2
M44	Service Building HVAC	Provides ventilation of working areas and offices inside the Service Building. 9A.4.18.1
M45	Circulating Water Pump House Ventilation	9.4.12.2.2
M48	Radwaste Building Control Room Ventilation	9.4.12.2.7
M50	Guard House (PAF) HVAC	9A.4.20.1; 9A.4.20.3
M52	Technical Support Center HVAC	9A.4.18; 9A.4.18.1; 12.6.6
M53	Training Center HVAC	9A.4.19.1
M54	Service Building Hot Machine Shop HVAC	The M54 system connects to the plant vent via the 2M38 system. Fire dampers located in 2M38 ductwork are scoped

Table 2.2-5
Mechanical Systems Not within the Scope of License Renewal

System Label	System Name	System Function or UFSAR Reference
		with the M38 system. 9A.4.18.1
N23	Condensate Filtration	1.2.2.5.8; 10.4.6.2; 10.4.6.3.a; 10.4.6.4
N24	Condensate Demineralization	1.2.2.5.8; 10.4.6.3.b; 10.4.6.4
N25	High Pressure Heater Drains and Vents	The N25 system supports thermal efficiency of the turbine heat cycle. The system routes condensate and non-condensable gases from the moisture separator reheaters and high-pressure heaters and maintains condensate level in these heaters. The system does not contain safety-related SSCs, does not contain nonsafety-related SSCs that mitigate accidents or transients, and does not contain nonsafety-related SSCs whose failure prevents safety-related SSCs from fulfilling their safety-related function. As such, it does not perform an intended function.
N26	Low Pressure Heater Drains and Vents	The N26 system supports thermal efficiency of the turbine heat cycle. The system routes condensate and non-condensable gases from low-pressure heaters and automatically maintains condensate level in these heaters. The system does not contain safety-related SSCs, does not contain nonsafety-related SSCs that mitigate accidents or transients, and does not contain nonsafety-related SSCs whose failure prevents safety-related SSCs from fulfilling their safety-related function. As such, it does not perform an intended function.
N31	Turbine	The function of the turbine to mitigate the radiological release of a Control Rod Drop Accident is evaluated with the N61 system. Ref. UFSAR 1.2.2.5.1, 10.2.2.2

Table 2.2-5
Mechanical Systems Not within the Scope of License Renewal

System Label	System Name	System Function or UFSAR Reference
N32	Main Turbine Control System EHC	The N32 system does not contain any mechanical components that are safety-related. Nonsafety-related N32 electrical components support the overspeed trip function. The functions of the main stop and control valves, the intermediate stop and intercept valves, and the extraction steam check valves to prevent or mitigate a turbine overspeed event are evaluated with the N11 and N36 systems. Ref. UFSAR 10.2.2.2, 10.2.2.3, 10.2.3.6.1.1, 10.2.2.4 and Table 10.2-1.
N33	Turbine Steam Seal	1.2.2.5.5, 10.4.3
N34	Turbine Lube Oil	The system supplies lubricating oil to the main turbine-generator and exciter for lubrication and heat removal and provides makeup oil for Hydrogen Seal Oil system.
N35	Generator H_2 and CO_2 Gas Control	10.2.5.1, 10.2.5.3
N39	Turning Gear	The turning gear slowly rotates the turbine shaft to prevent rotor distortion due to uneven heating or cooling during turbine startup or shutdown.
N42	Generator Hydrogen Seal Oil	10.2.5.3.3.a
N43	Generator Stator Cooling	The system cools the main generator stator windings and field excitation rectifiers.
N51	Excitation	1.2.2.5.1; 10.2.2.1
N62	Condenser Air Removal	System is in scope for electrical components only. For a low power Control Rod Drop Accident with mechanical vacuum pump(s) in operation, Plant Radiation Main Steam Line (MSL) Monitor A or C actuates the trip of the mechanical vacuum pumps

Table 2.2-5
Mechanical Systems Not within the Scope of License Renewal

		and closure of the associated isolation valves. 1.2.2.5.4; 10.4.2.3; 15.4.9.5
N71	Circulating Water	1.2.2.5.7; 10.4.5
P12	Condensate Seal Water	The system provides seal water to several plant systems' valves to prevent leakage into the main and auxiliary condensers, and to support operation of the hotwell pumps and feedwater booster pumps.
P20	Makeup Water Pretreatment	1.2.2.8.7, 9.2.3
P33	Turbine Plant Sampling	1.2.2.8.9, 9.3.2
P34	Nuclear Sampling	1.2.2.8.9, 9.3.2
P40	Service Water Screen Wash	9.2.7.3
P62	Auxiliary Boiler Fuel Oil	9.5.10.2
P65	Auxiliary Boiler Chemical Treatment	9.5.10.2
P81	Preoperational Chemical Cleaning	The system supported initial system cleaning and transport of flush water to a chemical cleaning lagoon. Much of the system has been removed/ blanked-off.
P82	Miscellaneous Chemical Treatment	The system supports injection of hydrazine from a drum into the hotwell pumps suction or discharge headers.
P83	Cooling Tower Acid Addition	The system supports addition of chemicals to the Circulating Water system (N71).
P84	Cooling Tower Chlorination and Plant Discharge Dechlorination	The system injects sodium bisulfite for Dechlorination of discharge water.
R13	Isolated Phase Bus Duct Cooling	8.1
W99	Waste Abatement and Low Level Processing	9A.4.22; 11.4.2.2

Table 2.2-5
Mechanical Systems Not within the Scope of License Renewal

System Label	System Name	System Function or UFSAR Reference
X11	FLEX	FLEX system components that are installed or pre-staged to support the FLEX system function but are not normally connected to installed plant systems are not fluid-filled or are not within structures containing safety-related components. These components perform functions associated with NRC order EA-12-049, which does not correspond to one of the license renewal scoping criteria in 10 CFR 54.4(a). FLEX piping and valves that are physically connected to other systems and perform a pressure boundary or leakage boundary function are evaluated with those systems. FLEX pipe supports and equipment restraints are addressed as part of structural scoping.
X12	Spent Fuel Pool Spray (FLEX)	FLEX system components that are installed or pre-staged to support the FLEX system function but are not normally connected to installed plant systems are not fluid-filled or are not within structures containing safety-related components. These components perform functions associated with NRC order EA-12-049, which does not correspond to one of the license renewal scoping criteria in 10 CFR 54.4(a). FLEX piping and valves that are physically connected to other systems and perform a pressure boundary or leakage boundary function are evaluated with those systems. FLEX pipe supports and equipment restraints are addressed as part of structural scoping.
X13	Spent Fuel Pool level instrumentation (FLEX)	Components associated with the X13 FLEX system are primarily electrical/ I&C in nature and do not include mechanical components pressurized with steam/water fluid. These systems

Table 2.2-5
Mechanical Systems Not within the Scope of License Renewal

System Label	System Name	System Function or UFSAR Reference
		perform functions associated with NRC Order EA-12-051 and NEI 12-01 for beyond design basis events, which does not correspond to one of the license renewal scoping criteria in 10 CFR 54.4(a).
X14	Control Room Satellite Communication (FLEX)	Components associated with the X14 FLEX system are primarily electrical/ I&C in nature and do not include mechanical components pressurized with steam/water fluid. These systems perform functions associated with NRC Order EA-12-051 and NEI 12-01 for beyond design basis events which does not correspond to one of the license renewal scoping criteria in 10 CFR 54.4(a).
Z99	Non-Plant System	The system includes a nonsafety-related, buried, 1000 gallon drain collection tank north of the Training Center and various assets that do not correspond to system components.

Table 2.2-6
Structures and Structural Components
Not within the Scope of License Renewal

Structure Name	**Structure Function or UFSAR Reference**
Access ramps for construction	These ramps have no current function because they were buried during final site grading. Figure 9.5-22 (sheets 1 and 3).
Acid Storage Tank Buildings, one for each unit	Both buildings have been abandoned in place. The buildings have no safety function and failure will not compromise any safety-related system or component and will not prevent safe reactor shutdown. Section 3.3.2.3 and Figures 1.2-2, 1.2-18, 2.4-3 and 2.5-186.
Administration Building, includes the Startup Building	Provides space for administrative and plant support personnel. Figures 1.2-2, 2.4-3, 2.5-186 and 9.5-1.
Barge Slip	Abandoned. Sections 2.4.5.5.3.3, 2.4.5.5.6 and 2.5.1.2.1.1; and Figures 2.4-39, 2.4-42, 2.5-36, 2.5-37, 2.5-186 and 2D-27.
Carbon Dioxide Storage Tank Foundation	Provides support to the carbon dioxide gas storage unit 1P54A0007, which is not in scope. Figure 9.5-5.
Chemical Cleaning Lagoon	Used for environmental controls. Figures 1.2-2, 1.2-18, 2.1-3, 2.2-3, 2.4-3 and 2.5-186; and Table 2.4-12.
Circulating Water Forebay and Forebay Flume, Unit 1	Allow water to flow from the cooling tower basin to the Circulating Water Pumphouse. Section 10.4.5.1, Figure 1.2-14, and Table 3.2-1 XXXIV 11.
Circulating Water Pumphouse, Forebay and Forebay Flume, Unit 2	Abandoned, the structures have no safety function and failure will not compromise any safety-related system or component and will not prevent safe reactor shutdown. Sections 1.2.2.5.7, 3.3.2.3 and 10.4.5.1; and Figures 1.2-2, 1.2-14, 1.2-18, 2.4-3, 2.5-186 and 9.5-1.
Condensate Storage Tank 2P11A0001 Foundation, Unit 2	Abandoned, the Unit 2 Condensate Storage Tank has been removed. Figures 1.2-2 and 2.5-186.
Condensate Storage Tank Dike and Instrument Missile Shield, Unit 2	Removed. Figures 1.2-2, 2.5-186 and 3.8-74.

Table 2.2-6
Structures and Structural Components
Not within the Scope of License Renewal

Structure Name	**Structure Function or UFSAR Reference**
Construction Access Shafts	Temporary shafts used during construction. Appendix 2D, Section 2.2 and Figures 2D-2 (sheet 16), 2D-3, 2D-11, 2D-12 and 3.8-70.
Cooling Tower, Unit 1	Hyperbolically shaped concrete shell supported on a concrete foundation. Sections 1.2.2.5.7, 10.4.5.2 and 10.4.5.3; Figures 1.2-2, 2.4-3, 2.4-39A, 2.5-33, 2.5-34, 2.5-36, 2.5-37, 2.5-48, 2.5-53, 2.5-186, 2D-3, 2D-11, 2D-12, 2D-27, 2E-1, 9.2-10 and 9.5-7; and Table 2.4-9.
Cooling Tower, Unit 2	Abandoned. Sections 1.2.2.5.7 and 10.4.5.3; and Figures 1.2-2, 1.2-18, 2.1-3, 2.2-3, 2.4-3, 2.5-33, 2.5-36, 2.5-37, 2.5-48, 2.5-53, 2.5-186, 2D-3, 2D-11, 2D-12, 2D-27, 2E-1 and 9.5-7.
Decant Control Structure	Houses components used for environmental controls. Section 9.4.10.2e (page 9.4-120) and Figures 1.2-2 and 2.5-186.
Dechlorination Building (Equip. Bldg.)	Used for environmental controls. Section 9.4.10.2e (page 9.4-120) and Figures 1.2-2, 2.4-3, 2.5-186 and 2.5-203.
Demineralized Water Storage Tank Foundations	Tanks 0P21A0001 and 0P22A0001 are not in scope. Figures 2.4-3 and 2.5-186; and Table 2.4-12.
Diesel Generator Fuel Oil Tank maintenance structures, Unit 2	The Unit 2 tanks and associated structures have been abandoned. Sections 9.5.4.3 and 9.5.9.1.3; and Figures 1.2-2, 1.2-5, 9.5-21 (sheet 2) and 9.5-22 (sheets 1 and 2).
Discharge Tunnel Entrance Structure and Downshaft	Nonsafety-related lake water discharge pathway. Sections 9.4.10.2e (page 9.4-120) and 10.4.5.2; Figures 1.2-2, 2.4-3, 2.4-39, 2.4-69, 2.5-34, 2.5-36, 2.5-143 (Sheet 2), 2.5-186, 2.5-203, 2D-3, 2D-11, 2D-12, 2D-15, 3.8-65, 3.8-66, 3.8-70, 9.2-10 and 9.2-14 and Table 3.2-1 XXXIV 13.
Emergency Vehicle Garage (GAR)	Building removed. Figures 1.2-2, 2.4-3 and 2.5-32 (sheet 3).
Fire Equipment Storage Building	Located between the cooling towers.

Table 2.2-6
Structures and Structural Components
Not within the Scope of License Renewal

Structure Name	**Structure Function or UFSAR Reference**
Fire Equipment Storage Building (old name)	Located east of the ISFSI pad. Now used for storage of maintenance materials and equipment.
Fire Service Construction Water Pump House	Houses only components that are abandoned or not in scope. Figures 1.2-2 and 2.5-186.
Fire Protection Water Storage Tank (Fabritank) Floor and Dike	Abandoned. Fire protection water is supplied from Lake Erie. Sections 9A.5E.2.(d), 9A.5E.2.(f) and 9A.6 III.A; and Figures 1.2-2, 2.1-3, 2.4-3, 2.5-33, 2.5-48 and 2.5-186.
Fire and Security Training Facility	Used for Security and Fire training. Does not house any in-scope SSCs.
Fuel Oil Storage Tank Foundation	Supports the Auxiliary Boiler Fuel Oil Storage Tank, which is not in scope. Section 9A.4.9.3 and Figures 2.4-3, 2.5-186 and 9A-1.
Fuel Storage Depot, Unit 1	Vehicle refueling tanks in impoundments near the Unit 2 Cooling Tower. Sections 2.2.3.1.1.5 and 2.2.3.1.3.
Hydrogen Bulk Storage Foundation and Associated Structures, Unit 1	Provides hydrogen for main generator operation. Sections 9A.4.9.4, 9A.4.9.5.1, 10.2.5.1b, 10.2.5.2 and 10.2.5.3; and Figures 1.2-2, 9A-1 and 10.2-4.
Hydrogen Bulk Storage Foundation and Associated Structures, Unit 2	Abandoned, the Unit 2 bulk storage components have been removed. Figure 1.2-2.
Hydrogen Water Chemistry Hydrogen and Oxygen Tanks and related equipment supports	Provides hydrogen and oxygen for hydrogen water chemistry control and main generator operation. Outside of the protected area. Sections 2.2.3.1.1.6, 2.2.3.1.3, 9A.4.9.6, 10.2.5.1b and 10.2.5.3.
I&C Annex (Johnson Control Building)	Building has been removed, only the abandoned foundation pad remains at grade elevation. Figures 2.4-3 and 2.5-186.

Table 2.2-6
Structures and Structural Components

Structure Name	**Structure Function or UFSAR Reference**
Integrated Containment Management (ICM) staging and storage area and access road to the east of the Unit 1 Turbine Building in the yard area.	This area is to store sealants and boxes with the equipment which are mobilized through the Fuel Handling Building. This location is northeast of the service water swale. The ICM staging and storage area is 100' x 50' concrete pad. An access road connecting the ICM staging and storage pad to the existing roadway is also installed.
Industrial Waste Lagoons	Used for environmental controls. UFSAR Figures 1.2-2, 1.2-18, 2.1-3, 2.2-3, 2.4-3, 2.4-39, 2.4-39A, 2.5-33, 2.5-48, 2.5-186 and 9.5-7; and UFSAR Table 2.4-12.
Interim Shoreline Protection	Used to delay or preclude the need for permanent shoreline protection. Sections 2.4.5.5.2, 2.4.5.5.3 and 2.4.5.5.9; and Figures 2.4-39 and 2.4-39A.
Independent Spent Fuel Storage Installation (ISFSI) Facility	Provides temporary on-site spent fuel dry storage; licensed and operated in accordance with 10 CFR Part 72. Section 9.1.4.2.10.14 and Figures 1.2-2, 2.4-3 and 9A-1.
Low Level Radioactive Waste Building (LLRWSPF or WARF/RISB)	Used for temporary storage of low-level radioactive waste and radioactive material that may be reused. Sections 3.3.2.3, 9A.4.22.1 and 11.4.2.2; and Figures 1.2-2, 1.2-18, 2.4-3, 9.5-1 and 9A-1.
Main and Auxiliary Transformer Foundations	Provide support for the Unit 1 main and auxiliary transformers, which are not in scope for license renewal. The Unit 2 transformers have been removed. Section 9A.4.9.5.2 and Figures 1.2-2, 1.2-5, 1.2-12, 2.4-3 and 8.2-3.
Maintenance Building (Office and Shop)	Provides space for maintenance work, training, offices and storage. Figures 2.4-3, 2.4-39, 2.4-39A, 2.5-186 and 9.5-1.
Maintenance Building Annex	Provides space for maintenance work, training, offices and storage. Figures 2.4-3 and 9.5-1.
Major Stream Diversion Sediment Control Dam	Used for environmental controls. Sections 2.4.3.5 and 2.5.1.2.1.2; and Figures 1.2-18, 2.1-3, 2.4-6, 2.4-9, 2.4-11, 2.5-33, 2.5-53 and 2E-1.

Table 2.2-6
Structures and Structural Components
Not within the Scope of License Renewal

Structure Name	Structure Function or UFSAR Reference
Manholes, nonsafety-related (except electrical manhole 7)	Provide access to nonsafety-related underground utilities. Section 2.4.13.3 and Figure 2.4-3.
Meteorological Tower and Instrumentation Shelter	Sections 2.3.2.3.1, 2.3.3.1 and 2.3.3.4; and Figures 1.2-18, 2.1-3, 2.3-15, 2.4-9 (previous location).
Microwave Towers and Equipment Shelter	One provides communications capability, the other is abandoned. Figures 1.2-18, 2.1-3, 2.5-186, 2D-12 and 2E-1.
Minor Stream Diversion Sediment Control Dam	Used for environmental controls. Sections 2.4.3.5 and 2.5.1.2.1.2; and Figures 1.2-18, 2.1-3, 2.4-7, 2.4-8, 2.5-33, 2.5-53, 2D-16 and 2E-1.
Northwest Storm Drainage Sediment Control Dam	Used for environmental controls. Sections 2.4.5.5.7 and 2.5.1.2.1.2; and Figures 2.5-33, 2.5-53 and 2E-1.
Northwest Storm Impound Spillway	Used for environmental controls. Section 2.4.5.5.7 and Figure 2.4-39A.
On-Site Storage Container (OSSC) Storage Pad	Used for temporary storage of low-level radioactive waste. Figure 1.2-2.
Plant Access Road	Used for vehicle access to the plant site. Sections 2.1.1.3, 2.4.2.2, 2.4.2.3, 2.4.3.5 and 9.2.1.2; and Figures 1.2-18, 2.1-3, 2.4-3, 2.4-6, 2.4-9, 2.4-11, 2.5-33 and 2D-12.
Plant Railroad	Provides rail access to the plant site. Sections 2.1.2.1, 2.1.2.3, 2.2.1.3b, 2.2.2.b.2, 2.4.2.3, 3.8.4.1.3.1, 9.1.4.2.1 and 9.3.3.2.5; and Figures 1.2-18, 2.1-3, 2.2-2, 2.4-6, 2.5-33, 2D-12 and 9.1-26.
Pre-Access Facility	An administrative facility that is used for badging/plant access requirements. This facility does not house any in-scope SSCs.
Procedures and Records Building (Warehouse)	Provides document storage space and office space for support personnel. Figures 1.2-2, 2.4-3 and 2.5-186.
Quincy Substation	Supplies power to lighting and other non-essential loads. Figures 1.2-18, 2.1-3, 2-2.3, 2.4-9, 2.5.33 and 2D-12.

Table 2.2-6
Structures and Structural Components
Not within the Scope of License Renewal

Structure Name	Structure Function or UFSAR Reference
Service Building Annex	Provides office space for plant support personnel. Sections 9.2.1.2.5.a.6 and 9A.4.21, and Figures 1.2-2 and 9.5-1.
Service Water Pumphouse and Tunnel Intake Riser	Supports and shelters out-of-scope components. Sections 9.2.7.3, 9.4.10.2i (page 9.4-120), 9A.4.15 and 10.4.5.2; Figures 1.2-2, 1.2-15, 2.4-39, 2.4-39A, 2.4-69, 2.5-34, 2.5-36, 2.5-37, 2.5-49, 2.5-143 (Sheets 1 and 2), 2.5-186, 2.5-203, 2D-3, 2D-10, 2D-11, 2D-12, 2D-14, 3.8-65, 3.8-66, 3.8-70, 9.2-10, 9.2-14, 9.3-31 (Sheet 1), 9.4-27, 9.5-1, 9.5-22 (Sheets 1 and 3) and 9A-1; and Table 3.2-1 XXXIV 11.
Service Water Weir Box or Weir Structure	Controls makeup water to the cooling tower. Section 10.4.5.2 and Figures 1.2-2, 2.4-3, 2.5-186, 9.2-10, 9.2-14 and 9.5-22 (Sheets 1 and 3).
Sewage Treatment Plant	Used for environmental controls. Figures 1.2-2 and 2.5-186.
Concrete sidewalk (new) East of the Unit 2 heater bay, turbine building, steam tunnel, and auxiliary building [ECP 16-0491-001]	This new sidewalk created a permanent walkway for normal and outage travel. High outage traffic combined with winter/spring weather conditions results in unacceptable travel paths to trailers parked East of Unit 2 buildings.
Sodium Hypochlorite Tank Foundations and Containment Dikes	Abandoned. Originally for abandoned tanks 0P48A0001, 1P84A0001 and 2P84A0001. Figures 1.2-2, 1.2-5, 1.2-15 and 9.5-22 (sheet 3).
Spare Transformer Foundations	Spare transformers have no current plant functions. Section 9A.4.9.5.1 and Figures 1.2-5 and 2.4-3.
Tool Service Warehouse	Used for storage of maintenance materials and equipment. Located between the Unit 2 Cooling Tower and the ISFSI.
Transmission Station Control House	Contains electrical control and monitoring for switchyard circuit breakers.
Training Center (TC or TEC)	Provides space for the plant simulator and other training facilities. Section 9A.4.19; Figures 1.2-2, 9.5-1 and 9A-1; and Table 3.2-1 XLVIII.

Table 2.2-6
Structures and Structural Components
Not within the Scope of License Renewal

Structure Name	Structure Function or UFSAR Reference
Warehouse and Office Building	Provides equipment storage space and personnel office space. Figures 1.2-2, 1.2-18, 2.1-3, 2.2-3, 2.4-3, 2.5-186, 2D-12, 2E-1, 9.5-1 and 9.5-7.
Warehouse 2	Provides equipment storage space. Figure 9.5-1.
Warehouse 3	Provides equipment storage space. Figures 1.2-18, 2.1-3, 2.2-3, 2.5-33, 2.5-186, 2D-12, 2E-1 and 9.5-1.
Weld Shop	Welding facility that does not contain any in-scope SSC
Wooden Poles	Support nonessential lighting and electrical distribution.

2.3 SCOPING AND SCREENING RESULTS: MECHANICAL SYSTEMS

The license renewal scoping and screening results for PNPP mechanical systems are detailed in the following four sub-sections of Section 2.3:

- Reactor Vessel, Internals, and Reactor Coolant Systems [Section 2.3.1];
- Engineered Safety Features [Section 2.3.2];
- Auxiliary Systems [Section 2.3.3]; and,
- Steam and Power Conversion Systems [Section 2.3.4].

Specifically, this section provides the following information for the PNPP mechanical systems within the scope of license renewal listed in Table 2.2-1:

- The system description;
- A list of license renewal intended functions, including which criteria of 10 CFR 54 [Reference 1.3-1] require the system to be in-scope;
- Reference to the applicable PNPP UFSAR section(s);
- Reference to the applicable license renewal boundary drawing(s); and,
- A list of mechanical component types that are subject to an aging management review with their associated component intended function(s).

Table 2.3-1 gives the definitions of component intended functions used in this application for mechanical components. The term "piping" in component lists includes pipe and pipe fittings such as elbows, reducers, tees, thermowells, instrument tubing, and other fittings, and also includes instrument valves that do not appear on the highlighted scoping drawings.

Table 2.3-1
Mechanical Component Intended Functions: Abbreviations and Definitions

Intended Function	Definition
Absorb neutrons	Absorb neutrons to maintain the assumptions of criticality analyses for spent fuel storage.
Direct flow	Provide control of the distribution or direction of flow (e.g., spray nozzles, some reactor vessel internal components, curbs or dikes). Red highlighting is used on drawings.
Filtration	Provide filtration. Red highlighting is used on drawings.
Flow control	Control or distribute fluid flow. Red highlighting is used on drawings.

Table 2.3-1
Mechanical Component Intended Functions: Abbreviations and Definitions

Intended Function	Definition
Flow restriction	Provide a restriction to flow to limit flow rates or to provide a pressure difference (e.g., for flow measurement). Red highlighting is used on drawings.
Heat transfer	Provide for heat transfer. Red highlighting is used on drawings.
Leakage boundary	Nonsafety-related component that maintains mechanical and structural integrity to prevent spatial interactions that could cause failure of safety-related systems, structures and components. Blue highlighting on drawings for Leakage boundary includes the nonsafety "Structural integrity" function, where applicable.
Pressure boundary	Provide pressure-retaining boundary so that sufficient flow at adequate pressure is delivered; or, provide fission product barrier for containment pressure boundary; or, provide containment isolation for fission product retention. Additionally, for components such as ductwork and fire damper housings, the pressure boundary function includes providing a barrier to the spread of fires. This function is shown on drawings with red highlighting.
Radiation shielding	Provide radiation shielding to reduce neutron or gamma radiation fluence.
Spray	Containment spray removes heat from containment and serves as a containment atmosphere fission product removal mechanism following an accident. Red highlighting is used on drawings.
Structural integrity	Nonsafety-related component that maintains mechanical and structural integrity to provide structural support to attached safety-related piping and components. Green highlighting is used on drawings where nonsafety-related piping provides support to attached safety-related piping but does not perform a leakage boundary function (i.e., it contains air or gas, or is in an area for which the leakage boundary function is not applicable).
Structural support	Provide structural support to ensure system functions are maintained.

2.3.1 REACTOR VESSEL, INTERNALS, AND REACTOR COOLANT SYSTEM

The following systems are included in this section.

- Fuel [Section 2.3.1.1]
- Nuclear Boiler [Section 2.3.1.2]
- Reactor Coolant Pressure Boundary [Section 2.3.1.3]
- Reactor Recirculation [Section 2.3.1.4]
- Reactor Vessel [Section 2.3.1.5]
- Reactor Vessel Internals [Section 2.3.1.6]

2.3.1.1 Fuel (J11)

System Description

Each fuel bundle contains fuel rods and water rods which are spaced and supported in a square (nxn) array by spacers and a lower and upper tie plate. Fuel bundle design descriptions are contained in GESTAR. The fuel bundle has two important design features:

1) The bundle design places minimum external forces on a fuel rod; each fuel rod is free to expand in the axial direction.

2) The unique structural design permits the removal and replacement, if required, of individual fuel rods.

A fuel rod consists of UO2 pellets and a Zircaloy cladding tube. Barrier fuel bundles consist of fuel rods with a thin, high purity zirconium liner, i.e., barrier, mechanically bonded to the cladding tube. A fuel rod is made by stacking pellets into the Zircaloy cladding tube which is evacuated, back-filled with helium and sealed by welding Zircaloy end plugs in each end of the tube. The rod is designed to withstand applied loads, both external and internal. The fuel pellet is sized to provide sufficient clearance within the fuel tube to accommodate axial and radial differential expansion between fuel and clad.

During the refueling outage approximately one-third of the core is removed and replaced with an equal number of fresh or reinserted bundles.

The fuel bundle types installed in the core for the current cycle are of the same basic design as other approved designs in GESTAR.

System Boundary

There are no system components that are subject to aging management review.

The fuel is periodically replaced and is not long-lived.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event.

Fuel cladding provides a fission product barrier. [10 CFR 54.4(a)(1)]

Component Types Subject to Aging Management Review and their component-level functions

No components are subject to aging management review – the fuel is periodically replaced and is not long-lived.

Table 3.1.2-1, Reactor Vessel, Internals and Reactor Coolant Systems – Fuel System – Summary of Aging Management Evaluation, is included for completeness. There are no components subject to aging management review.

UFSAR References: 4.1.2.1.3; Appendix 15B

License Renewal Drawings: N/A

2.3.1.2 Nuclear Boiler (B21)

System Description

The nuclear boiler system (system code B21) includes the main steam lines and the nuclear pressure relief system and automatic depressurization system components from the main steam lines to the suppression pool. The system also includes other piping components such as vents, drains and instrument lines.

All the main steam system flow paths originate at one of the four 26-inch diameter steam lines that direct steam from the reactor pressure vessel. From the reactor vessel, the steam lines penetrate the Drywell and Containment via guard pipes. Each of the Main Steam Lines contains a flow restrictor. The Main Steam line flow restrictors are of the venturi-type and are installed in each Main Steam line inside the primary containment. The restrictors are designed to limit the loss of coolant resulting from a main steam line break outside the primary containment. The coolant loss is limited so that reactor vessel water level remains above the top of the core during the time required for the main steam line isolation valves to close.

The nuclear pressure relief system consists of safety/relief valves located on the main steam lines between the reactor vessel and the first isolation valve within the drywell. These valves protect against overpressure of the nuclear system. Each safety/relief valve discharges steam through a discharge line to a point below the minimum water level in the suppression pool.

The automatic depressurization system (ADS), a subsystem of B21, rapidly reduces reactor vessel pressure in a loss-of-coolant accident (LOCA) in which the HPCS system fails to maintain the reactor vessel water level. The depressurization provided by the system enables the low pressure emergency core cooling systems to deliver cooling water to the reactor vessel. The ADS uses some of the relief valves that are part of the nuclear pressure relief system within B21.

Two main steam isolation valves are welded in a horizontal run of each of the four main steam pipes; one valve is as close as possible to the inside of the drywell and the other is just outside the containment. Attached to the upper end of the stem is an air cylinder that opens and closes the valve and a hydraulic dashpot that controls its speed. Normal operating air is supplied to the valves from the nonsafety-related plant instrument air system.

System Boundary

System components subject to aging management review include non-Class 1 components associated with the main steam lines from the reactor vessel to, and including the outside containment isolation valves, and the components associated with the main steam safety/relief valves and their discharge piping, along with piping components and valves supporting instrumentation associated with systems connected to the reactor vessel, as shown on the LR boundary drawings. The system contains the Class 1 piping attached to the head vent/RCIC penetration, but all ASME Class 1 components are evaluated within the Reactor Coolant Pressure Boundary report.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event and because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection (FP), environmental qualification (EQ), anticipated transients without scram (ATWS), and station blackout (SBO). The system also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1), (a)(3) – SBO]

Provide a relief path for steam in the event of a reactor overpressure condition. [10 CFR 54.4(a)(1), (a)(3) – FP, SBO]

Provide system isolation in the event of a steam line break in order to minimize the release of radioactive fission products to the environment. [10 CFR 54.4(a)(1)]

The pressure relief system is designed to automatically relieve pressure in the reactor vessel. [10 CFR 54.4(a)(1), (a)(3) – FP]

System instrumentation supports ESF and ATWS actuations and isolations. [10 CFR 54.4(a)(1), (a)(3) – ATWS].

Provide steam supply to the Reactor Core Isolation Cooling turbine driven pump. [10 CFR 54.4(a)(1), (a)(3) – FP]

The system contains components credited with compliance with 10 CFR 50.49 [Reference 1.3-7]. [10 CFR 54.4(a)(3) – EQ]

The integrity of nonsafety-related components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Direct steam flow to the Main Turbine and selected support equipment.

Component Types Subject to Aging Management Review

Table 2.3.1-2 lists the component types that require aging management review and their intended functions.

2.3.1.3 Reactor Coolant Pressure Boundary (RCPB)

System Description

This system is a consolidation of the ASME III Class 1 portions of plant systems other than the reactor vessel and internals. UFSAR Section 5.1 defines the Reactor Coolant Pressure Boundary to include all pressure-containing components such as pressure vessels, piping, pumps, and valves, which are:

a. Part of the reactor coolant system, or

b. Connected to the reactor coolant system, up to and including any and all of the following:

- The outermost containment isolation valve in piping which penetrates primary reactor containment.
- The second of the two valves normally closed during normal reactor operation in system piping which does not penetrate primary reactor containment.
- The reactor coolant system safety/relief valve piping.

The Reactor Coolant Pressure Boundary includes portions of the following plant systems:

B13 Reactor Vessel (reactor vessel drain line and control rod drive)

B21 Nuclear Boiler

B33 Reactor Recirculation

C41 Standby Liquid Control System

E12 Residual Heat Removal (the RHR system reactor coolant pressure boundary ends within containment for two lines that supply containment spray)

E21 Low Pressure Core Spray System

E22 High Pressure Core Spray System

E51 Reactor Core Isolation Cooling

G33 Reactor Water Cleanup

N27 Feedwater

System Boundary

System components subject to aging management review are the ASME III Class 1 components, other than the reactor vessel and internals components, as shown on the LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP and EQ.

The reactor coolant pressure boundary contains the coolant under operating temperature and pressure conditions and limits leakage and the release of fission products. [10 CFR 54.4(a)(1), (a)(3) – (FP)]

Provide system isolation in the event of a piping break in order to minimize the release of radioactive fission products to the environment. [10 CFR 54.4(a)(1)]

The system contains components credited with compliance with 10 CFR 50.49 [Reference 1.3-7]. [10 CFR 54.4(a)(3) – (EQ)]

Other functions associated with systems comprising the reactor coolant pressure boundary are listed with the specific system.

Component Types Subject to Aging Management Review

Table 2.3.1-3 lists the component types that require aging management review and their intended functions.

Table 3.1.2-3, Reactor Vessel, Internals and Reactor Coolant Systems – Reactor Coolant Pressure Boundary System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.1.4 Reactor Recirculation (B33)

System Description

The reactor recirculation system consists of two recirculation pump loops external to the reactor vessel. These loops provide the piping path for the driving flow of water to the reactor vessel jet pumps. Each external loop contains one high capacity two-speed motor-driven recirculation pump, two motor-operated maintenance valves and one hydraulically operated flow control valve. The variable position hydraulic flow control valve operates in conjunction with a low frequency motor-generator set to control reactor power level through the effects of coolant flow rate on moderator void content. The low frequency motor-generator source is only used to power the recirculation pumps at low power. When reactor power is greater than approximately 20-28 percent of rated, the recirculation pumps are switched to the 100 percent speed power source.

The jet pumps are part of the reactor vessel internals. The jet pumps provide a continuous internal circulation path for the major portion of the core coolant flow. The jet pumps are mounted in the annular region between the core shroud and the vessel inner wall. Any recirculation line break would still allow core flooding to approximately two-thirds of the core height (the level of the inlet of the jet pumps).

System Boundary

System components subject to aging management review include nonsafety-related hydraulic pumps, valves, tanks, and piping components associated with the reactor recirculation valve actuators, and safety-related valves and piping components associated with reactor recirculation instrumentation.

The jet pump assemblies and associated components internal to the reactor vessel are evaluated with the Reactor Vessel Internals system (B13b). The ASME Class 1 components of the system external to the reactor vessel are evaluated with the Reactor Coolant Pressure Boundary (RCPB).

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP and EQ.

Reactor recirculation provides forced circulation through the core to achieve full power operation and allows power to be varied without movement of the control rods.

Flow Control Valves (FCVs) Hydraulic Power Units maintain the associated reactor recirculation flow control valve available for operation. Both subloops auto shift to the Maintenance Mode and lock-up the FCVs when specific abnormal conditions are detected.

The system contains safety-related indication. [10 CFR 54.4(a)(1), (a)(3) – EQ]

Reactor Recirculation Reactor Coolant Pressure Boundary. [10 CFR 54.4(a)(1), (a)(3) – FP] (ASME Class 1 components are evaluated with the Reactor Coolant Pressure Boundary section)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Table 2.3.1-4 lists the component types that require aging management review and their intended functions.

Table 3.1.2-4, Reactor Vessel, Internals and Reactor Coolant Systems – Reactor Recirculation System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.1.5 Reactor Vessel (RXV)

System Description

The reactor vessel contains the core and supporting structures. The main connections to the vessel include steam lines, coolant recirculation lines, feedwater lines, control rod drive and in-core nuclear instrument housings, core spray lines, RHR/LPCI line, core differential pressure line, jet pump pressure sensing lines, and water level instrumentation lines.

The reactor vessel is a vertical, cylindrical pressure vessel of welded construction. The vessel top head is secured to the reactor vessel by studs and nuts. The vessel flanges are sealed with two concentric metal seal-rings designed to permit no detectable leakage through the inner or outer seal at any operating condition.

System Boundary

System components subject to aging management review include the reactor vessel and attached brackets and welds, vessel head, studs, nuts, support skirt, nozzles, safe ends, and welds are evaluated within this section. This scope comprises the components with functional location identifiers for the Reactor and Internals system with the following exceptions/clarifications:

- The components internal to the reactor vessel are evaluated with the Reactor Vessel Internals system.
- The vessel closure head o-rings are within the scope of license renewal, but are periodically replaced, and are not subject to aging management.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulation for FP.

The reactor vessel serves as a pressure boundary for containing the coolant under operating temperature and pressure conditions and for limiting leakage and the release of fission products. [10 CFR 54.4(a)(1), (a)(3) – FP]

The reactor vessel provides structural support for the vessel internals and fuel to maintain core geometry. [10 CFR 54.4(a)(1)]

Component Types Subject to Aging Management Review

Table 2.3.1-5 lists the component types that require aging management review and their intended functions.

Table 3.1.2-5, Reactor Vessel, Internals and Reactor Coolant Systems – Reactor Vessel System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.1.6 Reactor Vessel Internals (RVI)

System Description

The major reactor internal components are the core (fuel, channels, control blades, and instrumentation), the core support structure (including the shroud, top guide and core plate), the shroud head and steam separator assembly, the steam dryer assembly, the feedwater spargers, the core spray spargers, and the jet pumps.

The floodable inner volume of the reactor pressure vessel is the volume inside the core shroud up to the level of the jet pump suction inlet. The design arrangement of the reactor internals, such as the jet pumps, steam separators and guide tubes, is such that one end is unrestricted and thus free to expand. The LPCI couplings incorporate vertically oriented slip fit joints to allow free thermal expansion.

The core support structures and reactor vessel internals (exclusive of fuel, control rods and incore nuclear instrumentation) are identified below.

Core Support Structures

These structures form partitions within the reactor vessel, to sustain pressure differentials across the partitions, direct the flow of the coolant water and laterally locate and support the fuel assemblies.

a. Shroud

The shroud support, shroud and top guide make up a stainless steel cylindrical assembly that provides a partition to separate the upward flow of coolant through the core from the downward recirculation flow. This partition separates the core region from the downcomer annulus, thus providing a floodable region following a recirculation line break. The volume enclosed by this assembly is characterized by three regions. The upper portion surrounds the core discharge plenum, which is bounded by the shroud head on top and the top guide's grid plate below. The central portion of the shroud surrounds the active fuel and forms the longest section of the assembly. This section is bounded at the top by the grid plate and at the bottom by the core plate. The lower portion, surrounding part of the lower plenum, is welded to the reactor pressure vessel shroud support.

b. Shroud Support

The shroud support is designed to support the shroud and to support and locate the jet pumps. The shroud support provides an annular baffle between the reactor pressure vessel and the shroud. The jet pump discharge diffusers penetrate the shroud support to introduce coolant to the inlet plenum below the core.

c. Shroud Head and Steam Separator Assembly

This component is not a core support structure or safety class component. It is discussed here to describe the coolant flow paths in the reactor pressure vessel. The shroud head and steam separator assembly is bolted to the top of the top guide to form the top of the core discharge plenum. This plenum provides a mixing chamber for the steam-water mixture before it enters the steam separators. Individual stainless steel axial flow steam separators are attached to the top of standpipes that are welded into the shroud head. The steam separators have no moving parts. In each separator, the steam-water mixture rising through the standpipe passes vanes that impart a spin to establish a vortex separating the water from the steam. The separated water flows from the lower portion of the steam separator into the downcomer annulus.

d. Core Plate

The core plate consists of a circular stainless steel plate with bored holes stiffened with a rim and beam structure. The plate provides lateral support and guidance for the control rod guide tubes, in-core flux monitor guide tubes, peripheral fuel supports, and startup neutron sources. The last two items are also supported vertically by the core support plate. The entire assembly is bolted to a support ledge on the lower portions of the shroud.

e. Top Guide

The top guide consists of a circular grid plate with square openings welded to the bottom of the top guide cylinder. Each opening provides lateral support and guidance for four fuel assemblies, or in the case of peripheral fuel, less than four fuel assemblies. Notches are provided in the bottom of the intersections to anchor the in-core flux monitors and startup neutron sources. The top guide is bolted to the shroud. The core spray spargers are installed in the upper portion of the top guide cylinder.

f. Fuel Support

The fuel supports are of two basic types: peripheral supports and four-lobed orificed fuel supports. The peripheral fuel support is located at the outer edge of the active core and is not adjacent to control rods. Each peripheral fuel support will support one fuel assembly and contains a single orifice assembly designed to assure proper coolant flow to the peripheral fuel assembly. Each four-lobed orificed fuel support will support four fuel assemblies and is provided with four orifice plates to assure proper coolant flow distribution to each rod-controlled fuel assembly. The four-lobed orificed fuel supports rest in the top of the control rod guide tubes which are supported laterally by the core plate. The control rods pass through slots in the center of the four-lobed orificed fuel support. A control rod and the four adjacent fuel assemblies represent a core cell.

g. Control Rod Guide Tubes

The control rod guide tubes, located inside the vessel, extend from the top of the control rod drive housings up through holes in the core plate. Each tube is designed as the guide for a control rod and as the vertical support for a four-lobed orificed fuel support piece and the four fuel assemblies surrounding the control rod. The bottom of the guide tube is supported by the control rod drive housing, which in turn transmits the weight of the guide tube, fuel support and fuel assemblies to the reactor vessel bottom head. A thermal sleeve is inserted into the control rod drive housing from below and is rotated to lock the control rod guide tube in place. A key is inserted into a locking slot in the bottom of the control rod drive housing to hold the thermal sleeve in position.

Reactor Internals

a. Jet Pump Assemblies

The jet pump assemblies are not core support structures but are discussed here to describe coolant flow paths in the vessel. The jet pump assemblies are located in two semi-circular groups in the downcomer annulus between the core shroud and the reactor vessel wall. Each stainless steel jet pump consists of driving nozzles, suction inlet, throat or mixing section, and diffuser. The driving nozzle, suction inlet and throat are joined as a removable unit, and the diffuser is permanently installed. High pressure water from the recirculation pumps is supplied to each pair of jet pumps through a riser pipe welded to the recirculation inlet nozzle thermal sleeve. A riser brace consists of cantilever beams welded to a riser pipe and to pads on the reactor vessel wall. The nozzle entry section is connected to the riser by a metal-to-metal, spherical-to-conical seal joint. Firm contact is maintained by a hold-down clamp. The throat section is supported laterally by a bracket attached to the riser. There is a slip-fit joint between the throat and diffuser. The diffuser is a gradual conical section changing to a straight cylindrical section at the lower end.

b. Steam Dryer

The steam dryer assembly is not a core support structure or safety class component. It is discussed here to describe coolant flow paths in the vessel. The steam dryers remove moisture from the wet steam leaving the steam separators. The extracted moisture flows down the dryer vanes to the collecting troughs, then flows through tubes into the downcomer annulus. A skirt extends from the bottom of the dryer vane housing to the steam separator standpipe, below the water level. This skirt forms a seal between the wet steam plenum and the dry steam flowing from the top of the dryers to the steam outlet nozzles. The steam dryer and shroud head are positioned in the vessel during installation with the aid of vertical guide rods. The dryer assembly rests on steam dryer support brackets attached to the reactor vessel wall. Upward movement of the dryer assembly, which may occur under accident conditions, is restricted by steam dryer hold-down brackets attached to the reactor vessel top head.

c. Feedwater Spargers

These components are not core support structures or safety class components. They are discussed here to describe flow paths in the vessel. The feedwater spargers are stainless steel headers located in the mixing plenum above the downcomer annulus. A separate sparger is fitted to each feedwater nozzle and is shaped to conform to the curve of the vessel wall. Sparger end brackets are pinned to vessel brackets to support the spargers. Feedwater flow enters the center of the spargers and is discharged radially inward to mix the cooler feedwater with the downcomer flow from the steam separators and steam dryer before it contacts the vessel wall. The feedwater also serves to condense the steam in the region above the downcomer annulus and to sub-cool the water flowing to the jet pumps and recirculation pumps.

d. Core Spray Lines and Liquid Control Line

These components are not core support structures. They are discussed here to describe safety class features inside the reactor pressure vessel. The core spray lines are the means for directing flow to the core spray nozzles which distribute coolant during accident conditions. The core spray line associated with the high pressure core spray system also serves as the liquid control line for providing a path for liquid control solution injection. Two core spray lines enter the reactor vessel through the two core spray nozzles. The lines divide immediately inside the reactor vessel. The two halves are routed to opposite sides of the reactor vessel and are supported by clamps attached to the vessel wall. The lines are then routed downward into the downcomer annulus and pass through the top guide cylinder immediately below the flange. The flow divides again as it enters the center of the semicircular sparger, which is routed halfway around the inside of the top guide cylinder. The two spargers are supported by brackets designed to accommodate thermal expansion. The line routing and supports are designed to accommodate differential movement between the top guide and vessel. The other core spray line is identical except that it enters the opposite side of the vessel, and the spargers are at a slightly different elevation inside the top guide cylinder. The correct spray distribution pattern is provided by a combination of distribution nozzles pointed radially inward and downward from the spargers. Use of the HPCS spray line for liquid control solution injection facilitates good mixing and dispersion.

e. Vessel Head Spray Nozzle

This component is not a core support structure. It is included here to describe a safety class feature in the reactor pressure vessel that receives flow from the RCIC system, or can be aligned to receive flow from the RHR system, when those systems are in operation. When reactor coolant is returned to the reactor vessel, part of the flow can be diverted to a spray nozzle in the reactor head. This spray maintains saturated conditions in the reactor vessel head volume by condensing steam being generated by the hot reactor vessel walls and internals. The spray also decreases thermal stratification in the reactor vessel coolant. This ensures that the water level in the reactor vessel can rise. The higher water level provides conduction cooling to more of the mass of metal of the reactor vessel and, therefore, helps to maintain the cooldown rate. The vessel head spray nozzle is mounted to a short length of pipe and a flange, which is bolted to a mating flange on the reactor vessel head nozzle.

f. Differential Pressure Sensing Lines

These components are not core support structures or safety class components. The differential pressure lines enter the vessel through two bottom head penetrations and sense the differential pressure across the core support plate. One line terminates near the lower shroud with a perforated length below the core support plate to sense the pressure in that region. The other line terminates immediately above the core support plate and senses the pressure in the region outside the fuel assemblies.

g. In-Core Flux Monitor Guide Tubes

This component is not a core support structure. They provide a means of positioning fixed detectors in the core as well as provide a path for calibration monitors (TIP System). The in-core flux monitor guide tubes extend from the top of the in-core flux monitor housing in the lower plenum to the top of the core support plate. The power range detectors for the power range monitoring units and the dry tubes for the source range monitoring and intermediate range monitoring (SRM/IRM) detectors are inserted through the guide tubes. A latticework of clamps, tie bars and spacers give lateral support and rigidity to the guide tubes. The bolts and clamps are welded, after assembly, to prevent loosening during reactor operation.

h. Surveillance Sample Holders

This component is not a core support structure or a safety class component. The surveillance sample holders are welded baskets containing impact and tensile specimen capsules. The baskets hang from the brackets that are attached to the inside wall of the reactor vessel and extend to mid-height of the active core. The radial positions are chosen to expose the specimens to the same environment and maximum neutron fluxes experienced by the reactor vessel itself while avoiding jet pump removal interference or damage.

i. Low Pressure Coolant Injection (LPCI) Lines

This component is not a core support structure but is discussed here to describe the coolant flow paths in the reactor vessel. Three LPCI lines penetrate the core shroud through separate LPCI nozzles. Coolant is discharged inside the core shroud.

System Boundary

Components within the reactor vessel are evaluated within this system. This scope comprises the components with functional location identifiers for the Reactor and Internals system with the following exceptions/clarifications:

- The reactor vessel, vessel head, studs, nuts, CRD housing nozzles, safe ends, and welds are evaluated within the Reactor Vessel system. Additionally, non-Class I components of the control rod drive system external to the reactor vessel are evaluated within the Reactor Vessel system.
- The fuel assemblies and control rod assemblies are in scope for license renewal; however, they are short-lived components and are therefore not subject to aging management review. Fuel assemblies are further evaluated in the J11 System Scoping

Report. The following Reactor Vessel Internals components are not required to support intended functions and are not included within the scope of license renewal; the feedwater sparger, the shroud head and steam separator assemblies and guide rods, core plate differential sensing lines, and the surveillance sample holders. A safety assessment for these components has been documented in BWRVIP-06-A. The evaluation concluded that these components do not perform a safety related function. This report also concluded that failure of these components does not result in consequential failure of any safety-related equipment, including the potential effects of loose parts. The steam dryer is also nonsafety-related, but the safety assessment for this component credited inspections which would identify cracking before gross failure. Therefore, the steam dryer will be subject to aging management.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, perform a function that demonstrates compliance with the Commission's regulations for anticipated transients without scram (ATWS), and EQ, and because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The reactor vessel serves as a pressure boundary for containing the coolant under operating temperature and pressure conditions and for limiting leakage and the release of fission products. [10 CFR 54.4(a)(1)]

The reactor vessel provides a floodable volume in which the core can be adequately cooled in the event of a breach in the reactor coolant pressure boundary external to the reactor vessel. [10 CFR 54.4(a)(1)]

The reactor vessel internal components provide structural support of internals and fuel to maintain core geometry [10 CFR 54.4(a)(1)]

Reactor vessel internal components establish flow paths within the vessel to support removal of heat from the fuel and providing a path for liquid control solution injection. [10 CFR 54.4(a)(1), (a)(3) ATWS, EQ]

Failure of non-safety internal components could adversely affect flow paths within the vessel [10 CFR 54.4(a)(2)]

Component Types Subject to Aging Management Review

Table 2.3.1-6 lists the component types that require aging management review and their intended functions.

Table 3.1.2-6, Reactor Vessel, Internals and Reactor Coolant Systems – Reactor Vessel Internals System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.2 ENGINEERED SAFETY FEATURES SYSTEMS

The following systems are included in this section:

- Alternate Decay Heat Removal [Section 2.3.2.1]
- Annulus Exhaust Gas Treatment [Section 2.3.2.2]
- Containment Atmosphere Monitoring [Section 2.3.2.3]
- High Pressure Core Spray [Section 2.3.2.4]
- Low Pressure Core Spray [Section 2.3.2.5]
- Offgas [Section 2.3.2.6]
- Reactor Core Isolation Cooling [Section 2.3.2.7]
- Residual Heat Removal and Containment Spray [Section 2.3.2.8]
- Suppression Pool [Section 2.3.2.9]

2.3.2.1 Alternate Decay Heat Removal (G40)

System Description

The alternate decay heat removal (ADHR) system is a nonsafety-related, seismic Category I system. The ADHR system is designed to provide additional decay heat removal options through a nonsafety-related alternate decay heat removal system that can be used in MODE 4 and MODE 5 with the reactor depressurized and reactor coolant system temperature less than or equal to 200°F. The system is designed to remove the decay heat load that exists approximately 24 hours after plant shutdown from 100% power.

The system consists of an ADHR heat exchanger and pump, suction and return lines with tie-ins to the low pressure core spray (LPCS) system, residual heat removal (RHR) system, and condensate transfer and storage (CTS) system with the associated piping, valves, instrumentation and appurtenances. The cooling water for the ADHR heat exchanger is provided by the Service Water (SW) system. The ADHR system is limited to a heat removal rate corresponding to the decay heat production rate of the core 24 hours after a scram from sustained 100% power. Once the plant has been shut down for 24 hours or greater, is in MODE 4 or 5 and the reactor is depressurized, ADHR may be placed in service.

The ADHR system is nonsafety-related and is not required for the safe shutdown of the reactor. However, portions of the piping and valves in the ADHR system that are within the ASME boundaries of the RHR system and the LPCS system are safety-related.

System Boundary

System components subject to aging management review include a pump, heat exchanger, valves and other piping components, as shown on LR boundary drawings.

The radiation monitor for ADHR is evaluated as part of the plant radiation monitoring system (System D17).

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

1. System piping components support integrity of safety-related interfacing systems. [10 CFR 54.4(a)(1)]
2. The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]
3. Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]
4. Provide additional decay heat removal options in Modes 4 and 5.
5. Provide additional injection into the Reactor Pressure Vessel when Low Pressure Core Spray is unavailable to maintain adequate core cooling.
6. Provide additional cooling of the Suppression Pool when Residual Heat Removal is unavailable.

Component Types Subject to Aging Management Review

Table 2.3.2-1 lists the component types that require aging management review and their intended functions.

Table 3.2.2-1, Engineered Safety Features Systems – Alternate Decay Heat Removal System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.2.2 Annulus Exhaust Gas Treatment (M15)

System Description

The annulus exhaust gas treatment system (AEGTS) processes the ambient air in the annular space between the shield building and the primary containment vessel to limit the release to the environment of radioisotopes which may leak from the primary containment under accident conditions.

The annulus exhaust gas treatment system consists of two redundant subsystems designed to filter any airborne radioactive iodine and particulates from the air which leak out of the containment vessel. Each subsystem (consisting of a 100 percent capacity exhaust fan, roughing, HEPA, and charcoal filters) exhausts to the plant vent.

This system is Safety Class 2 and functions continuously during normal, shutdown and refueling operations, during loss of offsite power periods and following a LOCA to maintain a negative pressure differential between the containment vessel annulus and the outside.

System Boundary

System components subject to aging management review include fan housings, filter housings, damper housings and other ductwork components in the reactor building annulus, and in the intermediate building, as shown on the LR boundary drawing.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP and EQ.

AEGTS maintains the annulus space between shield building and containment vessel at a negative pressure. Processes the ambient air in the annular space between the shield building and the primary containment vessel to limit the release to the environment of radioisotopes which may leak from the primary containment under accident conditions. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Ventilation ducts penetrating the shield building wall are provided with fire dampers to limit the spread of fires. [10 CFR 54.4(a)(3) – FP]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ].

Component Types Subject to Aging Management Review

2.3.2.3 Containment Atmosphere Monitoring (D23)

System Description

The containment atmospheric monitoring system provides instrumentation for detecting and predicting the progression of abnormal occurrences in the containment and for monitoring after postulated accidents. Containment and Drywell temperature, pressure and differential pressure monitoring is provided by instrumentation and alarms. The system also provides suppression pool temperature monitoring instrumentation and Containment humidity instrumentation.

System Boundary

System components subject to aging management review include safety-related instrument sensing piping, orifices and valves, as shown on the LR boundary drawing.

The piping penetrating the containment is evaluated as "piping," with the structural penetration components evaluated as civil components. The protection tubes associated with suppression pool temperature elements are evaluated as civil components.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Provides indication of Drywell pressure and temperature, Containment pressure and temperature, Containment/Drywell differential pressure, suppression pool temperature, and sample line isolation valve position. [10 CFR 54.4(a)(1)]

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Component Types Subject to Aging Management Review

Table 2.3.2-3 lists the component types that require aging management review and their intended functions.

2.3.2.4 High Pressure Core Spray (E22)

System Description

The high pressure core spray (HPCS) system provides and maintains an adequate coolant inventory inside the reactor vessel to limit fuel cladding temperatures in the event of breaks in the reactor coolant pressure boundary. The system is initiated by either high pressure in the drywell or low water level in the vessel. It operates independently of all other systems over the entire range of pressure differences from greater than normal operating pressure to zero. Suction piping is provided from the condensate storage tank and the suppression pool. The standby liquid control system discharges into the Reactor Vessel via HPCS piping and the HPCS spargers. The suppression pool cleanup system takes its suction from the HPCS suppression pool suction line.

The pump discharge line is maintained full by a jockey pump that takes suction from the HPCS pump suction line and discharges downstream of the check valves on the HPCS pump discharge line.

System Boundary

System components subject to aging management review include a single motor-driven centrifugal pump and associated system piping, valves, controls, and instrumentation as shown on LR boundary drawings. The HPCS pump seal water cyclone separator and associated piping are not shown on LR boundary drawings but are within scope.

The ASME Class 1 piping components in the system are evaluated with the Reactor Coolant Pressure Boundary System, and the piping and spray sparger in the reactor vessel are evaluated with the Reactor Vessel Internals System. The HPCS diesel generator is evaluated with the Division 1 and 2 diesel generators.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ, ATWS, and SBO.

Spray coolant into the reactor vessel to mitigate accidents. This system along with the other ECCS systems satisfy the requirements of 10 CFR 50.46. [10 CFR 54.4(a)(1), (a)(3) - ATWS]

Containment isolation valves limit radiological release. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

The system is used as the means for removing decay heat following a Station Blackout event. [10 CFR 54.4(a)(3) – SBO]

Component Types Subject to Aging Management Review

2.3.2.5 Low Pressure Core Spray (E21)

System Description

The low pressure core spray (LPCS) system consists of one independent pump and the valves and piping to deliver cooling water to a spray sparger over the core. The system is actuated by conditions indicating that a breach exists in the reactor coolant pressure boundary. However, water is delivered to the core only after reactor vessel pressure is reduced.

The LPCS injection piping enters the vessel, divides and enters the core shroud at two points near the top of the shroud. A semicircular sparger is attached to each outlet. Nozzles are spaced around the sparger to spray the water radially over the core and into the fuel assemblies.

The pump discharge line is maintained full by a jockey pump that takes suction from the LPCS pump suction line from the suppression pool and discharges downstream of the check valves on the LPCS pump discharge line. This pump is also used to supply water to the feedwater leakage control system (FWLCS) (N27).

System Boundary

System components subject to aging management review includes pumps, valves and piping components to convey water from the suppression pool to ASME Class 1 piping (which connects to a sparger), as shown on LR boundary drawings. The system also includes a pump to keep the LPCS pump discharge piping full. The LPCS pump seal water cyclone separator and associated piping are not shown on LR boundary drawings but are within scope.

ASME Class 1 components within this functional boundary are evaluated with the reactor coolant pressure boundary system. The core spray piping and sparger within the reactor vessel are evaluated with the reactor vessel internals system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP and EQ.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

Provide core cooling by spraying coolant into the top of the fuel assemblies to mitigate accidents. This system along with the other ECCS systems satisfy the requirements of 10 CFR 50.46. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Provide low pressure reactor coolant make up after the vessel has been depressurized. [10 CFR 54.4(a)(3) – FP]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Component Types Subject to Aging Management Review

Table 2.3.2-5 lists the component types that require aging management review and their intended functions.

2.3.2.6 Offgas (N64)

System Description

The main condenser offgas treatment system reduces the gaseous radwaste emission from the station. The offgas system uses a catalytic recombiner to recombine radiolytically dissociated hydrogen and oxygen. After cooling (to approximately 130°F) to strip the condensable gases and reduce the volume; the remaining incondensable gases (principally air with traces of krypton and xenon) will be delayed in the nominal 10-minute holdup system. The gas is cooled to 45°F and filtered through a HEPA filter. The gas is then passed through a desiccant dryer that reduces the dew point between 0°F and -40°F and is then chilled between 0°F and +40°F. Charcoal adsorption beds, normally operating in a refrigerated vault between 40°F and 0°F, selectively adsorb and delay the xenon and krypton gases from the bulk carrier gas (principally dry air). After the delay, the gas is again passed through a HEPA filter and discharged to the environment through the offgas building vent.

The offgas system is designed to limit the dose to offsite persons from routine station releases to significantly less than the limits specified in 10 CFR 20 and to operate within the emission rate limits established in the Offsite Dose Calculation Manual. The system does not contain any safety-related mechanical components.

The offgas charcoal vault refrigeration system consists of four 50 percent capacity air handling units, three 50 percent series connected brine cooling packages, two 100 percent capacity brine recirculation pumps, brine expansion tanks, brine filter drier, air distribution ductwork, and brine distribution piping. The offgas vault is divided into two pairs of rooms. Each pair is served by two air handling units, each capable of handling the total load per pair of rooms. During normal operation one air handling unit per room is operating and the other is a backup unit. It supplies recirculated cooled air to the vault to dissipate the heat load and maintain the vault in its operating band (normal range of 0°F to +40°F).

Two separate radiological analyses are provided for the control rod drop accident (CRDA):

1. The first analysis assumes the accident occurs at a low reactor power level with the mechanical vacuum pumps in operation or at any power level with a coincident loss of offsite power (LOOP);

2. The second analysis assumes the accident occurs at a higher reactor power level with the Steam Jet Air Ejectors in operation such that the condenser gases are processed through the offgas filtration system.

For the first CRDA scenario:

A coincident LOOP condition results in the automatic closure of the MSIVs, thereby stopping the transport of the fission products to the condenser. Radioactive release to the environment follows due to the condenser leakage. Alternatively, if the mechanical vacuum pumps are in operation (i.e., low reactor power level) at the time of the CRDA and a LOOP does not occur, the high radiation condition will be detected by the main steam line radiation monitors causing an automatic isolation of the operating mechanical vacuum pump line. Once again, the radioactive release to the environment will occur as a function of condenser leakage.

For the second CRDA scenario:

The transport pathway consists of carryover with steam to the turbine condenser and leakage from the condenser to the environment via the offgas (N64) system. Of the activity reaching the condenser, 100 percent of the noble gases, 10 percent of the iodine, and 1 percent of the particulate radionuclides remain airborne. The activity airborne in the condenser is processed by the offgas filtration system prior to release to the environment. Only the noble gases are released from the offgas system.

System Boundary

That portion of the offgas system upstream of the gas dryer prefilters is housed in the turbine building, which is a non-seismic, nonsafety class, reinforced concrete structure below grade. The remaining portion of this system is in the offgas building, which is a Safety Class 3, Seismic Category I, reinforced concrete structure. As the only license renewal intended function of the offgas system components is to maintain a leakage boundary per 10 CFR 54.4(a)(2), the system components subject to aging management are piping and valves that provide a fluid leakage boundary in the offgas building.

The system includes a “brine” cooling subsystem which contains a liquid fluorocarbon refrigerant. The brine remains liquid at room temperature and pressure, so the brine cooling system is within scope with a leakage boundary function. The brine is cooled by a refrigerant system which uses a fluorocarbon working fluid that is gaseous at room temperature and pressure. The system that cools the brine therefore corresponds to a gas in NEI 95-10 [Reference 1.3-3] and does not have a leakage boundary intended function.

Components containing turbine building closed cooling water are evaluated with the turbine building closed cooling (P44) system.

As documented in the NRC Safety Evaluation for PNPP License Amendment 166, the second CRDA scenario that credits the N62 and N64 systems is not used as a basis for acceptance for PNPP CRDA radiological consequences. Ultimately, the N64 system has no effect on the radiological consequences of a control rod drop accident, and as such does not meet 54.4(a) scoping criteria for mitigation of a CRDA.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Offgas system processes and controls the release of gaseous effluents from the main and auxiliary condensers to the environment.

Component Types Subject to Aging Management Review

Table 2.3.2-6 lists the component types that require aging management review and their intended functions.

Table 3.2.2-6, Engineered Safety Features Systems – Offgas System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.2.7 Reactor Core Isolation Cooling (E51)

System Description

The reactor core isolation cooling (RCIC) system provides makeup water to the reactor vessel when the vessel is isolated. The RCIC system uses a steam-driven turbine-pump unit and operates automatically in time and with sufficient coolant flow to maintain adequate water level in the reactor vessel, for the following conditions:

a. Reactor vessel isolated and maintained in the hot standby condition.

b. Reactor vessel isolated and accompanied by loss of coolant flow from the reactor feedwater system.

c. Initiation of plant shutdown with a loss of normal feedwater system before the reactor is depressurized to a level where the shutdown coolant system can be placed into operation.

The RCIC pump can supply demineralized makeup water from the condensate storage tank to the reactor vessel, with an alternate supply from the suppression pool.

A water leg pump maintains the RCIC lines full of water up to the injection valve.

At PNPP, the reactor core isolation cooling (RCIC) system is not considered an emergency core cooling system (ECCS).

System Boundary

System components subject to aging management review include pumps, valves, piping components, and a steam turbine associated with the RCIC supply, as shown on LR boundary drawings. The system includes a water leg pump to keep the pump piping filled. The system also includes a pump to supply hydraulic pressure to support testing of selected check valves.

ASME Class 1 components in the steam supply and in the pump discharge flow path are evaluated with the reactor coolant pressure boundary system. The reactor vessel head spray nozzle (pump discharge flow path) is evaluated with the Reactor Internals.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP, EQ, ATWS and SBO.

Reactor Core Isolation Cooling ensures adequate core cooling by providing high pressure injection to the reactor vessel. [10 CFR 54.4(a)(1), (a)(3) – ATWS, FP]

Containment isolation limits radiological release. [10 CFR 54.4(a)(1), (a)(3) - SBO]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Component Types Subject to Aging Management Review

Table 2.3.2-7 lists the component types that require aging management review and their intended functions.

Table 3.2.2-7, Engineered Safety Features Systems – Reactor Core Isolation Cooling System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.2.8 Residual Heat Removal (E12) and Containment Spray (E15)

System Description

The residual heat removal (RHR) system removes decay and sensible heat during and after plant shutdown, injects water into the reactor vessel following a loss-of-coolant accident to reflood the core and maintain fuel cladding below peak cladding temperature consistent with 10 CFR 50.46 requirements. The RHR system removes heat from the containment following a loss-of-coolant accident to limit the increase in containment pressure. This is accomplished by cooling and recirculating the suppression pool water and by spraying the containment air space with suppression pool water. Containment spray uses two redundant subsystems, each with its own full capacity spray header. Each subsystem is supplied from a separate redundant RHR subsystem.

The RHR system is comprised of three independent loops. Each loop contains its own motor-driven pump, piping, valves, instrumentation and controls. Each loop has a suction source from the suppression pool and is capable of discharging water to the reactor vessel via a separate nozzle, or back to the suppression pool via a full flow test line. In addition, the A and B loops have heat exchangers which are cooled by emergency service water. Loops A and B can also take suction from the reactor recirculation system suction or fuel pool, and can discharge into the reactor via the feedwater line, fuel pool cooling discharge, or to the containment spray spargers.

The Division 1 pump discharge line is kept full by a jockey pump that takes a suction from the low pressure core spray pump suction line from the suppression pool and discharges downstream of the check valve on the RHR A pump discharge line. The Division 2 pumps' discharge lines are kept full by a jockey pump that takes suction from the C RHR pump suction line from the suppression pool and discharges downstream of the check valves on the B and C RHR pump discharge lines. These pumps are also used to supply water to the feedwater leakage control system (FWLCS) (N27).

The system has four primary modes of operation:

1. Residual Heat Removal Mode (Shutdown Cooling Mode) to remove decay and sensible heat from the reactor primary system.
2. Low Pressure Coolant Injection (LPCI) Mode to pump water from the suppression pool into the core region of the vessel using separate pump loops for a design-basis LOCA.
3. Suppression Pool Cooling Mode to cool and mix the suppression pool.
4. Containment Spray Cooling Mode to spray into the containment and suppression pool vapor space, reducing internal pressure to below design limits.

The Reactor Steam Condensing Mode of RHR operation is not used at PNPP.

System Boundary

System components subject to aging management review include three residual heat removal pumps, a water leg pump, four heat exchangers, valves, and piping components, including the containment spray rings and nozzles as shown on LR boundary drawings. The RHR pump seal water cyclone separators and associated piping are not shown on LR boundary drawings but are within scope.

ASME Class 1 piping components are evaluated with the reactor coolant pressure boundary. The RHR low pressure coolant injection (LPCI) lines inside the RPV and the LPCI flow deflector are evaluated with the reactor internals (B13b).

Thermowells PY-1E12W0003A & 3B and PY-1E12W0005A & 5B are evaluated with system P45, as they are in the emergency service water (ESW) piping. Valve PY-1E12F0565 is evaluated with liquid radwaste disposal system (G50), as it is within the piping for that system.

Combustible gas mixing system (M51) lube oil and after cooler valves that are supplied water from RHR are evaluated in this residual heat removal (E12) system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP, EQ and ATWS.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

Low-pressure coolant injection provides flow to the reactor vessel to mitigate accidents. This system along with the other ECCS systems satisfy the requirements of 10 CFR 50.46. [10 CFR 54.4(a)(1), (a)(3) - FP]

Provide a flow path for alternate injection sources to the reactor vessel. [10 CFR 54.4(a)(1)]

Remove heat from reactor and/or provide bulk mixing of the suppression pool to remove heat during normal and accident conditions. [10 CFR 54.4(a)(1), (a)(3) – FP, ATWS]

Containment spray removes heat from containment and serves as a containment atmosphere fission product removal mechanism. [10 CFR 54.4(a)(1)]

Remove heat from the upper fuel pool, and the spent fuel pool. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains safety-related indication. [10 CFR 54.4(a)(1), (a)(3) - EQ]

Component Types Subject to Aging Management Review

Table 2.3.2-8 lists the component types that require aging management review and their intended functions.

Table 3.2.2-8, Engineered Safety Features Systems – Residual Heat Removal and Containment Spray Systems – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.2.9 Suppression Pool (T21)

System Description

A suppression pool, located within containment, contains a large amount of water used to rapidly condense steam from reactor vessel blowdown or from a break in a major pipe. When needed to protect against overpressure, or to depressurize the reactor, safety/relief valves on the main steam lines (System B21 nuclear boiler) discharge steam through a discharge line to a point below the minimum water level in the suppression pool.

The suppression pool suction strainer provides filtered (strained) water from the suppression pool to the high pressure core spray pump, the low pressure core spray pump, the reactor core isolation cooling pump, and to the A, B, and C residual heat removal pumps. The suction strainer is designed to preclude the potential for loss of

NPSH caused by debris blockage during the period that the ECCS is required to maintain long-term cooling. The large toroidal passive strainer results in a very low approach velocity for water entering the strainer. The refueling bellows, which separates the drywell from the upper pool, is also evaluated within this system.

System Boundary

Mechanical components subject to aging management review are the suppression pool strainer, as shown on LR boundary drawings, and the refueling bellows, which separates the drywell from the upper pool.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP, ATWS and SBO.

Provides strained water for RHR pump operation, LPCS pump operation, HPCS pump operation and RCIC pump operation. [10 CFR 54.4(a)(1), (a)(3) – FP, ATWS, SBO]

The containment suppression pool provides steam suppression for transient discharges coming from the SRVs and the drywell vents; and provides a heat sink for pressure suppression during a LOCA. [10 CFR 54.4(a)(1), (a)(3) – FP, ATWS, and SBO]

The containment suppression pool provides a water seal between the containment vessel and drywell volume [10 CFR 54.4(a)(1)]

Provides a pressure barrier between the upper pool and the drywell (refueling bellows) during plant refueling operations. [10 CFR 54.4(a)(1)]

Component Types Subject to Aging Management Review

Table 2.3.2-9 lists the component types that require aging management review and their intended functions.

2.3.3 AUXILIARY SYSTEMS

The following systems are included in this section:

- Auxiliary Building Ventilation (Section 2.3.3.1)
- Breathable Air (Section 2.3.3.2)
- Building Heating (Section 2.3.3.3)
- Combustible Gas Control (Section 2.3.3.4)
- Computer Room HVAC (Section 2.3.3.5)
- Containment and Drywell Vacuum Relief (Section 2.3.3.6)
- Containment Integrated Leak Rate Test (Section 2.3.3.7)
- Containment Vessel and Drywell Purge (Section 2.3.3.8)
- Containment Vessel Chilled Water (Section 2.3.3.9)
- Control and Computer Room Humidification (Section 2.3.3.10)
- Control Complex Chilled Water (Section 2.3.3.11)
- Control Rod Drive (Section 2.3.3.12)
- Control Room HVAC and Emergency Recirculation (Section 2.3.3.13)
- Controlled Access and Miscellaneous Equipment Areas HVAC (Section 2.3.3.14)
- Diesel Generator and Auxiliaries (Section 2.3.3.15)
- Diesel Generator Building Ventilation (Section 2.3.3.16)
- ECCS Pump Room Cooling (Section 2.3.3.17)
- Emergency Closed Cooling (Section 2.3.3.18)
- Emergency Closed Cooling Pump Area HVAC (Section 2.3.3.19)
- Emergency Service Water (Section 2.3.3.20)
- Emergency Service Water Pump House Ventilation (Section 2.3.3.21)
- Emergency Service Water Screen Wash (Section 2.3.3.22)
- Feedwater Zinc Injection (Section 2.3.3.23)
- Fire Protection (Section 2.3.3.24)
- Floor and Equipment Drains (Section 2.3.3.25)
- Fuel Handling Area Ventilation (Section 2.3.3.26)
- Fuel Storage and Fuel Pool Cooling and Cleanup (Section 2.3.3.27)
- Hydrogen Water Chemistry (Section 2.3.3.28)
- Inclined Fuel Transfer System (Section 2.3.3.29)

- Industrial Waste Disposal (Section 2.3.3.30)
- Intermediate Building Ventilation (Section 2.3.3.31)
- Leak Detection (Section 2.3.3.32)
- Liquid Radwaste Disposal (Section 2.3.3.33)
- Liquid Radwaste Sumps (Section 2.3.3.34)
- MCC Switchgear and Miscellaneous Electrical Area HVAC, and Battery Room Exhaust (Section 2.3.3.35)
- Miscellaneous Area Ventilation (Section 2.3.3.36)
- Miscellaneous Electrical Areas Smoke Ventilation (Section 2.3.3.37)
- Miscellaneous Sump (Section 2.3.3.38)
- Nitrogen Supply (Section 2.3.3.39)
- Nuclear Closed Cooling (Section 2.3.3.40)
- Offgas Building Ventilation (Section 2.3.3.41)
- Penetration Electrical (Section 2.3.3.42)
- Penetration Pressurization (Section 2.3.3.43)
- Plant Foundation Underdrain (Section 2.3.3.44)
- Plant Radiation Monitoring and Process Monitoring, and Post Accident Radiation Monitoring (Section 2.3.3.45)
- Post-Accident Sampling (Section 2.3.3.46)
- Potable Water Supply (Section 2.3.3.47)
- Rx Plant Sampling (Section 2.3.3.48)
- Radwaste Building Ventilation (Section 2.3.3.49)
- Reactor Vessel Servicing Equipment (Section 2.3.3.50)
- Reactor Water Clean Up and Reactor Water Clean Up Filter Demineralizer (Section 2.3.3.51)
- Safety Related Instrument Air (Section 2.3.3.52)
- Sanitary Drain and Sewer (Section 2.3.3.53)
- Service Air and Instrument Air (Section 2.3.3.54)
- Service Water (Section 2.3.3.55)
- Standby Liquid Control (Section 2.3.3.56)
- Steam Tunnel Cooling (Section 2.3.3.57)
- Storm Drain and Sewer (Section 2.3.3.58)
- Suppression Pool Drain and Clean Up (Section 2.3.3.59)

- Suppression Pool Makeup (Section 2.3.3.60)
- Turbine Building Chilled Water (Section 2.3.3.61)
- Turbine Building Closed Cooling (Section 2.3.3.62)
- Turbine Building Ventilation (Section 2.3.3.63)

2.3.3.1 Auxiliary Building Ventilation (M38)

System Description

The auxiliary building ventilation system (ABVS) operates continuously to provide filtered and tempered outside air to various areas of the auxiliary building. The ABVS operates continuously to exhaust various areas of the auxiliary building and to direct this exhaust through a charcoal filter plenum to the unit vent. The supply system consists of one 100 percent capacity supply plenum housing roughing filters and hot water heating coils, two 100 percent capacity supply fans and supply distribution ducts. The exhaust system consists of one 100 percent capacity filter plenum which houses roughing, HEPA, charcoal and a second bank of HEPA filters, two 100 percent capacity exhaust fans, and exhaust distribution ducts. The supply and exhaust ductwork is arranged to serve the following areas:

a. Turbine building chiller hallway area;

b. LPCS pump room;

c. RHR "B" pump and heat exchanger room;

d. RHR "C" pump room;

e. RCIC pump room;

f. RHR "A" pump room and heat exchanger room;

g. HPCS pump room;

h. RWCU pump room;

i. Steam tunnel area;

j. Auxiliary building hallway; and

k. Alternate Decay Heat Removal (ADHR) System heat exchanger room.

During periods of emergency, the ABVS is not required to operate to safely shut down the plant.

The ABVS is classified as nonsafety-related and non-seismic category, except for the exhaust system charcoal filter plenum and for ductwork in close proximity to safety class equipment.

For the ADHR system, two packaged ABVS air conditioning units ensure that the temperature and relative humidity in the areas surrounding the ADHR pump and heat exchanger are not adversely impacted during the operation of the ADHR system.

System Boundary

System components subject to aging management review include fire dampers and associated duct, and condenser, plenum, valves, and piping components that provide leakage boundaries, as shown on the LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

System fire dampers prevent the spread of fires. [10 CFR 54.4(a)(3) – FP]

Provide filtered and tempered outside air to various areas of the auxiliary building.

Filter auxiliary building exhaust air to keep radioactivity release to the environment below permissible discharge limits.

Component Types Subject to Aging Management Review

Table 2.3.3-1 lists the component types that require aging management review and their intended functions.

Table 3.3.2-1, Auxiliary Systems – Auxiliary Building Ventilation System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.2 Breathable Air (P58)

System Description

Breathing protection apparatus are provided for control room occupants. Breathable air is provided by 10 compressed air cylinders located in the service building at elevation 620'-6". This air system supplies six breathable air stations with five connections on each station located in the control room. Self-contained breathing apparatus (SCBA) are provided for control room occupants. These SCBA can be supplied with air from the six breathable air stations in the control room or their own one hour compressed air bottle. The capacity of the 10 compressed air cylinders is sufficient to supply seven people for approximately six hours, plus each person has a one-hour supply in their SCBA bottle. The SCBA bottles and the large air cylinders can be filled by a breathable air compressor located onsite or via offsite services.

In the event of smoke or toxic gas in-leakage to the control room, the system provides a source of breathing air for use by operators.

System Boundary

System components subject to aging management review include filter housings, valves, tanks and piping components that supply breathing air to the control room personnel.

SCBA masks and (portable) air cylinders are consumables that do not require an aging management review.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent satisfactory accomplishment of functions credited for mitigation of a design basis event and contains components that are relied on to perform a function that demonstrates compliance with the regulations for FP.

In the event of smoke or toxic gas in-leakage to the Control Room, the system provides a source of breathing air for use by operators. [10 CFR 54.4(a)(2), (a)(3) – FP]

Component Types Subject to Aging Management Review

Table 2.3.3-2 lists the component types that require aging management review and their intended functions.

2.3.3.3 Building Heating (P55)

System Description

The heating system consists of two 100 percent shell and tube type heat exchangers (steam-water), two 100 percent circulation pumps, an expansion tank, a chemical mixing tank, hot water and electric unit heaters located at various buildings and elevations, valves, and distribution piping. The two steam sources for the hot water heating system are the extraction steam system (normal) and the auxiliary steam system (shutdown and startup). Two 100 percent heat exchangers are provided so that one heat exchanger will only use steam from the extraction steam system and the other heat exchanger will only use steam from the auxiliary steam system. This design precludes direct contamination of the auxiliary steam system by the extraction steam system.

During normal plant winter operation, the extraction steam heat exchanger and one of the two circulation pumps are in operation. Extraction steam is supplied to the shell of the heat exchanger to heat the water in the tube to 190°F. The steam heated water is then supplied to the hot water heating coils and hot water unit heaters located at various buildings and elevations. Hot water is also supplied to the mixed bed demineralizer system, two bed demineralizer system and condensate transfer and storage system heat exchangers for freeze protection. Hot water heating coils are used in conjunction with the building ventilation systems. They add heat to the supply air prior to distribution if the air temperature drops below the air temperature controller preset value. Hot water heating coils are used in the supply plenum of the following ventilation systems:

a. Auxiliary building ventilation system

b. Fuel handling building ventilation system

c. Heater bay ventilation system

d. Intermediate building ventilation system

e. Containment vessel purge supply system

f. Radwaste building ventilation system

g. Turbine power complex ventilation system

h. Turbine building ventilation system

Hot water and electric unit heaters are used to provide heat to the space they serve. When the space temperature drops below the preset value, the space thermostat provided with each heater will automatically operate the unit heater and will automatically stop the unit heater when the space temperature satisfies the thermostat set point. The following buildings are provided with hot water unit heaters:

a. Auxiliary Building
b. Auxiliary Boiler Building
c. Heater bay
d. Intermediate Building
e. Offgas Building
f. Radwaste Building
g. Turbine Building
h. Turbine Power Complex
i. Water Treating Building

The following buildings are provided with electric unit heaters:

a. Fuel Oil Pumphouse

b. Circulating Water Pumphouse
c. Diesel Generator Building
d. Discharge Tunnel Dechlorination Equipment Building
e. Decant Control Structure
f. Emergency Service Water Pumphouse
g. Reactor Building Annulus
h. Service Water Pumphouse
i. Control Complex stairway at Elevation 707’-2”

If heating is required during plant startup and shutdown, the aux steam heat exchanger and one of the two circulation pumps will operate. Operation is the same as described above except that steam is supplied to the heat exchanger by the auxiliary steam system. An expansion tank is also provided to allow water to expand as the water temperature rises. This tank is also pressurized with compressed nitrogen to help maintain the water pressure above the extraction steam pressure (60 psig minimum water pressure vs. 50 psig extraction steam pressure). This will prevent contamination of the hot water distribution system by the extraction steam. Pressure in the expansion tank is maintained at 70 psig by the addition of compressed nitrogen utilizing a nitrogen generator or N2 bottled gas. A pressure relief valve on the expansion tank relieves excessive tank pressure. Two-bed demineralized water (80-120 psig) is supplied for makeup water and water required to initially fill the system. This water is supplied through a valve controlled from level switches on the expansion tank. The valve closes when the water level in the expansion tank returns to high level. The valve is controlled between high and low level.

The system also provides Condensate Storage Tank freeze protection.

System Boundary

System components subject to aging management review include nonsafety-related area heaters, ventilation heaters, and piping system components that are located within structures that contain safety-related components, as shown on the LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Provide area and ventilation heating to maintain indoor area temperatures.

Provide Condensate Storage Tank freeze protection.

Component Types Subject to Aging Management Review

Table 2.3.3-3 lists the component types that require aging management review and their intended functions.

Table 3.3.2-3, Auxiliary Systems – Building Heating System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.4 Combustible Gas Control (M51)

System Description

The Containment Combustible Gas Control System (CCGCS) consists of four subsystems:

1. Hydrogen Analysis System
2. Hydrogen Mixing System
3. Hydrogen Recombination System
4. Combustible Gas Purge System

The hydrogen analysis system consists of two completely redundant hydrogen analyzers each with control room recorders and switch stations. One is supplied by Division 1, the other by Division 2. Each analyzer samples from four redundant sample lines: one from above the suppression pool, one from the space between the reactor vessel head and the drywell dome, one from the top of the drywell area, and one from the top of the dome of the containment vessel. Each sample point is manually selected for continuous sampling. After passing through the analyzers, the gas samples and any associated moisture are returned to the containment in an area above the suppression pool. Each analyzer has the capability to measure a range of 0-10% hydrogen concentration and is provided with reference and calibration gases as required. Each analyzer has alarms to annunciate in the control room for the following conditions; high and high-high hydrogen concentration, low sample flow, and system failure. The sample isolation valves are closed during normal plant operation. They are opened by an administratively controlled key operated switch prior to starting the hydrogen analyzers following a LOCA.

The hydrogen mixing system consists of two completely independent redundant systems located in adjacent quadrants of the containment building. Each system consists of one air compressor and related ductwork. Initial control of the hydrogen concentration following a LOCA will be accomplished by mixing volumes of potentially high and low hydrogen concentrations. Mixing is accomplished by means of redundant, 500 scfm, centrifugal air compressors which take suction from the containment volume just below the service floor and at the containment dome and discharge into the drywell. This pressurizes the drywell sufficiently to provide increase in drywell bypass leakage and uncover the upper row of suppression pool vents. The system is normally idle except for periodic testing. Following a LOCA, each mixing system is started manually on high hydrogen concentration in the drywell.

The hydrogen recombination system consists of two completely redundant systems located in the containment. Each system consists of a recombiner unit, a power supply cabinet and control panel which are separately mounted. The power supply cabinet and control panel are located outside containment. A wattmeter and thermocouple readout are provided on the control panel to monitor performance. The hydrogen recombiners are remote-manually initiated from the control complex. Except for periodic testing, the recombiners are idle during normal operation.

The combustible gas purge system is designed to aid in the cleanup of hydrogen. This purge system is manually operated from the control room. The system is designed to utilize the annulus gas treatment unit (AEGTS) to exhaust the hydrogen laden air from the drywell/containment. The system is provided with two containment isolation valves and a flow control valve failed in the open position which allows straight through flow to the AEGTS filters. The AEGTS is normally in service. The combustible gas purge system is normally used for drywell pressure control during plant startup and operation.

System Boundary

System components subject to aging management review include the recombiner housings, and various piping components associated with hydrogen analyzers, mixing compressor units, and the purge flow path as shown on the LR boundary drawings.

Piping and valves associated with the supply of emergency closed cooling water to the sample coolers are evaluated with the emergency closed cooling system (P42).

Piping and valves associated with the supply of RHR (cooling water) to the mixing compressors are evaluated with residual heat removal system (E12).

Piping associated with sample flow path to the PASS system is evaluated in post-accident sampling system (P87).

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Control hydrogen concentration in containment following a loss of coolant accident. [10 CFR 54.4(a)(1)]

Provide indication of containment hydrogen concentration. [10 CFR 54.4(a)(1)]

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Component Types Subject to Aging Management Review

Table 2.3.3-4 lists the component types that require aging management review and their intended functions.

Table 3.3.2-4, Auxiliary Systems – Combustible Gas Control System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.5 Computer Room HVAC (M27)

System Description

The computer room HVAC system operates continuously during normal plant operation to provide cooling and to maintain humidification in the computer room, to cool adjacent cable spreading areas and to supplement cooling of the control complex HVAC equipment room. The HVAC system consists of two 100 percent capacity supply air handling units, each including roughing filters, chilled water cooling coils and supply duct systems with steam humidifiers.

The duct systems are arranged so that cooled air from the air handling unit is ducted directly to the computer room. After absorbing heat from the computer room equipment, this air passes through the adjacent cable spreading area and returns to the heating and ventilating equipment room where the cooling cycle is repeated. During normal plant operation, power will be provided to this system from the preferred ac source. During periods of emergency, this system is not required to operate to safely shut down the plant.

This system is classified as nonsafety-related and non-seismic category. However, the cooling coils and related piping of this system will not rupture during a safe shutdown earthquake or an operating basis earthquake.

System Boundary

System components subject to aging management review are limited to fire dampers, as depicted on the LR boundary diagram.

Cooling water piping and cooler components associated with the air handling units are evaluated with the Control Complex Chilled Water system. Humidification components are evaluated with the Control and Computer Room Humidification system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

System fire dampers prevent the spread of fire. [10 CFR 54.4(a)(3) – FP]

Maintain computer room and cable spreading area temperature and humidity within normal limits.

Component Types Subject to Aging Management Review

Table 2.3.3-5 lists the component types that require aging management review and their intended functions.

2.3.3.6 Containment (M17) and Drywell (M16) Vacuum Relief

System Description

The containment vacuum relief system limits the buildup of negative pressure inside the containment vessel if one or both of the containment spray loops are inadvertently actuated. The check valves are normally closed while the motor operated isolation valves are normally open. The motor-operated isolation valve is closed automatically by a containment isolation signal. If vacuum relief is required during containment isolation, differential pressure devices provide an isolation override and automatically open the valve as required.

The drywell vacuum relief system equalizes pressure between the drywell and outer containment volume (portion of containment volume outside drywell). The only safety function of the system is to provide drywell to containment isolation. Both the check valves and the motor-operated isolation valves are normally closed when the differential pressure between the containment and drywell is zero or positive. When the differential pressure between the containment and drywell is negative, the motor-operated isolation valves are opened electrically. The check valves open in response to the differential pressure and thus provide vacuum relief. The motor-operated isolation valves also close automatically on a containment isolation signal which consists of reactor low-low level or drywell high pressure. The containment isolation signal is overridden, and the motor-operated isolation valves are automatically opened by a negative differential pressure signal.

System Boundary

System components subject to aging management review include safety-related valves and piping components that span the drywell and the containment and shield building walls, as depicted on the license renewal boundary drawing.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Maintain drywell integrity. [10 CFR 54.4(a)(1)]

Relieve the vacuum formed by inadvertent containment spray initiation. [10 CFR 54.4(a)(1)]

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Limit negative drywell/containment differential pressure to prevent Drywell flooding.

Component Types Subject to Aging Management Review

2.3.3.7 Containment Integrated Leak Rate Test (E61)

System Description

The containment integrated leak rate test system enables pressurizing the containment and drywell to measure leakage rates from these areas. Instrument test lines and pressurization lines terminate in the annulus, containment and drywell to provide for this testing. The primary purpose of the system is to measure the overall leakage rate of the containment vessel and all penetrations and appurtenances. The secondary purpose is to measure the drywell leakage rate.

System Boundary

System components subject to aging management review include safety-related piping components that either support pressure testing of containment and the drywell or provide a pressure boundary function, and the attached nonsafety-related piping that provides structural support to the safety-related piping, as shown on the LR boundary drawing.

The nonsafety-related piping that only penetrates the shield building is not attached to safety-related piping and does not perform a license renewal intended function.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

Containment and annulus isolation limits radiological release. [10 CFR 54.4(a)(1)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Component Types Subject to Aging Management Review

Table 2.3.3-7 lists the component types that require aging management review and their intended functions.

Table 3.3.2-7, Auxiliary Systems – Containment Integrated Leak Rate Test – Summary of Aging Management Evaluation, provides the results of the aging management review.

Table 2.3.3-7
Containment Integrated Leak Rate Test
Component Types Subject to Aging Management Review

Component Type	Intended function
Bolting	Pressure boundary
Piping	Pressure boundary, Structural integrity
Piping (Spectacle flange)	Pressure boundary
Valve body	Pressure boundary, Structural integrity

2.3.3.8 Containment Vessel and Drywell Purge (M14)

System Description

The system reduces the activity level in the containment vessel and drywell to a safe level for entry of personnel, maintains a safe atmosphere during refueling operations and provides a means of controlled release of activity to the environment.

The containment vessel and drywell purge system is divided into the containment vessel purge supply subsystem, drywell purge supply subsystem, and the purge exhaust subsystem.

The containment vessel purge supply subsystem is located in the intermediate building and provides filtered and heated outside air to the containment vessel at a constant rate. The supply air is discharged into the containment vessel and circulated by the containment vessel fan cooler units.

During the drywell purge mode of system operation (used during refueling and cold shutdown only) the drywell purge supply subsystem directs air from the containment vessel ambient into the drywell area where it is circulated by the drywell fan cooler units.

The section of the drywell purge supply lines between the isolation valves can be filled with water to provide shielding. The water provides shielding to minimize radiation streaming in the area of the containment adjacent to the drywell purge supply lines.

The purge exhaust subsystem is located in the intermediate building. It draws air from the containment vessel and drywell and exhausts it through two trains of roughing filters, HEPA prefilters, charcoal filters, and HEPA after-filters. The exhaust air is then discharged to the atmosphere through the unit vent. Drywell purge exhaust and supply subsystem isolation valves are passive isolation valves which remain closed during Modes 1, 2 and 3.

Components of the containment vessel and drywell purge system, except for the purge isolation valves and the charcoal exhaust plenums, are nonsafety-related and non-seismic classified. The purge isolation valves and accessories are classified as Safety Class 2, Seismic Category I. The charcoal exhaust plenums are classified as nonsafety-related, Seismic Category I.

The active purge supply and exhaust containment isolation valves are fast acting valves (4 seconds) which close on a containment isolation signal (high drywell pressure and/or low reactor vessel water level). These valves also close on a high radiation signal in the exhaust line.

System Boundary

System components subject to aging management review include isolation valves and piping components associated with (M14) drywell and containment penetrations in containment and the intermediate building, as shown on the LR boundary drawing.

Fire protection and hot water piping are evaluated in fire protection and building heating systems (P54 and P55, respectively).

Demineralized water system components associated with the fill/drain lines for the drywell purge supply ducting are evaluated with mixed bed demineralizer and distribution system (P22).

Radiation monitoring devices associated with the containment and drywell purge system (M14) are evaluated in the plant radiation monitoring system (D17).

Unit 2 Containment Isolation Valves 2M14F0040, 2M14F0085, and 2M14F0200 are evaluated within structural as part of the building penetration and are not addressed here.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Component Types Subject to Aging Management Review

Table 2.3.3-8 lists the component types that require aging management review and their intended functions.

Table 3.3.2-8, Auxiliary Systems – Containment Vessel and Drywell Purge System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.9 Containment Vessel Chilled Water (P50)

System Description

The containment vessel chilled water system operates continuously during normal operation to provide chilled water to the chilled water coils of the various containment vessel cooling system air handling units and the inservice inspection room air handling units for the purpose of cooling the air supplied to the areas served by these air handling units. Three 100 percent capacity water chilling machines and three 100 percent capacity chilled water recirculating pumps are provided. Normally, one set of chiller and pump provides service with the second and third sets as backup. Condenser water is provided by the nuclear closed cooling system during operation. This system is not required to operate during LOCA or loss of offsite power. The pumps, chillers, valves, piping, and tanks are of standard industrial design and are classified as nonsafety-related and non-seismic. However, isolation valves in the containment vessel penetration line are Safety Class 2 and Seismic Category I.

The containment vessel chilled water system is not required to operate to safely shut down the plant following a design basis accident.

System Boundary

System components subject to aging management review include ventilation cooling coils and headers, pumps, tanks, valves, and various piping components as shown on the LR boundary drawings. Various chiller subcomponents not shown on the boundary drawings are also subject to aging management review.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Provide chilled water to the containment vessel air handling units.

Component Types Subject to Aging Management Review

Table 2.3.3-9 lists the component types that require aging management review and their intended functions.

Table 3.3.2-9, Auxiliary Systems – Containment Vessel Chilled Water System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.10 Control and Computer Room Humidification (M29)

System Description

During normal operation, the electric steam boiler supplies the central type humidifiers with steam. The humidifiers are located in control room return duct downstream of the return fans and in the branch supply ducts of the computer room HVAC system. Humidity controllers located in the computer room and control room modulate the needle valve of the corresponding humidifier, thereby discharging the right quantity of steam to the air stream and satisfying humidity controller set point.

The boiler is an electric steam boiler generating steam by electric heating. The humidifiers are of the electric modulating control, steam separator type, providing full separation ahead of an integral steam jacketed control valve. The distribution manifold, located in the duct, provides uniform steam distribution (against air stream flow) over its entire length and is steam jacketed to ensure that the vapor discharged is free of water droplets.

The components of this system are of the standard industrial design and are classified as nonsafety and non-seismic.

The electric boiler can produce saturated steam at 5 to 10 psig. This boiler supplies a low pressure humidification system, with piping defined as high energy piping.

An analysis of possible effects of jets and pipe whip due to humidification system breaks shows that safe shutdown is not jeopardized. The low power rating of the boiler and the small energy reservoir of the system preclude any rapid environmental effects. Redundant leak detection sensors are provided to ensure that any failure is detected with ample time to shut off the boiler before environmental effects could compromise safe shutdown components.

System Boundary

System components subject to aging management review include the boiler, humidifiers, distribution manifolds, and piping and valves associated with the control room and computer room humidification system, as shown on the LR boundary drawing.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Maintain control room and computer room humidity within desired range.

Component Types Subject to Aging Management Review

Table 2.3.3-10 lists the component types that require aging management review and their intended functions.

2.3.3.11 Control Complex Chilled Water (P47)

System Description

The control complex chilled water system provides mechanically chilled water to the coils of the following control complex air handling units:

a. Control room.

b. Motor control center, switchgear and miscellaneous areas.

c. Controlled access and miscellaneous equipment areas.

d. Emergency closed cooling pump area.

e. Computer room (to cool the air supplied to the control complex area).

Three 100 percent capacity water chilling machines and three 100 percent capacity water recirculating pumps are provided. These are connected to two redundant chilled water piping systems, one of which is normally operating while the other is on manual standby. Loop A can be connected to chiller A or C, and loop B can be connected to chiller B or C. One set of isolation valves on the main header is normally closed. The other set of isolation valves is normally open to valve chiller C into either pipe loop A or B.

One chiller and one circulating pump are connected to the Division 1 standby diesel generator. Another chiller and circulating pump are connected to the Division 2 standby diesel generator. The third chiller and pump are connected to a non-diesel backed power supply. During all modes of operation, condenser water for the “A” and “B” chillers is provided by the emergency closed cooling system and condenser water for the “C” chiller is provided by the nuclear closed cooling system.

Electric motor-operated isolation valves are also provided to isolate the chilled water coils of the nonsafety-related air handling units to prevent draining the chilled water from the system if a coil failure occurs. The signal from the low level switch in the expansion tank will activate the corresponding isolation valves.

The portion of the system after the isolation valves (F290A, B and F295A, B) is nonsafety-related and non-seismically qualified, however, it will not rupture during a safe shutdown earthquake or an operating basis earthquake.

The control complex chilled water System is classified as Safety Class 3, Seismic Category I.

System Boundary

System components subject to aging management review include ventilation cooling coils and headers, pumps, tanks, valves, and various piping components as shown on the LR boundary drawings. Various chiller subcomponents not shown on the boundary drawings are also subject to aging management review.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

Provide chilled water to safety-related control complex air handling units. [10 CFR 54.4(a)(1), (a)(3) – FP]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Provide chilled water to nonsafety-related control complex air handling units.

Electric motor-operated isolation valves isolate the chilled water coils of the nonsafety-related and non-seismic air handling units to prevent draining the chilled water from the system if a coil failure occurs. [10 CFR 54.4(a)(1)]

Nonsafety-related cooling coils and related piping will not rupture due to an SSE or OBE earthquake. [10 CFR 54.4(a)(2)]

Component Types Subject to Aging Management Review

Table 2.3.3-11 lists the component types that require aging management review and their intended functions.

2.3.3.12 Control Rod Drive (C11)

System Description

The control rod drive system (CRD) controls gross changes in core reactivity by incrementally positioning neutron absorbing control rods within the reactor core in response to manual control signals. It is also required to quickly shut down the reactor (scram) in emergency situations by rapidly inserting withdrawn control rods into the core in response to a manual or automatic signal from the reactor protection trip system. The control rod drive system consists of locking piston control rod drive mechanisms and the CRD hydraulic system (including power supply and regulation, hydraulic control units, interconnecting piping, instrumentation, and electrical controls).

The CRD mechanism (drive) used for positioning the control rod in the reactor core is a double-acting, mechanically latched, hydraulic cylinder using water as its operating fluid.

The control rod drive hydraulic system supplies and controls the pressure and flow to and from the drives through hydraulic control units (HCUs). The water discharged from the control rod drives during a scram flows through the HCUs to the scram discharge volume. The water discharged from a drive during a normal control rod positioning operation flow through the HCU, then the exhaust header, and is returned to the reactor vessel via the HCUs of non-moving drives. There is one HCU for each control rod drive.

The scram accumulator stores sufficient energy to fully insert a control rod at any vessel pressure. The accumulator is a hydraulic cylinder with a free-floating piston. The piston separates the water on top from the nitrogen below. A check valve in the accumulator charging line prevents loss of water pressure in the event supply pressure is lost.

The scram discharge volume consists of header piping which connects to each HCU and drains into an instrument volume. The header piping is sized to receive and contain all the water discharged by the drives during a scram, independent of the instrument volume.

The alternate rod insertion (ARI) feature is designed to increase the reliability of the control rod drive system scram function. ARI provides for insertion of reactor control rods by depressurizing the scram air header through valves which are redundant and diverse from the reactor protection system scram valves.

System Boundary

System components subject to aging management review include non-Class 1 hydraulic supply pumps, valves, and associated equipment external to the control rod drive housing, the scram discharge volume, and the associated pneumatic components, as shown on LR boundary drawings. The Class 1 control rod drive housings are evaluated with the reactor pressure vessel. The Class 1 control rod drive mechanisms are evaluated with the reactor coolant pressure boundary. The control rod blade assemblies are evaluated with reactor vessel internals.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform functions that demonstrates compliance with the regulations for FP, ATWS, and EQ.

When a scram is initiated by the reactor protection system, the control rod drive system inserts the negative reactivity necessary to shut down the reactor. [10 CFR 54.4(a)(1), (a)(3) - FP]

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

System piping penetrating the drywell provide a drywell pressure boundary function. [10 CFR 54.4(a)(1)]

Control rods provide the means for reliable control of reactivity changes.

Scram Discharge Volume (SDV) maintains the reactor coolant pressure boundary following a scram. This includes closure of the vent and drain valves during a scram to limit the amount of reactor coolant discharged so that adequate cooling is maintained, and offsite doses remain within the limits of 10 CFR 100. [10 CFR 54.4(a)(1)]

System contains safety-related indication including control rod position and control rod scram valve indication. [10 CFR 54.4(a)(1), (a)(3) – EQ]

The ARI system provides an electrically diverse scram logic independent of the RPS. [10 CFR 54.4(a)(3) – ATWS]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Component Types Subject to Aging Management Review

Table 2.3.3-12 lists the component types that require aging management review and their intended functions.

2.3.3.13 Control Room HVAC (M25) and Emergency Recirculation (M26)

System Description

The control room HVAC system operates continuously to supply conditioned air, a portion of which is outside air, for ventilation to the control room to dissipate the internal heat load generated and maintain the control room ambient air conditions. During normal plant operation, a system supply and return fan runs continuously, the outside air intake dampers, and the return damper are open, and the exhaust air damper is closed. Either the “A” set or the “B” set of supply and return components is in operation with the idle redundant equipment as backup. The emergency recirculation system is idle and closed off from the HVAC system by its closed discharge damper. Normally, a portion of the supplied air is assumed to exfiltrate from the control room through normal openings, thereby ensuring a positive pressure inside the room.

The main components of this system are located in the control complex and consist of two redundant supply plenums, two redundant supply fans and two redundant return fans, each rated at 100 percent of the total required capacity.

Each supply plenum includes roughing filters and chilled water coils. Each outside air intake duct is provided with redundant dampers in series to reduce the outside air in-leakage when the system is in the emergency recirculation mode. A check damper is provided in the discharge duct of each supply fan. In addition, manually operated balancing dampers for balancing, and fire dampers for fire protection, are provided.

Each return unit consists of a centrifugal fan, an exhaust air isolation damper, a return air isolation damper, manually operated balancing dampers, and fire dampers. The exhaust isolation damper is normally closed and the return isolation damper is normally open.

In the event of high smoke condition, except during a LOOP/LOCA condition, the smoke can be purged by manually setting the mode selector switch in the “smoke clear” mode.

Electric heating coils (with SCR controllers) in the branch supply ducts to the various zones in the control room are provided to control the final ambient air temperature in each zone. An electronic thermostat in each zone is used to provide a signal to the SCR controller which will control the heating coil, depending upon final room temperature.

Humidification is also provided by the control and computer rooms humidification system (M29). An electronic humidity controller, with local indication, is located in the general area of the control room to modulate the electric motor-operated valve on the humidifier.

The fans, filter elements, coils, and dampers of the control room HVAC system are of standard industrial design manufactured in accordance with the Quality Assurance (QA) requirements of Safety Class 3, Seismic Category I items. The filter racks and plenums are specially designed to satisfy system space requirements and also meet the above QA requirements. However, the electric duct heating coils and the humidifiers are nonsafety-related items.

The control room emergency recirculation system routes the supply air through the charcoal filter train before being distributed to the control room. This system is idle during normal plant operation and is automatically activated by an emergency signal (such as LOCA), or high radiation, or by manually setting the mode selector switch to the emergency recirculation mode.

The main components of this system are in the control complex and consist of two 100 percent capacity filter trains. Each filter train includes the following sequential components: demisters, roughing filters, electric heating coil, HEPA prefilters, charcoal filters, HEPA after filters, centrifugal fan, isolation damper, and check damper.

The electric heaters are not required for the control room emergency recirculation system to perform its specified safety function based on the Alternate Source Term analyses.

The fans, filter elements and dampers of the control room emergency recirculation system are of standard industrial design, manufactured in accordance with Quality Assurance (QA) requirements of Safety Class 3, Seismic Category I items. The filter racks, frames and housing are specially designed to satisfy the system space requirements and meet the above QA requirements.

System Boundary

System components subject to aging management review include fan housings, dampers, and other ductwork components supporting control room ventilation as depicted on the LR boundary drawings.

Cooling water and fire protection components are evaluated within control complex chilled water and fire protection systems (P47 and P54, respectively).

Control room envelope is evaluated with structural components.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

Provide cooling, heating, and ventilation for the control room areas and offices [10 CFR 54.4(a)(1), (a)(3) – FP]

Supply filtered air to the control room areas and offices during emergency periods and other abnormal conditions for personnel protection. [10 CFR 54.4(a)(1), (a)(3) – FP]

The control room emergency recirculation system is an engineered safety features (ESF) filter system that reduces the concentration of airborne radioactive contaminants following a design basis accident. [10 CFR 54.4(a)(1)]

System tornado dampers control building pressure transient during a tornado. [10 CFR 54.4(a)(1)]

Provide smoke removal for the control room areas and offices [10 CFR 54.4(a)(3) – FP]

The system contains components within the scope of 10 CFR 50.49 [10 CFR 54.4(a)(3) – EQ]

The control room HVAC system is provided with oxygen monitors which alarm upon detecting a loss of oxygen in the air due to carbon dioxide buildup.

Component Types Subject to Aging Management Review

Table 2.3.3-13 lists the component types that require aging management review and their intended functions.

Table 3.3.2-13, Auxiliary Systems – Control Room HVAC and Emergency Recirculation System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.14 Controlled Access and Miscellaneous Equipment Areas HVAC (M21)

System Description

This ventilation system operates continuously during normal plant operation and during plant shutdown to provide cooling and heating for various areas, and exhaust capabilities for various laboratory hoods and the access area count room. The areas served by this system include the controlled access rooms, miscellaneous areas such as the nuclear closed cooling pump and heat exchanger rooms, emergency closed cooling pump and heat exchanger area, hot laundry area, laboratory hoods, HVAC equipment rooms, and electric maintenance room.

The duct systems and controls are arranged so that a mixture of outside air and return air from the HVAC equipment room is directed through the cooling plenum and is supplied to the various areas requiring cooling or heating. After satisfying the cooling or heating functions, room air from non-contaminated areas is ducted to the return air fan and from there is discharged to the HVAC equipment room. Room air from contaminated or potentially contaminated areas is ducted to the filter system and is then discharged to the unit plant vent. In the event of an emergency, the filter plenum discharge may be remote-manually redirected to a recirculation mode. In this mode, the exhaust from the filter plenum is directed to the supply plenum discussed above, with the outside air damper to the supply plenum closed.

In the event of loss of offsite power or a LOCA, the emergency closed cooling pump and heat exchanger area, and areas housing the chillers and service air compressors are cooled by the emergency closed cooling pump area cooling system (M28).

During normal plant operation and during plant shutdown, power will be provided to this system from the preferred ac source. During periods of emergency, this system is not required to operate to safely shut down the plant.

This system, excluding the filter plenum and tornado dampers, is classified as nonsafety-related and non-seismic category. However, the cooling coils and related piping of this system will not rupture during a safe shutdown earthquake or an operating basis earthquake. The filter plenum is classified as nonsafety-related, Seismic Category I. The tornado dampers are classified as safety-related, non-seismic.

System Boundary

System components subject to aging management review include fire and tornado dampers, ductwork that supports the tornado dampers' function, and filter housing drain piping and valves, as shown on the LR boundary drawing.

Fire protection and chilled water piping are evaluated within those systems (P54 and P47, respectively).

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

System tornado dampers control building pressure transient during a tornado. [10 CFR 54.4(a)(1)]

Selected nonsafety system ducting required to support control building pressure transient during a tornado. [10 CFR 54.4(a)(2)]

System fire dampers limit the spread of fires. [10 CFR 54.4(a)(3) – FP]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Provide ventilation for miscellaneous areas in the control building.

Component Types Subject to Aging Management Review

Table 2.3.3-14 lists the component types that require aging management review and their intended functions.

Table 3.3.2-14, Auxiliary Systems – Controlled Access and Miscellaneous Equipment Areas HVAC System – Summary of Aging Management Evaluation, provides the results of the aging management review.

Table 2.3.3-14

2.3.3.15 Diesel Generator and Auxiliaries (R43, R44, R45, R46, R47 & R48)

System Description

Note: Some division 3 diesel generator subsystems are assigned to the high pressure core spray Division 3 plant system (E22) but are evaluated with Division 1 & 2 diesels in systems R43 thru R48.

The Class 1E power system is designed with three independent divisions, each provided with a diesel engine driven, 4.16 kV, 3 phase, 60 Hz synchronous generator. Division 1 and Division 2 are redundant while Division 3 supplies power for the high pressure core spray system (HPCS). Division 3 is capable of being manually cross-tied to Division 2 during a station blackout to provide power to some Division 2 loads. Additionally, Division 3 is capable of being manually connected to Division 1 following a loss of coolant accident and a total loss of both the normal and emergency Division 1 AC electrical power sources, to provide power to the motor operated gate valves in the feedwater lines.

The diesel generator sets are electrically and physically isolated from each other and are located in a Seismic Category I structure adjacent to the control complex.

The continuous rating of the Division 1 and 2 diesel generators is 7,000 kW, while the Division 3 diesel generator is rated at 2600 kW. The Division 1 and 2 diesel generators were manufactured by Transamerica Delaval, Inc.

The HPCS (Division 3) diesel generator is a 20 cylinder EMD diesel generator equipped with a turbocharger. The HPCS system and its power supply unit is part of the ECCS. HPCS and the diesel generator by itself does not meet the single failure criterion, although the criterion is applicable at the ECCS level.

While the Division 3 diesel is not identical to the Division 1 and 2 diesels, each diesel has associated starting air, fuel oil, jacket cooling water, lubricating oil, and intake & exhaust subsystems. The scoping and aging management reviews are grouped by subsystem, and each subsystem addresses all three diesels.

Control Air (R43 – Division 1 and 2)

Control air for the Division 1 and 2 diesel generator protective features is supplied from the starting air system's air receiver.

The Division 1 and 2 diesel generator control air system functions to trip the diesel generators in the event of abnormal engine operating conditions. Nonessential trip functions are bypassed upon receipt of a LOCA or bus under/degraded voltage signal but will shut down the diesel generators when operating in all other modes. Only the generator differential and overspeed trip functions will shut down the diesel generators after a start resulting from a LOCA or bus under/degraded voltage signal. Categorically, the Division 1 and 2 diesel generator control air system functions to support starting and operation of the diesel generators.

Starting Air (R44)

Separate and independent starting air subsystems are provided for each of the three diesel generators; each subsystem is designed for complete redundancy and can supply enough air for a minimum of five consecutive engine starts.

The starting air subsystem for each diesel generator includes two redundant trains of components/piping. Each train has an air compressor, aftercooler, air dryer, and a receiver tank.

Fuel Oil (R45)

Separate fuel oil storage and transfer facilities are provided for each of the three diesel generators for at least seven days of operation carrying the design electrical load of the associated generator.

The standby diesel generators and the HPCS diesel generator each have an associated fuel oil storage and transfer system which consists of one diesel fuel oil storage tank, one fuel oil day tank, two transfer pumps, a motor-driven fuel oil pump, an engine driven fuel oil pump, and necessary piping, valves, strainers, filters, and instrumentation. The fuel storage tanks are buried, horizontal, cylindrical, atmospheric tanks.

The fuel oil storage tanks are designed so that all openings are above the ground water and Probable Maximum Flood (PMF) levels to prevent the entrance of water.

The fuel oil day tanks are 550 gallon (555 gallon for the HPCS diesel), vertical, cylindrical, atmospheric tanks mounted in the respective standby diesel generator room. The transfer pumps transport fuel between the underground storage tank and the day tank. The transfer pumps are located in the respective diesel generator room. Each pump is powered from a safety-related Class 1E 480 volt motor control center and has a capacity of 90 gpm. An overflow line is provided from the day tank to the associated diesel fuel oil storage tank to provide a closed recirculation loop. Because the day tanks are always full, corrosion of these tanks are minimized.

One engine-driven fuel oil booster pump and one motor-driven fuel oil booster pump are supplied with and located on each diesel engine. Each fuel oil booster pump supplies fuel from the day tank to the engine manifolds and starts when the diesel start signal is received. The fuel pumps draw more fuel oil from the day tank than is consumed by the engine. The excess fuel is returned to the day tank by a separate return line.

Cooling Water (R46)

The standby diesel generators (Division 1 & 2) are of a different manufacturer than the HPCS diesel generator (Division 3), but all three diesels utilize similar cooling systems.

The diesel generator cooling system is designed to remove heat generated by the diesel generator assembly during operation. The cooling system removes heat from the water jackets, the lube oil heat exchanger, and the turbocharger inter/aftercoolers. Additionally, the Division 1 and 2 standby diesel generators include a governor oil cooler not present on the Division 3 HPCS diesel. The coolant consists of demineralized water with corrosion inhibiting additives. Ethylene glycol may be added as allowed by manufacturer’s recommendations. Heat removed from the system is transferred to the emergency service water system. The cooling system for each diesel generator includes a standpipe/expansion tank. Each cooling system also includes an electric heat source and recirculation method for maintaining the engines warm when not running.

Lube Oil (R47)

The standby diesel generators (Division 1 & 2) are of a different manufacturer than the HPCS diesel generator (Division 3), but all three diesels utilize lubricating oil systems.

Each diesel generator lubrication system is designed to supply lube oil to the engine bearing surfaces at controlled pressure, temperature and cleanliness conditions. The systems include provisions for keeping the bearings flooded and the oil warm for fast start purposes. The system provides lubricating oil to the diesel engine and rejects the heat picked up during circulation to the diesel jacket water cooling system via the lube oil cooler. The turbochargers are equipped with pre-lubrication systems to minimize wear incurred during engine starts.

Air Intake and Exhaust (R48)

The standby diesel generators (Division 1 & 2) are of a different manufacturer than the HPCS diesel generator (Division 3), but all three diesels utilize similar intake air and exhaust systems.

The diesel generator combustion air intake and exhaust subsystem supplies air of reliable quality to the diesel generators and exhausts the products of combustion from the diesel generators through missile barriers to the atmosphere. The diesel generator combustion air intake and exhaust system is safety related, except for the exhaust silencers and associated exhaust piping outside of the diesel building which are nonsafety-related. The exhaust silencers are nonsafety grade since any blockage of the silencer would be automatically bypassed through the missile barrier discharge.

The combustion air intake and exhaust system consists of air intake filters, intake silencers (the HPCS diesel silencer is integral with its intake filter), expansion joints, exhaust silencers, and associated piping connecting the equipment. The system also contains the diesel engine turbochargers, which utilize diesel exhaust energy to compress the combustion intake air stream.

System Boundary

Control Air (R43)

System components subject to aging management review include safety related valves, and various piping and tubing components that comprise the Division 1 and 2 diesel control air system pressure boundary, as well as nonsafety-related tubing and piping components that provide a leakage boundary or structural integrity function as shown on the LR boundary drawings.

Starting Air (R44)

System components subject to aging management review include safety related tanks (air accumulators and air receivers), valves, and various piping components that supply starting air from the receivers to the diesels (and control air for Division 1 & 2), as well as nonsafety-related moisture separators and various piping components that provide a leakage boundary or structural integrity function as shown on the LR boundary drawings.

Fuel Oil (R45)

System components subject to aging management review include safety related tanks, pumps, valves, and various piping components that supply fuel oil from the buried tanks to the diesels, as well as nonsafety-related piping components that provide a leakage boundary or structural integrity function as shown on the LR boundary drawings.

Building and yard piping penetrations that perform an external flood mitigation function are addressed as part of structural scoping.

Cooling Water (R46)

System components subject to aging management review include safety related tanks, pumps, valves, and various piping components that supply jacket cooling water to the diesels, as well as nonsafety-related piping components that provide a leakage boundary or structural integrity function as shown on the LR boundary drawings.

Lube Oil (R47)

System components subject to aging management review include safety-related tanks (sumps), pumps, valves, filter and strainer housings, strainer elements, and various piping components that supply lube oil to the diesels, as well as small sections of nonsafety-related piping that provide a leakage boundary or structural integrity function as shown on the LR boundary drawings.

Air Intake and Exhaust (R48)

System components subject to aging management review include safety-related filters, intake silencers, turbochargers, and various piping components that direct the diesel intake air and exhaust, as well as small sections of nonsafety-related piping that provide a structural integrity function as shown on the LR boundary drawings.

Diesel generator room ventilation is addressed with the diesel generator building ventilation (M43) system. The Class 1E power system is addressed as part of electrical scoping. The diesel generator exhaust hallway structure and its insulated panels are evaluated under structural scoping. Building penetrations that perform an external flood mitigation function are addressed as part of structural scoping.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP and SBO.

Supplies independent AC power to the Class 1E 4.16 KV bus. [10 CFR 54.4(a)(1), (a)(3) – FP (Div. 1 & 2 only), (a)(3) – SBO (Div. 3)]

The Division 1 and 2 diesel generator control air, starting air, fuel oil, jacket water cooling, lube oil, intake and exhaust subsystems are all primary support systems for the Division 1 and 2 diesel generators. [10 CFR 54.4(a)(1), (a)(3) – FP]

The Division 3 (HPCS) diesel generator starting air, fuel oil, jacket water cooling, lube oil, intake and exhaust subsystems are all primary support systems for the HPCS diesel generator. [10 CFR 54.4(a)(1), (a)(3) – SBO]

Starting air (right or left bank) provides air to start all three DGs and provides air for the pneumatic control subsystems for the Division 1 and 2 DGs. [10 CFR 54.4(a)(1)]

The Division 1 and 2 diesel generator control air system functions to support starting and operation of the diesel generators. [10 CFR 54.4(a)(1)]

The fuel oil subsystem supplies fuel oil from the day tank to the engine, and transfers fuel oil from the storage tank to the day tank. [10 CFR 54.4(a)(1)]

The jacket water cooling subsystem removes heat during engine operation and keeps the engine warm while in standby. [10 CFR 54.4(a)(1)]

The lube oil subsystem supplies lube oil during engine operation, and during standby operation keeps the bearings flooded and the oil warm. [10 CFR 54.4(a)(1)]

The DG intake and exhaust subsystem provides combustion air and exhaust gas. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Division 3 diesel generator flame arrestors prevent the ignition of flammable vapors on one side of the arrestor if the other side is exposed to an ignition source.

Division 1 and 2 diesel generator flame arrestors prevent the ignition of flammable vapors on one side of the arrestor if the other side is exposed to an ignition source. [10 CFR 54.4(a)(3) – FP]

Component Types Subject to Aging Management Review

2.3.3.16 Diesel Generator Building Ventilation (M43)

System Description

The diesel generator building ventilation system (DGBVS) operates whenever the diesel generators operate (following loss of offsite power signal and following a LOCA signal) or during testing of the DGBVS, except for the auxiliary exhaust fans, which operate only when the associated diesel generator is not running.

The DGBVS for each diesel generator room consists of two 100 percent capacity supply air fans, two sets of exhaust louvers, outside air and return air dampers, ductwork arranged for cooling the diesel generators and related equipment, and a nonsafety-related auxiliary exhaust fan. Inactive supply fans are isolated by automatically controlled outside air dampers. However, when neither fan operates, the outside air and recirculation dampers automatically modulate to promote natural ventilation. The exhaust louver closest to the auxiliary exhaust fan is maintained open during exhaust fan operation. The exhaust fan withdraws air from the diesel room to further promote cooling during diesel standby conditions. When the CO2 system is activated, outside air and exhaust air dampers close, the return air dampers open and the ventilation fans stop.

Electric unit heaters are also provided to maintain the minimum room temperature when the diesel generators are not operating.

The auxiliary exhaust fans are not safety-related and are not backed with emergency power, nor are they relied upon for operation during accident conditions.

The DGBVS system is classified as Safety Class 3 and Seismic Category I.

System Boundary

System components subject to aging management review include safety-related fans, dampers, and associated ductwork as shown on the LR boundary drawing.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP and SBO.

Remove heat generated by the diesel engine and auxiliary equipment and maintain room temperature. [10 CFR 54.4(a)(1), (a)(3) – FP, SBO]

Isolate ventilation upon CO2 actuation to support fire suppression. [10 CFR 54.4(a)(3) – FP]

Component Types Subject to Aging Management Review

2.3.3.17 ECCS Pump Room Cooling (M39)

System Description

Each emergency core cooling system (ECCS) air handling unit operates whenever the associated pump operates. These operating periods occur during normal shutdown, during emergency or LOCA shutdown or during hot standby conditions. The ECCS pump room cooling system (ECCSCS) includes one air handling unit for each room to recirculate air and provide cooling for the RHR A pump and heat exchanger room, RHR B pump and heat exchanger room, RHR C pump room, HPCS pump room, LPCS pump room, and RCIC pump room. Each air handling unit is capable of removing 100 percent of the cooling requirements of the ECCS pump and related equipment. The dissipated heat for all air handling units except the HPCS is removed by the emergency closed cooling water system. The HPCS air handling unit is served by the emergency service water system. Each air handling unit includes roughing filters, cooling coils, a fan section and is located so that air is discharged directly toward the ECCS pumps and returns un-ducted to the operating air handling unit.

System Boundary

System components subject to aging management review are air handling units (filter/cooler/fan plenums).

Emergency closed cooling water and emergency service water fluid components (including cooling coils within the air handling units) are evaluated within emergency closed cooling (P42) and emergency service water (P45) systems, respectively.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP, SBO, ATWS and EQ.

Remove heat generated by the RHR pumps, HPCS pumps, LPCS pumps, RCIC pumps, piping, and auxiliary equipment. [10 CFR 54.4(a)(1), (a)(3) – FP, SBO, ATWS]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Component Types Subject to Aging Management Review

Table 2.3.3-17 lists the component types that require aging management review and their intended functions.

2.3.3.18 Emergency Closed Cooling (P42)

System Description

An emergency closed cooling (ECC) system serves Unit 1 and is designed to provide a reliable source of cooling water to safety-related components required for certain modes of normal reactor operation, as well as for accident conditions and loss of normal auxiliary power. The system is divided into two separate loops. The emergency closed cooling system is a closed system that has its heat exchangers cooled by the emergency service water system.

ECC A loop supplies cooling water to the low pressure core spray room cooler, RHR A pump and room cooler, RCIC room cooler, control complex chiller A, and hydrogen analyzer A. ECC Loop B supplies RHR B and C pumps and room coolers, control complex chiller B and hydrogen analyzer B. The ECC system provides seal water cooling to RHR pumps A, B and C whenever the RHR pumps are running. System design permits seal cooling under all operating modes, including post-accident conditions.

The emergency closed cooling system has two independent loops, each consisting of one pump, heat exchanger and a surge tank. A chemical addition tank is shared by both loops. The pumps may be operated from the preferred offsite power supply or from a standby onsite power source.

The ECC components associated with control complex chiller C do not provide a path for the emergency closed cooling system water, but instead provide the flow path and instrumentation for the supply of nuclear closed cooling water to the control complex chiller C.

The ECC system piping and components associated with Unit 2 serves to provide cooling water to the fuel pool heat exchangers following a design basis accident, if required. This portion of the Unit 2 ECC piping is connected to the Unit 1 emergency service water system. Unit 2 ECC pumps and heat exchangers provide structural support for ECC components/piping.

The emergency closed cooling system is classified as Safety Class 3 and Seismic Category I. Its primary safety function is to support the emergency core cooling system and other safety-related equipment following an accident.

System Boundary

System components subject to aging management review include the pumps, tanks, heat exchangers, valves, and various piping components associated with the ECC system as shown on the LR boundary drawings. Unit 2 and common ECC piping provides a pressure boundary function for the emergency service water system.

Heat exchangers shown on emergency closed cooling system (P42) drawings but associated with the control complex chilled water system (P47) are evaluated with the P47 system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for fire protection, environmental qualification, and anticipated transients without scram.

Safety-related Unit 2 and common ECC piping shown on Scoping Boundary Drawing 352-0621 provides a pressure boundary function for the emergency service water system during both normal/accident conditions. [10 CFR 54.4(a)(1)]

Remove heat from various ECCS and safety-related components. [10 CFR 54.4(a)(1), (a)(3) – FP, (a)(3)- ATWS]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components credited for EQ. [10 CFR 54.4(a)(3) - EQ]

2.3.3.19 Emergency Closed Cooling Pump Area HVAC (M28)

System Description

The emergency closed cooling pump area cooling system (ECPCS) operates whenever the Emergency Closed Cooling pumps operate (normal shutdown and emergency shutdown) or during testing of the ECPCS. The ECPCS consists of two 100 percent capacity air handling units and supply distribution ducts for recirculating air and for cooling the ECC pumps and related equipment. The dissipated heat is removed by cooling water from the safety-related chilled water system. Each air handling unit includes roughing filters, cooling coils and a fan section. Supply ducts from each air handling unit are extended to the ECC pump areas. The cooling air returns un-ducted to the operating air handling unit.

System Boundary

System components subject to aging management review include fans, duct, filter/cooler (air handling unit) housings, and dampers associated with the emergency closed cooling pump area, as shown on the LR boundary drawing.

Cooling water components associated with the air handling units are evaluated in the control complex chilled water system (P47).

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

Remove heat generated by ECC pumps and heat exchangers, instrument and service air compressors, and control complex chillers and pumps. [10 CFR 54.4(a)(1), (a)(3) – FP]

System fire dampers prevent the spread of fire. [10 CFR 54.4(a)(3) – FP]

Component Types Subject to Aging Management Review

Table 2.3.3-19 lists the component types that require aging management review and their intended functions.

Table 3.3.2-19, Auxiliary Systems – Emergency Closed Cooling Pump Area HVAC System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.20 Emergency Service Water (P45)

System Description

The emergency service water system is comprised of independent Loops A, B and C. The loops are defined as follows, with each loop supplying emergency service water to the equipment listed:

Loop A	**Loop B**	**Loop C**
RHR Heat Exchangers A & C	RHR Heat Exchangers B & D	HPCS Diesel Generator Heat Exchanger
Standby Diesel Generator A	Standby Diesel Generator B	HPCS Pump Room Cooler
Emergency Closed Cooling Heat Exchanger A	Emergency Closed Cooling Heat Exchanger B	
Fuel Pool Cooling Heat Exchanger A	Fuel Pool Cooling Heat Exchanger B	

These open loops take suction from Lake Erie. Each loop is supplied by a separate pump which is operated from a preferred power source or a standby power source (diesel-generator).

Initiation of the emergency service water system is accomplished by automatic signal or remote-manual action, depending upon the operational requirements. Specifically, all loops of the system are initiated automatically by LOCA signals or by loss of power to the associated 1E bus. Loop C is initiated automatically with the initiation of the HPCS system. Loop A is initiated automatically with the initiation of the RCIC system. Remote-manual action can be employed at any time but is not necessary for normal over-all plant operations.

As a contingency measure, the ESW system A and B Loops can be lined up to provide cooling water to the fuel pool cooling and clean-up heat exchangers (FPCC HXs) and ESW system B loop can be lined up to allow for containment flood during post-accident recovery.

A connection off the ESW system B loop is provided to accept a 1-1/2 inch fire hose which can be connected to the standby liquid control transfer system. This arrangement is to provide an emergency backup water supply to the standby liquid control auxiliary mixing tank.

The ESW system is provided with connections to the fire protection system. This arrangement provides a backup water supply to hose stations in the vicinity of safety shutdown equipment.

The emergency service water pumps, located in the emergency service water pumphouse, are of the vertical type. Emergency service water to the pump intake structure is taken from Lake Erie. The primary source of water to the emergency service water pumphouse is supplied by a branch tunnel taken off the main intake tunnel to the service water pumphouse. A backup supply is available by means of a branch tunnel from the main discharge tunnel. Should normal emergency service water (ESW) supply from the intake tunnel be interrupted, sluice gates open automatically upon receiving a low water level signal from the ESW pumphouse forebay, allowing water from the discharge tunnel to flow into the forebay and supply the ESW system. Upon indication on a control room panel that the sluice gates are open, manual valves will be administratively closed to prevent warm ESW from dumping to the discharge tunnel. With the manual valves closed, the ESW system discharges to the swale.

The applicable safety class for all ESW system equipment is Safety Class 3, except for the equipment that interfaces with the RHR system, which is Safety Class 2 (Containment Flooding Mode). The appropriate seismic criteria are Seismic Category I.

System Boundary

System components subject to aging management review include the pumps, heat exchangers, valves, and various piping components associated with the ESW system as shown on the LR boundary drawings.

Heat exchangers associated with the HPCS D/G, RHR, and ECC systems are evaluated with those systems. The intake and discharge tunnels, and the forebay and sluice gates are evaluated as structural components.

Unit 2 and Common emergency closed cooling system (P42) piping that directs ESW cooling water to and around the FPCC heat exchangers is evaluated under the P42 ECC system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for fire protection, station blackout, anticipated transients without scram, and environmental qualification.

Provide a reliable source of water to safety-related components required for certain modes of normal reactor operation, as well as for accident conditions and loss of normal auxiliary power. [10 CFR 54.4(a)(1) & (a)(3) - FP, (a)(3) - SBO (Division 3 D/G), (a)(3) - ATWS (cooling water for RHR A/B)]

Flood the containment for post-accident recovery (loop B only). [10 CFR 54.4(a)(1)]

Provide emergency makeup to the fuel pool cooling and cleanup system surge tank (loops A and B). [10 CFR 54.4(a)(1)]

De-ice the emergency service water pumphouse traveling screens (loops A and B). [10 CFR 54.4(a)(1)]

ESW sluice gates provide a barrier between the discharge tunnel and the ESW pumphouse forebay to prevent recirculation of plant discharge water thereby maintaining the ESW forebay at or below its maximum allowable temperature during all modes of plant operation including accident and transient mitigation. [10 CFR 54.4(a)(1)]

ESW suction sluice gates open automatically or manually to provide emergency water supply from discharge tunnel to ESW pump forebay upon low water level in ESW forebay. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) - EQ]

Provide emergency makeup to the emergency closed cooling system surge tanks (loops A and B).

Provide a seismic backup water supply to fire protection system (loops A and B).

Provide backup water supply to standby liquid control auxiliary mixing tank (loop B only).

Provide emergency makeup source for the diesel jacket water cooling systems (Div. 1 and Div. 2).

Component Types Subject to Aging Management Review

Table 2.3.3-20 lists the component types that require aging management review and their intended functions.

Table 3.3.2-20, Auxiliary Systems – Emergency Service Water System – Summary of Aging Management Evaluation, provides the results of the aging management review.

Table 2.3.3-20

2.3.3.21 Emergency Service Water Pump House Ventilation (M32)

System Description

The ESWVS consists of two 100 percent capacity supply fans, two operating relief louvers and supply ductwork with return dampers for cooling the ESW pumps and auxiliary equipment. The supply fans and duct are arranged so that cooling air is admitted to the south end of the building and after absorbing heat is relieved to the outside at the north end of the building. The amounts of outside air and recirculated return air used for cooling are automatically controlled by outside air and return air dampers.

Electric unit heaters are also provided to maintain the minimum room temperature when the ESW pumps are not operating.

Blocked closed Unit 2 Fan inlet dampers 2M32F0040A/B are structural components of the ESWPH wall and act as a barrier to air flow following a design basis tornado.

System Boundary

System components that are subject to aging management review include fans, dampers and ductwork associated with the ESW pumphouse, as shown on the LR boundary drawing.

The "fixed louvers" and "blocked closed Unit 2 Fan inlet dampers" shown on the boundary drawing are attached to the ESW building wall and are covered as part of the structural scoping.

Electric Unit Heaters are evaluated under P55 building heating system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

Remove the heat generated by the emergency service water pumps and auxiliary pump room equipment. System is started automatically when the ESW pumps operate. [10 CFR 54.4(a)(1), (a)(3) – FP]

Component Types Subject to Aging Management Review

Table 2.3.3-21 lists the component types that require aging management review and their intended functions.

2.3.3.22 Emergency Service Water Screen Wash (P49)

System Description

The ESW screen wash system traveling screens and their associated screen wash pumps, are automatically started electrically by a LOCA signal and will run continuously until the signal is cleared. The screen wash strainers are driven by nonsafety-related motors from safety-related power supplies. Therefore, these motors are prohibited from being operated electrically by the same LOCA signal discussed above. During a LOCA event, the screen wash strainer high differential pressure alarm will be monitored, and manual backwashing of the strainers will be performed as required. During a LOOP event, system logic and annunciator power are lost, necessitating a manual system startup. In the event of a LOCA concurrent with a LOOP, the traveling screens and their associated pumps will automatically start, and the screen wash strainers will be electrically prohibited from operating.

Operation of only one screen wash subsystem will ensure that one traveling screen is always kept clean at all times. One screen is enough to provide the flow requirements for all ESW pumps and fire protection pumps.

System Boundary

System components subject to aging management review are the safety-related screen wash pumps, strainers, traveling screens, and piping components within the emergency service water pumphouse as shown on the LR boundary drawing.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

Remove debris from water entering the ESW pump suction bays. [10 CFR 54.4(a)(1), (a)(3) – FP]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Component Types Subject to Aging Management Review

Table 2.3.3-22 lists the component types that require aging management review and their intended functions.

2.3.3.23 Feedwater Zinc Injection (P85)

System Description

The zinc injection system consists of a zinc injection skid which injects a dilute concentration of zinc oxide into the feedwater. A stream of water taken from the feedwater pump discharge is routed through a column containing zinc oxide pellets. The dissolution of the zinc pellets into the diverted feedwater stream provides the dilute concentration of zinc oxide. The dilute zinc oxide solution is returned to the feedwater pump suction and is blended with the main feedwater flow.

The zinc transported in the reactor water replaces Co-60 as the species in the oxide film layer formed on stainless steel. Lower Co-60 build-up results in lower radiation levels in such areas as the drywell and the reactor water cleanup pump rooms.

The zinc injection system is nonsafety-related and is not required for safe shutdown of the reactor.

System Boundary

System components subject to aging management review include nonsafety-related valves and piping components in areas containing safety-related components.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Reduce radiation levels in such areas as the drywell and the reactor water cleanup pump rooms.

Component Types Subject to Aging Management Review

Table 2.3.3-23 lists the component types that require aging management review and their intended functions.

2.3.3.24 Fire Protection (P54)

System Description

The following list provides a general description of the types of fire protection piping systems at PNPP and identifies the areas or hazards protected by each type:

a. Wet pipe automatic sprinkler system: Major components - alarm check valve, water flow pressure switch, shutoff valve with position switch.

    1. Turbine building below the operating floors, including areas beneath the turbine condenser.
    2. Diesel fire pump room in the emergency service water pumphouse.
    3. Radwaste storage and processing areas at Elevation 623’-6” of the radwaste building.
    4. Reactor core isolation cooling pump room at Elevation 574’-10” of the auxiliary building.
    5. Control complex at Elevation 599’-0” and the southern portion of Elevation 574’-10”.
    6. Service building, service building annex and technical support center, except CAS and Halon protected areas.
    7. Auxiliary boiler building.
    8. Fuel oil pumphouse.
    9. Intermediate building above Elevation 599’-0” excluding the instrument storage area and hot instrument shop.
    10. Intermediate building above Elevation 620’ excluding the Standby Liquid Control System area.
    11. Auxiliary building 620’ elevation in corridor at west end.
    12. Intermediate building Elevation 574’-10” in the tool decontamination and storage areas.

13. Sprinklers have been provided in other plant buildings where the fire hazard makes it necessary to detect a fire before it can propagate to plant structures, systems or components important to safety located in other buildings.

b. Water spray system: Major components - strainers, deluge valves, shutoff valve with position switch, waterflow pressure switch, control panel, spray nozzles, and heat detectors.

   1. Outdoor oil-filled transformers.

   2. Charcoal filter systems.

   3. Hydrogen seal oil units at Elevation 605'-0" of the turbine building.

c. Preaction water spray systems: Major components - strainers, deluge valves, waterflow pressure switch, shutoff valve with position switch, fusible element type spray nozzle, control panel, heat detectors, and supervised air supply.

   1. Turbine generator bearings.

   2. Feedwater pump turbine bearings at Elevation 647'-0" of the heater bay.

d. Preaction sprinkler system: Major components - strainer, deluge valve, waterflow pressure switch, shutoff valve with position switch, sprinklers, fusible element type spray nozzles, control panel, heat detectors, and a supervised air supply.

   Two systems exist: one for each cable spreading room (i.e., Unit 1, Division 1 and Division 2; Unit 2, Division 1 and Division 2). These systems also cover the control complex cable chases, cable tunnels and penetration areas.

e. Carbon dioxide total flooding system: Major components - low pressure CO2 tank, master valve, selector valve, control panel, fire detectors, and discharge nozzles.

   1. Each of the three diesel generator rooms.

   2. Turbine lube oil tank room at Elevation 620'-0" of the turbine building.

   3. Turbine lube oil purifier room at Elevation 593'-0" of the turbine building.

   4. Unit 1 computer room subfloor at Elevation 638'-0" of the control complex.

   5. Unit 1 control room subfloors at Elevation 654'-0" of the control complex. The control room subfloor is isolated into three main subsections, each protected by its own CO2 system.

f. Local application carbon dioxide systems: Major components - low pressure CO2 tanks, master valve, selector valve, heat detectors, control panel, and discharge nozzles.

Two systems exist: one for each of the reactor recirculation pump motors.

g. Halon 1301 system: Major components – Halon tanks, valves, and distribution piping. All systems are actuated either by manual release stations or automatically (after a time delay) by the associated smoke detector system. For automatic operation, a pre-discharge alarm is provided to allow personnel evacuation time prior to release of Halon.

   Halon systems are used in the training center, in the TSC computer room, and in the service building telephone equipment room and metrology lab.

h. Manual Fixed Foam System: The system is manually actuated from a local control panel. Foam is piped directly to the auxiliary boiler fuel oil storage tank for surface application and to hose stations in the fuel oil unloading area.

i. Water standpipe and hose system: All areas of the plant are provided with manual firefighting capability in the form of fire service water supplied hose stations. They are primarily 75 feet of 1-1/2 inch minimum diameter hose on a hose reel and are equipped with a fog nozzle. Where necessary, variations such as hose cabinets or additional hose are provided.

j. Portable fire extinguishers: Portable fire extinguishers of the type and size appropriate to match the hazard involved have been located throughout the plant.

Fire suppression water is supplied by two 2,500 gpm fire pumps, one diesel driven and one motor-driven, each with the capability to meet the largest system demand. A looped distribution piping system is provided which is arranged and valved so that a single worst break in the distribution piping will not prohibit any fixed water system from getting the required flow at the required pressure.

Structural features of the fire protection system include adjoining plant buildings being separated by three-hour fire walls. Additionally, most plant buildings are further subdivided into fire areas which are separated by three-hour fire floors and walls. Openings in these three-hour separations are provided with rated doors and fire seals of the corresponding three hour rating.

System Boundary

System components subject to aging management review include various piping system components that are credited with fire suppression (both water and CO2), and fluid piping components that are located within structures that contain safety-related components, as shown on the LR boundary drawings.

Fire barriers are evaluated within the structural section and are not addressed here. Fire detection components are electrical rather than mechanical in nature.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP and EQ.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Detect and suppress fires. [10 CFR 54.4(a)(3) – FP]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Provide alternate source of reactor pressure vessel injection.

Supply cooling water to the NCC heat exchangers during shutdown operation, when the service water system is out of service.

Component Types Subject to Aging Management Review

Table 2.3.3-24 lists the component types that require aging management review and their intended functions.

Table 3.3.2-24, Auxiliary Systems – Fire Protection System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.25 Floor and Equipment Drains (P68)

System Description

The equipment and floor drainage system (EFDS) is designed to provide for collecting radioactive and potentially radioactive liquid wastes from floor drains and equipment drains throughout the plant and convey these wastes to building sumps located in the basemats of the major structures. In addition, the evaluation of roof drains is included within this report. Roof drains convey rainwater from various structures' roofs through piping to storm drains.

The EFDS consists of five separate, independent drain piping networks for segregating wastes into one of five categories as follows:

a. Floor drains (medium-to-low purity with medium conductivity).

b. Equipment drains (high purity with low conductivity).

c. Chemical drains (high conductivity).

d. Detergent drains.

e. Oil drains.

Separate building sumps from the liquid radwaste sump system are provided for the collection of each of these types of waste. Liquid waste disposal is accomplished via the liquid radwaste disposal system. Piping in the basemats is embedded in the concrete; piping is also embedded in the upper concrete floors where thickness of the floors permit. The EFDS is designed for gravity flow at atmospheric pressure with the piping sloped downward to the building sumps. In general, the tops of floor drains and floor sumps are located one and one-half inches below the nominal high point of the floor.

Traps are provided on floor drains to prevent the spread of an oil fire through the drain piping in areas where oil is contained in the equipment.

Floor Drains

Drains of medium to low purity and medium conductivity (normally low radioactivity), will be collected in the floor drainage system. These miscellaneous vents, unidentified leakage, certain equipment drains, and floor area drains discharge into floor drain sumps (dirty radwaste) located in the basemat of the drywell, containment, auxiliary building, heater bay, turbine power complex, intermediate building, and radwaste building. The fluid collected in these sumps will be discharged by sump pumps to the liquid radwaste disposal system for processing. Provisions are made for removal of oil from this sump water discharge before entering the liquid radwaste system.

The annulus is provided with a floor drain sump with no additional floor drains, since very little drain water is anticipated in this area.

The turbine power complex floor drain sump receives wastes from the turbine power complex, turbine building, offgas building, heater bay (Elevation 600'-6" and above), auxiliary boiler building, and the auxiliary building pipe chase at Elevation 565'-6".

The intermediate building floor drain sump receives wastes from the intermediate building, control complex ventilating equipment floor at Elevation 679'-6", certain areas of the control complex controlled access floor at Elevation 599'-0". Floor drains located in the control complex (Elevation 599'-0") which are sent to the intermediate building floor drain sump are the nuclear closed cooling heat exchanger and pump area, safety showers in laboratories, shop facility area, and the corridors.

Floor and equipment drains from Elevation 574'-10" and portions of Elevation 599'-0" and 620'-6" of the control complex will be included in the discussion of the detergent drains. The control complex floor drains for fire protection service at the control room floor Elevation 653'-6", and cable spreading area and battery room drains at Elevation 638'-6", discharge by gravity to the exterior yard catch basin system. Manual gate valves, normally closed, are provided for each of the four drains in the control room recessed concrete floor. These valves prevent the loss of carbon dioxide from the fire protection system for the power generation control center (PGCC) floor modules. The valves would be opened to drain fire water in case the fire hoses discharge into the control room.

In the auxiliary building, common mode flooding of the emergency core cooling system (ECCS) equipment rooms (i.e., flooding in one room which results in flooding of redundant ECCS equipment in adjacent rooms) is precluded by the design of the drainage piping. All drainage connections to equipment (flushing, relief valve discharge, seals, etc.) are hard piped to either a manifold, which connects directly into a sump external to the pump rooms, or to the drainage sumps within each pump room. Since no portion of the equipment drains or manifold is open to the atmosphere, it is not possible for flooding in one room to extend or communicate to an adjacent room by drainage lines. Also, discharge from the pump room drainage sump is controlled by a remote-manual actuator on the drainage line valve which is normally closed. This ensures that drainage of the sumps to the main auxiliary building sumps is completely controllable.

Open floor drains connect directly to the respective ECCS pump room sump. Discharge from the sump is actuated and controlled as noted above.

Redundant nonsafety grade level switches are installed in each drainage pit which will alarm in the control room on high water level in the pit. If leakage from a seal or gasket in the ECCS system is detected in one of the pump rooms during normal plant conditions, the remotely operated isolation valve installed in the pump's suction line would be closed, thereby preventing drawdown of the suppression pool below the minimum level (Elevation 589'-0"). The piping and manual isolation valves meet seismic criteria. The manually operated valve in the drain line for each ECCS pump room will prevent back flooding following a safe shutdown earthquake that would cause failure of non-seismic piping systems.

Each ECCS pump compartment is provided with watertight doors which are normally dogged closed and an indication is provided to the control room via the Plant Computer Alarm Display when the doors are opened.

Equipment Drains

Drains of high purity and low conductivity (normally high radioactivity) are collected in the equipment drainage system. These equipment drains and residual heat removal system flush drains discharge into an equipment drain sump (clean radwaste) located in the basemat of the drywell, containment, auxiliary building, turbine power complex, intermediate building, radwaste building, and control complex. The turbine power complex clean radwaste equipment sump also receives drains from the turbine building and the offgas building.

The turbine building ventilation system (TBVS) plenum drains produce non-contaminated condensate when they are in the cooling mode. The condensate is produced when outside air is passed over the cooling coils. The water produced by the condensation of outside air is uncontaminated and is routed to the storm drain system. The TBVS plenum drains also have a means of directing flow to the equipment drain sump. During the winter months when the plenums are being used to heat the buildings, the piping will be aligned to the equipment drains. Prior to switching the flow to the storm drain, the drainage water will be sampled to ensure that it is uncontaminated. The water from this drain will also be sampled in accordance with plant instructions during the time period that it is aligned to the storm drain system. The fluid collected in these sumps discharges by sump pumps to the Liquid Radwaste system for processing. Provisions are made for removal of oil from this sump water discharge before entering the liquid radwaste system.

Major items of equipment and the building sump into which they drain are as follows:

a. Containment building

   1. Fuel pool leak detection drain.
   2. Fuel pool overflow drain.
   3. RWCU heat exchangers drains.

4. RWCU holding pump seal drains.
5. RWCU containment sample drain.
6. Containment vessel air handling cooling water drain.
7. RWCU backwash transfer pump seal leakage.

b. Drywell
    1. Reactor recirculating system maintenance drains.
    2. Drywell cooling supply plenum cooling coil drain.
    3. Reactor vessel drain.
    4. Miscellaneous CRW drains.

c. Auxiliary building
    1. HPCS flush drain.
    2. RHR flush drain and RHR pump relief valve.
    3. LPCS flush drain.
    4. RWCU flush drain.
    5. RWCU pump drain.
    6. Turbine building water chiller and pump drain.
    7. NCC pump relief valve.
    8. RCIC pump relief valve.

d. Turbine power complex
    1. Offgas cooler condenser and inlet piping drain.
    2. Offgas loop seal drain.
    3. Condensate booster pump drain.
    4. Condensate heaters drain.
    5. Condensate filter holding pump drain.
    6. Condenser hogging pump drain.
    7. Sample extraction pump drain.

8. Feedwater seal injection pump drain.
9. Generator stator cooling unit drain.
10. Turbine building closed cooling heater exchanger and pump drain.
11. Condensate transfer pump drain.

e. Intermediate building

1. Drivewater filter and pump drains.
2. Cask storage pit drain.
3. Cask pit drain pump drain.
4. Fuel transfer tube drain tank and pump drain.
5. Circulating pump drain.
6. Fuel pool cooling and cleanup heat exchanger, post-filter and holding pump drains.
7. FPCC surge tank overflow.
8. NCC maintenance drain and relief valve.
9. Containment chiller pump drain.
10. Fuel pool F/D backwash transfer pump seal water.

f. Radwaste

1. RWCU sludge decant pump drain.
2. Condensate sludge decant pump drain.
3. Waste sample pump drain.
4. Fuel pool sludge decant pump drain.
5. Waste collector transfer pump drain.
6. WCT tank overflow.
7. WCTP drain.
8. WCT flush drain.
9. WST overflow.

g. Control complex

1. Service and instrument air receiver drains.
2. Service and instrument air compressor drains.
3. Emergency closed cooling heat exchanger shell drain.
4. Emergency closed cooling pump drain.
5. Control complex water chiller and pump drains.
6. Nuclear closed cooling heat exchanger shell drain.
7. Nuclear closed cooling pump drain.
8. Instrument air dryer drain.

Chemical Drains

A chemical waste sump is located in the basemat of the turbine power complex. Drains from the condensate demineralizer regeneration chemical waste tank and the waste transfer pump are collected in this sump. In the control complex, drains from the fume hoods and the laboratory sinks located in the high and low level laboratories, and the sink in the health physics and radiation protection service room are directed by gravity to the liquid radwaste system chemical waste tank located in the radwaste building.

Detergent Drains

A laundry and floor drain sump is located in the basemat of the control complex. Inputs to this sump consist of personnel decontamination solutions from the personnel decontamination room and the respiratory cleaning facility, floor drains from nonradioactive areas of the control complex and drains from the lake water side of the nuclear closed cooling system heat exchangers. The fluid collected in these sumps discharges by sump pumps to the liquid radwaste system detergent drains tanks. The detergent drain tank waste is processed via the radwaste flow drain system.

Oil Drains

A lube oil area floor and equipment drain sump is located in the east end of the turbine building basemat at Elevation 593’-6”. Equipment drains and floor drains for the turbine lube oil system and other hydraulic operated equipment located in this area are directed to this sump. In addition, floor and equipment drains are collected in this sump from the floor trench at fuel oil pumps in the auxiliary boiler building, from the feedwater turbine lube oil purifier room and turbine-driven feedwater pump rooms in the heater bay, and from the battery room in the turbine power complex.

Drainage collected in the turbine lube oil area and turbine laydown area sumps is normally pumped to the liquid radwaste system. There is also a piping interconnection to the industrial waste disposal system. To prevent inadvertent discharge to industrial waste, administrative procedures require the contents of both sumps to be sampled before transfer to industrial waste, and each line interconnecting these sumps with the industrial waste disposal system is isolated by a valve that is normally locked closed.

Floor and equipment drains from each of the three diesel generator rooms drain separately by gravity to the industrial waste disposal system. A trap is provided in the drain header discharging from each of the diesel generator rooms. Provisions are made for removal of oil from the diesel generator room drains in the industrial waste disposal system.

Roof Drains

Safety and nonsafety building roofs are drained by a combination of roof pitch, roof drains, parapet openings and scuppers. The drainage on the roofs is controlled to ensure that water depths developed during the LIP rainfall do not exceed the structural capacity of the roof. In case of complete blockage of roof downspouts on safety related buildings, building scuppers and parapet openings have been sized to ensure roofs will not exceed the maximum allowable loading limits.

System Boundary

System components subject to aging management review include valves and piping components within safety-related structures, as shown on the referenced LR boundary drawings. Unless otherwise noted on Scoping Drawings, this includes equipment drain funnels that appear on many drawings, equipment drain pans, and HVAC and air handling unit drains.

Pipe Plug (PY-2P68X0001) installed in a Unit 2 turbine power complex pipe tunnel sump is treated as a structural commodity preventing internal flooding from Unit 2 to Unit 1.

Some drain valves from the liquid radwaste sumps system (G61), as shown on license renewal boundary drawings 911-0617 and 911-0628, are evaluated within this system.

Roof drain piping is also evaluated within this system but is not depicted on LR boundary drawings.

Building roof scuppers and parapets are evaluated as part of structural commodities.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Prevent flooding of the ECCS rooms by backflow through the floor drains. [10 CFR 54.4(a)(2)]

Auxiliary Building floor drains on the 599' and 620' elevation mitigate internal flooding. [10 CFR 54.4(a)(2)]

During a Local Intense Precipitation event the roof drains are credited to prevent failures of nonsafety building roofs and resultant internal flooding. [10 CFR 54.4(a)(2)]

Diesel generator floor drain traps prevent the spread of an oil fire through the drain piping. [10 CFR 54.4(a)(3) – FP]

Collect radioactive and potentially radioactive liquid wastes from floor drains and equipment drains throughout the plant.

Component Types Subject to Aging Management Review

Table 2.3.3-25 lists the component types that require aging management review and their intended functions.

Table 3.3.2-25, Auxiliary Systems – Floor and Equipment Drains System – Summary of Aging Management Evaluation, provides the results of the aging management review.

Table 2.3.3-25
Floor and Equipment Drains

2.3.3.26 Fuel Handling Area Ventilation (M40)

System Description

The Fuel Handling Area Ventilation (FHAVS) provides heating and ventilation for the various operating areas of the fuel handling area and ventilating equipment areas, and provides effective protection for personnel against airborne radioactive contaminants.

The supply subsystem (FHASS) continuously draws outside air through roughing filters and heating coils. One of the two 100 percent capacity supply fans normally operates to draw air through the supply plenum and discharge it to the supply ductwork for distribution. The areas provided with supply air are the control rod drive pump areas, the FHAVS equipment area, the railway and overhead crane area, and the periphery of the fuel pool area on all sides. The general air flow pattern in the fuel handling area is from areas of low probable airborne contamination to areas of high probable airborne contamination. The ventilation pattern in the fuel pool areas is from the supply around the periphery of the pools toward the exhaust located directly above the pools.

The exhaust subsystem (FHAES) continuously draws air from the CRD pump areas, the control rod drive maintenance area, the area above the fuel pools, and from the fuel pool cooling, cleaning and post-accident sampling system (PASS) equipment rooms located in the intermediate building. Two of the three 50 percent charcoal exhaust units are operating normally to draw air through the exhaust ductwork and discharge it to the atmosphere through the unit vent.

In the event that the radiation monitors located upstream of the charcoal exhaust units senses high radiation, the high radiation signal alarms in the control room and automatically trips the supply fan. The exhaust system remains operational to continue exhausting contaminated air from the fuel handling area through charcoal filters, thus precluding any uncontrolled release of radioactivity to the outside. Two barometric pressure relief dampers in the supply duct would relieve any excessive negative building pressure.

The FHASS and FHAES are classified as Safety Class 3, Seismic Category I.

The exhaust subsystem of fuel handling area ventilation system known as the fuel handling area exhaust subsystem (FHAES), is an engineered safety feature (ESF) filter system that reduces the concentration of airborne radioactive contaminants following a design basis accident. The remote possibility of release of airborne radioactive contaminants due to a fuel handling accident, the requirements of 10 CFR 50, Appendix A, General Design Criterion (GDC) 61, and the recommendations of Regulatory Guide 1.13 establish the need for FHAES to accomplish fuel pool area air filtration. GDC 61 requires, in part, that fuel storage and handling, and radioactive waste and other systems that may contain radioactivity be designed to ensure adequate safety under normal and postulated accident conditions and that appropriate filtering systems be provided. However, no accident dose calculations credit the FHAES as described in UFSAR sections 15.7.4 and 15.7.6.

System Boundary

System components subject to aging management review are safety-related filter plenums, fans, duct, dampers, and nonsafety-related drain plenum drain piping and valves.

Fire water and heating water components (including heating coils within filter plenum) are evaluated within fire protection and building heating systems (P54 and P55, respectively).

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, because it is relied on to perform a function that demonstrates compliance with the regulations for FP and for EQ.

Fuel Handling Area Ventilation is designed to remove and process the radiation release resulting from a fuel cladding failure accident event in the fuel handling area. [10 CFR 54.4(a)(1)]

Prevent excessive negative pressure in the fuel handling building. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

System fire dampers prevent the spread of fire. [10 CFR 54.4(a)(3) – FP]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Maintain the temperature of the fuel handling areas, and any other areas they serve, within a range suitable for operating personnel and equipment.

Component Types Subject to Aging Management Review

Table 2.3.3-26 lists the component types that require aging management review and their intended functions.

Table 3.3.2-26, Auxiliary Systems – Fuel Handling Area Ventilation System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.27 Fuel Storage (F16) and Fuel Pool Cooling and Cleanup (G41)

System Description

The fuel pool cooling and cleanup (FPCC) system removes decay heat from the spent fuel stored in the fuel pool and maintains water temperature, purity, clarity, and level. In the event of an abnormal heat load such as a full core offload, the RHR system can be used to supplement the normal cooling system while in cold shutdown or refueling mode. The fuel storage system provides new fuel racks, spent fuel racks, multi-purpose storage cavities and neutron absorbers.

The FPCC system cools the spent fuel storage pools by transferring the spent fuel decay heat to the nuclear closed cooling system during normal plant operation. The FPCC system consists of two parallel pumps and two parallel heat exchangers. Water from the upper and lower pools is transferred to the surge tanks in the fuel handling building. Overflow from the tanks is channeled to the radwaste system. The circulating pumps take suction from the bottom of the tanks and pump the water through the components of the system.

Clarity and purity of the pool water are maintained by a combination of filtration and demineralization. The cleanup system consists of two sets of filter demineralizers, each of which has its own piping and is capable of independent operation. Because the filter demineralizers are of the pressure precoat type, the system depends on flow to keep the filter medium on the filter elements. Each filter demineralizer uses a holding pump to automatically maintain flow across the filter in case loss of flow from the main system occurs.

New fuel storage racks are located in the new fuel storage vault and are designed to store fuel assemblies in an array which is sufficient to maintain K_{eff} of 0.95 or less in the normal dry condition or abnormal completely water flooded condition. New fuel may not be stored in the new fuel storage vaults until such time a criticality analysis is completed. PNPP procedures prohibit the storage of new fuel in the new fuel storage vaults.

Two kinds of spent fuel storage racks are used: those achieving subcriticality by spacing in a loose packed geometric array, and those using a neutron absorber to achieve subcriticality in a close packed or dense geometric array. The loose packed fuel storage racks are used in containment. The densified fuel storage racks are used in the spent fuel storage pits in the fuel handling and storage area of the intermediate building (also called the fuel handling building). Multi-purpose storage cavities that can hold defective fuel, guide tubes or control rods are also provided.

System Boundary

System components subject to aging management review include pumps, valves, heat exchangers, filter-demineralizers, and other piping components connected to the fuel pools, cask pit, reactor well and separator storage well, as depicted on LR boundary drawings. Spent fuel racks and neutron absorbers are also subject to aging management.

The leak detection cone strainer, which appears on drawing 302-0651, are evaluated with this system.

The pool liners, skimmers, and scuppers are evaluated as structural commodities.

The Cask Pit Pool Waste Storage Rack 1F16E0012, which provides a compact storage location for control rod blades, is evaluated as a structural commodity.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ and SBO.

Remove decay heat from the spent fuel stored in the fuel pool and reactor (during refueling) [10 CFR 54.4(a)(1)]

Spent fuel racks protect the fuel assemblies from physical damage. [10 CFR 54.4(a)(1)]

Spent fuel racks maintain stored fuel subcritical by at least 5 percent delta-K. [(a)(1)]

Maintain pool water level and reactor water level (during refueling) [10 CFR 54.4(a)(1)]

Minimize release of radioactive elements to the environment [10 CFR 54.4(a)(1)]

Containment isolation limits radiological release. [10 CFR 54.4(a)(1), (a)(3) - SBO]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [(a)(3) – EQ]

New fuel racks protect new fuel assemblies from physical damage.

Component Types Subject to Aging Management Review

Table 2.3.3-27 lists the component types that require aging management review and their intended functions.

2.3.3.28 Hydrogen Water Chemistry (P73)

System Description

The hydrogen water chemistry (HWC) system injects hydrogen into the feedwater system. The hydrogen combines with oxygen and oxides in the reactor water, lowering the Electrochemical Corrosion Potential (ECP) to below the −230mV Standard Hydrogen Electrode threshold to mitigate the potential and growth of Intergranular Stress Corrosion Cracking (IGSCC) of stainless steel piping and reactor internal components. Due to the recombination of free hydrogen and oxygen, this injection results in a substantial reduction of oxygen levels, thereby reducing a critical contributor to IGSCC. The hydrogen injection into the feedwater system results in an offgas mixture exiting the condenser that contains excess hydrogen. To prevent discharging this mixture and creating a potential fire or explosion hazard, a stoichiometric amount of oxygen is added upstream of the recombiner to recombine the hydrogen in the offgas system.

The hydrogen water chemistry system consists of a storage subsystem, a supply subsystem, an injection subsystem, and an On-Line NobleChem Monitoring system (OLNC). Liquid Hydrogen (H2) and Oxygen (O2) are cryogenically stored. The liquid hydrogen is pumped into supplemental gaseous storage tanks. The liquid hydrogen and oxygen are cryogenically stored in separate storage facilities remote from the nearest safety-related structure and air intakes into safety-related structures. This separation distance ensures that a potential hydrogen fire or explosion will not cause failure of any safety-related structures. The supply subsystem includes the hydrogen and oxygen pipelines and instrumentation lines between the storage facility and the turbine building. The hydrogen and oxygen are delivered to the Unit 1 turbine building and heater bay building by two 2-inch diameter pipes (one for each commodity). The supply subsystem piping is not routed inside or attached to the outside of safety-related structures. The injection subsystem consists of hydrogen and oxygen injection modules, control stations, and associated interfaces required to monitor and control the injection of hydrogen and oxygen. The HWC System includes a cross-tie connection to the generator hydrogen supply system to provide an alternate hydrogen supply to the main generator from the HWC storage facility.

The hydrogen water chemistry system is nonsafety-related and is not required for safe shutdown of the reactor. The hydrogen injection system is located in a portion of the heater bay (hydrogen injection) and turbine building (oxygen injection) remote from safety-related equipment. In the event an accident occurs, there is no interaction between the HWC injection system and other plant components which may need to perform a safety-related function.

The On-Line NobleChem (OLNC) system is a nonsafety-related sub-system to the HWC system. The OLNC system is comprised of an injection system and a Mitigation Monitoring System (MMS). The injection portion injects a noble metal compound into the reactor feedwater system during plant operation, to produce catalytic deposits on the reactor internal surfaces. The OLNC injection portion can also inject into the reactor water cleanup (RWCU) system when the Feedwater injection point is not available. The MMS analyzes the amount of noble metal remaining on the monitor’s sample coupons, which is representative of the amount of noble metal remaining on the internal surfaces of the reactor vessel.

System Boundary

System components subject to aging management review include nonsafety-related flow elements, valves and piping components within safety-related structures, as shown on the referenced LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Inject hydrogen into Feedwater to control oxygen content.

Inject oxygen upstream of offgas recombiner to control offgas hydrogen content.

Monitor coolant chemical control.

Component Types Subject to Aging Management Review

Table 2.3.3-28 lists the component types that require aging management review and their intended functions.

2.3.3.29 Inclined Fuel Transfer System (F42)

System Description

The inclined fuel transfer system is used to transfer fuel, control rods, defective fuel storage containers, and other small items between the containment and the fuel building pools by means of a carriage traveling in a transfer tube (a 23-inch I.D. stainless steel pipe). At the containment upper pool, the transfer tube connects to pool penetration and to a sheave box. Connected to the sheave box is a 24-inch flap valve, a vent pipe, cable enclosures, and a fill valve. In the fuel building pool, the transfer tube connects to a 24-inch gate valve. A bellows connects the fuel building penetration to the valve and transfer tube to prevent water entrapment between the tube and penetration.

A four-inch weld-o-let located on the transfer tube approximately two feet above the fuel building pool water level and a motor-operated valve are provided for connections to a drainpipe for water level control in the transfer tube. A containment isolation assembly containing a blind flange and a bellows which connects from the containment penetration to the assembly are provided to make containment isolation.

A hydraulic power unit with attendant piping and valves is provided in the fuel handling building and the reactor building to actuate the cylinders attached to the upenders, the fill valve, the flap valve, and the fuel building gate valve.

Containment is made by the containment isolation assembly and blind flange, containment bellows and the steel containment penetration. Special gaskets and double ply bellows are provided for leak checking to ensure containment isolation. A bellows assembly with a test connection is installed to permit confirmatory leak testing of the double ply bellows. When the blind flange is removed in operating Modes 1, 2, or 3, containment is made by the remaining portion of the containment isolation assembly, containment bellows, steel containment penetration, transfer tube, drain line, drain valve, and local leak rate test valve. A time restriction of 60 days per cycle exists for this configuration, i.e., the blind flange removed in operating Modes 1, 2, or 3.

The Unit 1 inclined fuel transfer system provides a pressure boundary for maintaining water inventory in the safety-related containment upper pools.

The Unit 2 transfer tube, bellows and associated piping components are retired in place but portions still provide a leakage boundary function.

System Boundary

System components subject to aging management review include the inclined fuel transfer tube and associated valves and equipment, the hydraulic components that provide motive force for the lower transfer tube valve, and the refueling bellows, as shown on LR boundary drawings. The Unit 2 inclined fuel transfer tube and associated components as shown on LR boundary drawing 302-0970 are also subject to aging management review.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

Provide containment integrity. [10 CFR 54.4(a)(1), (a)(2)]

Provide a pressure boundary for maintaining water inventory in the containment upper pools. [10 CFR 54.4(a)(1), (a)(2)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Support movement of fuel and other components between containment and the fuel building.

Component Types Subject to Aging Management Review

Table 2.3.3-29 lists the component types that require aging management review and their intended functions.

Table 3.3.2-29, Auxiliary Systems – Inclined Fuel Transfer System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.30 Industrial Waste Disposal (P64)

System Description

The industrial waste disposal system contains oil interceptors to process drains from transformer basins. The separated water is directed to catch basins. A sludge holding sump receives blowdown from the makeup water pretreatment system, as well as the discharge from an oil separator that processes plant drains. The plant oily drains collected in the turbine lube oil area and turbine laydown area sumps are normally pumped (remote manual initiation) to the liquid radwaste system but may be directed to the industrial waste disposal system.

Floor and equipment drains from the diesel generator building drain separately by gravity to an oil interceptor tank buried in the yard. That oil interceptor tank connects to the sludge holding sump in the industrial waste disposal system. A trap is provided in the drain header discharging from each of the diesel generator rooms.

A waste lagoon receives non radiological chemical cleaning and flushing wastes, and can be decanted to the makeup water pretreatment system to allow the settled sludge to be removed by truck.

The system is entirely nonsafety-related and is located in the plant yard and yard structures.

System Boundary

The oil interceptor tank vent lines and the sludge holding sump flapper valve are subject to aging management review.

The oil interceptor tank and manway cover are scoped as structural commodities.

System Functions (and scoping criteria, if intended function)

The system contains mechanical components that are nonsafety-related whose failure could result in failure of a safety-related function. The system does not contain any mechanical components that are safety-related or that are credited for regulated events.

Receive and process oily drains and industrial wastes.

The oil interceptor tank vent line openings are located above the water surface elevation for a probable maximum precipitation (PMP) event, and along with the tank manway cover combine to preclude flooding of the oil interceptor tank and the diesel generator building. [10 CFR 54.4(a)(2)]

The sludge holding sump flapper valve (0P64F-0511) provides a boundary to the oil interceptor tank to prevent high sump levels from flooding the oil interceptor tank and the diesel generator building. [10 CFR 54.4(a)(2)]

Component Types Subject to Aging Management Review

Table 2.3.3-30 lists the component types that require aging management review and their intended functions.

2.3.3.31 Intermediate Building Ventilation (M33)

System Description

The intermediate building ventilation supply unit continuously draws outside air through roughing filters (the supply roughing filters may be removed to preclude snow buildup on the filters) and heating coils and supplies it to the general areas of the building. This supply air is drawn through the various ventilation equipment rooms and is then discharged to the atmosphere by the unit vent. The supply air drawn through the fuel pool cooling and cleanup system equipment rooms and the post-accident sampling room is directed through the charcoal filter train of the fuel handling area exhaust system before being discharged to the atmosphere by the unit vent. The supply air drawn through the Intermediate Building tool storage/tool decontamination areas is directed through the sub-exhaust unit, which contains a filter train consisting of roughing filters, HEPA pre-filters, charcoal filters and HEPA after-filters. After passing through the filter train, the exhaust air from these areas is carried through the system exhaust ductwork and is exhausted to the atmosphere through the unit vent. During periods of emergency, as may result from a LOCA or loss of offsite power, this system is not required to operate.

This system is nonsafety-related and non-seismic classified, except for the sub-exhaust charcoal filter plenum which is designed to satisfy the requirements of Seismic Category I items.

The intermediate building ventilation Unit 1 and 2 plant vent flow elements (straighteners) are safety-related and indications from them are used together with the Unit 1 & 2 plant vent radiation monitors to establish a release rate.

Select ductwork, access doors and duct external strapping provide an HVAC-related tornado depressurization barrier.

System Boundary

System components subject to aging management review include fire dampers and duct, filter plenum, and plenum drain piping and valve as shown on the LR boundary drawing.

Fire protection and hot water heating fluid components are evaluated with the P54 fire protection and P55 building heating systems.

The intermediate building ventilation safety-related Unit 1 and 2 plant vent flow elements are evaluated as part of the D17 & D19 (plant radiation monitoring and process monitoring, and post-accident radiation monitoring) systems.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Selected nonsafety system ducting required to support control building pressure transient during a tornado. [10 CFR 54.4(a)(2)]

System fire dampers prevent the spread of fires. [10 CFR 54.4(a)(3) – FP]

Provide adequate ventilation in the intermediate building.

Component Types Subject to Aging Management Review

Table 2.3.3-31 lists the component types that require aging management review and their intended functions.

2.3.3.32 Leak Detection (E31)

System Description

The nuclear leak detection and monitoring system consists of temperature, pressure, flow, and fission product sensors with associated instrumentation and alarms. This system detects, annunciates and in some cases isolates leakage in the following systems:

a. Main steam lines

b. Reactor water cleanup (RWCU) system

c. Residual heat removal (RHR) system

d. Reactor core isolation cooling (RCIC) system

e. Feedwater system

f. ECCS systems

g. Miscellaneous systems

Small leaks generally are detected by monitoring the air coolers condensate flow, radiation levels and drain sump fill-up and pump-out rates. Large leaks are also detected by changes in reactor water level and changes in flow rates in process lines.

System Boundary

System components subject to aging management review include piping components, valves, and instrumentation associated with leakage from the above systems, as shown on LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

System piping penetrating the drywell provide a drywell pressure boundary function. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Safety-related instrumentation detects, annunciates and in some cases creates isolation signals on indications of system leakage. [10 CFR 54.4(a)(1), (a)(3) - EQ]

Component Types Subject to Aging Management Review

Table 2.3.3-32 lists the component types that require aging management review and their intended functions.

Table 3.3.2-32, Auxiliary Systems – Leak Detection System – Summary of Aging Management Evaluation, provides the results of the aging management review.

Table 2.3.3-32
Leak Detection

2.3.3.33 Liquid Radwaste Disposal (G50)

System Description

The system collects, monitors, treats, stores, and recycles or releases radioactive liquid wastes. These wastes are collected in sumps and drain tanks at various locations throughout the plant and then transferred to collection tanks in the radwaste facility for treatment, storage and recycle or release.

Wastes are processed on a batch basis with each batch being processed by methods appropriate for the quality and quantity of materials present. Most of the processed liquid is returned to the condensate system.

Incoming streams of liquid waste are collected and treated in one of four separate process streams according to their composition. These four subdivisions are high purity/low conductivity wastes (primarily equipment drains), medium-to-low purity/medium conductivity wastes (primarily floor drains), high conductivity chemical wastes, and detergent drains.

In addition to handling these four categories of liquid waste, the liquid radwaste (LRW) system collects spent resin slurries and filter backwash slurries prior to being sent to the solid radwaste (SRW) disposal system.

It is postulated that an unspecified event causes a failure of a tank in the radwaste building in order to assess the consequences of a liquid containing tank failure.

System Boundary

System components subject to aging management review include the fuel pool filter--demin backwash receiving tank, pumps, valves and piping components within the auxiliary, control, intermediate, and reactor buildings, as depicted on the LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ and SBO.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1), (a)(3)-SBO]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

For the liquid containing tank failure event, it is conservatively assumed that 80 percent of the design capacity is immediately released from the building, i.e., no credit is taken for retention of any of the released liquids in the Seismic Category I radwaste building.

Component Types Subject to Aging Management Review

Table 2.3.3-33 lists the component types that require aging management review and their intended functions.

Table 3.3.2-33, Auxiliary Systems – Liquid Radwaste Disposal System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.34 Liquid Radwaste Sumps (G61)

System Description

The liquid radwaste sumps system receives input from floor and equipment drains, chemical waste drains, and laundry drains (system P68). The turbine lube oil area floor drain sump discharge to the plant industrial waste system (P64). The chemical waste drain sumps and laundry drains sumps discharge directly to the liquid radwaste system (G50), while other equipment and floor drains sumps discharge to the liquid radwaste system via oil separators.

System Boundary

System components subject to aging management review include pumps, valves, orifices and piping components associated with sump discharge piping within safety-related structures, as shown on the referenced LR boundary drawings.

The portions of nonsafety-related sump pumps that are submerged in sumps cannot cause spatial interactions with nearby safety-related equipment (i.e., by leaking or spraying below the waterline). The design of some sump pumps has a casing that extends above the waterline to the discharge piping connection. In another design, the pump casing is completely submerged, with a discharge riser pipe connecting to the casing under water. Only the portions of the pumps, discharge piping and bolting above the waterline are within scope. In addition, portions of nonsafety-related cooling coils that are submerged in sumps cannot cause spatial interactions with nearby safety-related equipment (i.e., by leaking or spraying below the waterline). Only the portions of the piping above the waterline are within scope.

The aux building sump discharge valves shown on license renewal boundary drawing 911-0617 and the new fuel storage pool drain valves shown on license renewal boundary drawing 911-0628 are evaluated in the floor and equipment drain (P68) system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ and SBO.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1), (a)(3) - SBO]

Provide indication/alarm of high water level that could be an indication of system leakage. [10 CFR 54.4(a)(2)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Collect liquid drains and transport the liquids for disposal.

Component Types Subject to Aging Management Review

Table 2.3.3-34 lists the component types that require aging management review and their intended functions.

Table 3.3.2-34, Auxiliary Systems – Liquid Radwaste Sumps – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.35 MCC Switchgear and Miscellaneous Electrical Area HVAC, and Battery Room Exhaust (M23 & M24)

System Description

The MCC, switchgear and miscellaneous electric equipment areas HVAC system operates continuously to provide cooling or heating during normal plant operation, during plant shutdown and following loss of offsite power or a LOCA. The areas served by this system include MCC, switchgear, dc switchgear rooms, battery rooms, HPCS switchgear rooms, reactor protection system rooms, remote panel shutdown rooms, cable spreading areas, and HVAC equipment rooms. The HVAC system consists of two 100 percent capacity supply plenums that house roughing filters and chilled water-cooling coils, two 100 percent capacity supply fans, a supply duct system with electric reheat coils, and a return duct system.

The duct systems and controls are arranged so that a mixture of outside air and return air from the HVAC equipment room is directed through the cooling plenum and supplied to the various areas requiring cooling or heating. Room air, from all areas except the battery rooms, after satisfying the cooling or heating function, is directed to the return fan and delivered to the HVAC equipment room.

The battery room exhaust system operates continuously during normal plant operation, during plant shutdown and following loss of offsite power or a LOCA to exhaust the battery rooms to the outside. In the event of an emergency, the exhaust may be remote-manually redirected to a recirculation mode. In this mode, the exhaust air from the battery rooms is directed to the supply plenum of the MCC, Switchgear and Miscellaneous Area HVAC fans.

The MCC, switchgear, & misc area HVAC and battery room exhaust systems, excluding the electric reheat coils, is classified as Safety Class 3, Seismic Category I. The electric reheat coils are classified as nonsafety-related and non-seismic category.

System Boundary

System components subject to aging management include fans, dampers, and associated ducting components as depicted on the LR boundary drawing.

Cooling water components associated with the supply plenums are evaluated in the control complex chilled water (P47) system.

Structural missile barriers provided on the relief air ducts to prevent external missiles from entering the control complex are evaluated as structural.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

Remove heat generated in the dc switchgear rooms, HPCS switchgear rooms, reactor protection rooms, cable spreading areas, and HVAC equipment rooms. [10 CFR 54.4(a)(1), (a)(3) – FP]

Prevent the accumulation of combustible gas in the battery rooms. [10 CFR 54.4(a)(1), (a)(3) – FP]

Provide smoke exhaust capability for the cable spreading, MCC and switchgear rooms, and the control complex chase. [10 CFR 54.4(a)(3) – FP]

Component Types Subject to Aging Management Review

Table 2.3.3-35 lists the component types that require aging management review and their intended functions.

Table 3.3.2-35, Auxiliary Systems – MCC Switchgear and Miscellaneous Electrical Area HVAC, and Battery Room Exhaust – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.36 Miscellaneous Area Ventilation (M46)

System Description

The miscellaneous area HVAC system consists of the following nonsafety-related subsystems:

- Turbine lube oil storage area ventilation
- Service water pumphouse ventilation
- Diesel driven fire pump area ventilation

- Auxiliary boiler building ventilation
- Inservice inspection equipment room ventilation
- Sanitary waste treatment control house ventilation
- Discharge tunnel dechlorination equipment building ventilation
- Fuel oil pumphouse ventilation
- Cement storage area ventilation
- Fire service & construction water pump house ventilation
- Decant control structure heater
- Various elevator equipment rooms ventilation
- Spent fuel dry storage electrical building ventilation
- Health Physics control point and office area ventilation

The only subsystems which include components that require aging management review are the turbine lube oil storage area ventilation system, the diesel driven fire pump area ventilation system, and the HP control point ventilation system, each of which contain fire dampers that provide a three-hour rated barrier. The diesel driven fire pump area ventilation subsystem also supports operation of the diesel driven fire pump.

The Turbine Lube Oil Storage area ventilation system functions during normal plant operation. It provides heating and ventilation in the turbine lube oil storage areas. During summer operation, ventilation of the lube oil areas is accomplished by drawing outside air through a supply fan and discharging the air to various storage areas. This supply air is relieved to the atmosphere through wall louvers. Operation of the supply fans is initiated from a local control switch. During winter operation, a portion of the ambient air is recirculated depending upon the outdoor temperature.

Also, hot water unit heaters with remote thermostats are provided to maintain suitable minimum ambient temperature.

The diesel driven fire pump area ventilation system provides ventilation in the diesel driven fire pump area to maintain suitable environment for equipment operation. Ventilation of the diesel driven fire pump area is accomplished by supply fans that draw ambient air from the emergency service water pumphouse and discharge it to the fire pump area. This supply air is then relieved to the atmosphere through a ducted relief louver. Operation of the supply fans is initiated whenever the diesel driven fire pump starts. The fans may also be manually started from the local selector switches. High temperature switches in the supply fan discharge ducts and the exhaust duct automatically stop the supply fans on indication of high temperature.

The health physics access control point and office facility HVAC System consists of three air handling units and one exhaust fan. The AHUs consist of a cooling coil, roughing filter, and fan in one single unit. All AHU components are located above the ceiling at the HP access control facility which is located in the 620 elevation of the control complex building. The exhaust fan takes a suction on the RCA access corridor within the service building and discharges this air to the M54 SB hot shop HVAC system. The exhaust fan is located in the SB hot machine shop. A fire damper associated with this exhaust fan provides a fire barrier between fire zone IB-3 and the service building.

System Boundary

System components subject to aging management review include fire dampers, ductwork, bolting, and fan housings as shown on the LR boundary drawings. This includes the PY-0M46 duct test specimens located in the IB-585 pipe chase that are tested each refuel outage for indication of age-related degradation of silicon sealant used in ESF ventilation system ductwork per Commitment L01090.

Heating and cooling water components are evaluated in the P55 building heating system and P50 containment vessel chilled water system respectively. Motor operated wall louvers associated with the system are evaluated in the L53 motor operated louvers system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

System fire dampers prevent the spread of fires. [10 CFR 54.4(a)(3) – FP]

Miscellaneous HVAC Diesel Driven Fire Pump Area Fans provide air to the diesel-driven fire pump area during fire pump operation. [10 CFR 54.4(a)(3) – FP]

Maintain a suitable environment for equipment operation.

Component Types Subject to Aging Management Review

Table 2.3.3-36 lists the component types that require aging management review and their intended functions.

2.3.3.37 Miscellaneous Electrical Areas Smoke Ventilation (M49)

System Description

With the exception of the tornado dampers and associated ducting, the miscellaneous electrical areas smoke venting system is nonsafety and functions only when a high smoke condition occurs in the electrical areas such as the motor control center and switchgear rooms, cable spreading areas, duct and cable chases, and the cable tunnels. The smoke venting system will clear the smoke and enhance visibility to aid fire fighters in the affected areas.

Smoke venting is accomplished by exhausting air from the affected electrical areas through an axial flow fan and discharging the exhaust air to the atmosphere through the unit vent. Operation of the smoke venting fans is initiated manually from the intermediate building upon receipt of high smoke alarm from any of the electrical areas served.

Two axial fans are provided, and each electrical power division is served independently by a separate exhaust fan.

System Boundary

System components subject to aging management review include fan housings, dampers, and duct components as shown on the LR boundary drawing.

Unit 2 miscellaneous electrical areas smoke ventilation (M49) fire dampers and tornado depressurization duct blank-off plates are evaluated as structural.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

System tornado dampers control building pressure transient during a tornado. [10 CFR 54.4(a)(1)]

Selected nonsafety system ducting required to support control building pressure transient during a tornado. [10 CFR 54.4(a)(2)]

Clear smoke and enhance visibility to aid fire fighters in the affected areas. [10 CFR 54.4(a)(3) – FP]

Fire dampers prevent the spread of fire. [10 CFR 54.4(a)(3) – FP]

2.3.3.38 Miscellaneous Sump (G60)

System Description

The miscellaneous sumps system provides a means of collecting and routing drainage in the circulating water pumphouse, service water pumphouse, and emergency service water pumphouse to their respective floor drain sumps, and for the removal of this collected drainage to the respective pumphouse forebay. This system also provides for the removal of collected water in the service water valve pit to ground level using an installed pump, and for pump-out of selected manholes to catch basins.

System Boundary

System components subject to aging management review include the nonsafety sump discharge piping within the safety-related service water valve pit, as shown on the LR boundary drawing.

The portions of the nonsafety-related sump pump that is submerged in the service water valve pit sump cannot cause spatial interactions with nearby safety-related equipment (i.e., by leaking or spraying below the waterline). Only the pump discharge piping and bolting above the waterline are within scope.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Collect and route drainage for selected structures.

Component Types Subject to Aging Management Review

Table 2.3.3-38 lists the component types that require aging management review and their intended functions.

2.3.3.39 Nitrogen Supply (P86)

System Description

The nitrogen supply System supplies nitrogen gas to the scram accumulators of the hydraulic control units associated with the control rod drive hydraulic system (C11).

The system consists of a nitrogen storage vessel, a tube trailer discharging stanchion, pressure reducing valves, and the associated piping to distribute the nitrogen to hose connections located within the proximity of the hydraulic control units.

Other than safety-related piping and isolation valves associated with the piping penetration into containment, the system is nonsafety-related.

System Boundary

System components subject to aging management review include safety related valves and piping components associated with a containment penetration, and the connected nonsafety valves and piping components that provide support, as shown on LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Supply nitrogen gas to the scram accumulators of the Hydraulic Control Units.

Component Types Subject to Aging Management Review

2.3.3.40 Nuclear Closed Cooling (P43)

System Description

The nuclear closed cooling system (NCC) is designed to provide a reliable source of cooling water to the auxiliary nuclear plant equipment.

The system flow is maintained by the necessary combinations of three 50 percent capacity pumps with three 50 percent capacity heat exchangers dissipating the heat load to the service water system. A surge tank is also provided to account for system volume variations. Two pumps are powered from Unit 1 diesel backed ac power sources; the third pump is powered from a Unit 2 ac power source. The pumps are manually initiated and operated. Under a loss of preferred ac power, the system can be manually restarted and loaded onto the emergency diesel stub bus.

The nuclear closed cooling system is not required for safe shutdown of the reactor following a loss-of-coolant accident. Upon a signal in the control room of accident conditions, the “A” and “B” NCC pumps are shut down and the containment isolation valves are closed. The fuel pool heat exchanger equipment isolation valves are also automatically closed. Cooling is then restored from the Unit 2 emergency closed cooling system.

System Boundary

System components subject to aging management review are limited to safety-related valves and piping associated with containment penetrations, and nonsafety-related pumps, tanks, heat exchangers, valves and various other piping components within structures that contain safety-related components, as shown on the LR boundary drawings.

The Recirculation pump seal water coolers which act as a pressure boundary within the reactor coolant pressure boundary are addressed as part of the reactor coolant pressure boundary scoping.

Safety related piping that supplies NCC cooling to the fuel pool cooling and cleanup (G41) heat exchangers and the control complex chilled water (P47) system chiller C, by way of the emergency closed cooling water (P42) system piping is addressed as part of the emergency closed cooling water system scoping.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

Drywell isolation valves ensure drywell boundary. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains component credited for EQ. [10 CFR 54.4(a)(3) - EQ]

Remove heat from equipment required for power production.

2.3.3.41 Offgas Building Ventilation (M36)

System Description

The offgas building exhaust system exhausts air from the offgas building and from potentially contaminated areas like the steam jet air ejector area, catalytic recombiner area, and various rooms and equipment cells in the condensate polishing area. This exhaust air passes through a charcoal filter train before it is discharged to the atmosphere through an elevated release point (offgas vent duct). The offgas exhaust system is operated continuously during normal operation.

The main components of this system are located in the offgas building at elevation 635'-0," and consist of two 100 percent capacity charcoal filter trains and two 100 percent capacity centrifugal fans with isolation dampers for idle unit isolation. The charcoal filter trains include roughing filters, HEPA prefilters, charcoal filters, and HEPA after-filters.

Components of this system located in the turbine building, turbine power complex, and located above elevation 660' of the offgas building are nonsafety class and are of standard industrial design. Components located below elevation 660' of the offgas building are designed to satisfy system space requirements and to satisfy the requirements for Safety Class 3 and Seismic Category I items.

System Boundary

System components subject to aging management review include safety related ventilation fans, filter plenums and associated duct components, safety related dampers and fire dampers, along with nonsafety-related duct components, dampers, filter drain piping and valves, as shown on the LR boundary drawing.

Fire protection fluid components are evaluated in the fire protection system (P54).

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

Offgas ventilation exhausts air from turbine power complex, and turbine and offgas buildings through a filter. [10 CFR 54.4(a)(1), (a)(2)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

System fire dampers prevent the spread of fires. [10 CFR 54.4(a)(3) – FP]

Component Types Subject to Aging Management Review

2.3.3.42 Penetration Electrical (R72)

System Description

Electrical penetrations provide for the transition of electrical cables through the containment barrier while maintaining containment integrity.

Any deterioration of the electrical penetration epoxy insulation is monitored by a leakage monitoring system using nitrogen. During normal operation, the nitrogen pressure will be kept at or above 10 psig, the PNPP containment accident pressure plus margin. This pressure is maintained in a very small volume between the seals of each penetration module to achieve high sensitivity in leak monitoring. Penetration pressures are routinely inspected during plant operation to assure prompt detection of leaky penetrations.

The system includes nonsafety-related piping, valves and nitrogen bottles used to maintain electrical penetrations pressurized with nitrogen.

System Boundary

There are no mechanical system components subject to aging management review. The penetration components that support containment pressure boundary integrity are evaluated as structural components.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Maintain containment integrity [10 CFR 54.4(a)(1), but this function is not performed by mechanical components]

The system contains components credited with compliance with 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Support monitoring of penetration integrity.

Component Types Subject to Aging Management Review

None. The penetrations are evaluated as structural commodities.

2.3.3.43 Penetration Pressurization (P53)

System Description

The penetration pressurization system serves as a testing system which measures leakage rates from penetrations after being pressurized with air.

Leakage from the personnel air locks is also controlled by this system by placing a vacuum on the space between the pair of door seals on the outer doors of the personnel air locks. The vacuum between the door seals is created by routing a small line into the containment annulus. The containment annulus is kept at a slight negative pressure by the annulus exhaust gas treatment system. Any bypass leakage past the personnel airlock outer door seals is routed back into the containment annulus where it is sent to the annulus exhaust gas treatment system. This system is classified as Safety Class 2 and is designed to survive and function through a single active failure.

The function of the pneumatic air lock seal pressurization system is to provide air to the inflatable seals and accumulator tanks on the airlock doors. Each personnel air lock door has two inflatable seals. The seals, when inflated impinge upon stainless steel surfaces in the door jamb.

System Boundary

System components subject to aging management review include safety-related air tanks, valves and piping components that support penetration testing and the nonsafety piping directly attached to the safety-related piping as shown on the LR boundary drawings.

The containment personnel access airlocks, containment equipment access hatch and the drywell personnel access airlock are reviewed as part of their respective structures.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

Control airlock leakage [10 CFR 54.4(a)(1)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Measure containment penetration leakage rates

Component Types Subject to Aging Management Review

Table 2.3.3-43 lists the component types that require aging management review and their intended functions.

Table 3.3.2-43, Auxiliary Systems – Penetration Pressurization System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.44 Plant Foundation Underdrain (P72)

System Description

The main objective of the pressure relief underdrain system is to ensure that the groundwater level around the nuclear island does not exceed elevation 590.0 feet. Safety-related structures serviced by the underdrain system are designed to withstand all loading conditions at this maximum level.

The underdrain system consists of a porous concrete blanket, nominally one foot thick, which underlies all of the structures of the nuclear island. Between some of the buildings and around the perimeter of the nuclear island, the blanket is increased in thickness to incorporate a one-foot diameter porous concrete pipe. The pipe carries the collected water to individual pumps located in manholes on the East and West sides of the nuclear island. The underdrain pumps discharge into the gravity discharge system and drain to Lake Erie via the emergency service water pumphouse.

This system includes two discharge systems (pumping and gravity drain). In the pumped discharge system, the design groundwater inflow of 80 gpm flows by gravity through the porous concrete blanket and pipes to collection manholes containing the service underdrain pumps.

Three service underdrain pumps are set to maintain a water surface elevation of 568.0' or below. If for some reason the pumps fail to start or cannot keep up with the rising water level, then, a high water level alarm will sound in the control room and a backup pump in manhole #6 will automatically start, providing an additional 50 gpm nominal capacity to the pumping discharge system.

Should all of the underdrain service pumps and the backup pumps fail, the groundwater level would rise until it reaches the gravity drain discharge system which is provided to ensure that the groundwater level around the nuclear island never exceeds elevation 590.0’. The gravity discharge drain system is designed to provide a redundant periphery discharge which incorporates a gravity outfall, having no active components, to handle a 15,000 gpm flow entering the underdrain system on either side of the plant.

Postulating an accidental release of radioactive materials occurring at the radwaste building of the PNPP, the pumps installed in the pumping manholes of the pressure relief underdrain system will be manually shut off, allowing groundwater to build up to the gravity drain discharge elevation and discharge via the gravity drains to the emergency service water pumphouse and eventually into Lake Erie.

The manholes (structures) are seismic Category I, and the gravity drain piping is safety-related. There are no safety-related components within the manholes to be protected from leakage.

System Boundary

System components subject to aging management review are limited to the safety-related gravity drain piping between manholes, and to the emergency service water pumphouse, as shown on the referenced LR boundary drawing.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event.

Prevent the buildup of hydrostatic pressures under the building foundations from exceeding a condition equivalent to a static water surface elevation of 590.0’. [10 CFR 54.4(a)(1)]

Maintain groundwater level below 575.0 ft elevation under normal operating conditions to allow time for radioactive isotopes to decay prior to discharging groundwater to the lake in the event of a design basis accident (liquid radwaste tank failure).

The plant operating procedures require that upon indication of a seismic event or unexpected high radiation levels in the radwaste building, the service and backup underdrain pumps are manually tripped with a positive, safety-related cutoff switch. [10 CFR 54.4(a)(1) electrical only].

Component Types Subject to Aging Management Review

Table 2.3.3-44 lists the component types that require aging management review and their intended functions.

2.3.3.45 Plant Radiation Monitoring and Process Monitoring (D17), and Post Accident Radiation Monitoring (D19)

System Description

This system consists of airborne radiation monitors, gaseous process and effluent radiation monitors, liquid process and effluent radiation monitors, and post-accident radiation monitors. The intermediate building ventilation system (M33) flow straighteners in the Unit 1 and 2 plant Vents are also evaluated within this system.

Airborne radiation monitoring:

An airborne radiation monitor typically consists of a particulate measuring channel, an iodine measuring channel and a gas measuring channel. A representative sample of air from a ventilation duct is drawn through a sample line to the airborne monitor unit by means of an air blower. Sampling of the ducts is achieved using an isokinetic sample probe placed in the air stream. The sample passes through a particulate, iodine and gas channel in series. Each channel is independent. In the particulate channel, the sample air passes through a fixed or moving filter which collects particulates and is monitored by a beta scintillation detector, the output of which is pre-amplified and transmitted to a ratemeter located in the control room. In the iodine channel, the sample passes through an activated charcoal cartridge which traps the radioactive iodine. The gas is exhausted back to the ventilation duct. Differential pressure switches across the filter and charcoal cartridges are provided to give a low flow alarm at the unit and in the control room.

Gaseous process and effluent monitoring:

Gaseous process monitors are provided for detecting and monitoring radiation levels in certain plant process streams.

The Gaseous effluent units monitor a sample of the effluent discharge for particulate, iodine and gas radioactivity and provide samples of the collected particulate and halogen for laboratory analysis. For the unit vents a representative sample is continuously extracted from each plant vent through an isokinetic probe. The sample is supplied through a 1-inch sample line which is also used to supply a representative sample to the post-accident effluent radiation monitors. For the offgas and turbine building/heater bay vents a representative sample is continuously extracted from the vent pipe downstream of the exhaust fans.

Liquid process and effluent radiation monitoring:

These units monitor the gamma radiation levels of liquid process and effluent streams. With the exception of the radwaste system effluent, the streams monitored normally contain only background levels of radioactive materials. Increases in radiation level may be indicative of heat exchanger leakage or equipment malfunction.

For each liquid monitoring location, except for the underdrain system, a continuous sample is extracted from the liquid process pipe, passed through a liquid sample panel which contains a detection assembly for gross gamma radiation monitoring, and returned to the process pipe. The detection assembly consists of a scintillation detector mounted in a shielded sample chamber equipped with a check source. A ratemeter in the control room displays the measured gross radiation level and the analog signal is recorded.

Post-accident radiation monitoring:

Some monitors are designated and installed as post-accident radiation instruments. They provide radiation level readings and alarm functions. These monitors include area monitors, vent radioactive gas release monitors and area airborne activity monitors.

System Boundary

System components subject to aging management review include the following, as shown on LR boundary drawings:

- Safety-related post-accident effluent radiation monitors.
- Safety-related air sample piping and the attached nonsafety air sample piping up to an equivalent anchor for the containment and drywell atmosphere monitors,
- Nonsafety-related (liquid) sample piping, valves, pumps and monitor equipment for the ADHR service water, radwaste effluent to ESW, NCC, and ESW loops A and B monitors.

Other radiation monitors either have no passive mechanical components, or do not perform a function corresponding to the criteria in .

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform functions that demonstrates compliance with the regulations for EQ.

Safety-related piping provides system pressure boundary integrity. [10 CFR 54.4(a)(1)]

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

Indication from the intermediate building ventilation safety related flow elements (straighteners) is used together with the Unit 1 & 2 plant vent radiation monitors to establish a release rate. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Plant radiation monitoring provides actuation logic to limit radiological release. [10 CFR 54.4(a)(1) applicable only to active electrical components]

Process radiation monitoring systems are provided to monitor and control radioactivity in process and effluent streams and to activate appropriate alarms and controls.

Provide the capability to detect an offgas system failure by an alarmed increase in activity at the plant vent.

Component Types Subject to Aging Management Review

Table 2.3.3-45 lists the component types that require aging management review and their intended functions and Table 2.3.3-45a summarizes the scoping determination for individual monitors.

Table 3.3.2-45, Auxiliary Systems – Plant Radiation Monitoring and Process Monitoring and Post Accident Radiation Monitoring System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.46 Post-Accident Sampling (P87)

System Description

The post-accident sampling system (PASS) permits sampling of the containment building environments and the reactor coolant systems after a loss-of-coolant accident (LOCA). Sample analysis can be performed by using either onsite or offsite analytical instruments.

The sampling station is centrally located in the intermediate building along the wall which separates the control complex from the intermediate building at elevation 574'-10". Samples are drawn individually from the following points:

- Drywell atmosphere
- Containment atmosphere
- Suppression pool atmosphere

- Annulus atmosphere
- Reactor water recirculation system - 2 points
- Reactor water cleanup system - 3 points
- Residual heat removal system - 2 points
- Drywell floor drain sump
- Suppression pool

Liquid sample streams drawn from selected sample locations pass through a remotely located cooler rack to the grab sample panel. Atmospheric samples drawn from any one of the four selected sample locations flow to the grab sample panel. Each sample is collected in a sample bottle for analysis.

Demineralized water is supplied to the sampling station for decontamination of the sampling station plenums, flushing of liquid sample lines and dilution of liquid samples. Nitrogen is supplied to the sampling station for drying of the sample lines and various components, and for purging of gas sample lines.

PNPP License Amendment 124 deleted Technical Specification 5.5.3, "Post Accident Sampling System (PASS)," and thereby eliminated the requirements to have and maintain the PASS at PNPP, Unit 1. Portions of the system remain safety-related to maintain system and containment integrity.

System Boundary

System components subject to aging management review include pumps, heat exchangers, sample panels, valves and piping components as shown on the LR boundary drawing.

Both the grab sample panel and the chemical sample panel are designed to contain and control leakage and spills within the panels. As such, the panels themselves provide a leakage barrier function such that leakage of internal panel components will not result in spatial impact to nearby safety-related components.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Support sampling of the containment building environments and the reactor coolant systems.

Component Types Subject to Aging Management Review

Table 2.3.3-46 lists the component types that require aging management review and their intended functions.

Table 3.3.2-46, Auxiliary Systems – Post-Accident Sampling System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.47 Potable Water Supply (P71)

System Description

The potable water system supplies and distributes both hot and cold water throughout the plant for potable and sanitary purposes.

The supply of potable and sanitary water is obtained from the Lake County Department of Utilities water main, which is extended onto the site. Potable water is distributed to the plumbing fixtures located in the plant.

Hot water is generated by two large electric hot water storage heaters located in the service building and the control complex. Small electric water heaters are located in the turbine building. Hot water recirculating systems are used where excessive lengths of hot water piping warrant inclusion of such systems to maintain water temperature.

The potable water system is not nuclear safety-related.

System Boundary

System components subject to aging management review include a pump, tanks, valves and piping components within safety-related structures, as shown on the referenced LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Distribute hot and cold water throughout the plant for potable and sanitary purposes.

Component Types Subject to Aging Management Review

Table 2.3.3-47 lists the component types that require aging management review and their intended functions.

2.3.3.48 Rx Plant Sampling (P35)

System Description

The Rx plant sampling system is a process sampling system provided to permit monitoring of equipment and system performance (chemistry) during normal plant operation. Information gathered by the process sampling system is used to make operational decisions for the plant but is not used for reactor shutdown or accident mitigation.

The Rx plant sampling system consists of the following sample stations in the containment building:

1. Reactor water cleanup filter/demineralizer inlet header.
2. Each reactor water cleanup filter/demineralizer outlet.
3. One reactor water recirculation loop.
4. Control Rod Drive water

This system does not include sample points provided for process and effluent radiological monitoring. Such sample points are addressed in plant radiation monitoring and post-accident radiation monitoring systems (D17 and D19, respectively). In addition, there are numerous local grab sample locations that are part of their parent systems.

System Boundary

P35 reactor plant sampling system components subject to aging management review include nonsafety-related valves, heat exchangers, sample sink and piping as shown on the LR boundary drawing.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of non-safety related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Monitor equipment and system performance (chemistry) during normal plant operation.

Component Types Subject to Aging Management Review

Table 2.3.3-48 lists the component types that require aging management review and their intended functions.

Table 3.3.2-48, Auxiliary Systems –Rx Plant Sampling System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.49 Radwaste Building Ventilation (M31)

System Description

The radwaste building ventilation supply system operates continuously to provide filtered air to various areas of the radwaste building. The exhaust system operates continuously to exhaust these areas and to direct this exhaust through a charcoal filter plenum to the unit vent. The supply system consists of one 100 percent capacity supply plenum which houses roughing filters and hot water heating coils, two 100 percent capacity supply fans and supply distribution ducts. The exhaust system consists of two 100 percent capacity filter plenums, housing roughing, HEPA, charcoal and a second bank of HEPA filters, two 100 percent capacity exhaust fans and exhaust distribution ducts. During periods of emergency, system operation is not required to safely shut down the plant.

System Boundary

System components that are subject to aging management review are limited to fire dampers, as shown on the LR boundary drawing.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

System fire dampers prevent the spread of fire. [10 CFR 54.4(a)(3) – FP]

Provide filtered ventilation to radwaste building areas.

Minimize the release of activity to the environment in accordance with Reg Guide 1.140.

Component Types Subject to Aging Management Review

Table 2.3.3-49 lists the component types that require aging management review and their intended functions.

2.3.3.50 Reactor Vessel Servicing Equipment (F13)

System Description

The system consists of tools and equipment used when the reactor is shut down and being disassembled or assembled. The system contains safety-related civil components that are used for lifting or storing the reactor components. The system contains components such as the safety related main steam line plugs and nonsafety-related temporary isolation devices that are used in support of maintenance to prevent drain down of upper pool water during refueling.

System Boundary

There are no mechanical components in the system that are subject to aging management.

Safety-related civil components that are used for lifting or storing the reactor components are evaluated under structural.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains both safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event. This scoping determination applies to temporarily installed components in support of maintenance that are subject to periodic removal and inspection. There are no mechanical system components subject to aging management within the scope of License Renewal.

Ensure reactor water level is greater than 23 feet over fuel assemblies during a Fuel Handling Accident inside Containment [(a)(1) - Steam line plugs, not permanently installed components and are subject to periodic removal and inspection].

The system supports reactor assembly and disassembly.

Temporary Isolation Devices used for maintenance activities are controlled by Tech Spec 3.5.2, RPV Inventory Control, to prevent an RPV draining event below the top of active fuel (TAF) [(a)(2) - not permanently installed components and are subject to periodic removal and inspection]

Component Types Subject to Aging Management Review

None

Table 3.3.2-50, Auxiliary Systems – Reactor Vessel Servicing Equipment – Summary of Aging Management Evaluation, was added for completeness. There are no components subject to aging management review.

2.3.3.51 Reactor Water Clean Up and Reactor Water Clean Up Filter Demineralizer (G33 & G36)

System Description

The reactor water cleanup (RWCU) system recirculates a portion of reactor coolant through a filter demineralizer to remove particulate and dissolved impurities from the reactor coolant. It also removes excess coolant from the reactor system under controlled conditions.

The system can take suction from the inlet of each reactor main recirculation pump and from the reactor pressure vessel bottom head. The process fluid is circulated with the cleanup pumps through regenerative and nonregenerative heat exchangers for cooling, through the filter demineralizers for cleanup and back through the regenerative heat exchangers for reheating. The processed water is returned to the RPV, the main condenser or radwaste.

System Boundary

System components subject to aging management review include the RWCU pumps, valves, filter-demineralizers, heat exchangers, valves, and piping components as shown on LR boundary drawings.

The ASME Class 1 portions of the system are evaluated with the reactor coolant pressure boundary system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ and SBO.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1), (a)(3) - SBO]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Maintain the reactor water within acceptable conductivity and chemistry limits.

Control Reactor Pressure Vessel level during shutdowns.

Remove decay heat from the reactor vessel under certain conditions.

Component Types Subject to Aging Management Review

Table 2.3.3-51 lists the component types that require aging management review and their intended functions.

Table 3.3.2-51, Auxiliary Systems – Reactor Water Clean Up and Reactor Water Clean Up Filter Demineralizer (G33 & G36) – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.52 Safety Related Instrument Air (P57)

System Description

The safety-related instrument air system supplies clean, dry, oil-free air to the automatic depressurization system (ADS) safety relief valve accumulators to support operation of the safety relief valves. The "B" train safety-related instrument air system also provides post-accident makeup to the outboard MSIV air accumulators. Air receiver tanks are sized by volume to provide a sufficient quantity of air for recharging the ADS accumulators, outboard MSIV accumulators and the low-low set relief valve accumulator under accident conditions. In addition, the tanks contain a sufficient volume of air to provide makeup for system leakage for a period of seven days after an accident occurs.

Compressed air is provided by a reciprocating type air compressor and air dryer. The system has a connection for recharging the receiver tanks or safety relief valve accumulators directly to supplement compressor recharging in emergency and normal situations when the compressor is out-of-service.

One large, low pressure air receiver tank is provided for safety-related air storage in each of two supply lines for the ADS and low-low set relief valve accumulators. Two small air receiver tanks are also provided in each supply line to supply nonsafety air storage to minimize compressor cycling. Only the large air receiver tanks are designated as Safety Class 3; the small air receiver tanks are designated as nonsafety class.

System Boundary

System components subject to aging management review include safety-related tanks, valves and piping components, as well as nonsafety-related valves and piping components as shown on the LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for FP, EQ and SBO.

Provide compressed air to automatic depressurization system (ADS) safety relief valve (SRV) and to one Low Low Set of SRV accumulators. [10 CFR 54.4(a)(1), (a)(3) – FP, SBO]

Provide compressed air to outboard main steam isolation valve (MSIV) accumulators. [10 CFR 54.4(a)(1)]

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/non-safety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Component Types Subject to Aging Management Review

Table 2.3.3-52 lists the component types that require aging management review and their intended functions.

2.3.3.53 Sanitary Drain and Sewer (P66)

System Description

The sanitary drains and sewer system consists of a series of drain and vent piping that gravity drains from various sinks, drains and sanitary appliances throughout the control complex to the 574' level of the control complex. Two ejectors then pump the waste to the sewage pumping station in the yard.

The control room envelope is provided with fire protection equipment, adequate lighting, communications equipment, kitchen, sanitary, administrative and storage facilities, and spaces necessary to perform the normal plant operations required to maintain the plant in a safe condition following an accident.

System Boundary

System components subject to aging management review are limited to the nonsafety-related fluid piping components within structures that contain safety-related components, as shown on the LR boundary drawings. With the exception of the sanitary loop seals within the control room envelope, the control room envelope boundary is addressed as part of structural scoping.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Maintain the control room habitability boundary. [10 CFR 54.4(a)(2) (Structural scoping)]

Sanitary loop seals within the control room envelope are required to support the integrity of the control room envelope boundary. [10 CFR 54.4(a)(2)]

Collect sewage and wastewater from various locations throughout the Control Complex and transfer this waste to the sewage pump station.

Component Types Subject to Aging Management Review

Table 2.3.3-53 lists the component types that require aging management review and their intended functions.

Table 3.3.2-53, Auxiliary Systems – Sanitary Drain and Sewer – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.54 Service Air (P51) and Instrument Air (P52)

System Description

The compressed air systems include the instrument air system and the service air system. The safety-related instrument air system (P57) is addressed separately.

The service air system consists of two motor-driven compressors (the Unit 2 compressor is located in the control complex building, and is used to support Unit 1 operation), each with an integral intercooler and aftercooler, an air intake filter silencer, lube oil subsystem, filters, condensate traps, controls, a receiver tank, and a piping network for distribution throughout the plant.

The service air compressors are each sized to provide the normal load capacity for the entire plant. During normal operation, one compressor is running and the other is in the automatic standby mode. The service air compressor is operated continuously to provide a nominal output pressure. If the service air system pressure drops below a set value, the standby air compressor starts automatically and restores system pressure to the normal range.

A separate instrument air system is provided to supply clean, dry, oil free air for control purposes throughout the plant. The normal supply of air to the instrument air system is from the service air system, and the instrument air compressor for each unit (the Unit 2 compressor is located in the control complex building and is used to support Unit 1 operation) is used as a backup. Each instrument air compressor also includes an after cooler (integral with the compressor), a receiver tank, a prefilter, an air dryer, an after-filter, and a piping network for distribution throughout the plant. All instrument air leaving the receiver tank passes through the filters and the air dryer.

Except for that portion between the containment isolation valves, the instrument air and service air systems are nonsafety-related. All safety-related components using compressed air are either designed to fail to a condition that corresponds with the safe shutdown of the reactor plant or are equipped with accumulators to satisfy their required air demands.

System Boundary

System components subject to aging management review include safety-related containment and drywell penetration piping components, the nonsafety piping directly attached to the safety-related piping, and valves and other piping components associated with condensation drains as shown on the LR boundary drawings. Various compressor oil subcomponents not shown on the boundary drawings are also subject to aging management review.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

Ensure drywell boundary. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Supply air to the instrument air system.

Supplies filtered and dried compressed air to plant distribution headers.

Component Types Subject to Aging Management Review

Table 2.3.3-54 lists the component types that require aging management review and their intended functions.

Table 3.3.2-54, Auxiliary Systems – Service Air and Instrument Air System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.55 Service Water (P41)

System Description

The service water system consists of an open loop piping network in which lake water from the cooling water intake structure is pumped through the tube side of the shell and tube type heat exchangers being cooled and directed as necessary to the cooling tower basin as makeup. That amount of water not required for makeup is returned to the lake by way of the discharge tunnel water return line. The system includes four one-third capacity vertical wet pit pumps, automatic self-cleaning strainers, and a piping network to distribute cooling water to the tube side of the heat exchangers being cooled.

The service water system is nonsafety-related and is not required for the safe shutdown of the reactor. For the postulated case of (circulating water) expansion joint rupture and resultant turbine building flooding, two Safety Class III, Seismic Category I motor-operated butterfly valves provided in the makeup line to the cooling towers will be automatically closed, thereby limiting the flooding to the water volume in the cooling tower basin.

The cooling water for the alternate decay heat removal (ADHR) heat exchanger, and the air conditioning units for the ADHR heat exchanger area and low pressure core spray (LPCS) pump room is provided by the service water system.

System Boundary

System components subject to aging management review are limited to the safety-related valves and piping within the valve pit (that function to isolate makeup to circulating water on high water level in the turbine basement), and nonsafety-related piping components within structures that contain safety-related components, as shown on the LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

Isolate the cooling tower make-up supply to mitigate the extent of turbine building flooding. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

The integrity of nonsafety-related, fluid-retaining service water piping in the Unit 1 and 2 auxiliary buildings precludes internal flooding that could affect safety-related components. [10 CFR 54.4(a)(2)]

Service water pump B automatic restart following the loss-of offsite power (LOOP) event enables the supply of cooling water to the NCC heat exchanger so that control rod drive can be restored.

Provide cooling water to various auxiliary heat exchangers for the power conversion process.

Provide cooling water to the alternate decay heat removal heat exchanger and associated AC units during modes 4 and 5 for equipment outages.

Provide makeup water to maintain cooling tower basin level.

Provide keepfill water to each of the three trains (A, B, and C) of emergency service water when the respective emergency service water pump is not running.

Component Types Subject to Aging Management Review

Table 2.3.3-55 lists the component types that require aging management review and their intended functions.

Table 3.3.2-55, Auxiliary Systems – Service Water System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.56 Standby Liquid Control (C41)

System Description

The standby liquid control system (SLCS) provides backup capability for reactivity control, independent of normal reactivity control provisions, and is able to shut down the reactor if normal control becomes inoperative. The system makes possible an orderly and safe shutdown in the event that not enough control rods can be inserted into the reactor core to accomplish shutdown in the normal manner. The backup system has the capacity for controlling the reactivity difference between the steady-state rated operating condition of the reactor with voids and the cold shutdown condition, including shutdown margin, to ensure complete shutdown from the most reactive condition at any time in core life.

The SLCS is manually initiated in the main control room to pump a boron neutron absorber solution into the reactor if the operator determines the reactor cannot be shut down or maintained shut down with the control rods.

The specified neutron absorber solution is a mixture of sodium borate (borax-$Na_2B_4O_7 \cdot 10H_2O$) and boric acid (H_3BO_3). The solution is prepared by dissolving borax and boric acid in demineralized water in a nominal Na_2O:B_2O_3 molar ratio of 0.229.

Following SLCS injection, the SLC transfer system supports the main injection system by providing capability to add additional batches of borax-boric acid to the main SLC storage tank. The transfer system allows plant personnel to mix these additional batches of borax-boric acid without entering the containment.

An alternate boron injection system is provided to address an ATWS event coupled with the loss of both trains of the standby liquid control (SLC) system, which is a beyond design bases event. The alternate boron injection system design is nonsafety-related.

System Boundary

System components subject to aging management review include tanks, pumps, valves and piping components associated with standby liquid control and alternate boron injection as shown on the LR boundary drawings. ASME Class 1 piping components that provide reactor coolant pressure boundary and containment integrity are evaluated with the reactor coolant pressure boundary evaluation.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform functions that demonstrates compliance with the regulations for ATWS and EQ.

SLCS injects a neutron absorbing boron solution of sufficient concentration, temperature and quantity into the RPV for reactivity control. [10 CFR 54.4(a)(1), (a)(3) - ATWS]

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

For the design basis LOCA analysis SLC is used to maintain pH of the Suppression Pool. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

The alternate boron injection system provides an alternate means to inject a neutron absorbing solution into the reactor core, via high pressure core spray, if the normal SLC is not available or is not effective in shutting down the reactor.

Component Types Subject to Aging Management Review

Table 2.3.3-56 lists the component types that require aging management review and their intended functions.

2.3.3.57 Steam Tunnel Cooling (M47)

System Description

The steam tunnel cooling system (STCS) operates continuously to provide filtered and cooled air to the steam tunnel. Cooling air is directed from the auxiliary building general area through the cooling plenum, to the steam tunnel, and is then relieved to the turbine building and to the auxiliary building exhaust system. The STCS consists of one 100 percent capacity supply plenum which houses roughing filters and chilled water cooling coils, two 100 percent capacity supply fans, supply and relief distribution ducts.

The STCS is classified as nonsafety-related and non-seismic, and is not required to safely shut down the plant.

A temporary supplemental steam tunnel cooling system can be installed and operated as needed to assist the STCS for maintaining steam tunnel ambient temperatures.

System Boundary

System components subject to aging management review are limited to fire dampers, as shown on the LR boundary drawings.

Cooling water components are evaluated in the turbine building chilled water system (P46).

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

System fire dampers prevent the spread of fires. [10 CFR 54.4(a)(3) – FP]

Maintain the area ambient temperature.

Component Types Subject to Aging Management Review

Table 2.3.3-57 lists the component types that require aging management review and their intended functions.

2.3.3.58 Storm Drain and Sewer (P67)

System Description

Surface drainage is provided by a combination of overland drainage features and the site's nonsafety-related storm drain system. Three separate subsurface storm drainage systems (east, west and south system) assist in surface drainage. Site topography and the storm drain system are designed to reduce the effects of the local intense precipitation (LIP) flooding event. The LIP flooding model incorporates the plant roof and storm drain systems providing discharge analyses for these systems. The site surface drainage ability is largely influenced by site topography and ground cover type; location and dimensions of above grade objects, structures and buildings; roof drainage and storage; surface drainage features; and subsurface storm drain systems.

The controlling flood hazard is the local intense precipitation (LIP) event.

The LIP domain comprises the site property bordered to the north by Lake Erie, to the east by the diversion stream and to the west and south by the major stream. All safety related buildings are located within the LIP domain.

Except for the roofs of the service water pumphouse, the emergency service water pumphouse and the circulating water pumphouse, the roofs of all buildings are drained to the storm drain system which discharges into the major and remnant minor streams that feed into Lake Erie. The roofs of the service water pumphouse, the emergency service water pumphouse and the circulating water pumphouse all drain to building wet wells.

In the event of the rupture or leakage of an onsite reservoir (e.g., cooling tower basins and industrial waste lagoons), the discharge will generally drain overland away from the plant into neighboring streams and thus to Lake Erie. The area surrounding the plant is also provided with a storm drain system which will collect surface water approaching the plant and assist in drainage of the power block area.

The flow from the south storm drain system discharges to the major stream and ultimately into Lake Erie. The flow from the east storm drain system discharges into the remnant minor stream which flows through the remnant minor stream culvert and ultimately into Lake Erie. The flow from the west storm drain system discharges at a topographic low point near the bluff and ultimately into Lake Erie.

Most of the storm drain conduit material is corrugated metal pipe (CMP) with a paved invert, and some small fraction of the conduit material is reinforced concrete pipe (RCP) as specified on the various drawings. There are also limited uses of polyvinyl chloride, cast iron, plastic pipe and high-density polyethylene in the storm drain system.

The storm drain system is nonsafety-related.

System Boundary

There are no mechanical system components subject to aging management review. The P67 storm drain and sewer system components are scoped under structural as water control structures. Building roof drains are evaluated under the P68 floor and equipment drains system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

Collect and remove storm and flood water [10 CFR 54.4(a)(2)]

Component Types Subject to Aging Management Review

None

Table 3.3.2-58, Auxiliary Systems – Storm Drain and Sewer System – Summary of Aging Management Evaluation, is included for completeness. There are no mechanical components in the scope of license renewal that are subject to aging management review.

2.3.3.59 Suppression Pool Drain and Clean Up (G42)

System Description

The purpose of the suppression pool cleanup (SPCU) system is to maintain water purity and reduce activity levels in the suppression pool.

The system uses a mixed bed non-regenerative demineralizer. The main benefit of the system is to significantly reduce operator exposure to radioiodides which would evolve relatively slowly from the pool after depressurization of the reactor to the suppression pool. The system also provides a means for draining the suppression pool when necessary.

System Boundary

System components subject to aging management review include a pump, valves and associated piping components within the auxiliary building and the intermediate building that support cleanup of the suppression pool, as shown on the LR boundary drawing.

The system components in the radwaste building are not in scope because they are nonsafety-related and do not perform a License Renewal intended function.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

System pressure boundary supports ESF system operation and limits radiological release. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Component Types Subject to Aging Management Review

Table 2.3.3-59 lists the component types that require aging management review and their intended functions.

Table 3.3.2-59, Auxiliary Systems – Suppression Pool Drain and Clean Up System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.60 Suppression Pool Makeup (G43)

System Description

Following a LOCA, the suppression pool makeup system provides water from the upper containment pool to the suppression pool by gravity flow. The quantity of water provided is sufficient to account for all conceivable post-accident entrapment volumes (i.e., places where water can be stored while maintaining long term drywell vent water coverage).

The piping system consists of two lines which penetrate the separator storage section of the upper containment pool through the side walls. One line is located on either side of the separator pool. From there, each line is routed down to the suppression pool on opposite sides of the steam tunnel.

The volume of water available to dump from the upper containment pool, when combined with the suppression pool, is adequate to supply all post-accident entrapment volumes and keep the suppression pool at an acceptable level (2 feet above the top of the horizontal drywell vents) to condense steam exiting the vents, and to ensure continuous coverage of the RHR A/B test return line post-accident.

The system gravity dump time through one of the two redundant lines is less than or equal to the minimum pump time; pump time is determined by dividing pumping volume (upper pool makeup volume plus volume in the suppression pool stored between LLWL and minimum top vent coverage) by the total maximum runout flow rate from all five ECCS pumps.

System Boundary

System components subject to aging management review include valves and piping components that support gravity transfer of water from the upper pools to the suppression pool, as well as valves and piping components that penetrate containment to support instrumentation, as shown on the LR boundary drawing.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ and SBO.

Timely transfer of upper pool water to suppression pool for accident mitigation. [10 CFR 54.4(a)(1)]

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

The upper containment pools are dumped during SBO to moderate suppression pool temperature. [10 CFR 54.4(a)(3) – SBO]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Transfer of upper pool water to suppression pool to support refueling activities.

Component Types Subject to Aging Management Review

Table 2.3.3-60 lists the component types that require aging management review and their intended functions.

2.3.3.61 Turbine Building Chilled Water (P46)

System Description

The turbine building chilled water system operates continuously, as required, during normal operation to provide chilled water to the chilled water coils of various air handling units for the purpose of cooling the air supplied to the areas served by these air handling units.

Two 100 percent capacity water chilling machines and two 100 percent capacity chilled water recirculating pumps are provided. One set of chiller and pump are normally operated with the other set as backup. During operation, condenser water is provided by the nuclear closed cooling system. This system is not required to operate during a LOCA or loss of offsite power and is normally not required to operate during the winter season.

Initial fill and makeup water for this system is supplied by the two bed water distribution system. An open-type expansion tank (130 gallons flooded) and a chemical addition tank are provided.

The turbine building chilled water system is not safety-related and is not required to operate to safely shut down the plant following a design basis accident.

System Boundary

System components subject to aging management review include the pumps, chillers, heat exchangers, valves, and various piping components as shown on the LR boundary drawings.

Tubes within ventilation cooling units are within scope for leakage boundary, but tubes within closed systems such as chiller units do not perform a leakage boundary function – leakage from these tubes would require system repairs but would not result in external leakage that could impact a safety function.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Provide chilled water to the turbine building air handling units (turbine building ventilation system), turbine power complex air handling unit (turbine power complex ventilation system), turbine plant sample panel (turbine plant sampling system), and the steam tunnel air handling unit (steam tunnel cooling system).

Component Types Subject to Aging Management Review

Table 2.3.3-61 lists the component types that require aging management review and their intended functions.

Table 3.3.2-61, Auxiliary Systems – Turbine Building Chilled Water System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.3.62 Turbine Building Closed Cooling (P44)

System Description

The turbine building closed cooling system consists of a closed-cycle network in which treated condensate-quality water is cooled with lake water in a heat exchanger and is circulated through the components being cooled. The system includes three half-capacity pumps, two full-capacity closed loop cooling heat exchangers, a system surge tank, a chemical treatment tank, and a piping network to circulate the cooling water through the components being cooled.

The three half-capacity pumps used for circulating cooling water in the system are of the single stage, horizontal, split-case centrifugal type. Two full-capacity heat exchangers are provided to cool the closed loop cooling water, one of which is normally in service. The heat exchangers are of the shell and tube type with lake water in the tubes and closed loop cooling water in the shell. A surge tank is provided to maintain the required pump suction head and to provide for system surge capacity. The tank is vented to atmosphere and is at the highest point in the system to ensure positive pressure in all system components. Level in the surge tank is maintained with a pneumatic level controller and a diaphragm operated makeup valve. A chemical treatment tank is provided for adding chemicals to the closed loop cooling water. The tank is connected to the suction and discharge of the closed loop cooling pumps in order to utilize the pump head for adding chemical to the system.

The turbine building closed cooling system is nonsafety-related and is not required for the safe shutdown of the reactor.

System Boundary

System components subject to aging management review are limited to the nonsafety-related piping components within the off-gas building, as shown on the LR boundary drawings. Additionally, System N64 (off gas) vault refrigeration heat exchangers are evaluated within this system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

Provide cooling water for the removal of heat from various turbine plant components to support power production.

The integrity of nonsafety-related fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Component Types Subject to Aging Management Review

Table 2.3.3-62 lists the component types that require aging management review and their intended functions.

2.3.3.63 Turbine Building Ventilation (M35)

System Description

The supply units provide clean, filtered and cooled or heated air to the condenser bay area, condensate pump area, steam piping and valve area, turbine operating floor, condensate polishing area, and to the offgas building for the purpose of maintaining an ambient temperature suitable for operating plant equipment. Ducted exhaust air is provided at the roof of the turbine building. The supply air is drawn through the turbine operating floor, exhausted at the roof and discharged to the atmosphere by centrifugal fans through an elevated release point (heater bay vent duct). The supply system draws outside air, passes it through filters, heating coils and cooling coils (as required) and distributes the air to the condenser bay area, condensate pump area, steam piping and valve area, condensate polishing area, and to the offgas building. The air supply to the different areas in the turbine building is partly exhausted by the offgas building exhaust system, and the rest is drawn through the turbine operating floor by the turbine building/heater bay exhaust fans and discharged to the atmosphere through elevated release points.

The turbine building ventilation system is not required to operate during a LOCA or loss of offsite power. Components of this system are classified as nonsafety and non-seismic.

System Boundary

System components subject to aging management review are limited to fire dampers, as shown on the LR boundary drawing.

Fluid piping components associated with the supply of cooling and heating water are evaluated with the P46 turbine building chilled water and P55 building heating systems, and the plenum drain piping components are evaluated with the floor and equipment drains system.

Some of the dampers as shown on drawing 912-0614 are evaluated with the M36 offgas building ventilation system.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it is relied on to perform a function that demonstrates compliance with the regulations for FP.

System fire dampers prevent the spread of fires. [10 CFR 54.4(a)(3) – FP]

Turbine building ventilation provides cooled/heated air to turbine building areas, condensate polishing area, and off-gas building to maintain suitable ambient temperature.

Component Types Subject to Aging Management Review

Table 2.3.3-63 lists the component types that require aging management review and their intended functions.

2.3.4 STEAM AND POWER CONVERSION SYSTEMS

The following systems are included in this section.

- Auxiliary Steam and Drains (Section 2.3.4.1)
- Condensate (Section 2.3.4.2)
- Condensate Transfer and Storage (Section 2.3.4.3)
- Control Rod Drive Rebuild Equipment (Section 2.3.4.4)
- Extraction Steam (Section 2.3.4.5)
- Feed Water Control, Feedwater and Feedwater Leakage Control (Section 2.3.4.6)
- Main Condenser (including the Main Turbine Shell) (2.3.4.7)
- Main and Reheat Steam (Section 2.3.4.8)
- Main, Reheat, Extraction, and Miscellaneous Drain (Section 2.3.4.9)
- Respirator Cleaning (Section 2.3.4.10)
- Service Water and Emergency Service Water Chlorination (Section 2.3.4.11)
- Two Bed Demineralizer and Distribution, and Mixed Bed Demineralizer and Distribution (Section 2.3.4.12)

2.3.4.1 Auxiliary Steam and Drains (P61)

System Description

Auxiliary steam is supplied by two packaged boilers fired with No. 2 fuel oil from the auxiliary boiler fuel oil system. Each boiler is capable of discharging 100,000 lb/hr of steam, at a drum pressure of 175 psig, through the auxiliary steam distribution header. Condensate from the auxiliary steam hot water heat exchangers and the drain pots on the distribution headers are returned to the common deaerator. Makeup water is supplied to the deaerator from the mixed bed demineralizer and distribution system.

The system can provide steam to the following components:

- Hot water heat exchangers (for building heating)
- Aux steam deaerator
- MSR blanketing
- Turbine steam sealing
- RCIC and reactor feed pump turbines (testing)

- Offgas preheater
- Steam jet air ejectors

System Boundary

System components subject to aging management review are limited to the nonsafety-related piping components within structures that contain safety-related components, as shown on the LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Provide steam to the building heating heat exchanger for area temperature control and condensate storage tank heating.

Provide steam supply to main turbine and reactor feed pump turbine steam seals during startup conditions and as a backup steam seal supply.

Component Types Subject to Aging Management Review

Table 2.3.4-1 lists the component types that require aging management review and their intended functions.

Table 3.4.2-1, Steam and Power Conversion Systems – Auxiliary Steam and Drains System – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.4.2 Condensate (N21)

System Description

The condensate system transports condensate from the main condenser hotwell to the hot surge tank, maintaining proper water levels in the surge tank for all operating conditions. The condensate system provides the overall steam cycle water inventory required to accommodate reactor water level variations arising from load changes. The condensate system also serves as a cooling source for the offgas condenser, the steam jet air ejector condenser and the steam packing exhauster. The condensate system is also the water supply for the control rod drive system (C11).

The condensate system consists of three 50 percent motor-driven hotwell pumps, three 50 percent motor-driven condensate booster pumps, three stages of closed low pressure feedwater heaters, a direct contact heater and hot surge tank, and associated piping, valves and instrumentation. Feedwater heaters 1A, 1B, 1C, 2A, 2B, and 2C are located in the main condenser necks. Equipment interacting with, but not part of the condensate system includes the condensate cleanup system, the offgas condenser, the steam jet air ejector condensers, and the steam packing exhauster. The hotwell pumps take suction from the hotwell storage area below the IP condenser. The condensate is pumped through the condensate cleanup system, the offgas condenser, the steam jet air ejector condenser, and the steam packing exhauster, providing sufficient NPSH for the condensate booster pumps during all operating conditions. The hotwell pumps are the vertical-can centrifugal type. The condensate booster pumps are designed to pump condensate through three stages of closed low pressure feedwater heaters and into the direct contact heater. System flow requirements at the valves wide open (VWO) condition are met by two 50 percent capacity hotwell pumps and two 50 percent capacity booster pumps operating in series. The direct contact heater is of the horizontal spray type and is directly mounted on a horizontal hot surge tank. The direct contact heater and hot surge tank are designed in accordance with Section VIII, Division I of the ASME Code and meet the performance criteria of the Heat Exchange Institute (HEI) and ASTM D888-66. The low pressure feedwater heaters are shell and U-tube heat exchangers designed in accordance with Section VIII, Division I of the ASME Boiler and Pressure Vessel Code.

System Boundary

System components subject to aging management review include nonsafety-related valves and piping components in the auxiliary and intermediate buildings, as depicted on LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The integrity of non-safety related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Transport condensate from the main condenser hotwell to the hot surge tank, maintaining proper water levels in the surge tank for all operating conditions.

Serve as a cooling source for the offgas condenser, the steam jet air ejector condenser and the steam packing exhauster.

Component Types Subject to Aging Management Review

Table 2.3.4-2 lists the component types that require aging management review and their intended functions.

2.3.4.3 Condensate Transfer and Storage (P11)

System Description

The condensate transfer and storage system consists of one 500,000 gallon capacity storage tank with associated makeup and distribution systems. The tank is located outdoors adjacent to the turbine building.

A gravity header is provided to distribute water to the main condensers on a low water level signal in the condensers. On high water level in the main condensers, the condensate booster pumps discharge water back to the condensate storage tank through the same 12-inch line used for makeup. The gravity header also supplies water to the suction of three transfer pumps which provide pressurized water for the fuel pool cooling and cleanup system (FPCCS) filter backwash, the spent fuel pool, the radwaste system, the reactor water cleanup system, the refueling water (upper pool) system, and other miscellaneous uses that cannot be gravity fed.

A separate Safety Class 2, Seismic Category I header is provided near the bottom of the tank and sized to supply water simultaneously to the RCIC and HPCS systems. The alternate water supply to these systems for safe shutdown is the suppression pool.

A high level annunciator is provided to alert the operator of a potential tank overflow condition. A header is provided to return water from the RCIC and HPCS pumps during testing and from the control rod drive pumps during minimum recirculation.

The portion of the system between the containment isolation valves and the supply header to the RCIC and HPCS systems are Safety Class 2, Seismic Category I. The water contained in the storage tank will normally come in directly from the mixed bed water storage tank through the cycle. The cycle water will have passed through the condenser hotwell where it is held up for a minimum of two minutes for radioactive decay. To preclude an uncontrolled release of the content of the condensate storage tank, the tank is located within a concrete retaining structure designed to Seismic Category I requirements. This retaining structure is designed to accommodate the total liquid capacity of the condensate storage tank with at least one foot freeboard.

If water level in the condensate storage tank becomes low, RCIC and HPCS pump suctions are automatically transferred from the condensate storage tank to the suppression pool.

System Boundary

System components subject to aging management review include safety related valves and piping components associated with containment penetrations, piping /components and level sensing lines that supply water to the RCIC and HPCS systems, nonsafety-related piping and valves in areas containing safety-related components including HPCS, RCIC, and CRD return piping, and the condensate storage tank. Other piping attached to the condensate storage tank is included in scope up to the first isolation valve to provide an age-managed pressure boundary for the tank.

Insulation on CST level sensing instrumentation lines is addressed as part of structural scoping.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ and SBO.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1), (a)(3) - SBO]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Non-safety related piping up to and including the first equivalent anchor beyond safety/non-safety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

The system contains components within the scope of 10 CFR 50.49. [10 CFR 54.4(a)(3) – EQ]

Provide a minimum water storage capacity for the high pressure core spray System. [10 CFR 54.4(a)(3) – SBO]

Provide a minimum water storage capacity for the reactor core isolation cooling system.

Provide makeup to the main turbine cycle.

Store excess water returned from the main turbine cycle.

Component Types Subject to Aging Management Review

Table 2.3.4-3 lists the component types that require aging management review and their intended functions.

2.3.4.4 Control Rod Drive Rebuild Equipment (L59)

System Description

The system provides a source of demineralized water and a tank for ultrasonic cleaning of control rod drive components.

System Boundary

System components subject to aging management review include tanks, filter housings, valves and piping components associated with support of control rod drive maintenance, as shown on the system boundary drawing. Pump casings, strainer body, and flexible hoses are made of polymers/elastomers and are not long-lived.

All components are nonsafety-related and are located in the control rod drive maintenance area on the 599 elevation of the intermediate building.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Provide demineralized, filtered water to support cleaning and maintenance of control rod drive equipment.

Component Types Subject to Aging Management Review

Table 2.3.4-4 lists the component types that require aging management review and their intended functions.

2.3.4.5 Extraction Steam (N36)

System Description

The extraction steam system (N36) preheats feedwater through the use of excess steam that passes through the main turbine. The extracted steam is used as a heat source for feedwater heaters, first stage reheaters, the steam seal evaporator and the hot water heat exchanger.

High pressure feedwater heaters 5A(B) and 6A(B) receive extraction steam from the high pressure turbine. Low pressure feedwater heaters 1A(B,C), 2A(B,C), 3A(B) and direct contact heater number 4 receive extraction steam from the three low pressure turbines.

Extraction steam flows through the shell side of the heaters where it gives up heat to the condensate/feedwater flowing through the tubes, except for heater number 4 which is a direct contact heater.

The turbine maximum potential overspeed analysis assumes turbine load is suddenly reduced from maximum to zero, with no restraint of reverse flow in the extraction lines being considered, but all other turbine control and extraction non-return valves operate normally. This analysis demonstrates that these bottled-up volumes of steam and water within the turbine and extraction steam system will not cause the turbine speed to rise above a certain maximum value after a full load rejection or trip.

There are two steam sources for the building heating system (P55); the extraction steam system (N36), which is the normal source, and the auxiliary steam system (P61), which is the source during startup and shutdown.

System Boundary

System components within scope of license renewal are limited to nonsafety-related valves associated with limiting reverse steam flow from the first stage moisture separator reheaters, feedwater heaters 3, 5 and 6, the steam seal evaporator, and from the direct contact heater back to the turbine during an overspeed event. All these components are active and not subject to aging management review.

System Functions (and scoping criteria, if intended function)

The N36 extraction steam system does not contain any mechanical components that are safety-related or that are credited for regulated events. The N36 extraction steam system does contain mechanical components that are nonsafety-related whose failure could result in failure of a safety-related function. However, all those components are active and are not subject to aging management review. No N36 extraction steam system components perform a pressure boundary or leakage boundary intended function.

Limit extraction steam reverse flow to the turbine after a turbine trip to prevent a turbine overspeed event. [10 CFR 54.4(a)(2)]

Supply steam to the steam seal evaporator, moisture separator reheaters and feedwater heaters.

Extraction Steam supplies steam to the building heating heat exchanger.

Component Types Subject to Aging Management Review

None

Table 3.4.2-5, Steam and Power Conversion Systems – Extraction Steam System – Summary of Aging Management Evaluation, is included for completeness. There are no mechanical components in the scope of license renewal that are subject to aging management review.

License Renewal Drawings: None

2.3.4.6 Feed Water Control (C34), Feedwater and Feedwater Leakage Control (N27)

System Description

The feedwater system is designed to pump condensate from the direct contact heater hot surge tank through two stages of feedwater heating to maintain the reactor vessel water level. Reactor feedwater flow is automatically controlled to maintain vessel water level within predetermined levels during all modes of plant operation.

The feedwater system is comprised of: four, one-third capacity motor-driven booster pumps, one stage of intermediate pressure heating with external drain cooler, two nominal half capacity horizontal reactor feedwater pumps with variable speed turbine drives, one 20 percent capacity motor-driven reactor feedwater pump, one stage of high pressure heating, valves, instrumentation and controls, and associated piping. Three booster pumps take water from the hot surge tank and discharge it through one stage of heating to the reactor feed pump suction. Both feed pumps discharge water through one stage of high pressure heaters into a mixing header before passing through two parallel feedwater shutoff valves to the reactor.

The feedwater leakage control (FWLC) system consists of two subsystems designed to eliminate through-line leakage in the feedwater piping by providing a positive seal for the stem, bonnet and seat of the outboard isolation valve on each line. The Division 2 subsystem uses the residual heat removal (RHR) waterleg pump and the Division 1 subsystem uses the low pressure core spray (LPCS) waterleg pump to supply sealing water through the bonnets of the MOVs. Following closure of the MOVs, the sealing water seals the stems, bonnets and seats, and isolates the feedwater lines.

The FWLC system will provide an adequate seal within approximately one hour following a LOCA. During this first hour, operation of the feedwater system will maintain a system pressure higher than the drywell pressure, thus ensuring water leakage into the vessel. Should the feedwater system become inoperable during the rapid vessel depressurization following a LOCA, the water in the feedwater piping will begin to flash into the drywell. It is expected that a water seal would remain for enough time following the accident until the operator remotely isolates the motor-operated valve. Thus, a water seal would exist in the piping beyond (outboard) of the motor-operated valve.

The feedwater control system controls the flow of feedwater into the reactor vessel to maintain the vessel water level within predetermined limits during all normal plant operating modes. The range of water level is based on the requirements of the steam separators (this includes limiting carryover, which affects turbine performance, and carryunder, which affects recirculation pump operation). The feedwater control system uses vessel water level, steam flow and feedwater flow as a three-element control. Single-element control is also available based on water level only. Normally, the signal from the feedwater flow is equal to the steam flow signal; thus, if a change in the steam flow occurs, the feedwater flow follows. The steam flow signal provides anticipation of the change in water level that will result from change in load. The level signal provides a correction for any mismatch between the steam and feedwater flow which causes the level of the water in the reactor vessel to rise or fall accordingly. The feedwater control system's functions are not considered essential for safety of the plant.

The shutdown sequence following a fire involves the use of the residual heat removal system in shutdown cooling mode. When the reactor reaches approximately 135 psig, the shutdown cooling mode of RHR A or RHR B would be initiated, at which time reactor water is pumped from one of the recirculation loops, through the RHR heat exchangers, then back to the reactor vessel by way of the feedwater system.

System Boundary

System components subject to aging management review include the piping components in the feedwater, feedwater control and feedwater leakage control systems as depicted on LR boundary drawings. The ASME Class 1 portions of the system are evaluated within the reactor coolant pressure boundary evaluation.

System Functions (and scoping criteria, if intended function)

The systems are within the scope of license renewal because they contain safety-related components that are relied upon to remain functional during or following a design basis event, because they contain nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because they are relied on to perform a function that demonstrates compliance with the regulations for FP, ATWS, and EQ.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1)]

The system supports achieving safe shutdown. [10 CFR 54.4(a)(1), (a)(3) – FP]

Feedwater leakage control provides a water seal with the LPCS/RHR A or RHR B/C water-leg pump on the feedwater motor operated valve bonnets and internal seating volumes to maintain containment integrity during LOCA conditions. [10 CFR 54.4(a)(1)]

Post-LOCA, the feedwater system will maintain a system pressure higher than the drywell pressure. [10 CFR 54.4(a)(2)]

The system contains safety-related instrumentation. [10 CFR 54.4(a)(1), (a)(3) – EQ]

Feedwater flow is limited upon receipt of a high pressure signal and confirmed failures to scram from the RRCS logic, thereby reducing power and steam discharge to the suppression pool without operator action. [10 CFR 54.4(a)(3) – ATWS]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Supply feedwater to the reactor vessel for power conversion and reactor heat removal.

The feedwater system may be used for reactor water level control during ATWS mitigation.

Component Types Subject to Aging Management Review

Table 2.3.4-6 lists the component types that require aging management review and their intended functions.

Table 3.4.2-6, Steam and Power Conversion Systems - Feed Water Control, Feedwater and Feedwater Leakage Control – Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.4.7 Main Condenser and Auxiliaries (N61)

System Description

The main condenser is a three shell, three pressure type with a rubber expansion joint in each neck. Differential water levels are maintained in each of the three condenser hotwells allowing condensate to flow from the lowest pressure to the intermediate pressure, then to the highest pressure hotwell where it is reheated. From there it flows to the hotwell storage located under the intermediate pressure condenser. This hotwell is an extension of the high pressure condenser hotwell and is connected to it by a cross-under pipe. The hotwell storage is isolated from the IP condenser by a solid divider plate and is vented to the HP condenser. Condensate leaves the hotwell through two outlets. During normal operation the main condenser receives the following flows:

a. Main turbine exhaust steam.

b. Auxiliary condenser condensate.

c. Drains from low pressure heater No. 1.

d. Steam packing exhauster drains.

e. Steam jet air ejector (SJAE) condenser drains.

f. Offgas condenser drains.

g. Feedwater heater vents.

h. Turbine governor valve leakoffs.

i. Seal steam header flow.

j. Feed pump seal leakoff.

k. Main, reheat, extraction, and miscellaneous drains.

The main condensers are not required to affect or support the safe shutdown of the reactor, or to support in the operation of reactor safety features.

The radiological consequences for the most limiting case of a control rod drop accident occurs as the result of a release to the environment due to the condenser leakage, following closure of the main steam isolation valves. Of the activity reaching the condenser, 100 percent of the noble gases, 10 percent of the iodines, and 1 percent of the particulate radionuclides (due to partitioning and plateout) remain airborne. The activity airborne in the condenser is assumed to leak directly to the environment at a rate of 1.0 percent per day, for a period of 24 hours.

System Boundary

System components subject to aging management review include the external shell for the main condenser (including interconnecting vent and air removal lines), the N31 system turbine casing, and condenser tubesheet.

The air removal lines and N62 condenser air removal system components are shown on drawing 302-0131. These components are evaluated under N61 main condenser system and illustrated on the scoping drawing 302 0103.

Interfacing systems such as Main Steam (N11) and Extraction Steam (N36) are evaluated separately.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

Provide hold up volume for radioactive decay, and limit leakage to the environment for 24 hours following a control rod drop accident. [10 CFR 54.4(a)(2)]

Condense steam from the main turbine and/or steam bypass and pressure regulating system for power conversion; and for reactor heat removal.

Collect miscellaneous turbine plant condensate, leakoff, vents, and drain flows.

Component Types Subject to Aging Management Review

Table 2.3.4-7 lists the component types that require aging management review and their intended functions.

Table 3.4.2-7, Steam and Power Conversion Systems - Main Condenser and Auxiliaries – System Summary of Aging Management Evaluation, provides the results of the aging management review.

2.3.4.8 Main and Reheat Steam (N11)

System Description

The main steam piping consists of four 28-inch O.D. lines from the outer containment isolation valves to the main turbine stop valves, and connecting lines to supply steam to the second stage reheater, the condenser steam jet ejectors, offgas preheaters, the main turbine bypass valves, the reactor feed pump turbines, and the seal steam evaporator. All piping in the system is carbon steel.

Pipe restraints are provided to protect safety-related piping and valves from the effects of pipe rupture from any cause. A moment resisting pipe restraint system is provided for both the main steam and feedwater system. The system consists of two restraint locations for each system to provide a couple type moment resistance. Both restraint locations are in the safety-related portion of the steam tunnel in the auxiliary building. One of the two restraints is located adjacent to the point at which the classification of the steam tunnel changes. Therefore, effects of pipe rupture downstream of the motor-operated stop valves will not be transmitted to the isolation valves.

A reliable, redundant, fail-safe turbine overspeed system is incorporated for the safety of plant personnel and equipment, and to ensure no mitigation of engineered safety systems employed for safe, orderly shutdown of the reactor system. In the event of a turbine overspeed condition, the overspeed trip system releases the fluid pressure on the disk dump valves for main stop and control valves and intermediate stop and intercept valves, thereby closing the turbine steam valves. In addition to overspeed trip signals, the emergency trip system closes the main stop and control valves, and the intermediate stop and intercept valves, thereby shutting down the turbine on the trip signals due to mechanical faults and generator electrical faults.

Two separate radiological analyses are provided for the control rod drop accident (CRDA):

1. The first analysis assumes the accident occurs at a low reactor power level with the mechanical vacuum pumps in operation or at any power level with a coincident loss of offsite power (LOOP);

2. The second analysis assumes the accident occurs at a higher reactor power level with the steam jet air ejectors in operation such that the condenser gases are processed through the offgas filtration system.

For the first CRDA scenario:

A coincident LOOP condition results in the automatic closure of the MSIVs, thereby stopping the transport of the fission products to the condenser. Radioactive release to the environment follows due to the condenser leakage.

For the second CRDA scenario:

The transport pathway consists of carryover with steam to the turbine condenser and leakage from the condenser to the environment via the offgas (N64) system.

System Boundary

System components subject to aging management review include safety related valves and piping components from the main steam line outside containment isolation valves, up to and including the main steam shutoff valves in the steam tunnel, and the connected nonsafety-related piping within the steam tunnel and the piping necessary to encompass the equivalent anchors beyond the safety class boundary, as shown on LR boundary drawings.

Based on the results of Calculation 3.2.15.2.1, Rev. 1, and the NRC Safety Evaluation for PNPP License Amendment 166, the second CRDA scenario that credits steam flow from the Reactor to the Condenser and eventual release to the environment through the N62 air removal and N64 off gas systems is not used as a basis for acceptance for PNPP CRDA radiological consequences. Ultimately, the N11 main and reheat system has no effect on the radiological consequences of a control rod drop accident, and as such does not meet 54.4(a) scoping criteria for mitigation of a CRDA.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Limiting steam flow to the turbine after a turbine trip to prevent a turbine overspeed event is an active function, relying on valves to reposition to stop or divert steam flow to the turbine. The passive pressure boundary function is not credited, as leakage of steam to the environment serves to mitigate the event. No mechanical components are subject to aging management to support this function.

To prevent a failure that could lead to the release of radioactivity, the main steam system is designed to accommodate the most severe conditions of coincident pressure, temperature and loading, including operational basis and safe shutdown earthquake conditions and protection from postulated external phenomena. [10 CFR 54.4(a)(1)]

The integrity of non-safety related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Non-safety related piping up to and including the first equivalent anchor beyond safety/non-safety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Limit steam flow to the turbine after a turbine trip to prevent a turbine overspeed event [10 CFR 54.4(a)(2)]

The system contains components credited with compliance with 10 CFR 50.49. [10 CFR 54.4(a)(3) EQ]

Supply steam to the main turbine for power conversion and reactor heat removal.

Supply steam to Reactor Feed Pump Turbines and Moisture Separator Reheaters for feedwater supply and thermal performance.

Component Types Subject to Aging Management Review

2.3.4.9 Main, Reheat, Extraction, and Miscellaneous Drains (N22)

System Description

The main, reheat, extraction, and miscellaneous drains system consists of drains located at low points and pockets in the steam piping system before and after seats of various valves, valve stem leak offs, and equipment shell drains and vents. Many of these drain lines contain valves, strainers and restricting orifices to ensure proper drainage and water removal from system piping during system warm up, startup, and normal load operations.

System Boundary

System components subject to aging management review include safety-related valves and piping, and nonsafety-related piping components in the steam tunnel, as depicted on LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, and because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

Provide safety-related piping integrity. [10 CFR 54.4(a)(1)]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Remove condensed steam from the various steam lines and components and direct it to the main condenser.

2.3.4.10 Respirator Cleaning (L58)

System Description

Respirator cleaning equipment is provided to support cleaning and maintenance of respiratory protection equipment.

System Boundary

System components subject to aging management review include piping components used to support respirator cleaning as depicted on the LR boundary drawing.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Provide demineralized water to support cleaning and maintenance of respiratory protection equipment.

Component Types Subject to Aging Management Review

2.3.4.11 Service Water and Emergency Service Water Chlorination (P48)

System Description

The service water and emergency service water chlorination system is a liquid biocide injection system which is used, as required, to minimize algae and plant growth. Sodium hypo-chlorite, rather than chlorine, is used as a biocide. This is done on a regular basis at each individual pump suction. Sample points are provided in the discharge piping to determine biocide concentrations. Discharged effluent water quality will be maintained in accordance with PNPP's National Pollution Discharge Elimination System (NPDES) permit.

System Boundary

System components subject to aging management review are limited to nonsafety-related piping components within the emergency service water pumphouse as listed on the LR boundary drawings.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function.

The integrity of non-safety related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Minimize algae and plant growth within the emergency service water and service water systems.

Component Types Subject to Aging Management Review

Table 2.3.4-11 lists the component types that require aging management review and their intended functions.

2.3.4.12 Two Bed Demineralizer and Distribution (P21), and Mixed Bed Demineralizer and Distribution (P22)

System Description

The primary water source for the demineralized water makeup system is raw Lake Erie water supplied by the service water system. The Lake Erie water is pretreated and transferred to a clearwell (makeup water pretreatment system). Part of the clearwell water is used for miscellaneous services and the remainder is used for plant makeup to the demineralizers.

The demineralizer system is not safety-related. The system is designed to produce sufficient water to meet plant makeup requirements. The demineralized water is used to supply miscellaneous services and makeup to the condenser, or alternatively, the condensate storage tank.

The portion of the demineralizer system consists of a vendor-owned and operated water treatment skid. This water treatment skid produces demineralized water for plant use. The effluent of the vendor water treatment skid supplies both the two-bed and mixed bed water storage tanks. Two-bed and mixed bed storage tank water is distributed to various plant locations via the associated distribution pumps and piping.

System Boundary

System components subject to aging management review include safety-related piping and valves associated with containment/drywell penetrations and the water fill for the containment vessel and drywell purge system penetrations, and nonsafety-related valves, piping components and appliances located in areas containing safety-related components.

System Functions (and scoping criteria, if intended function)

The system is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event, because it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and because it is relied on to perform a function that demonstrates compliance with the regulations for EQ.

Containment isolation limits radiological release. [10 CFR 54.4(a)(1), (a)(3) – EQ]

Drywell isolation valves ensure drywell boundary by minimizing potential paths to the environment and ensure drywell pressure suppression capability. [10 CFR 54.4(a)(1), (a)(3) – EQ]

The integrity of nonsafety-related, fluid-retaining components in safety-related area(s) prevents interactions that could affect safety-related SSCs. [10 CFR 54.4(a)(2)]

Nonsafety-related piping up to and including the first equivalent anchor beyond safety/nonsafety interface(s) provides mechanical support for safety-related SSCs. [10 CFR 54.4(a)(2)]

Store and supply demineralized water to the main condenser and miscellaneous services.

Component Types Subject to Aging Management Review

2.4 SCOPING AND SCREENING RESULTS: STRUCTURES

The following structures and structural components are within the scope of license renewal:

- Containment structure, (reactor building complex), Unit 1 (Section 2.4.1)
- Turbine buildings and associated structures, process facilities, yard structures and unit 2 structures (Section 2.4.2)
- Water control structures (Section 2.4.3)
- Structural bulk commodities (Section 2.4.4)

Specifically, this section provides the following information for the Perry structures within the scope of license renewal listed in Table 2.2-2:

1. The description;
2. A list of license renewal intended functions, including which criteria of 10 CFR 54 [Reference 1.3-1] require the structure to be in-scope;
3. Reference to the applicable Perry UFSAR [Reference 1.3-6] section(s);
4. Reference to the applicable license renewal boundary drawing(s); and,
5. A list of component types that are subject to an aging management review with their associated component intended function(s).

Table 2.4-1 provides a list of the abbreviations and definitions for the intended functions assigned in the following sections.

Note: Structural bulk commodities located within all the in-scope structures are described in Section 2.4.4.

Table 2.4-1
Intended Functions: Abbreviations and Definitions

Intended Function	Abbreviation	Definition
Absorb Neutrons	ABN	Provide neutron absorption (e.g., neutron absorbers in spent fuel pool storage racks)
Direct Flow	DF	Provide spray shield or curbs for directing flow (e.g., safety injection flow to the suppression pool)
Expansion or Separation	EXP	Provide for thermal expansion or seismic separation
Fire Barrier	FB	Provide rated fire barrier to confine or retard a fire from spreading to or from adjacent areas
Flood Barrier, including Temporary Flood Barrier	FLB	Provide flood protection barrier (internal and external flooding event)
Gaseous Release Path	RP	Provide path for release of filtered and unfiltered gaseous discharge
Heat Sink	HS	Provide heat sink during SBO or design basis accidents
HELB Shielding	HELB	Provide shielding against high energy line breaks (HELB)
Missile Barrier	MB	Provide missile barrier (internally or externally generated)
Pipe Whip Restraint	PW	Restrain piping motion related to HELB
Pressure Relief	PR	Provide over-pressure protection
Shelter or Protection	EN	Provide shelter or protection to safety-related equipment (includes HELB, radiation shielding)
Shielding	SHD	Provide radiation shielding to reduce neutron or gamma radiation fluence
Structural Pressure Boundary	SPB	Provide pressure boundary or essentially leak tight barrier to protect public health and safety in the event of postulated design basis events. Limit radiological exposures as result of accidents comparable to those referred to in 10CFR50.67.
Support for Criterion (a)(1) Equipment	SSR	Provide structural or functional support to safety-related equipment

Intended Function	Abbreviation	Definition
Support for Criterion (a)(2) Equipment	SNS	Provide structural or functional support to nonsafety-related equipment whose failure could prevent satisfactory accomplishment of required safety functions (includes Seismic II over I considerations)
Support for Criterion (a)(3) Equipment	SRE	Provide structural or functional support required to meet the Commission's regulations for the regulated events in 10 CFR 54.4(a)(3)

2.4.1 CONTAINMENT STRUCTURE, UNIT 1 (REACTOR BUILDING COMPLEX)

Description

Containment Structure (Reactor Building Complex)

The reactor building complex consists of the interior structure (including drywell and suppression pool), containment vessel, annulus concrete, and shield building. These structures house and protect the reactor and some safety class equipment, and the structures are supported by a common foundation mat at elevation 574'-10". The interior structure is separate from the containment vessel, annulus concrete and shield building above the mat, however the containment vessel and shield building are tied together by the annulus concrete, to elevation 598'-4".

The purpose of the Unit 1 Mark III containment structure is to serve both as a biological shield and as a pressure suppression containment during loss-of-coolant accidents (resulting from the spectrum of postulated piping breaks within the reactor coolant pressure boundary). The containment structure is comprised of a free standing steel containment vessel and annulus concrete acting compositely. The shield building forms a housing for the steel containment, and concrete is added in the annulus between the containment vessel and the shield building, which strengthens and stiffens the containment vessel. The leak tight containment vessel surrounds the drywell and the suppression pool. The drywell encloses the reactor pressure vessel, the reactor coolant recirculation loops and pumps, and other branch connections of the reactor primary system.

The containment structure as well as all penetrations and the interior structures are seismic Category I structures. The primary containment and secondary containment, in conjunction with other engineered safety features, limit radiological effects of accidents resulting in the release of radioactive material to the containment volumes to less than the prescribed acceptable limits.

The structures of the containment structure are addressed individually, below.

Shield Building and Annulus Concrete

The shield building has the following functions:

- Forms a biological shield for radiation from the reactor.
- Provides protection for the containment vessel from ground water contact and pressure.
- Provides weather and exterior missile protection for the containment vessel.

- Provides a relatively leak tight structure to act as a secondary containment so that the annulus exhaust gas treatment system can be used to minimize the escape of fission products to the environment.

The shield building is a reinforced concrete structure consisting of a flat foundation mat, a cylindrical wall and a shallow dome. The foundation mat, common to the shield building, annulus concrete, containment vessel, and interior structure is circular with a diameter of 136 feet and a thickness of 12 feet 6 inches. The foundation mat is founded on Chagrin shale.

The shield building cylindrical wall extends from the top of the foundation mat at elevation 574’-10” to elevation 749’-9”. The shield building is a cylindrical reinforced concrete structure with a spherical dome enclosing the containment vessel. The internal diameter is 130 feet and the outside diameter is 136 feet. The shield building dome has a thickness of 2 feet 6 inches. There is no thickened ring girder, but the elevation of the wall at the junction of the wall and dome was raised to provide a greater section to help resist the outward thrust of the dome.

A 12-inch thick layer of porous concrete and a 4-inch thick concrete mud mat form a supporting medium between the bottom of the foundation mat and the Chagrin shale. The porous concrete is part of the plant foundation underdrain system (Section 2.3.3.44) that is used to reduce the hydrostatic pressure acting on plant structures. Adjacent safety class structures are separated by enough space (rattle space) to accommodate seismic movements. The walls of adjacent safety class structures are designed for water elevation at 590 feet, corresponding to the design basis groundwater elevation.

Access to the inside of the containment vessel though the shield building is provided by two personnel airlocks. The airlocks use inflatable seals to maintain the containment pressure boundary. The inflatable seals are short-lived and are periodically replaced.

A separate shield building equipment hatch allows for access from the fuel handling building during outages. This octagonal opening in the shield building is 20 feet across the flats. The opening is shielded by removable reinforced concrete beams which are provided with seals to minimize the leakage of air.

The design of mechanical and electrical penetration sleeves and bellows allows differential movement between the shield building and the containment vessel. The annulus concrete extends from the top of the foundation mat to elevation 598 feet 4 inches and has a radial thickness of 4 feet 10.5 inches. The annulus concrete provides stiffness to the steel containment vessel to reduce the dynamic response of the steel containment vessel due to the postulated safety/relief valve discharge loading phenomena. The containment vessel is also structurally strengthened by the annulus concrete.

The space between the shield building and the containment vessel largely comprises secondary containment. The shield building is designed to collect the fission product leakage from the primary containment during and following a postulated design basis LOCA and delay it until it can be released to the environs after processing through the annulus exhaust gas treatment system such that the resultant offsite doses are less than the values set forth in 10 CFR 50.67 [Reference 1.3-7].

Containment Vessel

A leak-tight containment vessel surrounds the drywell and the suppression pool. The steel containment vessel is designed, fabricated and erected in accordance with the requirements of ASME Code Section III for Class MC components. The containment vessel is a pressure-retaining structure composed of a free-standing steel cylinder with an ellipsoidal dome, secured to a steel-lined, reinforced concrete foundation mat. The mat is the common foundation for the three major structures of the reactor building complex. The free-standing portion of the containment vessel is supported by and anchored into the foundation mat.

The basic dimensions of the containment vessel are:

a. cylinder inside diameter - 120 feet.

b. cylinder height - 152 feet - 2 inches.

c. ellipsoidal dome ratio - 2:1.

The containment vessel cylinder has six external stiffening rings at various elevations. Two personnel access airlocks and one equipment hatch are provided. The lower 18 feet 6 inches of the containment vessel forms the outside of the suppression pool. Corrosion of the lower 23 feet 6 inches of the containment vessel and exposed steel mat liner is minimized using stainless steel clad.

Final design plate thickness of the containment vessel cylinder and dome is 1-1/2 inches. This is increased to three-inch thick plate around the penetrations in the Suppression Pool region to provide local reinforcement for containment vessel pressure loads as well as penetration loads. Base liner plates are 3/8-inch thick carbon steel where they are covered by concrete, and 1/2-inch thick stainless clad where they are exposed to the suppression pool water.

Steel test channels are provided along welds of the steel liner of the foundation mat so that local leak testing of welds can be performed.

Missile protection is provided within the containment for internally generated missiles, such as from rotating equipment or pressurized component failure.

No fuel is stored in the containment upper pool during plant operation. The aluminum spent fuel storage racks in the containment upper pool achieve subcriticality by spacing in a loose packed geometric array.

The containment polar crane is designed to Seismic Category I requirements. The crane consists of two crane girders and a trolley. The circular runway (rails) which supports the crane girders is supported from the containment vessel.

The pressure suppression containment system is designed to have the following functional capabilities:

- The containment and drywell have the capability to maintain functional integrity during and following peak transient pressures and temperatures which would occur following any postulated loss-of-coolant accident (LOCA).
- The containment, in combination with other accident mitigation systems, limits fission product leakage during and following the postulated design basis accident to values less than leakage rates that would result in offsite doses greater than those stated in 10 CFR 50.67 [Reference 1.3-7].
- The containment system provides means to channel the flow from postulated pipe ruptures in the drywell to the suppression pool.

<u>Drywell</u>

The drywell encloses the reactor pressure vessel, the reactor coolant recirculation loops and pumps, and other branch connection of the reactor primary system. The drywell is a cylindrical reinforced concrete structure with a removable steel head. The drywell is subdivided into two regions. The lower 26 feet 2 inches of the drywell is the vent region. The main suppression pool area in the containment vessel is connected to the drywell by vents. The vent structure consists of two concentric one-inch thick steel cylinders with a ten percent stainless steel cladding. The annulus between the cylinders is stiffened vertically by radial steel plates and is filled with concrete. The vent sleeves are 28 inch outside diameter, 1/4-inch thick, stainless steel tubes located in 3 rows of 40 vents.

The vent region is anchored to the containment base mat. The upper drywell wall region is a reinforced concrete cylinder connected to the lower vent region by cadwelding all vertical and diagonal rebars to the ring girder. The upper drywell wall extends up to the drywell top slab. Above the vent region, the inside face of the drywell is formed with a steel plate. The drywell top slab is a flat, horizontal, circular, reinforced concrete slab. It contains a central circular opening which is closed by the drywell head. The entire drywell cylindrical wall is recessed into the reactor building foundation and provides a continuous shear key for resisting radial/transverse shear forces by direct bearing of the drywell wall base on the foundation mat.

Penetrations through the drywell wall for piping and electrical systems are of the single barrier leak tight type. The main steam lines are anchored at the drywell and are provided with guard pipes through to the isolation valves outside containment. All such guard pipes vent to the drywell. A personnel airlock provides access to the drywell. The personnel access air lock has an outside diameter of 9 feet 8 inches and is located at the 599’-9” elevation floor to provide access to the drywell. For large pieces of equipment, a bolted, double gasket sealed, equipment access hatch is provided.

The foundation mat provides support for the reactor pressure vessel (RPV) pedestal. This support is a concrete filled, double steel walled cylinder, located directly beneath the RPV and the biological shield wall. A support structure for the control rod drive mechanisms is located inside of the inner shell of the pedestal. The RPV pedestal is anchored to the foundation mat. The RPV pedestal is haunched at the top to provide bearing area for the RPV sole plate. The RPV skirt is bolted to the RPV pedestal.

A 2-foot thick reinforced concrete biological shield wall surrounds the RPV and is supported on the RPV pedestal. The biological shield wall is a concrete-filled, double steel walled cylinder. The outside plates of the biological shield wall and the pedestal are continuous. This wall also supports a platform at elevation 599 feet, 9 inches, and provides missile protection. Flow diverters are fitted to the recirculation suction line penetrations so that the flow from a reactor pressure vessel safe end nozzle break is directed into the drywell volume with minimal pressurization of the annulus between the biological shield wall and the RPV.

Suppression Pool and Weir Wall

The drywell, suppression pool and the containment vessel are designed to condense the steam and contain fission product releases from the postulated design bases accident, i.e., the double-ended rupture of the largest pipe in the reactor coolant system. The suppression pool contains a large amount of water used to rapidly condense steam from reactor vessel blowdown or from a break in a major pipe. Part of the suppression pool water is inside the drywell (retained by a cylindrical concrete weir wall), but the major portion is outside the drywell between the drywell wall and the containment wall. The lower 18 feet, 6 inches of the containment vessel forms the outside of the suppression pool; the inside of the suppression pool is formed by the drywell weir wall. The weir wall is 24 feet, 2 inches high and 1 foot, 6 inches thick. The outer face of the weir wall is lined with stainless steel. The weir wall provides missile protection.

The suppression pool provides a water source for each of the emergency core cooling systems.

Refueling and Reactor Servicing Areas

Fuel assemblies are transferred through the transfer tube between the reactor building and the fuel handling building. The fuel assemblies inside the containment are handled by the refueling platform. The handling of the reactor head, removable internals and drywell head, during refueling, is accomplished using the containment polar crane.

The fuel storage and transfer pools are rectangular shaped compartmented structures, constructed of reinforced concrete lined with stainless steel. This structure is supported on the drywell and drywell top slab. The top slab is stiffened by two longitudinal reinforced concrete walls which are part of the upper pool wall system. The fuel transfer penetration connects the upper fuel pool above the drywell to the fuel handling building.

This penetration has a guard pipe and is inclined at an angle of 57 degrees to the horizontal.

The containment building is supplied with a refueling platform for fuel movement and servicing, and an auxiliary platform for servicing operations from the refueling floor level.

The refueling platform is a gantry crane which is used to transport fuel and reactor components to and from pool storage and the reactor vessel. The platform spans the fuel storage and vessel pools on embedded tracks in the refueling floor. A telescoping mast and grapple suspended from a trolley system is used to lift and orient fuel bundles for core, storage rack, or upender placement.

An auxiliary platform is provided to allow versatility of operations. This platform operates over the reactor building pool and provides an additional work area for reactor servicing. A half-ton design load capacity hoist is provided for reactor servicing tasks. The hoist is administratively limited to 500 pounds. The design of the auxiliary platform allows for concurrent reactor servicing with fuel movements by the refuel platform.

Functions (and scoping criteria, if intended function)

The containment structure is within the scope of license renewal because it contains safety-related related components that are relied upon to remain functional during or following a design basis event, and because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection, equipment qualification, anticipated transients without scram, and station blackout. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The containment structure has the following intended functions for 10 CFR 54.4(a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1)]
- Provide physical support, shelter, and protection for systems, structures, and components relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for fire protection (10 CFR 50.48), equipment qualification (10 CFR 50.49), anticipated transients without scram (10 CFR 50.62), and station blackout (10 CFR 50.63) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]
- Limits fission product leakage during and following the postulated design basis accident to values less than leakage rates that would result in offsite doses greater than those stated in 10 CFR 50.67. [10 CFR 54.4(a)(1)]
- Control the release of fission products to the secondary containment in the event of a design basis loss-of-coolant accident (LOCA) so that offsite consequences are within acceptable limits. [10 CFR 54.4(a)(1)]

- The containment and drywell have the capability to maintain functional integrity during and following peak transient pressures and temperatures which would occur following any postulated loss-of-coolant accident (LOCA). [10 CFR 54.4(a)(1)]
- The suppression pool provides a source of water for emergency core cooling systems. [10 CFR 54.4(a)(1)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]

Component Types Subject to Aging Management Review

Table 2.4.1-1 lists the component types that require aging management review and their intended functions.

Table 3.5.2-1, Structures – Containment Structure, Unit 1 – Summary of Aging Management Evaluation, provides the results of the aging management review.

Table 2.4.1-1
Containment Structure, Unit 1
Component Types Subject to Aging Management Review

Component Type	Intended function
Annulus and shield building cable supports	SNS, SSR, SRE
Beams, columns, floor slabs and interior walls	EN, FLB, MB, SRE, SSR, SHD
Beams, columns, floor slabs and interior walls (containment (drywell) (steam tunnel)	MB, SNS, SPB, SSR, SHD, EN, SRE
Beams, columns, floor slabs and interior walls (annulus concrete)	SSR
Bolting	SPB, SSR
Containment auxiliary platform equipment assembly and rails	SNS
Containment base slab	FLB, SNS, SPB, SRE, SSR
Containment equipment hatch	EN, MB, SPB, SSR
Containment equipment hatch crane girders and rails	SNS
Containment foundation	SNS, SRE, SSR
Containment guard pipes	EN, MB, SPB, HELB
Containment monorails	SNS

Component Type	Intended function
Containment penetration bellows and welds	SPB, SSR
Containment personnel airlocks and seals	EN, SPB, SSR
Containment refueling platform and rails	SNS
Containment sump structures	SSR
Containment vessel	EN, MB, SNS, SPB, SSR
Containment vessel electrical penetrations	SNS, SPB, SRE, SSR
Containment vessel mechanical penetrations	SPB, SSR, SNS, SRE
Drywell	EN, FB, MB, SPB, SSR, DF, RP, PR, SRE
Drywell electrical penetrations	EN, SPB, SSR, FB, SRE
Drywell equipment hatch and seals	EN, MB, SPB, SSR
Drywell floor slab	EN, SSR, SNS, SRE
Drywell head	EN, MB, SPB, SSR
Drywell liner plate	EN, MB, SPB, SSR
Drywell mechanical penetrations	EN, SPB, SSR, FB, SRE
Drywell personnel airlock	EN, SPB, SSR
Drywell wall vent structure	EN, MB, SPB, SSR
Drywell wall vents	SSR, PR, RP
Drywell weir wall	EN, MB, SPB, SSR
Fuel transfer tube penetration	SPB, SSR, FB
Grounding bar	EN, SNS, SPB, SSR
Polar crane and rails	SSR
Quencher supports	SSR
Reactor pedestal	SSR
Service level 1 coatings	SNS
Shield building cylinder wall and dome	EN, FB, FLB, MB, SNS, SPB, SRE, SSR, RP, SHD
Shield building electrical penetration seals and sealant	FB, SPB, SSR, SRE
Structural steel	EN, MB, SNS, SSR
Sump liners and penetrations	EN, SPB, SSR
Upper containment pool floor and walls	EN, MB, SNS, SPB, SSR

Component Type	Intended function
Upper containment pool gates and seals	EN, SPB

Note: Drywell radiant barrier (heat shield) is considered a bulk commodity and is addressed in the Bulk Commodities section as Radiant Barrier and Radiant Energy Shield commodities. See Table 2.4.4-1, Bulk Commodities - Component Types Subject to Aging Management Review.

2.4.2 TURBINE BUILDINGS AND ASSOCIATED STRUCTURES, PROCESS FACILITIES, YARD STRUCTURES AND UNIT 2 STRUCTURES

The following structures are included in this review:

Turbine Building, Unit 1 (2.4.2.1)

Turbine Power Complex (Condensate Demineralizer Building), Unit 1 (2.4.2.2)

Steam Tunnel, Unit 1 (2.4.2.3)

Auxiliary Boiler Building (2.4.2.4)

Heater Bay, Unit 1 (2.4.2.5)

Auxiliary Building, Unit 1 (2.4.2.6)

Control Complex (2.4.2.7)

Diesel Generator Building (2.4.2.8)

Intermediate Building (2.4.2.9)

Fuel Handling Building (2.4.2.10)

Offgas Building, Unit 1 (2.4.2.11)

Radioactive Waste Building (2.4.2.12)

Service Building (2.4.2.13)

Reactor Building, Unit 2 (2.4.2.14)

Auxiliary Building, Unit 2 (2.4.2.15)

Turbine Building, Unit 2 (2.4.2.16)

Turbine Power Complex (Condensate Demineralizer Building), Unit 2 (2.4.2.17)

Heater Bay, Unit 2 (2.4.2.18)

Offgas Building, Unit 2 (2.4.2.19)

Steam Tunnel, Unit 2 (2.4.2.20)

Central Oil Unloading/Tank Fill Station (2.4.2.21)

Diesel Generator Fuel Oil Tank Maintenance Structures (2.4.2.22)

Circulating Water Pumphouse (2.4.2.23)

Condensate Storage Tank Dike and Instrument Missile Shield (2.4.2.24)

Foundations (Tanks, Transformers, Transmission Towers, etc.) (2.4.2.25)

Fuel Oil Storage Tank Dike (2.4.2.26)

Fuel Oil Pumphouse (2.4.2.27)

High Mast Light #7 (2.4.2.28)

Hydrant Houses (2.4.2.29)

Manholes and Duct Banks (2.4.2.30)

Primary Access Facility (2.4.2.31)

Railroad Bridge (2.4.2.32)

Service Water Valve Pit (2.4.2.33)

Spent Fuel Dry Storage (SFDS) Electrical Building (2.4.2.34)

Thrust Blocks (2.4.2.35)

Transformer Concrete Curbs and Fire Barriers (2.4.2.36)

Transmission Towers (2.4.2.37)

Valve Support Slabs (2.4.2.38)

Water Treatment Building (2.4.2.39)

Notes:

1. Structural bulk commodities located within all the in-scope structures are described in Section 2.4.4.
2. See Table 2.4.2-1 for a list of Component Types Subject to Aging Management Review and the respective component intended functions supporting the Structures intended functions.
3. License Renewal Drawing: Perry LR Site Map

2.4.2.1 Turbine Building, Unit 1

Description

The turbine building is a non-seismic Category I structure located north of the Unit 1 auxiliary building. The turbine building is a five-story structure, bounded by the water treatment building on the west, the offgas building, turbine power complex and steam tunnel along most of the south wall, and is partially bounded by the heater bay and auxiliary boiler building on the north. The remainder of the north, south and east walls are exposed. The turbine building has two overhead cranes (east and west) and both cranes are considered as structural bulk commodities for the purpose of aging management review.

The turbine building houses the turbine generator and related auxiliaries, condensing equipment, moisture separator-reheaters, the first two stages of feedwater heating, some of the piping/equipment for the offgas system, and part of the offgas building ventilation equipment.

The entire five story building is considered a single fire area. The turbine building supports and protects: the main condenser credited for limiting the radiological consequences of a control rod drop accident; feedwater piping credited to support feedwater leakage control post-LOCA; and main steam and extraction steam piping and valves credited to mitigate turbine trip events.

Walls separating the turbine building from other buildings are constructed of either reinforced concrete or drywall and are 3-hour fire resistance rated. Floors are of reinforced concrete with numerous penetrations and metal gratings where equipment extends through floors. The roof is of steel frame and metal deck construction with roofing that meets fire protection requirements. Doorways in boundary walls between the turbine building and other buildings are equipped with Class A fire doors. Other penetrations in these boundary walls are sealed to provide a 3-hour fire resistance rating.

Although there are safety-related instruments in the turbine building, failure of the building would not prevent accomplishment of their credited safety functions (reactor protection or leak detection). Power cables from the Unit 1 Startup Transformer are routed through the turbine building to the Turbine Power Complex, an offsite power source credited for recovery from station blackout.

In the event of a postulated circulating water line break in the turbine building, the resultant internal flooding would be limited by isolation of service water make-up to the circulating water system using safety-related valves activated by a signal from water level indicators in the turbine building. Several turbine building wall penetrations are designed to allow flooding of the adjacent heater bay and condensate demineralizer building to maximize the amount of internal flooding volume within the turbine building complex.

Total failure of the turbine building due to tornado loads is precluded by design. The design approach used is based on a building siding that blows off at a predictable wind load, considerably below maximum tornado wind pressure. Therefore, the critical load on the turbine building is the tornado wind pressures on the structural skeleton of the building. The structural components of the turbine building, including the foundation, are designed for these tornado wind pressures.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection and station blackout. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The turbine building Unit 1 has the following intended functions for 10 CFR 54.4 (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(2)]
- House equipment credited in the Appendix R safe shutdown analysis for fire protection (10 CFR 50.48) and station blackout (10 CFR 50.63). [10 CFR 54.4(a)(3)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected (mitigation of control rod drop accident, turbine trip, internal flooding, and feedwater leakage post-LOCA). [10 CFR 54.4(a)(2)]

2.4.2.2 Turbine Power Complex (Condensate Demineralizer Bldg.), Unit 1

Description

The turbine power complex is a four-story structure. The Unit 1 turbine power complex is bounded by the turbine building on the north, the steam tunnel on the east and the offgas building on the west; the south wall is partially bounded by the auxiliary building with the remainder of the wall exposed.

This building contains equipment for the condensate demineralizer system, condensate filtration system, motor control centers, dc distribution equipment, and metal clad switchgear. The entire turbine power complex is considered a single fire area.

The turbine power complex exterior walls are constructed of metal siding. Walls adjacent to other buildings are of reinforced concrete or drywall construction. These walls have 3-hour fire resistance ratings and penetrations are provided with 3-hour fire rated seals. Doorways to adjacent structures are equipped with Class A fire doors. Floors are constructed of reinforced concrete. The roof is of metal deck construction with roofing that meets fire protection requirements.

The turbine power complex, Unit 1, has the condensate demineralizer building as its basement. The turbine power complex is a non-seismic Category I structure that is adjacent to the seismic Category I Unit 1 auxiliary building. The condensate demineralizer building volume is used to mitigate internal flooding from a circulating water line break, and its penetrations prevent flooding of the seismic Category I, Unit 1 auxiliary building below the 599 ft. elevation. The turbine power complex, Unit 1 provides support and shelter for electrical equipment that connects the Unit 1 startup transformer to the safety-related electrical power system.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains nonsafety-related components that are relied upon to remain functional during or following a design basis event, because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection and station blackout. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The turbine power complex, Unit 1 has the following intended functions for 10 CFR 54 [10 CFR 54.4(a)(2)] and [10 CFR 54.4(a)(3)] [Reference 1.3-1]:

- Provide shelter, support and protection for nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(2)]
- House equipment credited for fire protection (10 CFR 50.48) and station blackout (10 CFR 50.63). [Reference 1.3-7] [10 CFR 54.4(a)(3)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected (internal flooding mitigation; Seismic II/I). [10 CFR 54.4(a)(2)]

UFSAR: 3.8.4 / Appendix 9A.4.11.1 / 10.4.5.3.1 / Figure 1.2-6

2.4.2.3 Steam Tunnel, Unit 1

Description

The Unit 1 steam tunnel is a structure with floor elevations at 614'-6" and 620'-6" that houses main steam, feedwater and other major pipes extending from the reactor building. The tunnel extends in the north-south direction from the reactor building through the auxiliary building at elevation 620'-6", connects to the east end of the turbine power complex and continues to the turbine building. The portion of this structure from the reactor building to the end of the auxiliary building is safety-related, seismic Category I. The steam tunnel also serves to maintain radiological shielding around the main steam lines. The steam tunnel is considered one fire zone.

Walls, floor and ceiling are constructed of reinforced concrete. The east and west walls and the south reactor building walls are 3-hour rated and penetrations are provided with 3-hour rated fire seals. There is no wall adjacent to the turbine building. The floor is 3-hour rated and penetrations are provided with 3-hour fire rated seals. Access to the steam tunnel is through roof hatches at elevation 652'-0" from the auxiliary building, or from doorways/openings in the turbine building.

Beyond the auxiliary building, the steam tunnel, Unit 1, is a non-seismic Category I structure that is adjacent to the seismic Category I auxiliary building. Although there are safety-related instruments in this part of the steam tunnel, failure of the building would not prevent accomplishment of the credited safety function (leak detection). The steam tunnel is integral to the auxiliary building steam tunnel fire area.

The steam tunnel serves as a conduit for essentially all high energy piping between the reactor building and the turbine building. The steam tunnel is designed to contain the environmental effects (pressure and temperature) resulting from a full circumferential pipe break (double ended rupture) of either a main steam or feedwater pipe. Following such a postulated event, the steam tunnel vents the blowdown from the break to the turbine building. Rapid closing isolation valves close to limit the release of mass and energy from the break. Feedwater piping in the Unit 1 steam tunnel maintains its integrity post-LOCA to support feedwater leakage control.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, and it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The steam tunnel, Unit 1 has the following intended functions for 10 CFR 54.4 (a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1), 10 CFR 54.4(a)(2)]

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected (internal flooding mitigation; Seismic II/I). [10 CFR 54.4(a)(2)]
- Houses equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7] [10 CFR 54.4(a)(3)]

2.4.2.4 Auxiliary Boiler Building

Description

The auxiliary boiler building is a one-story structure. The building is located at the northeast corner of the plant. It is bounded on the south by the turbine building and on the west by the heater bay; the north and east walls are exposed. The auxiliary boiler building houses the auxiliary boiler, piping and other equipment associated with the auxiliary boiler system. The entire building is considered a single fire area.

The south and west walls separate the auxiliary boiler building from adjacent buildings and are constructed of reinforced concrete. The north and east walls are exposed to the outside and are constructed of metal siding. Walls to adjacent buildings have 3-hour fire resistance ratings with penetrations provided with 3- hour fire rated seals. Doorways to adjacent buildings are equipped with Class A fire doors. The floor is constructed of reinforced concrete and the roof is of steel frame and metal deck construction with roofing that meets FM Class I requirements.

The auxiliary boiler building is a non-seismic Category I structure that is not near any seismic Category I structures. There is in-scope fire protection water piping inside the auxiliary boiler building. There are no safe shutdown components in the auxiliary boiler building.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection.

The auxiliary boiler building has the following intended functions for 10 CFR 54.4 (a)(3) [Reference 1.3-1]:

- House equipment credited for fire protection (10 CFR 50.48) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]

References

UFSAR: 3.6.2.3.5.8 / Appendix 9A.4.17.1 / Figure 1.2-2

2.4.2.5 Heater Bay, Unit 1

Description

The heater bay is a four-story structure. The heater bay is bounded by the turbine building on the south, with the north and west walls exposed; most of the east wall is bounded by the auxiliary boiler building with the remainder of the wall exposed.

This building contains heaters associated with the condensate, feedwater and building heating systems, and pumps for feedwater and building heating. The entire heater bay is considered a single fire area. Walls are constructed of reinforced concrete, except for metal siding on the north wall. Doorways to adjacent buildings are equipped with Class A fire doors. Walls to adjacent buildings have 3-hour fire resistance ratings with all penetrations having 3-hour fire rated seals. Floors are constructed of reinforced concrete. Feedwater piping in the heater bay maintains its integrity post-LOCA to support feedwater leakage control. There is no safe shutdown equipment located in the heater bay.

The heater bay, Unit 1, is a non-Seismic Category I structure that is not near any Seismic Category I structures. There is in-scope fire protection water piping inside heater bay, Unit 1. The heater bay is credited with mitigation of internal flooding from the circulating water line break.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains nonsafety-related components that are relied upon to remain functional during or following a design basis event, because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The heater bay, Unit 1 has the following intended functions for 10 CFR 54.4 (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(2)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected (external and internal flooding mitigation). [10 CFR 54.4(a)(2)]
- House equipment credited for fire protection (10 CFR 50.48) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]

References

UFSAR: 3.6.2.3.5.8 / 3.8.4 / Appendix 9A.4.12 / 10.4.5.3.1 / Figure 1.2-2

2.4.2.6 Auxiliary Building, Unit 1

Description

The auxiliary building, Unit 1, is a three-story seismic Category I structure that is adjacent to the seismic Category I reactor building, radioactive waste and intermediate buildings. It is also adjacent to the non-seismic Category I Unit 1 turbine power complex and steam tunnel. The auxiliary building, Unit 1 is a concrete structure approximately 97 feet high by 102 feet wide by 192 feet long with the top of mat at elevation 568 feet 4 inches. The concrete floors are supported by interior columns, interior walls and by exterior walls. Exterior walls and the roof are a minimum of two feet thick for protection of safety-related equipment from exterior missiles, tornado wind pressure, and tornado depressurization. This building houses safety class systems and components for plant operation such as the residual heat removal (RHR) system, reactor core isolation cooling (RCIC) system, high and low pressure core spray (HPCS, and LPCS, respectively), reactor water cleanup (RWCU) system, and ventilation systems.

The auxiliary building has a tunnel to house the main steam and feedwater lines which run from the reactor building complex to the turbine building steam tunnel. The auxiliary building tunnel is approximately 36 feet wide and 28 feet high. The function of this tunnel is to withstand the pressures and temperatures that could be produced by a postulated break in a feedwater or main steam line. Seals are provided around the tunnel at its junction with the steam tunnel on one end and a similar tunnel coming from the shield building on the other end. The seals do not form a structural connection to these other tunnels and, therefore, the auxiliary building remains structurally separate from other buildings above the foundation.

The auxiliary building, Unit 1, is a three-story building. Doorways are equipped with fire doors. Walls and ceilings have 3-hour fire resistance ratings. Wall and ceiling penetrations have 3-hour fire rated seals.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection, equipment qualification, anticipated transients without scram, and for station blackout. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The auxiliary building, Unit 1 has the following intended functions for 10 CFR 54.4 (a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related equipment and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1); 10 CFR 54.4(a)(2)]

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]
- House equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48), for equipment qualification (10 CFR 50.49), for anticipated transients without scram (10 CFR 50.62), and for station blackout (10 CFR 50.63) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]

References

UFSAR: 3.3.2.2 / 3.8.4.1.2 / Appendix 9A.4.2 / Appendix 15C / Appendix 15.H / Figure 1.2-2 / Table 3.2-1

2.4.2.7 Control Complex

Description

The control complex is a seismic Category I structure that is located between the seismic Category I diesel generator building and intermediate building. It is also adjacent to the seismic Category I radwaste building on the north and the non-seismic Category I service building on the south. This building is a steel framed structure with exterior concrete walls of approximate dimensions 132-feet high, 141-feet wide and 142-feet long, with the top of the foundation mat at elevation 574 feet 10 inches.

The outside walls and roof of the control complex are 2-feet thick concrete for shielding and protection from exterior missiles and tornado wind pressure. The interior structure consists of steel columns, girders and beams with the floor decks of concrete. The building has no structural connection with other structures. The control complex is designed to limit depressurization caused by a design basis tornado.

The control complex is a six-story structure. Floors one and two are below grade and house heating, ventilation, and air conditioning equipment, mechanical equipment, offices and meeting rooms. Both floors house safe shutdown equipment. The third floor houses the 4.16 kV and 480 volt switchgear, remote shutdown panels, and 480-volt motor control centers for safety-related equipment. The fourth floor houses 125-volt dc distribution equipment and batteries. Cable spreading areas are also located on the fourth floor.

The control room is located on the fifth floor. The sixth floor houses heating, ventilation and air conditioning equipment.

Fire service piping located in the control complex is seismically supported in cases where analysis showed that rupture could cause failure of safety-related equipment by flooding. A flood barrier at door IB-103 (an 18" tall steel curb) has been installed to prevent water from a service water leakage crack in the control complex from entering the intermediate building.

The control room envelope comprises those areas to which the control room operator could require access during an emergency. The envelope includes those components that provide a boundary between the environment inside the control room and surrounding atmosphere. The components include the control room ventilation system, structural penetrations (electrical and mechanical), access doors (plenum, duct, personnel), door seals, as well as the walls, ceiling, and floor of the 654' elevation of the control complex and duct chase.

Housed within this control room envelope are the monitoring equipment, instrumentation and control panels required for safe operation and shutdown of the plant. The control room envelope is provided with fire protection equipment, adequate lighting, communications equipment, kitchen, sanitary, administrative and storage facilities, and spaces necessary to perform the normal plant operations required to maintain the plant in a safe condition following an accident.

Radiation protection, as required by 10 CFR 50.67 [Reference 1.3-7], is provided by shield walls on the four exposures, shield slabs at floor and ceiling, radiation monitoring equipment, and emergency filtering systems.

Sanitary fixtures inside the control room provide loop seals for maintaining the integrity of the control room envelope to protect personnel. Sanitary fixtures are considered as bulk commodities.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection, anticipated transients without scram, and for station blackout. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The control complex has the following intended functions for 10 CFR 54.4 (a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1), 10 CFR 54.4(a)(2)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected (internal flooding mitigation). [10 CFR 54.4(a)(2)]
- House equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48), for anticipated transients without scram (10 CFR 50.62) and for station blackout (10 CFR 50.63). [10 CFR 54.4(a)(3)]

2.4.2.8 Diesel Generator Building

Description

The diesel generator building is a seismic Category I structure that is located adjacent to the seismic Category I radioactive waste building and control complex, and to the non-seismic Category I service building. This structure is a reinforced concrete building approximately 165-feet long, 78-feet wide and 26-feet high, with the top of the foundation mat at elevation 620 feet 6 inches. The structural system consists of walls and a roof sized for protection against internal and external missiles. The exposed reinforced concrete walls and roofs of Seismic Category I structures have a minimum concrete thickness of 24 inches.

A reinforced concrete air intake and exhaust structure, 165-feet long, 32-feet wide and 20-feet high, is mounted to the roof of the building. The walls and top of this housing are also designed for missile protection, tornado wind pressure and tornado depressurization. In addition, concrete barriers are provided at the ventilation exhaust louvers to prevent external missiles from entering the diesel generator building.

The diesel generator building houses emergency generators, day tanks and other equipment necessary to supply standby electric power to operate safety systems in the event of a power failure of the plant generating equipment and offsite power.

Insulation has been installed within the emergency diesel generator exhaust missile barrier to protect the concrete from the combustion exhaust heat. During diesel generator operation, the temperature of the concrete surface is within the ACI 349 guidelines for short term operation.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection and station blackout. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The diesel generator building has the following intended functions for 10 CFR 54.4 (a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1), 10 CFR 54.4(a)(2)]

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]
- House equipment credited in the Appendix R safe shutdown analysis, for fire protection (10 CFR 50.48 [Reference 1.3-7]) and for station blackout (10 CFR 50.63 [Reference 1.3-7]) [10 CFR 54.4(a)(3)]

References

UFSAR: 3.8.4.1.7 / Appendix 9A.4.5.1 / Figure 1.2-2 / Table 3.2-1

2.4.2.9 Intermediate Building

Description

The intermediate building and fuel handling building share a common integral structure but are evaluated separately based on their unique functions. The intermediate building is a five-story reinforced concrete seismic Category I structure located between the fuel handling building and the control complex in the east-west direction and the two reactor buildings in the north-south direction. A 3-inch rattle space isolates the intermediate and fuel handling buildings from all other structures. The exterior walls are sized to insure protection from exterior missiles. The top of the foundation mat is at elevation 574'-10". The exposed walls and roofs of seismic Category I structures have a minimum concrete thickness of 24-inches and are reinforced each way on each face.

The function of the intermediate building is to house safety-related systems and equipment. Some of the systems in the intermediate building include the fuel pool cooling and cleanup system, reactor building chilled water systems, the annulus exhaust gas treatment system, reactor building and drywell purge system, and ventilation system equipment for the intermediate building and the fuel handling building.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection and anticipated transients without scram. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The intermediate building has the following intended functions for 10 CFR 54.4 (a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1); 10 CFR 54.4(a)(2)]

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]
- House equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7] and for anticipated transients without scram (ATWS) (10 CFR 50.62) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]

UFSAR: 3.8.4.1.4 / Appendix 9A.4.3 / Appendix 15C.5 / Figure 1.2-2 / Table 3.2-1

2.4.2.10 Fuel Handling Building

Description

The fuel handling building is a three-story building. The approximate plan dimensions are 144 feet by 108 feet with the top of the foundation mat at elevation 574 feet, 10 inches. The entire exterior of the building is reinforced concrete including the foundation, the walls and the roof slab. The seismic Category I building is designed to withstand tornado missiles, tornado wind pressure and tornado depressurization. The roof slab is supported by structural steel framing. Reinforced concrete is also used for the interior walls and slabs. The exposed walls and roofs of seismic Category I structures have a minimum concrete thickness of 24-inches and are reinforced each way on each face.

The functions of the fuel handling building are:

- Store new and spent fuel assemblies;
- House safety class equipment required to maintain the fuel assemblies;
- Protect the fuel assemblies and safety class equipment from the effects of the environment;
- Provide access to containment through the equipment access hatch;
- House additional safety-related equipment required to secure systems in the containment structure.

The fuel handling building is provided with four pools for fuel handling and storage. The pools are interconnected by means of gates, to allow the underwater passage of fuel assemblies from one pool to another. Each pool is a stainless steel lined concrete structure. The pool concrete structure with the liner is designed to seismic Category I requirements to prevent damage to the stored fuel. Spent fuel in the fuel handling building pools is stored in densified racks.

An overhead gantry crane is provided to handle and maneuver fuel assemblies between pools. A bridge crane traveling at right angles to the gantry crane handles fuel casks.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The fuel handling building has the following intended functions for 10 CFR 54.4 (a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related and nonsafety-related equipment within the scope of license renewal [10 CFR 54.4(a)(1), 10 CFR 54.4(a)(2)].
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected [10 CFR 54.4(a)(2)].
- House equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7] [10 CFR 54.4(a)(3)].

2.4.2.11 Offgas Building, Unit 1

Description

The offgas building, Unit 1 is a seismic Category I structure that is located adjacent to the non-seismic Category I Unit 1 turbine power complex and turbine building. This building is a reinforced concrete structure that houses equipment used in the filtering and absorption of radioactive non-condensable gases from the main and auxiliary condensers. The building is a four-story structural system that is completely enclosed by a 2-foot thick roof slab and exterior walls of 2-foot minimum thickness, which are designed to resist the postulated exterior missiles, tornado wind pressure and tornado depressurization. The top of the concrete mat foundation is at elevation 584 feet.

Functions (and scoping criteria, if intended function)

The offgas building is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, and it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The offgas building, Unit 1 has the following intended functions for 10 CFR 54.4 (a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1)]; [10 CFR 54.4(a)(2)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected (Seismic II/I). [10 CFR 54.4(a)(2)]
- Houses equipment credited for fire protection (10 CFR 50.48) [Reference 1.3-7], [10 CFR 54.4(a)(3)]

References

UFSAR: 3.8.4.1.8 / Appendix 9A.4.13.1 / Figure 1.2-2 / Table 3.2-1

2.4.2.12 Radioactive Waste Building

Description

The radioactive waste (radwaste) building is a seismic Category I structure that is located adjacent to the seismic Category I diesel generator building, control complex, intermediate building and auxiliary building, Unit 1. The safety-related portion of this building is a reinforced concrete structure of approximate dimensions 70 feet high, 101 feet wide and 217 feet long, with the top of the foundation mat at elevation 574 feet 10 inches. The radwaste building houses equipment used in the storage and processing of liquid and solid radioactive wastes. The exterior walls and roof of the safety class portion of the structure consists of 2 and 3 foot thick reinforced concrete to provide radiation shielding from the radioactive wastes.

Although the radwaste building contains no safety-related mechanical components, there are three safety-related conduits at Elevation 621 feet (approximately). The conduits support and protect electrical cables between the Control Complex on the south and an underground duct bank at the north wall of the radwaste building. There is in-scope fire protection water piping inside the radwaste building.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and non-safety-related components that are relied upon to remain functional during or following a design basis event, because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The radioactive waste building has the following intended functions for 10 CFR 54.4 (a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1); 10 CFR 54.4(a)(2)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]
- House equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]

References

UFSAR: 3.8.4.1.6 / Appendix 9A.4.14 / Figure 1.2-2 / Table 3.2-1

2.4.2.13 Service Building

Description

The service building is a three-story structure. It is bounded by the diesel generator building and control complex on the north, the intermediate building on the east, with the south and west walls exposed. The east wall is exposed above the roof of the hot shop addition. The service building contains offices, administrative facilities and shops for the plant, the security office, and the technical support center (TSC). The TSC is located in the basement. This entire three-story building, together with the basement, is considered a single fire area.

The service building north wall of the basement is constructed of reinforced concrete and constitutes a 3-hour rated fire barrier. Above elevation 620'-6" the north wall is constructed of drywall. Above the service building hot shop roof the east wall is an exterior wall constructed of metal siding. The south and west walls are exterior walls constructed of metal siding. The east side of the hot shop abuts the west wall of the Intermediate Building, which has a three-hour fire rating. The roof is of steel frame and metal deck construction with roofing that meets fire protection requirements. Doorways in the north wall are equipped with class A fire doors. A class A roll-up door is provided in the east side of the hot shop (el. 620'-0") in the intermediate building wall. Penetrations in the north wall are sealed to provide a 3-hour fire resistance rating.

No safe shutdown equipment is located in the service building.

Total failure of the service building due to tornado loads is precluded by design. The design approach used is based on building siding that blows off at a predictable wind load, considerably below maximum tornado wind pressure. Therefore, the critical load on the service building is the tornado wind pressures on the structural skeleton of the building. The structural components of the service building, including the foundation, are designed for these tornado wind pressures.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The service building has the following intended functions for 10 CFR 54.4 (a)(2) and (a)(3) [Reference 1.3-1]:

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]
- House equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]

References

Unit 2 Structures

On November 1, 2001, the NRC issued a letter to First Energy Nuclear Operating Company (FENOC) concluding that the Unit 2 Construction Permit (CP) CPPR-149 had been terminated (TAC NO. MA2219). This letter also referred to a PNPP letter to the NRC dated December 29, 1994 (PY-CEI/NRR-1899L), which included a Site Stabilization Plan. The Site Stabilization Plan stated the following:

> *"The Site Stabilization Plan concludes that termination of the PNPP, Unit 2, CP will not adversely impact the safe operation of PNPP, Unit 1. The licensee asserted that final reclamation and restoration of the PNPP site will be addressed upon decommissioning of PNPP, Unit 1. Systems and equipment that were originally to be shared by both units or intended for Unit 2, but are now used to support Unit 1 operations, will continue under full control of PNPP, Unit 1 programs. In addition, activities at the PNPP site which would have been conducted under the authority of the Unit 2 CP will be addressed, as appropriate, in PNPP, Unit 1, programs. Examples of such activities include the Physical Security Plan, the Quality Assurance Program, and the Fire Protection Program."*

The above statement is considered a commitment as issued in the Safety Evaluation Report (SER).

2.4.2.14 Reactor Building, Unit 2

Description

The reactor building Unit 2 is a safety-related, seismic Category I structure that is located adjacent to the seismic Category I intermediate, fuel handling, and Unit 2 auxiliary buildings. Although the reactor building Unit 2 was constructed similar to the Unit 1 reactor building, it contains no operating systems/equipment, it is not subject to any hydrodynamic loads, and its functions are limited to support and protection of interfacing systems/structures. A shield building forms a housing for the steel containment. The Unit 2 shield building is required to fulfill the structural integrity and shelter/protect license renewal functions.

The Unit 2 reactor building is a self-enclosed, domed structure that is seismically separated from adjacent structures by a 3-inch rattle space; however, the nuclear safety-related intermediate building and fuel handling building share part of the Unit 2 reactor building wall.

All piping and components going through penetrations to Unit 1 structures, regardless if active or retired-in-place, serve a license renewal function and act as a barrier to protect the spread of fire and flooding. The Unit 2 reactor building continues to remain as a seismic Category I structure.. The Unit 2 containment vessel acts as the anchor for structural integrity of some piping and components. The Unit 2 containment vessel functions are limited to structural support and as a rated fire barrier.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it provides shelter, support and protection for safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, and it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The Unit 2 reactor building has the following intended functions for 10 CFR 54.4 (a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1)]; [10 CFR 54.4(a)(2)]
- House equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]

References

UFSAR: 3.8.1.1 / 3.8.4.1.3.1 / 3.8.4.1.4 / Appendix 9A.4.23.1 / Appendix 9A.4.1 / Figure 1.2-2 / Figure 1.2-5 / Figure 1.2-6 /Figure 9A-3

2.4.2.15 Auxiliary Building, Unit 2

Description

The auxiliary building, Unit 2 is a seismic Category I structure that is adjacent to the Unit 2 reactor building and the intermediate building. It is also adjacent to the non-seismic Category I Unit 2 turbine power complex and steam tunnel. The Unit 2 auxiliary building is a concrete structure with the top of mat at elevation 568 feet, 4 inches. The concrete floors are supported by interior columns, interior walls and by exterior walls. Exterior walls and the roof are a minimum of two feet thick for protection of equipment from exterior missiles, tornado wind pressure, and tornado depressurization.

The Unit 2 auxiliary building combustible loading is very low. Due to the presence of combustibles, the Unit 2 auxiliary building has 3-hour rated fire separation from the intermediate building, which contains equipment required for Unit 1 operation. This separation is provided by the reinforced concrete intermediate building south wall, fire doors, and penetration seals. Penetrations, doors, and ducts are adequately sealed to prevent fire spread. The Unit 2 auxiliary building houses M38 system ducting and louvers that connect to the plant vent that serves to connect service building hot shop ventilation to the plant vent.

All piping and components going through penetrations from the Unit 2 auxiliary building to Unit 1 structures, regardless if active or retired-in-place, serve license renewal function and act as a barrier to protect the spread of fire and flooding.

The Unit 2 auxiliary building has no safety-related nor safe shutdown equipment. The building provides seismic support for nonsafety-related service water piping to meet break exclusion criteria.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it provides shelter, support and protection for nonsafety-related components that are relied upon to remain functional during or following a design basis event, and because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The Unit 2 auxiliary building, has the following intended functions for 10 CFR 54.4 (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(2)]

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]
- Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for fire protection (10 CFR 50.48) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]

UFSAR: 3.6.2.3.5.2 / Appendix 9A.4.23.2 / Figure 1.2-2

2.4.2.16 Turbine Building, Unit 2

Description

The Unit 2 turbine building is a five-story structure bounded by the Unit 2 offgas building, Unit 2 turbine power complex and Unit 2 steam tunnel along the majority of the north wall, and is partially bounded by the Unit 2 heater bay on the south. The remainder of the north and south walls, and the east and west walls, are exposed. This building does not contain components required for safe shutdown of Unit 1 and is not designated as a fire area. Also, the Perry Appendix R Evaluation, Safe Shutdown Capabilities Report, does not credit turbine building Unit 2 for fire protection. However, it does contain equipment that supports Unit 1 operation. Walls separating the turbine building from other buildings are constructed of either reinforced concrete or drywall. Floors are of reinforced concrete with numerous penetrations and metal gratings where equipment extends through floors. The roof is of steel frame and metal deck construction.

Fire propagation from the Unit 2 turbine building to the Unit 1 buildings is prevented by spatial separation of the buildings and the 3-hour rated barriers between the Unit 2 reactor building, Unit 2 auxiliary building and the intermediate building.

The Unit 2 turbine building is a non-seismic Category I structure that is not near any seismic Category I structures. A number of the turbine building penetrations are designed to control flooding by allowing service water to flow into the adjacent heater bay and condensate demineralizer buildings. The source of service water is postulated to be from a service water piping crack or break in the Unit 2 turbine power complex.

Power cables from the Unit 2 startup transformer are routed through the Unit 2 turbine building to the Unit 2 turbine power complex.

P54 fire water piping to Unit 2 startup transformer is routed through the Unit 2 auxiliary building, turbine power complex (and condensate demineralizer building), and Unit 2 turbine building.

Total failure of the turbine building due to tornado loads is precluded by design. The design approach used is based on building siding that blows off at a predictable wind load, considerably below maximum tornado wind pressure. Therefore, the critical load on the turbine building is the tornado wind pressures on the structural skeleton of the building. The structural components of the turbine building, including the foundation, are designed for these tornado wind pressures.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it provides shelter, support and protection for nonsafety-related components that are relied upon to remain functional during or following a design basis event, and because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for station blackout. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions. The structure is also relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for fire protection.

The Unit 2 turbine building, has the following intended functions for 10 CFR 54.4 (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(2)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]
- House equipment credited for station blackout (10 CFR 50.63) [10 CFR 54.4(a)(3)].
- Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for fire protection (10 CFR 50.48). [10 CFR 54.4(a)(3)]

References

UFSAR: 3.3.2.3 /3.6.2.3.5.9.2 / Appendix 9A.4.23 / Appendix 9A.4.23.5 / Figure 1.2-2 / Table 3.2-1

2.4.2.17 Turbine Power Complex (Condensate Demineralizer Bldg.), Unit 2

Description

The Unit 2 turbine power complex is a four story structure bounded by the Unit 2 turbine building on the south, the Unit 2 steam tunnel on the east and the Unit 2 offgas building on the west; the north wall is partially bounded by the Unit 2 auxiliary building with the remainder of the wall exposed. This building does not contain components required for safe shutdown of Unit 1 and is not designated as a fire area. Also, the Perry Appendix R Evaluation, Safe Shutdown Capabilities Report does not credit the Unit 2 turbine power complex for fire protection. However, it does contain equipment that supports Unit 1 operation.

Exterior walls are constructed of metal siding. Walls adjacent to other buildings are of reinforced concrete or drywall construction. These walls are built to 3-hour rated construction specifications; however, all penetrations are not sealed. Doorways to the adjacent Unit 2 auxiliary building are equipped with fire doors. Floors are constructed of reinforced concrete. The roof is of metal deck.

With the presence of smoke detection in Unit 2 turbine power complex, the low combustible loading in the adjacent Unit 2 auxiliary building, and the 3-hour fire barrier separating Unit 2 reactor building, the Unit 2 auxiliary building, and the intermediate building, adequate protection is provided to prevent fire propagation from the Unit 2 turbine power complex to Unit 1 fire areas.

The Unit 2 turbine power complex has the condensate demineralizer building as its basement. The Unit 2 turbine power complex is a non-seismic Category I structure located adjacent to the seismic Category I Unit 2 auxiliary building. Parts of the structure are retired in place. The condensate demineralizer building volume is used to mitigate internal flooding from a service water line break, and its penetrations prevent flooding of the Unit 2 auxiliary building below the 599 ft. elevation. The Unit 2 turbine power complex provides support and shelter for electrical equipment that connects the Unit 2 startup transformer to the safety-related electrical power system.

P54 fire water piping to the Unit 2 startup transformer is routed through Unit 2 auxiliary building, Unit 2 turbine power complex (and condensate demineralizer building), and Unit 2 turbine buildings.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it provides shelter, support and protection for nonsafety-related components that are relied upon to remain functional during or following a design basis event, and because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for station blackout. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions. The structure is also relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for fire protection.

The Unit 2 turbine power complex has the following intended functions for 10 CFR 54.4 (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for nonsafety-related equipment within the scope of license renewal [10 CFR 54.4(a)(2)].
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected [10 CFR 54.4(a)(2)].
- House equipment credited for station blackout (10 CFR 50.63 [Reference 1.3-7]) [10 CFR 54.4(a)(3)].

- Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for fire protection (10 CFR 50.48) [Reference 1.3-7] [10 CFR 54.4(a)(3].

2.4.2.18 Heater Bay, Unit 2

Description

The Unit 2 heater bay is a four-story structure bounded by the Unit 2 turbine building on the north, with the east, south and west walls exposed. This building does not contain components required for safe shutdown of Unit 1 and is not designated as a fire area. Walls are constructed of reinforced concrete, except for metal siding on the south wall. Walls to adjacent buildings have 3-hour rated construction. Floors are constructed of reinforced concrete. Fire propagation from the Unit 2 heater bay to Unit 1 buildings is prevented by spatial separation of the buildings and the 3-hour rated barriers between the Unit 2 auxiliary building and the intermediate building.

The Unit 2 heater bay is a non-seismic Category I structure that is not near any seismic Category I structures. There is a section of in-scope fire protection water piping inside the Unit 2 heater bay. The heater bay is credited with mitigation of internal flooding from a service water line break. Penetrations between the Unit 2 heater bay and the Unit 2 turbine building have been credited for internal flood protection.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions. The Unit 2 heater bay has the following intended functions for 10 CFR 54.4 (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(2)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected (external and internal flooding mitigation). [10 CFR 54.4(a)(2)]
- House equipment credited for fire protection (10 CFR 50.48 [Reference 1.3-7]). [10 CFR 54.4(a)(3)]

2.4.2.19 Offgas Building, Unit 2

Description

The Unit 2 offgas building is located adjacent to the Unit 2 turbine power complex and Unit 2 turbine building. The building is a four-story structure that is completely enclosed by 2-foot thick reinforced concrete roof slab and exterior walls, which are designed to resist the postulated exterior missiles, tornado wind pressure and tornado depressurization. This building does not contain components required for safe shutdown of Unit 1 and is not designated as a fire area. Fire propagation from the Unit 2 offgas building to the Unit 1 buildings is prevented by spatial separation of the buildings and the 3-hour rated barriers between the Unit 2 auxiliary building and the intermediate building.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The Unit 2 offgas building has the following intended function for 10 CFR 54.4 (a)(2) [Reference 1.3-1]:

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]

2.4.2.20 Steam Tunnel, Unit 2

Description

The Unit 2 steam tunnel is a structure located between Elevations 614”-6” and 620’-6” that was designed to house main steam, feedwater and other major pipes extending from the Unit 2 reactor building. The tunnel extends in the north-south direction from the Unit 2 reactor building, through the Unit 2 auxiliary building at Elevation 620’-0”, connects to the east end of the Unit 2 turbine power complex, and continues to the Unit 2 turbine building. It is constructed of reinforced concrete. This structure does not contain components required for safe shutdown of Unit 1 and is not designated as a fire area. Fire propagation from the Unit 2 Steam Tunnel to the Unit 1 buildings is prevented by the 3-hour rated barriers between the Unit 2 reactor building and the intermediate building, and the Unit 2 auxiliary building and the intermediate building.

The steam tunnel, Unit 2 structure is credited for flood mitigation purposes.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The Unit 2 steam tunnel has the following intended function for 10 CFR 54.4 (a)(2) [Reference 1.3-1]:

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected (external flooding mitigation). [10 CFR 54.4(a)(2)]

Yard Structures

2.4.2.21 Central Oil Unloading/Tank Fill Station

Description

The central oil unloading/tank fill station is a Seismic Category I structure located west of the Seismic Category I diesel generator building. The structure provides a central location for unloading diesel fuel for the underground diesel generator fuel tanks. The above ground piping is protected by missile shields.

Flood barriers are used to ensure that the floodwater elevations for a local intense precipitation event do not exceed and enter the Unit 1 diesel generator flame arrestors.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event and includes nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The central oil unloading/tank fill station has the following intended functions for 10 CFR 54.4 (a)(1) and (a)(2) [Reference 1.3-7]:

- Provide shelter, support and protection for safety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]

References

UFSAR: 9.5.4 / Figure 1.2-2 / Table 1.8-1 / 3.5-5 / 3.5-6

2.4.2.22 Diesel Generator Fuel Oil Tank Maintenance Structures

Description

The diesel generator fuel oil tank maintenance structures are seismic Category I structures located near the seismic Category I diesel generator building. The maintenance structures are concrete structures that provide access to the underground diesel fuel oil storage tanks. The maintenance structures also provide tornado missile protection to the tanks and associated mechanical components.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event.

The diesel generator fuel oil tank maintenance structures have the following intended functions for 10 CFR 54.4 (a)(1) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1)]

References

UFSAR: 9.5.4.3 / Appendix 9A.4.6.2.1 / Figures 1.2-2 / 9.5-22 sheet 2 / Table 3.5-5

2.4.2.23 Circulating Water Pumphouse

Description

The circulating water pumphouse is a non-Seismic Category I steel-framed structure that is not near any Seismic Category I structures. There is in-scope fire protection water piping inside the pumphouse.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection. The circulating water pumphouse has the following intended functions for 10 CFR 54.4 (a)(3) [Reference 1.3-1]:

- House equipment credited for fire protection (10 CFR 50.48) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]

References

UFSAR: Figure 1.2-2 / Table 3.2-1

2.4.2.24 Condensate Storage Tank Dike and Instrument Missile Shield

Description

The condensate storage tank (CST) dike and instrument missile shield is a seismic Category I structure that is not near any seismic Category I structures. The structures protect the CST and associated instrumentation. The CST is supported by a ring girder which in turn rests on a 3 feet-6 inch common foundation mat with the dike. To preclude an uncontrolled release of the content of the CST, the tank is located within a concrete retaining structure (dike) designed to seismic 1 requirements. The dike is designed to accommodate the total liquid capacity (i.e., 500,000 gallons) of the CST with at least one-foot freeboard.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event. The condensate storage tank dike and instrument missile shield have the following intended functions for 10 CFR 54.4 (a)(1) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related equipment and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1)]

2.4.2.25 Foundations (Tanks, Transformers, Transmission Towers, etc.)

Description

The foundations (tanks, transformers, transmission towers, etc.) are foundations for yard structures that are of similar construction. Foundations that are associated with concrete yard structures are evaluated as part of those structures. The foundations for the following yard structures are evaluated in this general foundation category:

- carbon dioxide tank
- high mast light #7
- hydrant houses for fire hydrants
- interbus transformers
- start-up transformers
- transmission towers and other switchyard components

The carbon dioxide tank is north of the Seismic Category I fuel handling building and provides carbon dioxide for fire protection.

High mast light #7 is close enough to the safety-related intermediate building that it could strike the building if it were to fall.

Hydrant house foundations are in scope for each in-scope fire hydrant that is provided with a hydrant house.

Interbus and start-up transformers are available for SBO recovery.

Transmission towers and other switchyard components support the pathways available for SBO recovery. Transmission towers are located in the transmission switchyard and the Plant Yard.

Functions (and scoping criteria, if intended function)

The structures are within the scope of license renewal because they contain components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection and station blackout, and because they contain nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The foundations (tanks, transformers, transmission towers, etc.) have the following intended functions for 10 CFR 54 (a)(2) and (a)(3) [Reference 1.3-1]:

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]
- House or supports equipment credited in the Appendix R safe shutdown analysis for fire protection (10 CFR 50.48 [Reference 1.3-7]) and station blackout (10 CFR 50.63 [Reference 1.3-7]). [10 CFR 54.4(a)(3)]

2.4.2.26 Fuel Oil Storage Tank Dike

Description

The reinforced concrete fuel oil storage tank dike surrounds the auxiliary boiler fuel oil storage tank that is located approximately 240 feet east of the Unit 1 auxiliary boiler and turbine buildings. The dike surrounds the tank to contain potential spillage which helps prevent a fire in this region of the yard area from spreading to buildings or locations containing safe shutdown equipment.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it is relied on to perform a function that demonstrates compliance with the regulations for fire protection.

The fuel oil storage tank dike has the following intended function for 10 CFR 54.4 (a)(3) [Reference 1.3-1]:

- Supports equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7], [10 CFR 54.4(a)(3)]

References

UFSAR: 2.2.3.1.3.1 / Appendix 9A.4.9.3

2.4.2.27 Fuel Oil Pumphouse

Description

The fuel oil pumphouse is a single-story structure located next to the auxiliary boiler fuel oil storage tank. The exterior walls are made of concrete blocks. The roof is made up of steel deck with foam insulation. This building houses fire protection piping, and suppression equipment associated with the auxiliary boiler fuel oil storage tank.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection.

The fuel oil pumphouse has the following intended function for 10 CFR 54.4 (a)(3) [Reference 1.3-1]:

- Supports equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7], [10 CFR 54.4(a)(3)].

References

UFSAR: 3.3.2.3 / 9.5.1.2.5.a

2.4.2.28 High Mast Light #7

Description

High mast light #7 is close enough to the safety-related fuel handling / intermediate building that it could strike the building if it were to fall.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it is a nonsafety-related component whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

High mast light #7 has the following intended function for 10 CFR 54.4 (a)(2) [Reference 1.3-1]:

- Maintain integrity of non-safety related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)].

References

None

2.4.2.29 Hydrant Houses

Description

Each in-scope fire hydrant is provided with a hydrant house containing 2-1/2 inch hose, combination fog nozzle and auxiliary equipment. Hydrant houses are prefabricated galvanized steel buildings.

Functions (and scoping criteria, if intended function)

The structures are within the scope of license renewal because they contain components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection.

- The hydrant houses have the following intended function for 10 CFR 54.4 (a)(3) [Reference 1.3-1]:
- Supports equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7], [10 CFR 54.4(a)(3)]

References

UFSAR: Appendix 9A.4.9.1.1/ Appendix 9A.4.9.2.1.1/ Appendix 9A.4.9.3.1/ Appendix 9A.4.9.4.1/ Appendix 9A.5E.2(g)

2.4.2.30 Manholes and Duct Banks

Description

Manholes

Manholes are reinforced concrete structures that are used in various systems. There are five safety-related in-scope electrical manholes, 13 underdrain manholes and 13 gravity discharge manholes that are in-scope. Manholes are seismic class 1 structures. The manhole roofs were designed to resist tornado missiles. In particular, the removable 30-inch deep beams were designed to resist a maximum equivalent static load determined from consideration of the impact of tornado missiles on the roof of the manholes.

Underdrain Manholes

The 13 underdrain manholes and the 13 gravity discharge manholes are all part of the pressure relief underdrain system. The in-scope manholes are seismic Category I structures. The underdrain manholes are reinforced concrete vertical shafts having rectangular cross sections with 18-inch thick walls. All 26 of the manholes are penetrated by the steel gravity drainpipe at approximate invert elevation 585’-0”. The underdrain manholes are also penetrated by a 12-inch diameter porous concrete pipe at elevation 568’-6” or lower. Manholes are concrete structures buried in structural backfill. All underdrain system manholes have gasketed, watertight covers installed at the surface.

Electrical Manholes

The electrical manholes are reinforced concrete boxes used as distribution points for cable routing. The manholes are all less than 18 feet deep, and approximately 15 feet by 15 feet in plan or smaller. The walls are 18 inches thick for four of the five safety class manholes and 12 inches thick for one relatively small manhole (7 feet by 7 feet in plan). All these manholes have 30-inch thick roofs for missile protection. Access to the manholes is provided through 30-inch deep removable concrete beams. Permanent steel curbing is installed around the hatches of four safety-related, electrical manholes to protect against flooding.

Note: There are four safety-related electrical manholes, however, the fifth manhole, even though constructed as safety-related and described in UFSAR, does not contain any SR cables. Therefore, for the purpose of aging management, the four safety-related electrical manholes are in scope. Electrical Manhole MH7, which is nonsafety-related, contains cables which perform a license renewal intended function and therefore is within the scope of license renewal.

Duct Banks

Duct banks are used at Perry to allow underground routing of cables and piping. Seismic Category I concrete underground duct banks support safety-related electrical cables. Other concrete underground duct banks support nonsafety-related cables for station blackout or fire protection. Duct banks are founded on compacted class A backfill or on controlled low strength material (CLSM). The concrete foundations for the duct banks have been designed using the code ACI-318-71 [Reference 1.3-18].

Functions (and scoping criteria, if intended function)

The manholes and duct banks are within the scope of license renewal because they provide shelter, support and protection for safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, and because they contain components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection and station blackout. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The manholes and duct banks have the following intended functions for 10 CFR 54.4 (a)(1), (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related and nonsafety-related equipment within the scope of license renewal [10 CFR 54.4(a)(1), 10 CFR 54.4(a)(2)];
- Maintains integrity of nonsafety-related structural components such that safety functions are not affected (external flooding mitigation) [10 CFR 54.4(a)(2)]; and,
- House equipment credited in the Appendix R safe shutdown analysis for fire protection (10 CFR 50.48 [Reference 1.3-7]) and for station blackout (10 CFR 50.63 [Reference 1.3-7]) [10 CFR 54.4(a)(3)].

2.4.2.31 Primary Access Facility

Description

The primary access facility (PAF) is a non-seismic Category I steel framed structure that is not near any seismic Category I structures. The PAF is a two-story building located west of the service building. It is an isolated structure containing offices and personnel processing equipment. There is no safe shutdown equipment located in the PAF. There is a section of in-scope fire protection water piping inside the PAF.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection.

The primary access facility has the following intended functions for 10 CFR 54.4 (a)(3) [Reference 1.3-1]:

- House equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7], [10 CFR 54.4(a)(3)].

References

UFSAR: Appendix 9A.4.20/ Figure 1.2-2

2.4.2.32 Railroad Bridge

Description

The reconstituted major stream probable maximum flood (PMF) analysis introduces a new potential failure mechanism for the railroad bridge which could result in a downstream flow restriction should the bridge fail and inherently decreases the reliability of the bridge to perform as intended. This condition has been analyzed and based on the current configuration confirms that the bridge and supporting structure can withstand the resultant forces from the PMF including any debris that may be transported by the watercourse.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it is a nonsafety-related component whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The railroad bridge has the following intended function for 10 CFR 54.4 (a)(2) [Reference 1.3-1]:

- The railroad bridge is a nonsafety-related structure whose failure could prevent satisfactory accomplishment of any of the functions of safety-related systems (external flood mitigation), [10 CFR 54.4(a)(2)].

References

UFSAR: 2.4.3.5

2.4.2.33 Service Water Valve Pit

Description

The service water valve pit is a seismic Category I structure that is located east of the reactor building. The service water valve pit is an underground concrete structure approximately 18 feet high by 15 feet wide by 18 feet long, with the top of the mat at Elevation 602 feet. It houses safety class valves for the service water system. The concrete mat, walls and roof are two feet thick. The function of this structure is to protect the safety class service water valves from a seismic event and external missile hazards.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it provides shelter, support and protection for safety-related components that are relied upon to remain functional during or following a design basis event.

The service water valve pit has the following intended function for 10 CFR 54.4 (a)(1) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1)]

References

UFSAR: 3.8.4.n / 3.8.4.1.15 / 3.8.4.3.2.1.k / Figure 1.2-2 / Figure 3.8-75

2.4.2.34 Spent Fuel Dry Storage (SFDS) Electrical Building

Description

The spent fuel dry storage (SFDS) electrical building is a one story, non-seismic Category I concrete block structure with a steel roof that is not near any seismic Category I structures. There are flood barriers inside the SFDS electrical building.

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The SFDS electrical building has the following intended functions for 10 CFR 54.4 (a)(2) [Reference 1.3-1]:

- House nonsafety-related equipment that protects safety-related equipment from flooding. [10 CFR 54.4(a)(2)]

References

UFSAR: 9.1.4.2.10.14 / Appendix 9A.4.9.7 / Figure 1.2-2

2.4.2.35 Thrust Blocks

Description

Thrust blocks are underground concrete blocks that protect fire protection water piping from excessive movement.

Functions (and scoping criteria, if intended function)

The structures are within the scope of license renewal because they are relied on to perform a function that demonstrates compliance with the regulations of fire protection.

The Thrust Blocks have the following intended function for 10 CFR 54.4 (a)(3).

- Supports equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7] [10 CFR 54.4 (a)(3)].

References

None

2.4.2.36 Transformer Concrete Curbs and Fire Barriers (U1 Main, U1/2 Startup, U1/2 Interbus Transformers)

Description

The Unit 1 startup transformer, unit auxiliary transformer and main transformer (which consists of three single phase transformers) are located in the Unit 1 portion of the yard area just north of the turbine building and west of the heater bay and hydrogen storage tanks. Three Unit 1 interbus transformers are located along the outside of the south wall of the Unit 1 turbine power complex. The Unit 2 startup transformer is located just outside of the west wall of the Unit 2 turbine building. Three Unit 2 interbus transformers are located along the outside of the north wall of the Unit 2 turbine power complex.

Fire suppression for the Unit 1 main transformers, Unit 1 startup transformer and the Unit 2 startup transformer is provided by a water spray deluge system that is manually activated. Heat detectors located at each of these transformers provide annunciation signals to the Control Room that can be used to determine if initiation of the deluge system is necessary. Fire suppression for the Unit 1 auxiliary transformer, the Unit 1 interbus transformers and the Unit 2 interbus transformers consists of a deluge water spray system that is activated automatically by a signal from the heat detectors located at each transformer.

Fire barriers are provided between phases of the main transformer and on the east and west sides of the unit auxiliary transformer. Each transformer is surrounded by a curb to contain any oil leakage. Interbus transformers are separated from each other by fire barriers and are surrounded by a curb to contain any oil leakage. All building walls located within 50 feet of any of these transformers has a minimum fire resistance rating of 2 hours.

The concrete curb and fire barriers provide fire protection for the transformers. These are considered as structural bulk commodities, for details, refer to Section 2.4.4.

2.4.2.37 Transmission Towers

Description

The transmission towers are non-seismic category 1 structures that are located in the transmission station switchyard and the yard, isolated from seismic Category I structures. The transmission towers provide support for the power lines that are credited to provide offsite power for accident mitigation and recovery from a station blackout. The towers have been designed for worst case environmental conditions and tested beyond the governing national electric safety code requirements. The analysis and testing to this code shows that the structural failure of one tower will not result in the loss of the preferred power supply to the onsite electrical distribution system.

Functions (and scoping criteria, if intended function)

The structures are within the scope of license renewal because they provide support for nonsafety-related components that are relied upon to remain functional during or following a design basis event, and support components that are relied on to perform a function that demonstrates compliance with the regulations for station blackout.

The transmission towers have the following intended functions for 10 CFR 54.4 (a)(2) and (a)(3) [Reference 1.3-1]:

- Provide support for nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(2)]
- Supports equipment credited for recovery from station blackout (10 CFR 50.63 [Reference 1.3-7]). [10 CFR 54.4(a)(3)]

References

UFSAR: 3.8.4 / 3.9.1.2.6.g / 8.2.1 / 8.2.2.1.c / Figure 1.2-2 / Figure 8.2-3

2.4.2.38 Valve Support Slabs

Description

The valve support slabs are non-seismic Category I buried structures that are located under fire protection water valves. The valve support slabs provide support for the valves.

Functions (and scoping criteria, if intended function)

The structures are within the scope of license renewal because they are relied on to perform a function that demonstrates compliance with the regulations of fire protection.

The Valve Support Slabs have the following intended functions for 10 CFR 54.4 (a)(3):

- Supports equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48) [Reference 1.3-7] [10 CFR 54.4 (a)(3)].

References

None

2.4.2.39 Water Treatment Building

Description

The water treatment building is a two-story structure. The building is located on the Unit 1 side of the plant. It is bounded by the turbine building on the east; the north, south and west walls are exposed. The water treatment building houses process equipment required to convert raw water into the various grades of water used in the plant. For fire hazards analysis, this entire two-story building is considered a fire area.

The east wall, shared with the turbine building, is constructed of drywall and has a 3-hour fire resistance rating. The north, south and west walls are exterior walls constructed of metal siding. The roof is of steel frame and metal deck construction with roofing that meets Factory Mutual (FM) Class I requirements. Doorways in the east wall are equipped with Class A fire doors. Other penetrations in this wall are sealed to provide a 3-hour fire resistance rating. No safe shutdown equipment is located in the water treatment building.

The objective for this fire area is to prevent fire within the water treatment building from endangering the ability to safely shut down the plant. This objective is achieved since this building has a low fire loading and is remote from safe shutdown equipment in other buildings.

The water treatment building houses components within the scope of license renewal (e.g., a flapper valve located in the sludge holding sump within the building which prevents back flow into the DG building oil interceptor tank).

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection, and the structure contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The water treatment building has the following intended functions for 10 CFR 54 [(a)(2)] and [(a)(3)] [Reference 1.3-1]:

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected (external flooding mitigation). [10 CFR 54.4(a)(2)]
- Relied on in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for fire protection (10 CFR 50.48) [Reference 1.3-7]. [10 CFR 54.4(a)(3)]

2.4.3 WATER CONTROL STRUCTURES

The following structures are included in this review:

- Emergency Service Water (ESW) Pumphouse
- ESW Intake and Discharge (Alternate Intake) Tunnels including Ice Protection Caissons, Intake Structures, and Discharge Structure
- ESW Swale, and
- Major and Minor Streams

Descriptions

2.4.3.1 Emergency Service Water Pumphouse

Description

The emergency service water pumphouse (ESWPH) is a single story reinforced concrete structure, rectangular in plan, located between the nonsafety-related service water pumphouse (SWPH) and the nonsafety-related discharge tunnel entrance structure. It is an isolated structure located north of the main plant area with the SWPH as the closest building. The five-foot thick foundation mat is placed on one foot of porous concrete which is founded on chagrin shale at approximately elevation 531 feet. The structure has a reinforced concrete floor at elevation 586 feet 6 inches, which supports the pumps and screens. Above this floor an overhead crane is supported on steel girder rails which bear on reinforced concrete wall pilasters. Above that is a 2-foot thick reinforced concrete roof supported by steel girders spanning the width of the building. Penetrating through the foundation mat are the 10-foot diameter riser shafts from the emergency and alternate emergency intake tunnels, which supply the ESWPH with water from Lake Erie, the ultimate heat sink. Below the floor at elevation 586 feet 6 inches, the ESWPH is divided into compartments that are separated by means of reinforced concrete walls. During normal operation, lake water will be supplied to the ESW pumps through the intake tunnel. Should the intake tunnel become obstructed, an alternate source of lake water is available through the discharge tunnel. Under normal operating conditions, the discharge tunnel is isolated from the ESWPH by means of motor operated sluice gates. During an emergency, these gates will be opened to supply the necessary lake cooling water to the ESW pumps.

The concrete floor and roof slabs, as well as the concrete walls of the ESWPH structure have been designed to withstand local seismic accelerations; those below ground level and submerged in water are designed to resist the forces due to sloshing earthquake effect. The walls and floors below ground level retaining the backfill are designed to resist the dynamic (earthquake) soil pressure.

The shell of the structure (exterior above ground walls and the roof) were designed for tornado and missile loads. Further, the exterior walls below grade level were checked for the extreme environmental loads of the water table to grade. A 10-foot diameter cross tie tunnel between the Discharge Tunnel and the ESWPH is provided as a redundant water supply for the emergency service water pumps. The ESWPH includes a porous concrete blanket beneath the foundation base mat, extending vertically up along the exterior building walls. For fire hazards analysis, the ESWPH is divided into two fire areas and two fire zones.

This building houses pumps and associated equipment required to supply cooling water for safe shutdown systems. One area of the ESWPH houses the motor driven fire pump and equipment for the ESW system, including ESWPH traveling screens/motors, screen wash pumps, ESW pumps, discharge strainers, and associated control equipment. The ESWPH also houses nonsafety-related equipment that are within the scope of license renewal, e.g., portable water hose connections, eyewash and safety shower, flow elements and test isolation valves and tubing that provide a leakage boundary, failure of which may result in spatial interaction or spraying/wetting of safety-related equipment.

Walls, floor and ceiling are constructed of reinforced concrete. Access to the area is provided from the outside by doors at grade. The northeast corner of the ESWPH houses the diesel driven fire pump, control panel, diesel engine, and diesel fuel oil tank in the fire service room. Room walls, floor and ceiling are constructed of reinforced concrete. Interior walls have a 3-hour fire resistance rating and are equipped with Class A fire doors. The walls and ceiling have 3-hour fire resistance ratings (except for a 2 ft by 2 ft hatch in the ceiling, which is not required to be fire rated).

The ESWPH also provides storage of FLEX pumps and other miscellaneous equipment. Perry's FLEX lake water pumps have been pre-deployed in this building.

Interim shoreline protection near the ESWPH structure has been installed since 1983. In 2015, as part of the diversion stream installation, an armor stone revetment was installed at the outfall of the diversion stream. The armor stone revetment protects approximately 100 feet of shoreline.

The Interim Shoreline Protection is not credited or relied upon to protect any safety-related SSC since periodic monitoring assures sufficient margin exists in maintaining the minimum distance from toe/crest of bluff to the ESWPH structure. If the shoreline retreat becomes threatening to the safety-related structures, the shoreline will be protected by a suitable permanent construction that will protect the face and toe of the bluff. Final design and permit applications for the shoreline permanent protection construction will be initiated when the lake shoreline (toe of bluff) has receded to a point 250 feet away from the closest safety class structure [ESWPH].

Functions (and scoping criteria, if intended function)

The structure is within the scope of license renewal because it contains safety-related and nonsafety-related components that are relied upon to remain functional during or following a design basis event, because it contains components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection, anticipated transients without scram, and station blackout. The structure also contains nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The ESW pumphouse and associated structures have the following intended functions for 10 CFR 54.4 (a)(1), (a)(2), and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related equipment and within the scope of license renewal. [10 CFR 54.4(a)(1)]
- Provide access to the ultimate heat sink to the emergency service water system for mitigation of design basis events. [10 CFR 54.4(a)(1)]
- Provides missile (internal or external) barrier. [10 CFR 54.4(a)(1)]
- Sluice gates provide a pressure boundary function to isolate the ESW forebay from the discharge tunnel. [10 CFR 54.4(a)(1)]
- Provide shelter, support and protection for nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(2)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]
- House equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48 [Reference 1.3-7]), anticipated transients without scram (10 CFR 50.62 [Reference 1.3-7]) and for station blackout (10 CFR 50.63 [Reference 1.3-7]). [10 CFR 54.4(a)(3)]

2.4.3.2 ESW Intake and Discharge (Alternate Intake) Tunnels Including Ice Protection Caissons, Intake Structures and Discharge Structure

Description

Intake and Alternate Intake (Discharge) Tunnels

Cooling water for PNPP is obtained from Lake Erie, carried to the plant site through a greater than 2,800 feet long, 10-foot diameter intake tunnel located in the underlying bedrock. The water is then returned to the lake through a similar discharge tunnel approximately 2,000 feet long. Two 10 foot diameter tunnels, each only a few hundred feet long, intersect the main cooling water tunnels near the shore facilities. Their only purpose is to draw cooling water for the ESWPH, either from the intake or the discharge tunnel.

The portions of the tunnels that supply water to the emergency service water cooling system, as well as the intake structure, discharge tunnel and ESWPH, are designed as seismic category I structures. All safety-related emergency service water discharge structures and piping are either tornado missile protected or have been evaluated for the probability of tornado missile strikes.

Intake Structure

Located approximately 2,600 feet offshore, each of the two independent intake structures is a submerged steel plate multiport structure, circular in plan, resting on a working mat founded in shale bedrock at a minimum depth of four feet below the bottom of Lake Erie. Each intake is composed of an independent 36-foot diameter circular intake head that is connected to a six-foot diameter vertical down-shaft which conveys the cooling water to the underground ten-foot diameter intake tunnel. Each of the two intake heads is provided with a horizontal circular velocity cap and vertical inflow ports around the periphery.

The Intake Structure is a safety-related structure as it supplies water to both the ESWPH and the SWPH. The portions of the tunnels that supply water to the emergency service water cooling system, as well as the intake structure, discharge tunnel and ESWPH, are designed as seismic category I structures.

Discharge Structure

The discharge structure is located approximately 1,650 feet offshore. The offshore discharge structure consists of a submerged 3-foot diameter steel diffuser nozzle encased in a 17-foot diameter protective reinforced concrete ice protection caisson founded in chagrin shale a minimum of 7 feet below lake bottom. A six-foot diameter riser shaft connects the 10-foot diameter underground discharge tunnel to the nozzle.

Ice Protection Caissons

Each intake structure is surrounded by 10 vertically-reinforced concrete ice protection caissons, which are placed in a 70-foot diameter circle around each intake. The caissons are six feet in diameter with the exception of two caissons around the No. 1 Intake Structure, which are seven feet in diameter due to the poorer foundation conditions of weathered and/or fractured shale at their locations. All caissons are founded in chagrin shale a minimum of 12 feet below lake bottom. The embedment depth of each caisson varies between 12 and 20.8 feet depending on the depth of weathered shale at each location.

The Ice Protection Caissons act as a barrier to any floating ice island which could block ports of the intake structures. For the very unlikely case where complete blockage of the intake structures would occur, water for the emergency service water system will be drawn from the discharge tunnel.

Functions (and scoping criteria, if intended function)

The structures are within the scope of license renewal because they are relied upon to remain functional during or following a design basis event, because they contain components that are relied on to perform a function that demonstrates compliance with the regulations for fire protection, anticipated transients without scram, and station blackout.

The water control structures associated with the ESW intake and alternate intake tunnels have the following intended functions for 10 CFR 54.4 (a)(1) and (a)(3) [Reference 1.3-1]:

- Provide shelter, support and protection for safety-related equipment. [10 CFR 54.4(a)(1)].
- Provide access to the ultimate heat sink to the emergency service water system for mitigation of design basis events, including station blackout (SBO) and anticipated transients without scram (ATWS). [10 CFR 54.4(a)(1)] and [10 CFR 54.4(a)(3)]
- Provide access to the ultimate heat sink for the fire protection system. [10 CFR 54.4(a)(3)]

2.4.3.3 ESW Swale / Major Stream and Minor Stream/Diversion Stream / Diversion Stream Berm

Description

ESW Swale

Should the normal ESW supply from the intake tunnel be interrupted, sluice gates open automatically upon receiving a low water level signal from the ESWPH forebay, allowing water from the discharge tunnel to flow into the forebay and supply the ESW system. Upon indication on a control room panel that the sluice gates are open, manual valves will be administratively closed to prevent warm ESW from dumping to the discharge tunnel. Instead, the ESW system will discharge via standpipes to the yard outside of the Auxiliary Building. At this location an overland swale is provided to carry the flow from the Auxiliary Building area, between the cooling towers, to the Remnant Minor Stream's engineered channel on the east side of the plant. This water then flows in the channel over the sediment control dam and ultimately enters Lake Erie at the shoreline.

Major Stream

The major stream has a drainage basin of 7.44 square miles and runs northwestward within 1,000 feet of the southwest corner of the plant. If a probable maximum flood (PMF) is experienced, the stream will be contained within its drainage basin with no site impact except for the overtopping of the crossing at the plant main access road, which would temporarily prevent road access. Topography along the plant-side bank of the major stream will preclude flooding of the site by the PMF, allowing the plant to continue uninterrupted operation. The major stream culvert, underlying the plant's main access road, is assumed to remain functional with the major stream's PMF analysis.

Remnant Minor Stream/Diversion Stream

The minor stream borders the plant area to the east and south. The minor stream's natural watercourse discharges into an engineered channel located to the east of the facility (called the diversion stream). The diversion stream was installed in 2015 and diverts streamflow away from the original engineered channel portion of the minor stream; a large fill area at the base of the remnant minor stream channel forces streamflow into the diversion stream. The original engineered channel, now referred to as the remnant minor stream, functions as a swale pathway for the local intense precipitation (LIP) domain rather than as a traditional stream or river. The two channels run parallel to each other on the east side of the plant and are separated by an earthen embankment structure named the diversion stream berm (these channels do not communicate). The drainage area of the diversion stream is 0.6 square mile and includes the drainage basin of the natural minor stream watercourse. The drainage area for the remnant minor stream is limited to only a portion of the LIP domain. The diversion stream and associated berm prevent the PMF flow from reaching any plant safety-related equipment.

The remnant minor stream channel outfall to the lake was constructed using 96-inch diameter corrugated metal pipe installed over a layer of 500 to 8,000-pound dumped stone riprap. The pipe was terminated at the sheet piling protection installed along the lake shoreline in front of the plant site. An inline spillway structure at the outfall of the Diversion Stream channel was constructed to accommodate conveyance of flow to Lake Erie. Improvements include installation of an armor revetment structure to provide shore protection within the location of the spillway.

Diversion Stream Berm

The diversion stream berm is installed between the Remnant Minor Stream channel and the Diversion Stream. The berm is constructed using the compacted excavation spoils from the Diversion Stream channel. The berm is nonsafety-related and not seismically qualified. Berm failure is evaluated and included for flooding considerations. Periodic inspection of the berm is performed to ensure long-term stability and reliability of the topographic feature including inspection for settlement and piping formation.

Functions (and scoping criteria, if intended function)

The structures are within the scope of license renewal because they are relied upon to remain functional during or following a design basis event. The integrity of these structures is necessary to preclude spatial interactions that could affect safety-related functions.

The ESW swale, major stream, remnant minor stream, diversion stream and diversion stream berm structures have the following intended functions for 10 CFR 54.4 (a)(2) [Reference 1.3-1]:

- Provide flood protection for safety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(2)]
- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]

2.4.3.4 Oil Interceptor Tanks (OITs)

Description

The purpose of the OITs is to collect the oil in case of a spill in the diesel generator building or other plant buildings. The oil will flow through pipes to these tanks and get collected in the tank. There are five OITs that are constructed of reinforced concrete walls, base slab and top slab. A manhole cover provides access to these tanks that are sealed for flood protection. Each tank has 2-inch diameter vent lines that protrude 2-foot above the grade. Based on the flooding analysis, the vent lines are sufficiently above the flood plane to prevent floodwater ingress. However, failure of these vent lines and the manhole covers will result in floodwater ingress to the tanks and may eventually flood the diesel generator building.

Functions (and scoping criteria, if intended function)

The structures are within the scope of license renewal because they are nonsafety-related components whose integrity is necessary to preclude spatial interactions that could affect safety-related functions.

The oil interceptor tanks have the following intended functions for 10 CFR 54.4 (a)(2) [Reference 1.3-1]:

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]

2.4.3.5 Exterior Flood Protection

Description

Flood Barriers at the entrance of various plant buildings (Passive and Deployable):

The flood protection barriers at PNPP include passive (permanent or normally installed) barriers and deployable incorporated barriers. Concrete and aluminum flood walls are installed at or near the building environmental interface for nonsafety-related buildings. For safety-related buildings, credit is taken for flood mitigation via the existing concrete exterior walls. The plant doors have flood barriers installed at the doorways to provide a seal to prevent water from entering building structures. The barriers consist of permanently installed steel end channels that are attached to the building structure and allow for the installation of aluminum stop logs with seals to provide the flood protection. These barriers are sized for the effects of the probable maximum precipitation (PMP) event over the localized intense precipitation (LIP) domain. Select plant doorways are also provided with ramps/curbs which provide passive protection for precipitation events up to and including the standard project storm (SPS); in some cases, door barriers (stop logs) are normally deployed and administratively controlled for SPS protection.

Incorporated barriers along the structure-environment interface of nonsafety-related structures, such as concrete and aluminum wall panels, constitute permanent, passive protection (“hardened protection” per RG 1.59) to ensure no gross leakage occurs through nonsafety-related plant exterior walls (Unit 1 and Unit 2).

Operator actions are limited to the deployment of removable incorporated barriers in the form of aluminum flooding stop logs. The requirements and guidance for this action is incorporated into plant off-normal instructions.

Flood protection features used at Perry are generally nonsafety-related.

Flood Barriers around safety-related Electrical Manholes

The electrical manholes are reinforced concrete boxes used as distribution points for cable routing. Permanent steel curbing is installed around the hatches of four safety-related electrical manholes (containing safety-related cables) to protect against flooding.

Roof features to accommodate Probable Maximum Precipitation (PMP)

Most of the site structures include parapets that result in the accumulation of rainwater on building roofs. Various roof features exist (such as roof drains, scuppers, and removed parapets) to create a scenario in which all roofs remain structurally sound during a design basis PMP event. Additionally, these features allow water level margin on roofs of various plant buildings to accommodate a beyond design basis (BDB) precipitation event.

Plant Storm Drain and Roof Drain Systems

The storm drain system consists of three subsystems, East, West, and South. Most of the storm drain conduit material is corrugated metal pipe (CMP) with paved invert. A much smaller fraction of the conduit material is reinforced concrete pipes (RCP) as specified on the various drawings. To account for uncertainty associated with pipe capacity reduction possibly due to sediment/debris, the storm drainpipe segments are analyzed at 90 percent capacity.

The plant storm drain system is credited in mitigating the effects of the local intense precipitation event as well as lesser (non-PMP) precipitation events. The storm drain system is nonsafety-related. In addition, the plant roof drain system is also included in the system modeling. The roof drain system is hydraulically coupled to the storm drain system; therefore, to avoid potential non-conservatisms related to hydraulic head and capacity reduction, the roof drain system is considered part of the storm drain system. The overall flooding analysis includes crediting the nonsafety-related storm drain system and nonsafety-related permanent and temporary incorporated barriers (flood panels) to collectively mitigate the effects of a design basis local intense precipitation event.

Structural Functions (and scoping criteria, if intended function):

The structures are within the scope of license renewal because they are nonsafety-related components whose integrity is necessary to preclude adverse effects from external flooding that could affect safety-related functions.

The Exterior Flood Protection structures have the following intended functions for 10 CFR 54.4 (a)(2) [Reference 1.3-1]

- Mitigate the effects of external flooding. [10 CFR 54.4 (a)(2)]

Notes:

1. For the purposes of aging management review, the structural elements associated with the flood barriers (passive and deployable), scuppers, and piping for plant roof and storm drain systems are considered structural bulk commodities and as such are addressed under Structural Bulk Commodities.

2. Structural bulk commodities located within all the in-scope structures are described in Section 2.4.4.

Component Types Subject to Aging Management Review

Table 2.4.3-1 lists the component types that require aging management review and their intended functions.

2.4.4 STRUCTURAL BULK COMMODITIES

Description

Bulk commodities subject to aging management review are structural components or commodities that perform or support intended functions of in-scope systems, structures and components (SSCs). Bulk commodities unique to a specific structure are included in the review for that structure. Bulk commodities common to in-scope SSCs (e.g., anchors, embedments, pipe and equipment supports, instrument panels and racks, cable trays, conduits, etc.) are addressed in this section as well as seismic II/I supports. Components (including snubbers, struts and their associated passive components, include passive components associated with spring cans, and constant and variable spring cans).

Bulk commodities evaluated in this section are designed to support both safety-related and nonsafety-related equipment during design basis events. Bulk commodities subject to aging management review are structural components or commodities that perform or support intended functions of in-scope SSCs.

Note: Piping is considered a mechanical component and their material descriptions are addressed in the individual mechanical aging management reports. However, pipe plugs and storm drain piping are considered as bulk commodities.

Functions (and scoping criteria, if intended function)

The Bulk Commodities structural group is within the scope of license renewal because it contains safety-related components that are relied upon to remain functional during or following a design basis event it contains nonsafety-related components whose failure could prevent accomplishment of a safety-related function, and it is relied on to perform a function that demonstrates compliance with the regulations for fire protection, anticipated transient without scram, and station blackout.

Bulk commodities are structural components that support the various intended functions performed by the structures in which they are located. These functions for 10 CFR 54.4(a)(1), (a)(2), and (a)(3) [Reference 1.3-1] include the following:

- Provide support, shelter and protection for safety-related equipment and nonsafety-related equipment within the scope of license renewal. [10 CFR 54.4(a)(1)] [10 CFR 54.4(a)(2)]

- Insulation may have the specific intended functions of (1) maintaining local area temperatures within design limits or (2) maintaining integrity such that falling insulation does not damage safety-related equipment. [10 CFR 54.4(a)(1)] [10 CFR 54.4(a)(2)]

- Maintain integrity of nonsafety-related structural components such that safety functions are not affected. [10 CFR 54.4(a)(2)]

- Provide support and protection for equipment credited in the Appendix R safe shutdown analysis and for fire protection (10 CFR 50.48 [Reference 1.3-7]), for anticipated transients without scram (10 CFR 50.62 [Reference 1.3-7]), and for station blackout (10 CFR 50.63 [Reference 1.3-7]). [10 CFR 54.4(a)(3)]

Tornado Doors	SSR, SRE, FB
Waterproofing Membranes	EN, FLB
Water Stops	FLB
Wood Clamps (Maple)	SSR, SNS, SRE

2.5 SCOPING AND SCREENING RESULTS: ELECTRICAL AND INSTRUMENTATION AND CONTROL SYSTEMS

The determination of electrical and instrumentation and control (I&C) systems within the scope of license renewal is made through application of the process described in Section 2.1. The results of the electrical and I&C systems scoping review are contained in Section 2.2.

Section 2.1 also provides the methodology for determining the components within the scope of 10 CFR 54.4 [Reference 1.3-1] that meet the requirements contained in 10 CFR 54.21(a)(1). The electrical and I&C components that meet these screening requirements are identified in this section. These identified components require an aging management review (AMR) for license renewal.

Components that support or interface with electrical and I&C components, for example, instrument racks, panels, cabinets, cable trays, conduit, and their supports (including foundations for outdoor equipment), are included in the civil-structural assessment documented in Section 2.4.

Information describing the electrical and I&C systems can be found in the Updated Final Safety Analysis Report (UFSAR) [Reference 1.3-6] Chapter 7 for I&C systems, UFSAR Chapter 8 for electrical power systems, and UFSAR Section 8.2 for the station offsite power system. UFSAR Appendix 15.H, Station Blackout (SBO), provides the requirements regarding Station Blackout coping. UFSAR Appendix 9A.4, Fire Hazards Analysis, provides requirements regarding fire protection for electrical and I&C components. UFSAR Chapter 3 provides requirements regarding environmental qualification for electrical and I&C components. USAR Appendix 15C provides the licensing basis for anticipated transients without scram (ATWS) and USAR 7.6.1.12 describes the design features for ATWS.

2.5.1 ELECTRICAL AND I&C SCREENING PROCESS

The screening process identifies the electrical component commodity groups that are subject to AMR for in-scope plant systems that include electrical and I&C components. Electrical component commodity group identification is done in accordance with the requirements of 10 CFR 54.21(a) [Reference 1.3-1] and the guidance of NEI 95-10 [Reference 1.3-3], Appendix B. Electrical components that are active and electrical components that are replaced on a specified time schedule are not subject to AMR. Only long-lived, passive components that perform a license renewal intended function are subject to AMR.

2.5.2 Application of Screening Criteria 10 CFR 54.21(a)(1)(i) to Electrical and I&C Component Commodity Groups

The screening determination with respect to the passive criterion is taken directly from NEI 95-10 [Reference 1.3-3]. Appendix B of NEI 95-10 delineates which commodity groups are active and which are passive. The active components are excluded from further review, by the direction of 10 CFR 54.21(a)(1)(i) [Reference 1.3-1].

Specific Perry documents were reviewed to determine the applicability of the industry standard commodity groups (i.e., single-line drawings, maintenance rule functions, UFSAR [Reference 1.3-6] Chapter 7, Chapter 8, Appendix 9A.4, and electrical layout drawings, etc.). The screening review also evaluated the environmental qualification status of the electrical and I&C components. The screening review did not identify any additional commodity groups for evaluation.

2.5.3 Elimination of Component Commodity Groups with no License Renewal Intended Functions

The following electrical and I&C component commodity groups do not perform a license renewal function and are excluded from AMR, in accordance with 10 CFR 54.21(a)(1)(i) [Reference 1.3-1].

2.5.3.1 Uninsulated Ground Conductors

Uninsulated ground conductors limit equipment damage and provide personnel protection in the event of a circuit failure.

Uninsulated ground conductors are not safety-related and their failure cannot cause the loss of a safety-related function. They are not required for any fire protection commitment, and they are not part of the station blackout or anticipated transients without scram evaluations. They are not included in the environmental qualification (EQ) program. Uninsulated ground conductors are not relied upon in safety analyses or plant evaluations to perform any function consistent with the requirements of 10 CFR 54.4(a)(3) [Reference 1.3-1]. Therefore, uninsulated ground conductors are not within the scope of license renewal and are not subject to aging management review.

2.5.3.2 Metal-Enclosed Bus

Isolated Phase Bus at the Main Generator has no license renewal intended function. The in-scope bus components for the 13.8-kV and 4.16-kV electrical systems utilize insulated cable routed in raceway. There are no segregated phase or non-segregated phase metal enclosed bus at PNPP.

2.5.3.3 Cable Tie Wraps

Kellum grips are used in cable installation vertical risers greater than 20 feet. Kellum grips are a basket weave cable grip used to support the weight of the cables. They are in addition to tie wraps. Kellum grips and tie wraps are included as structural bulk commodities and are not included as electrical commodities.

Tie wraps are used in cable installations (in panels and raceway) to hold groups of cables together for restraint and ease of maintenance by keeping cable runs neat and orderly. There are no current license basis requirements for tie wraps at Perry. Tie wraps are not required to remain functional during and following design basis events. Tie wraps are not required for maintaining cable ampacity, ensuring the maintenance of minimum bend radius, or maintaining cables within vertical raceways. Tie wraps are not required for any seismic analysis.

2.5.3.4 Unit 2 Buildings

The PNPP Unit 2 Construction Permit has been withdrawn. The NRC issued a Safety Evaluation dated November 1, 2001 that addressed withdrawal of the Unit 2 construction permit and Unit 2 site stabilization. Some shared components are used to support Unit 1 operations and are located in some Unit 2 buildings.

Most components and commodities in the Unit 2 turbine building, the Unit 2 turbine power complex, and the Unit 2 auxiliary building do not perform an intended function and are not in scope. Those components and commodities that support Unit 1 operations with a license renewal intended function include:

- The Unit 2 startup transformer and the Unit 2 interbus transformer A (in the yard).
- Nonsafety-related 480V distribution panel F2A04 to support the Unit 2 startup transformer and the associated cable and raceway. This transformer provides preferred offsite power, supports GDC-17 [Reference 1.3-7] and supports station blackout recovery. These EIC components and commodities are located at the 620’-624’ elevation in the north area of the turbine building.
- The Unit 2 turbine power complex houses Unit 2 transmission and distribution components and commodities that support Unit 1 license renewal intended functions.
- Fire protection components and commodities for protection of the spaces and Unit 2 transformers are located in both the Unit 2 turbine building and the Unit 2 turbine power complex.
- The western portion of the Unit 2 auxiliary building contains cable and raceway to support the various Unit 2 components and commodities supporting Unit 1 functions.

The Unit 2 heater bay, off-gas, and reactor buildings contain no EIC components or commodities within the scope of license renewal.

2.5.4 APPLICATION OF SCREENING CRITERIA 10 CFR 54.21(A)(1)(II) TO ELECTRICAL AND I&C COMPONENT COMMODITY GROUPS

The 10 CFR 54.21 (a)(1)(ii) [Reference 1.3-1] screening criterion was applied to the specific commodities that remained following application of the 10 CFR 54.21 (a)(1)(i) criterion. 10 CFR 54.21 (a)(1)(ii) allows the exclusion of those commodities that are subject to replacement based on a qualified life or specified time period. Electrical commodities identified for exclusion by the criteria of 10 CFR 54.21 (a)(1)(ii) are electrical and I&C components and commodities included in the Environmental Qualification (EQ) Program. This is because electrical and I&C components and commodities included in the EQ Program have defined qualified lives and are replaced prior to the expiration of their qualified lives. No electrical and I&C components and commodities within the EQ Program are subject to aging management review in accordance with the screening criteria of 10 CFR 54.21 (a)(1)(ii). See Section 4.4 for the TLAA evaluation of the Environmental Qualification (EQ) of Electric Components program. The remaining commodities, all or part of which are not in the EQ Program or in excluded Unit 2 buildings, require aging management review and are discussed below.

2.5.5 ELECTRICAL AND I&C COMPONENT COMMODITY GROUPS REQUIRING AN AGING MANAGEMENT REVIEW

Table 2.5-1 provides the definitions of electrical intended functions used in this application for electrical commodities. The electrical and I&C component commodity groups that require AMR are listed in Table 2.5-2, along with their intended functions. Electrical and I&C component commodity groups that require an AMR are discussed in the following sections.

2.5.5.1 Non-Environmentally Qualified Insulated Cables and Connections

The non-EQ insulated cables and connections commodity group includes all in-scope electric power cables, control cables, and instrumentation cables that are not addressed by the EQ program, and those in-scope connections (e.g., splices, terminal blocks, electrical penetration assemblies, and electrical connectors) that are not addressed by the EQ program. Also included in this group are the metallic parts of electrical cable connections.

An insulated cable is an assembly consisting of one or more conductors (aluminum or copper) with a covering of insulation, and may include fillers and a jacket to cover the entire assembly. The assembly may also include a metallic shield. The jacket, filler, and metallic shield are not evaluated for the purposes of license renewal; the insulation is the only portion subject to evaluation.

Cable connectors are used to connect the cable conductors with other cables or with a variety of electrical devices (e.g., motors or instruments). Examples of connectors are compression fittings, fusion connectors (used primarily for uninsulated ground conductors), plug-in connectors, and terminal blocks (including fuse blocks).

Splices are used to connect cable conductors to penetration pigtails or to motor leads, and are also used to connect sections of cable during repair or replacement. Splices may also have been utilized during original cable installation.

A terminal block consists of an insulating base with fixed metallic points for landing wires (conductors) or for connecting terminal rings (lugs). Terminal blocks are installed in an enclosure such as a panel, control board, motor control center, terminal box, or other enclosure.

Electrical penetration assemblies are components utilized to carry electrical conductors through the Shield Building and Containment Vessel (via a canister-type configuration), while providing electrical continuity for the applicable circuits. The electrical penetrations consist of sealants, feed-throughs (the conductors), connections, plates and other support sub-components.

The function of insulated cables and connections is to provide electrical connection to specified portions of an electrical circuit to deliver voltage, current, or signals. Non-EQ insulated cables and connections are passive, long-lived components. Therefore, non-EQ insulated cables and connections meet the criteria of 10 CFR 54.21(a)(1) [Reference 1.3-1] and are subject to an AMR.

2.5.5.2 Fuse Holders (Not Part of Active Equipment)

Fuse holders are blocks of rigid insulation material with metallic clamps attached to the blocks to hold each end of the fuse. The clamps can be spring-loaded clips, or they can be bolt lugs.

A systematic review was performed to determine if there were any fuse holders that were in scope for Perry license renewal. The fuse holders evaluated for license renewal are those in passive, stand-alone applications. Fuse holders in active electrical panels (those containing active electrical components) are excluded. Based on review of Perry electrical drawings, fuse documentation, and other engineering documents, there are plant fuse holders that are not part of active equipment. These fuse holders are subject to aging management review. They provide backup fusing protection for the electrical penetrations.

2.5.5.3 Switchyard Bus and Connections, Transmission Conductors and Transmission Connectors

Switchyard bus is uninsulated, unenclosed, rigid electrical conductor used in plant switchyards and switching stations to connect two or more elements of an electrical power circuit.

The switchyard bus is connected to flexible connectors that are supported by insulators and ultimately by structural components such as concrete footings and structural steel.

The switchyard bus and connections provide electrical connection between the plant electrical system and the transmission grid to deliver voltage and current. Switchyard bus and connections are passive, long-lived components. Therefore, the switchyard bus and connections meet the criteria of 10 CFR 54.4(a)(3) [Reference 1.3-1] to recover from a station blackout and are subject to an AMR.

Transmission conductors are aluminum conductor steel reinforced (ACSR), stranded aluminum conductors wrapped around a steel wire core. They are uninsulated, high-voltage conductors used to carry loads in plant switchyards and in distribution applications. The connections are cast aluminum or galvanized steel, with stainless steel washers.

The section of transmission conductor within the scope of license renewal is located between the startup transformers and the plant switchyard. The in-scope transmissions conductors are shown in drawing 206-0010 LR (the conductor from the switchyard to the startup transformers).

The function of transmission conductors and connections is to provide electrical connection to specified portions of an electrical circuit to deliver voltage and current. Transmission conductors provide the supply of off-site power to the plant to mitigate accidents/transient and to recover from station blackout conditions. Transmission conductors and connections are passive, long-lived components. Therefore, the transmission conductors and connections meet the criteria of 10 CFR 54.4(a)(3) to recover from a station blackout and the expectations of NUREG 1800, Section 2.1.3.1.3 and are subject to an AMR.

2.5.5.4 High-Voltage Insulators

A high-voltage insulator is a component designed to physically support a high-voltage conductor and to separate the conductor electrically from another conductor or object.

Station post insulators are large and rigid and are used to support stationary equipment, such as short lengths of transmission conductors, switchyard bus, and disconnect switches. Strain insulators are used in applications where movement of the supported conductor is expected and allowed, including maintaining tensional support of transmission conductors between transmission towers or other supporting structures.

The high-voltage insulators within the license renewal scope are the station post insulators associated with the startup transformers, and the high-voltage insulators (post and suspension insulators) associated with the 345-kV switchyard.

The function of high-voltage insulators is to insulate and support an electrical conductor (transmission conductor and switchyard bus). High voltage insulators are passive, long-lived components. Therefore, high voltage insulators meet the criteria of 10 CFR 54.4(a)(3) to recover from station blackout and are subject to an AMR.

Table 2.5.2 lists the component types that require aging management review and their intended functions.

Table 2.5-1
Electrical Commodity Intended Function Definitions

Intended Function	Determination
Electrical Continuity	To provide electrical connections to specified sections of an electrical circuit to deliver voltage, current, or signals.
Insulate (Electrical)	To insulate and support an electrical conductor.

Table 2.5-2
Electrical Commodities Subject to Aging Management

Passive Electrical Commodities	Intended Function
Cable Connection (Metallic Parts)	Electrical Continuity
Insulation Material for Electrical Cables and Connections	Insulate (Electrical)
Switchyard Bus and Connections, Transmission Conductors, and Transmission Connectors	Electrical Continuity
Fuse holders (not part of active equipment): insulation material	Insulate (Electrical)
Fuse holders (not part of active equipment): metallic clamps	Electrical Continuity
High-Voltage Insulators (e.g., porcelain switchyard insulators, transmission line insulators)	Insulate (Electrical)

3.0 AGING MANAGEMENT REVIEW RESULTS

This section provides the results of the Aging Management Review (AMR) for those structures and components identified in Section 2.0 as being subject to AMR. Descriptions of the service environments that were used in the AMRs to determine aging effects requiring management are included in Table 3.0-1, PNPP Service Environments for Mechanical and Structural Aging Management Reviews. The environments used in the aging management reviews are listed in the AMR Environment column. The second column identifies one or more of the NUREG-1801 [Reference 1.3-8] environments that were used when comparing the PNPP AMR results to the NUREG-1801 results. Material and component type equivalences to NUREG-1801 are provided in site supporting documents. The electrical environments in Table 3.0-2, PNPP Service Environments for Electrical Aging Management Reviews, are consistent with the environments in Table IX.D, NUREG-1801. Most of the AMR results information in Section 3 is presented in the following two tables:

- **Table 3.x.1** – where '3' indicates the LRA section number, 'x' indicates the subsection number from NUREG-1800 [Reference 1.3-9] chapter 3, and '1' indicates that this is the first table type in Section 3. For example, in the Reactor Vessel, Internals, and Reactor Coolant System subsection, this table would be number 3.1.1, in the Engineered Safety Features subsection, this table would be 3.2.1, and so on. For ease of discussion, this table will, hereafter, be referred to in this Section as "Table 1."

- **Table 3.x.2-y** – where '3' indicates the LRA section number, 'x' indicates the subsection number from NUREG-1800 chapter 3, and '2' indicates that this is the second table type in Section 3; and 'y' indicates the table number for a specific system. For example, for the Nuclear Boiler, within the Reactor Vessel, Internals, and Reactor Coolant System subsection, this table would be 3.1.2-2 and for the Reactor Coolant Pressure Boundary, it would be Table 3.1.2-3. For the Reactor Core Isolation Cooling System, within the Engineered Safety Features (ESF) subsection, this table would be 3.2.2-7. For the next system within the ESF subsection, it would be Table 3.2.2-8. For ease of discussion, this table will, hereafter, be referred to in this section as "Table 2."

TABLE DESCRIPTION

NUREG-1801, "Generic Aging Lessons Learned (GALL) Report," contains the generic evaluation of existing plant programs. It documents the technical basis for determining where existing programs are adequate without modification, and where existing programs should be augmented for the period of extended operation (PEO). The evaluation results documented in NUREG-1801 indicate that many of the existing programs are adequate to manage the aging effects for structures or components, within the scope of license renewal, without change. NUREG-1801 also contains recommendations on specific areas for which existing programs should be augmented for license renewal. To take full advantage of NUREG-1801, a comparison between the PNPP AMR results and the tables of NUREG-1801 has been performed. The results of that comparison are provided in the following two tables.

Table 1

The purpose of Table 1 is to provide a summary comparison of how the facility aligns with the corresponding tables of NUREG-1800. The table is essentially the same as Tables 3.1.1 through 3.6.1 provided in NUREG-1800, except that the "ID" and "Type" columns have been replaced by an "Item Number" column, and the "Rev2 Item" and "Rev1 Item" columns have been replaced by a "Discussion" column. The "Item Number" column provides the reviewer with a means to cross-reference from Table 2 to Table 1. The "Discussion" column is used to provide clarifying or amplifying information. The following are examples of information that might be contained within this column:

- "Further Evaluation Recommended" information or reference to where that information is located;
- The name of a plant-specific aging management program (AMP) being used, if applicable;
- Exceptions to the NUREG-1800 assumptions, if applicable;
- A discussion of how the line is consistent with the corresponding line item in NUREG-1800, when that may not be intuitively obvious;
- A discussion of how the item is different than the corresponding line item in NUREG- 1800 when it may appear to be consistent (e.g., when there is exception taken to an aging management program that is listed in NUREG-1800), if applicable.

The format of Table 1 provides the reviewer with a means of aligning a specific Table 1 row with the corresponding NUREG-1800 table row, thereby allowing for the ease of checking consistency.

Table 2

Table 2s provide the detailed results of the aging management reviews for those components identified in LRA Section 2 as being subject to aging management review. There will be a Table 2 for each of the systems within a Chapter 3 Section grouping. For example, for PNPP, the Engineered Safety Features System Group contains tables specific to systems such as Residual Heat Removal system, Containment Spray system, Low Pressure Core Spray system, High Pressure Core Spray system, Reactor Core Isolation Cooling system, and Suppression Pool system. Table 2 consists of the following ten columns:

- Row
- Component Type
- Intended Function

- Material
- Environment
- Aging Effect Requiring Management
- Aging Management Program(s)
- NUREG-1801 Item
- Table 1 Item
- Notes

Row – The first column provides a sequential Reference Number for each row within each table.

Component Type – The second column identifies all component types from Section 2 of the LRA that are subject to aging management review. They are listed in alphabetical order.

Intended Function – The third column identifies the license renewal intended functions for the listed component types. Definitions of intended functions are contained in Table 2.3-1 (mechanical), Table 2.4-1 (structural), and Table 2.5-1 (electrical).

Material – The fourth column lists the materials of construction for the component type.

Environment – The fifth column lists the environments to which the component types are exposed. Service environments are indicated, and a list of these environments is provided in Table 3.0-1, PNPP Service Environments for Mechanical and Structural Aging Management Reviews and Table 3.0-2, PNPP Service Environments for Electrical Aging Management Reviews.

Aging Effect Requiring Management – As part of the aging management review process, the aging effects that are required to be managed to maintain the intended function of the component type are identified for the material and environment combination based on operating experience. These aging effects requiring management are listed in the sixth column.

Aging Management Programs (AMPs) – The aging management program(s) used to manage the aging effects requiring management is listed in the seventh column of Table 2. Aging management programs are described in Appendix B.

NUREG-1801 Item – Each combination of component type, material, environment, aging effect requiring management, and aging management program that is listed in Table 2, is compared to NUREG-1801, with consideration given to the standard notes, to identify consistency with the corresponding NUREG-1801 item. Consistency is documented by noting the appropriate NUREG-1801 item number in the eighth column of Table 2. If there is no corresponding item number in NUREG-1801, this field in column eight contains "N/A." Thus, a reviewer can readily identify the correlation between the plant-specific tables and the NUREG-1801 tables.

Table 1 Item – Each combination of component, material, environment, aging effect requiring management, and aging management program that has an identified NUREG-1801 item number must also have a Table 3.x.1 line item Reference number. The corresponding line item from Table 1 is listed in the ninth column of Table 2. If there is no corresponding item in NUREG-1801, this field in column nine contains "N/A." The Table 1 Item allows correlation of the information from the two tables.

Notes – The notes provided in each Table 2 describe how the information in the table aligns with the information in NUREG-1801. Each Table 2 contains standard lettered notes and, if applicable, plant-specific numbered notes. The standard lettered notes (e.g., A, B, C) provide standard information regarding comparison of the PNPP aging management review results with the NUREG-1801 Aging Management Table line item identified in the eighth column. In addition to the standard lettered notes, numbered plant-specific notes provide additional clarifying information when appropriate.

TABLE USAGE

Table 1

The reviewer evaluates each row in Table 1 by moving from left to right across the table. Since the Component, Aging Effect, Aging Management Programs and Further Evaluation Recommended information is taken directly from NUREG-1800, no further analysis of those columns is required. The information intended to help the reviewer the most in this table is contained within the Discussion column. Here the reviewer will be given plant-specific information necessary to determine, in summary, how the PNPP evaluations and programs align with NUREG-1800. This may be in the form of descriptive information within the Discussion column or the reviewer may be referred to other locations within the LRA for further information.

Table 2

Table 2 contains the Aging Management Review information for the plant, regardless whether it aligns with NUREG-1801. For a given row within the table, the reviewer can see the intended function, material, environment, aging effect requiring management and aging management program combination for a specific component type within a system. In addition, if there is a correlation between the combination in Table 2 and a combination in NUREG-1801, this alignment will be identified by a referenced item number in column eight, NUREG-1801 Item. The reviewer can refer to the item number in NUREG-1801, if desired, to verify the correlation. If the column contains an "N/A," no corresponding combination in NUREG-1801 was found. As the reviewer continues across the table from left to right within a given row, the next column is labeled Table 1 Item. If there is a Reference number in this column, the reviewer can use that reference number to locate the corresponding row in Table 1. The discussion in Table 1 amplifies the level of the consistency for this alignment with the NUREG-1801 item and with PNPP components, materials, aging effects, and aging management program. Table 2 provides the reviewer with a means to navigate from the components subject to

Aging Management Review (AMR) in LRA Section 2 all the way through the evaluation of the programs that will be used to manage the effects of aging of those components. A listing of the acronyms used in this section is provided in the LRA Preface.

Cumulative Fatigue Damage and TLAAs in Table 2

A fatigue analysis is considered to be a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3 when it is within the current licensing basis and is based upon transient cycle assumptions associated with 40 years of plant operation. This includes explicit ASME Section III, Class 1 analyses for piping and components and implicit ASME Section III, Class 2 and 3 and ANSI B31.1 analyses for piping. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c)(1).

Table 1 and Table 2 include an entry in the Aging Management Program column indicating "TLAA" for each line item that has a component for which a fatigue TLAA (explicit or implicit) has been identified. See LRA Section 4 for details regarding the PNPP fatigue design bases, fatigue TLAAs identified, and TLAA evaluations for the period of extended operation.

Table 3.0-1
PNPP Service Environments for
Mechanical and Structural Aging Management Reviews

AMR Environment	NUREG 1801 Environment(s) used for AMR comparison [1,2]	Definition
Air - dry	Air - dry	Air that has been treated to reduce its dew point well below the system operating temperature. Within piping systems, unless otherwise specified, this environment may be either internal or external.
Air – indoor, uncontrolled	Air; Air – indoor controlled; Air – indoor, uncontrolled; Air – indoor uncontrolled >35°C (>95°F); Air with Reactor Coolant Leakage; Moist air, System temperature up to 288°C (550°F)	Indoor air with temperatures higher than the dew point. Condensation can occur but only rarely, equipment surfaces are normally dry. If the ambient temperature is maintained <95°F, any resultant thermal aging of organic materials can be considered as insignificant over the 60-yr period of extended operation. For high temperature systems, this environment includes the potential for elevated temperatures that supports cumulative fatigue damage. This name is also used to describe the internal environment of undried compressed air.
Air - outdoor	Air – outdoor; Moist air	The outdoor environment consists of moist, atmospheric air at temperatures and humidity, and exposure to weather, including precipitation and wind. PNPP is not in a coastal area near a body of saltwater but is near roads that are treated with salt during winter months. The component is exposed to air and local weather conditions. Outdoor air does not include the potential to pool water; outdoor environments with the potential for pooled water are called Raw water, Condensation, or Soil (for tank bottoms).
Air with reactor coolant leakage	Air; Air with reactor coolant leakage; System temperature up to 288°C (550°F); Air with steam or water leakage	Air and reactor coolant leakage is on high temperature systems and is applicable only to closure bolting located near the Reactor Pressure Vessel.

Table 3.0-1 (cont.),

PNPP Service Environments for

Mechanical and Structural Aging Management Reviews

AMR Environment	NUREG 1801 Environment(s) used for AMR comparison [1,2]	Definition
Closed-cycle cooling water	Closed-cycle cooling water	Treated water subject to the closed cycle cooling water chemistry program. Closed-cycle cooling water describes the environment in treated closed-cooling and heating systems.
Closed cycle cooling water >60˚C (>140˚F)	Closed-cycle cooling water; Closed-cycle cooling water >60˚C (>140˚F)	Treated water subject to the closed-cycle cooling water chemistry program. Closed-cycle cooling water >60˚C (>140˚F) allows the possibility of stainless steel SCC and may describe the environment in treated closed-cooling or heating systems.
Concrete	Concrete	The external environment of components embedded in concrete.
Condensation	Condensation	Condensation on the surfaces of systems with temperatures below the dew point, or in the associated drains. Condensation may be internal or external but is not used for environments when temperatures exceed 140˚F. Condensation includes the potential for concentration of contaminants. Condensation is also used to describe the dry air environment within the Instrument Air system, to permit alignment with the NUREG-1801 rows that recommend the use of the Compressed Air Monitoring program to preclude moisture.
Diesel exhaust	Diesel exhaust	Gases, fluids, and particulates present in diesel engine exhaust.
Fuel oil	Fuel oil	Diesel oil, No. 2 oil, or other liquid hydrocarbons used to fuel diesel engines. Fuel oil used for combustion engines may include water contamination. The fuel oil environment does not exceed the threshold temperature for cracking of stainless steel (140˚F).
Gas	Gas	Environments of inert or non-reactive gases. Oxygen is not considered to be present in this environment. Gas is used to describe Freon, CO_2 and Halon environments. Reactive replacement gases for Freon and Halon are not included in this environment.

Table 3.0-1 (cont.), PNPP Service Environments for Mechanical and Structural Aging Management Reviews

AMR Environment	NUREG 1801 Environment(s) used for AMR comparison [1,2]	Definition
Lubricating oil	Lubricating oil	Lubricating oils are low-to-medium viscosity hydrocarbons, with the possibility of containing contaminants and/or moisture, used for bearing, gear, and engine lubrication. This name is also used to describe non-water based hydraulic fluid (Fyrquel), and the 3M NOVEC™ 7100 refrigerant used in the Offgas system.
Raw water	Ground water; Raw water; Water, flowing or standing	Raw, untreated, river, lake, ground or potable water. Raw water does not exceed the threshold temperature for SCC of stainless steels (140°F). If raw water is considered aggressive to structural components, additional aging management methods may be required.
Reactor coolant	Reactor coolant	Treated water in the reactor coolant system and connected systems at or near full operating temperature. Reactor coolant includes the steam phase. The Reactor coolant environment name is used for the reactor vessel and internals components. The environment for connected piping and systems is referred to as one of the Treated water environments.
Reactor coolant >250°C (>482°F) and neutron flux	Reactor coolant; Reactor coolant >250°C (>482°F); Reactor coolant >250°C (>482°F) and neutron flux; Treated water	Water in the reactor coolant system above the thermal embrittlement threshold for CASS, and above the fluence threshold for neutron embrittlement. The Reactor coolant environment name is used for the reactor vessel and internals components. The environment for connected piping and systems is referred to as one of the Treated water environments.
Reactor coolant and neutron flux	Reactor coolant; Reactor coolant and neutron flux	Reactor core environment that will result in a neutron fluence exceeding the threshold for management at the end of the license renewal term. The Reactor coolant environment name is used for the reactor vessel and internals components. The environment for connected piping and systems is referred to as one of the Treated water environments.

Table 3.0-1 (cont.),
PNPP Service Environments for
Mechanical and Structural Aging Management Reviews

AMR Environment	NUREG 1801 Environment(s) used for AMR comparison [1,2]	Definition
Sodium pentaborate solution	Sodium pentaborate solution, Treated water	Treated water that contains a mixture of borax and boric acid.
Soil	Soil; Water - flowing under foundation; Water – flowing or standing	External environment for components exposed to soil (including the air/soil interface) or buried in the soil, including groundwater in the soil. This name is also used to describe the environment for exterior surface of outdoor tank bottoms that are mounted on a concrete pad. Buried components are not expected to exceed the threshold temperature for SCC (140°F).
Treated water	Treated water; Reactor coolant; Steam	Treated water is demineralized water. Treated water could be deaerated and include corrosion inhibitors, biocides, other additives such as glycol, or some combination of these treatments. Treated water does not contain significant concentrations of boric acid at PNPP. This environment may represent liquid or steam/vapor.
Treated water >250°C (>482°F)	Steam, Reactor coolant, Treated water, Reactor Coolant >250°C (>482°F)	Treated water above the thermal embrittlement threshold for cast austenitic stainless steel of 250°C (482°F). This environment may represent liquid or steam/vapor.
Treated water >60°C (>140°F)	Treated water; Treated water >60°C (>140°F)	Treated water above the 60°C (140°F) stress corrosion cracking threshold for stainless steel. This environment may represent liquid or steam/vapor.
Waste water	Waste water	Radioactive, potentially radioactive, or non-radioactive water that is collected from equipment and floor drains. Waste waters may contain contaminants, including oil, as well as originally-treated water that is not monitored by a chemistry program.

Table 3.0-1 Notes

1. For metallic bolting and closure bolting, any AMR environment is considered equivalent to any GALL environment for evaluation of GALL consistency for Loss of preload due to thermal effects, gasket creep.
2. Air with borated water leakage is not used as it is germane to PWRs and not BWRs.

Table 3.0-2

PNPP Service Environments for

Electrical Aging Management Reviews

AMR Environment	**NUREG-1801 Environment(s) used for AMR comparison**	**Definition**[1]
Adverse Localized Environment	Adverse Localized Environment	An adverse localized environment is an environment limited to the immediate vicinity of a component that is hostile to the component material, thereby leading to potential aging effects. As used in GALL, the conductor insulation used for electrical cables in instrumentation circuits can be subjected to an adverse localized environment. As represented by a specific GALL AMR Item, an adverse localized environment can be due to any of the following: (1) exposure to significant moisture (LP-35), (2) heat, radiation, or moisture (L-01 or LP-34), or (3) heat, radiation, moisture, or voltage (L-05).
Air - indoor, controlled	Air - indoor, controlled	This environment is one to which the specified internal or external surface of the component or structure is exposed; a humidity-controlled (i.e., air conditioned) environment. For electrical purposes, control must be sufficient to eliminate the cited aging effects of contamination and oxidation without affecting the resistance.
Air - indoor, uncontrolled	Air - indoor, uncontrolled	Uncontrolled indoor air is associated with systems with temperatures higher than the dew point (i.e., condensation can occur, but only rarely; equipment surfaces are normally dry).
Air - indoor uncontrolled >35˚C (>95˚F) (Internal/External) [2]	Air -indoor uncontrolled >35˚C (>95˚F) (Internal/External)	Uncontrolled indoor air >35˚C (>95˚F) is above a thermal stress threshold for elastomers (i.e., <95˚F). It is an environment to which the internal or external surface of the component or structure can be exposed. If the ambient temperature is maintained <95˚F, any resultant thermal aging of organic materials can be considered as insignificant over the 60-yr period of extended operation. (Ref 3) [4] However, elastomers can be subjected to aging effects from other factors, such as exposure to ozone, oxidation, and radiation.

Table 3.0-2 (cont.),

PNPP Service Environments for

Electrical Aging Management Reviews

AMR Environment	**NUREG-1801 Environment(s) used for AMR comparison**	**Definition** [1]
Air – outdoor[3]	Air – outdoor	The outdoor environment consists of moist, possibly salt-laden atmospheric air, ambient temperatures and humidity, and exposure to weather, including precipitation and wind. The component is exposed to air and local weather conditions, including salt water spray (if present). A component is considered susceptible to a wetted environment when it is submerged, has the potential to collect water, or is subject to external condensation.

Table 3.0-2 Notes

1. The environments used in Section 3.6 are consistent with the definitions in NUREG-1801, Section IX.D, which are reproduced here.
2. This environment is not used in Table 3.6.2 – Electrical Commodities - Summary of Aging Management Evaluation. It is listed as a mutually exclusive alternative to Air – Indoor, uncontrolled. For higher temperatures see Adverse localized environments caused by heat. As noted in NUREG-1801, Section IX.D, "when applied to the elastomers used in electrical cable insulation, it should be noted that most cable insulation is manufactured as either 75°C (167°F) or 90°C (194°F) rated material."
3. PNPP is not in a coastal area near a body of saltwater but is near roads that are treated with salt during winter months. Outdoor air does not include the potential to pool water.
4. The source reference material is cited as (Ref 3) referring to Reference 3 in Section IX.G of NUREG-1801, Revision 2.

3.1 AGING MANAGEMENT OF REACTOR VESSEL, INTERNALS, AND REACTOR COOLANT SYSTEM

3.1.1 INTRODUCTION

This Section provides the results of the aging management reviews for components identified in Section 2.3.1, Reactor Vessel, Internals and Reactor Coolant System, as being subject to aging management review. The systems, or portions of systems, which are addressed in this Section are described in the Sections indicated below.

- Fuel (Section 2.3.1.1)
- Nuclear Boiler (Section 2.3.1.2)
- Reactor Coolant Pressure Boundary (Section 2.3.1.3)
- Reactor Recirculation (Section 2.3.1.4)
- Reactor Vessel (Section 2.3.1.5)
- Reactor Vessel Internals (Section 2.3.1.6)

3.1.2 RESULTS

The following tables summarize the results of the aging management review for Reactor Vessel, Internals, and Reactor Coolant System:

- Table 3.1.2-1 Fuel
- Table 3.1.2-2 Nuclear Boiler
- Table 3.1.2-3 Reactor Coolant Pressure Boundary
- Table 3.1.2-4 Reactor Recirculation
- Table 3.1.2-5 Reactor Vessel
- Table 3.1.2-6 Reactor Vessel Internals

Note that Table 3.1.2-1 Fuel System did not have any components subject to aging management review and the corresponding AMR results table contains no components.

3.1.2.1 Materials, Environment, Aging Effects Requiring Management and Aging Management Programs

The following sections list the materials, environments, aging effects requiring management, and aging management programs for the Reactor Vessel, Internals, and Reactor Coolant System components subject to aging management review. Aging Management Programs are described in Appendix B. Further details are provided in the system tables.

3.1.2.1.1 Fuel

Fuel components are constructed of the following materials:

- N/A

Environments

Fuel components are exposed to the following environments:

- N/A

Aging Effects Requiring Management

The following aging effects associated with the Fuel components require management:

- N/A

Aging Management Programs

The following aging management programs manage the effects of aging on Fuel components:

- N/A

3.1.2.1.2 <u>Nuclear Boiler</u>

Materials

Nuclear Boiler components are constructed of the following materials:

- aluminum
- nickel alloy
- stainless steel
- steel

Environments

Nuclear Boiler components are exposed to the following environments:

- air – dry
- air – indoor, uncontrolled

- treated water
- treated water >60˚C (>140˚F)

Aging Effects Requiring Management

The following aging effects associated with the Nuclear Boiler components require management:

- cracking
- cumulative fatigue damage
- loss of material
- loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Nuclear Boiler components:

- Bolting Integrity (B.2.7)
- Compressed Air Monitoring (B.2.16)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.1.2.1.3 Reactor Coolant Pressure Boundary

Materials

Reactor Coolant Pressure Boundary components are constructed of the following materials:

- CASS
- High strength steel
- Stainless steel
- Steel
- Steel with stainless steel cladding

Environments

Reactor Coolant Pressure Boundary components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air with reactor coolant leakage
- Closed-cycle cooling water
- Sodium pentaborate solution
- Treated water
- Treated water >250˚C (>482˚F)
- Treated water >60˚C (>140˚F)

Aging Effects Requiring Management

The following aging effects associated with the Reactor Coolant Pressure Boundary components require management:

- Cracking
- Cumulative fatigue damage
- Loss of fracture toughness
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Reactor Coolant Pressure Boundary components:

- ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3)
- Bolting Integrity (B.2.7)
- BWR Stress Corrosion Cracking (B.2.12)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- One-Time Inspection (B.2.35)
- One-Time Inspection of ASME Code Class 1 Small Bore-Piping (B.2.36)
- TLAA
- Water Chemistry (B.2.44)

3.1.2.1.4 Reactor Recirculation

Materials

Reactor Recirculation components are constructed of the following materials:

- Aluminum
- Copper Alloy >15% Zn
- Glass
- Gray cast iron
- Stainless steel
- Steel

Environments

Reactor Recirculation components are exposed to the following environments:

- Air – indoor, uncontrolled
- Gas
- Lubricating oil
- Treated water
- Treated water >60°C (>140°F)

Aging Effects Requiring Management

The following aging effects associated with the Reactor Recirculation components require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Reactor Recirculation components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.1.2.1.5 Reactor Vessel

Materials

Reactor Vessel components are constructed of the following materials:

- High strength steel
- Nickel-alloy
- Stainless steel
- Steel
- Steel with stainless steel cladding

Environments

Reactor Vessel components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air with reactor coolant leakage
- Reactor coolant
- Reactor coolant and neutron flux

Aging Effects Requiring Management

The following aging effects associated with the Reactor Vessel components require management:

- Cracking
- Cumulative fatigue damage
- Loss of fracture toughness
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Reactor Vessel components:

- ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3)
- Bolting Integrity (B.2.7)
- BWR Control Rod Drive Return Line Nozzle (B.2.9)
- BWR Feedwater Nozzle (B.2.10)
- BWR Penetrations (B.2.11)
- BWR Stress Corrosion Cracking (B.2.12)
- BWR Vessel ID Attachment Welds (B.2.13)
- One-Time Inspection (B.2.35)
- Reactor Head Closure Stud Bolting (B.2.39)
- Reactor Vessel Surveillance (B.2.40)
- TLAA
- Water Chemistry (B.2.44)

3.1.2.1.6 Reactor Vessel Internals

Materials

Reactor Vessel Internals components are constructed of the following materials:

- CASS
- Nickel-alloy
- Stainless steel
- X-750

Environments

Reactor Vessel Internals components are exposed to the following environments:

- Air – indoor, uncontrolled
- Reactor coolant
- Reactor coolant >250°C (>482°F) and neutron flux
- Reactor coolant and neutron flux

Aging Effects Requiring Management

The following aging effects associated with the Reactor Vessel Internals components require management:

- Cracking

- Cumulative fatigue damage
- Loss of fracture toughness
- Loss of material

Aging Management Programs

The following aging management programs manage the effects of aging on Reactor Vessel Internals components:

- BWR Vessel Internals (B.2.14)
- TLAA
- Water Chemistry (B.2.44)

3.1.2.2 Further Evaluation of Aging Management as Recommended by NUREG-1800

NUREG-1800 (Reference 1.3-9) indicates that further evaluation is necessary for certain aging effects and other issues discussed in Section 3.1.2.2 of NUREG-1800. The following sections are numbered in accordance with the discussions in NUREG-1800 and explain the PNPP approach to these areas requiring further evaluation. Programs are described in Appendix B.

Note - Italicized text at the beginning of each Further Evaluation subsection is taken directly from NUREG-1800 as supplemented by LR-ISG-2011-04 and LR-ISG-2011-05.

3.1.2.2.1 Cumulative Fatigue Damage

Fatigue is a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). This TLAA is addressed separately in Section 4.3, "Metal Fatigue Analysis," of this SRP-LR.

Fatigue is a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). The evaluation of metal fatigue as a TLAA for the Reactor Vessel, Reactor Vessel Internals, Reactor Coolant Pressure Boundary, Nuclear Boiler, and Reactor Recirculation system are discussed in Section 4.3.1 (Class 1) and 4.3.2 (non-Class1). In addition, non-Class 1 components from the Auxiliary Systems (Post Accident Sampling) and Steam and Power Conversion Systems (Main and Reheat Steam, Main, Reheat, Extraction, and Miscellaneous Drains, and Auxiliary Steam and Drains) are discussed in Section 4.3.2 either specifically or as part of the global evaluation. Likewise, metal fatigue of the Auxiliary Steam and Drains, Main and Reheat Steam, Main, Reheat, Extraction and Misc Drains, and Post Accident Sampling systems is also addressed in Section 4.3. See Section 4.3 for a complete evaluation of metal fatigue.

3.1.2.2.2 Loss of Material Due to General, Pitting, and Crevice Corrosion

1. *Loss of material due to general, pitting, and crevice corrosion could occur in the steel PWR steam generator upper and lower shell and transition cone exposed to secondary feedwater and steam. The existing program relies on control of water chemistry to mitigate corrosion and Inservice Inspection (ISI) to detect loss of material. The extent and schedule of the existing steam generator inspections are designed to ensure that flaws cannot attain a depth sufficient to threaten the integrity of the welds. However, according to NRC Information Notice (IN) 90-04, the program may not be sufficient to detect pitting and crevice corrosion, if general and pitting corrosion of the shell is known to exist. The GALL Report recommends augmented inspection to manage this aging effect. Furthermore, the GALL Report clarifies that this issue is limited to Westinghouse Model 44 and 51 Steam Generators, where a high-stress region exists at the shell to transition cone weld. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

This paragraph in NUREG-1800 pertains to pressurized water reactor (PWR) steam generators and is therefore not applicable to PNPP.

2. *Loss of material due to general, pitting, and crevice corrosion could occur in the steel PWR steam generator shell assembly exposed to secondary feedwater and steam. The existing program relies on control of secondary water chemistry to mitigate corrosion. However, some applicants have replaced only the bottom part of their recirculating steam generators, generating a cut in the middle of the transition cone, and, consequently, a new transition cone closure weld. The GALL Report recommends volumetric examinations performed in accordance with the requirements of ASME Code Section XI for upper shell-to and lower shell-to transition cones with gross structural discontinuities for managing loss of material due to general, pitting, and crevice corrosion in the welds for Westinghouse Model 44 and 51 Steam Generators, where a high-stress region exists at the shell to transition cone weld.*

   The new continuous circumferential weld, resulting from cutting the transition cone as discussed above, is a different situation from the SG transition cone welds containing geometric discontinuities. Control of water chemistry does not preclude loss of material due to pitting and crevice corrosion at locations of stagnant flow conditions. The new transition area weld is a field-weld as opposed to having been made in a controlled manufacturing facility, and the surface conditions of the transition weld may result in flow conditions more conducive to initiation of general, pitting, and crevice corrosion than those of the upper and lower transition cone welds. Crediting of the ISI program for the new SG transition cone weld may not be an effective basis for managing loss of material in this weld, as the ISI criteria would only perform a VT-2 visual leakage examination of the weld as part of the system leakage test performed pursuant to ASME Section XI requirements. In addition, ASME Section XI does not require licensees to *remove insulation when performing visual examination on non-borated treated water systems. Therefore, the effectiveness of the chemistry control program should be verified to ensure that loss of material due to general, pitting and crevice corrosion is not occurring.*

For the new continuous circumferential weld, the GALL Report recommends further evaluation to verify the effectiveness of the chemistry control program. A one-time inspection at susceptible locations is an acceptable method to determine whether an aging effect is not occurring or an aging effect is progressing very slowly, such that the component's intended function will be maintained during the period of extended operation. Furthermore, the GALL Report clarifies that this issue is limited to replacement recirculating steam generators with a new transition cone closure weld.

This paragraph in NUREG-1800 pertains to PWR steam generator shell assemblies and is therefore not applicable to PNPP.

3.1.2.2.3 Loss of Fracture Toughness due to Neutron Irradiation Embrittlement

1. *Neutron irradiation embrittlement is a TLAA to be evaluated for the period of extended operation for all ferritic materials that have a neutron fluence greater than 1017 n/cm2 (E >1 MeV) at the end of the license renewal term. Certain aspects of neutron irradiation embrittlement are TLAAs as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c)(1). This TLAA is addressed separately in Section 4.2, "Reactor Vessel Neutron Embrittlement Analysis," of this SRP-LR.*

Neutron irradiation embrittlement is a TLAA evaluated for the period of extended operation in accordance with 10 CFR 54.21(c). The evaluation of loss of fracture toughness for the reactor vessel beltline shell and welds is discussed in Section 4.2.

2. *Loss of fracture toughness due to neutron irradiation embrittlement could occur in BWR and PWR reactor vessel beltline shell, nozzle, and welds exposed to reactor coolant and neutron flux. A reactor vessel materials surveillance program monitors neutron irradiation embrittlement of the reactor vessel. The reactor vessel surveillance program is plant-specific, depending on matters such as the composition of limiting materials, availability of surveillance capsules, and projected fluence levels. In accordance with 10 CFR Part 50, Appendix H, an applicant is required to submit its proposed withdrawal schedule for approval prior to implementation. Untested capsules placed in storage must be maintained for future insertion. Thus, further staff evaluation is required for license renewal. Specific recommendations for an acceptable AMP are provided in Chapter XI, Section M31 of the GALL Report.*

The Reactor Vessel Surveillance Program manages reduction in fracture toughness due to neutron embrittlement of reactor vessel beltline materials. PNPP is a participant in the Boiling Water Reactor Vessel and Internals Project (BWRVIP) Integrated Surveillance Program (ISP). This program monitors changes in the fracture toughness properties of ferritic materials in the reactor pressure vessel (RPV) beltline region. As described in Appendix B, the Reactor Vessel Surveillance Program is consistent with the program described in NUREG-1801, (Reference 1.3-8) Section XI.M31, Reactor Vessel Surveillance.

3. Ductility – Reduction in Fracture Toughness is a plant-specific TLAA for Babcock and Wilcox (B&W) reactor internals to be evaluated for the period of extended operation in accordance with the staff's safety evaluation concerning "Demonstration of the Management of Aging Effects for the Reactor Vessel Internals," Babcock and Wilcox Owners Group report number BAW-2248, which is included in BAW-2248A, March 2000. Plant-specific TLAAs are addressed in Section 4.7, "Other Plant-Specific Time-Limited Aging Analyses," of this SRP-LR.

This paragraph in NUREG-1800 pertains to a plant-specific TLAA for Babcock and Wilcox reactor internals and is therefore not applicable to PNPP.

3.1.2.2.4 Cracking due to Stress Corrosion Cracking (SCC) and Intergranular Stress Corrosion Cracking (IGSCC)

1. Cracking due to stress corrosion cracking (SCC) and intergranular stress corrosion cracking (IGSCC) could occur in the stainless steel and nickel alloy BWR top head enclosure vessel flange leak detection lines. The GALL Report recommends that a plant-specific AMP be evaluated because existing programs may not be capable of mitigating or detecting cracking due to SCC and IGSCC. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

This paragraph in NUREG-1800 addresses cracking due to stress corrosion cracking (SCC) and intergranular stress corrosion cracking (IGSCC) in stainless steel and nickel-alloy BWR top head enclosure vessel flange leak detection lines. The top head enclosure vessel flange leak detection line at PNPP is carbon steel piping, not stainless steel, and is therefore not susceptible to SCC or IGSCC.

2. Cracking due to SCC and IGSCC could occur in stainless steel BWR isolation condenser components exposed to reactor coolant. The existing program relies on control of reactor water chemistry to mitigate SCC and on ASME Section XI ISI to detect cracking. However, the existing program should be augmented to detect cracking due to SCC and IGSCC. The GALL Report recommends an augmented program to include temperature and radioactivity monitoring of the shell-side water and eddy current testing of tubes to ensure that the component's intended function will be maintained during the period of extended operation. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

This paragraph in NUREG-1800 pertains to BWR isolation condenser components. PNPP does not have an isolation condenser, so this paragraph was not used.

3.1.2.2.5 Crack Growth due to Cyclic Loading

Crack growth due to cyclic loading could occur in reactor vessel shell forgings clad with stainless steel using a high-heat-input welding process. Growth of intergranular separations (underclad cracks) in the heat-affected zone under austenitic stainless steel cladding is a TLAA to be evaluated for the period of extended operation for all the SA-508-Cl-2 forgings where the cladding was deposited with a high heat input welding process.

This paragraph in NUREG-1800 applies to PWRs only and is therefore not applicable to PNPP.

3.1.2.2.6 Cracking due to Stress Corrosion Cracking

1. *Cracking due to SCC could occur in the PWR stainless steel reactor vessel flange leak detection lines and bottom-mounted instrument guide tubes exposed to reactor coolant. The GALL Report recommends further evaluation to ensure that these aging effects are adequately managed. The GALL Report recommends that a plant-specific AMP be evaluated to ensure that this aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

2. *Cracking due to SCC could occur in Class 1 PWR cast austenitic stainless steel (CASS) reactor coolant system piping, piping components, and piping elements exposed to reactor coolant. The existing program relies on control of water chemistry to mitigate SCC; however, SCC could occur for CASS components that do not meet the NUREG- 0313 guidelines with regard to ferrite and carbon content. The GALL Report recommends further evaluation of a plant-specific program for these components to ensure that this aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

Both paragraphs in NUREG-1800 apply to PWRs only and are therefore not applicable to PNPP.

3.1.2.2.7 Cracking due to Cyclic Loading

Cracking due to cyclic loading could occur in steel and stainless steel BWR isolation condenser components exposed to reactor coolant. The existing program relies on ASME Section XI ISI. However, the existing program should be augmented to detect cracking due to cyclic loading. The GALL Report recommends an augmented program to include temperature and radioactivity monitoring of the shell-side water and eddy current testing of tubes to ensure that the component's intended function will be maintained during the period of extended operation. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

This paragraph in NUREG-1800 pertains to BWR isolation condenser components. As PNPP does not have an isolation condenser, this paragraph was not used.

3.1.2.2.8 Loss of Material due to Erosion

Loss of material due to erosion could occur in steel steam generator feedwater impingement plates and supports exposed to secondary feedwater. The GALL Report recommends further evaluation of a plant-specific AMP to ensure that this aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

This paragraph in NUREG-1800 applies to PWRs only only and is therefore not applicable to PNPP.

3.1.2.2.9 Cracking due to Stress Corrosion Cracking and Irradiation-Assisted Stress Corrosion Cracking

Cracking due to SCC and irradiation-assisted stress corrosion cracking (IASCC) could occur in inaccessible locations for stainless steel and nickel-alloy Primary and Expansion PWR reactor vessel internal components. If aging effects are identified in accessible locations, the GALL Report recommends further evaluation of the aging effects in inaccessible locations on a plant specific basis to ensure that this aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

Removed per LR-ISG-2011-04.

3.1.2.2.10 Loss of Fracture Toughness due to Neutron Irradiation Embrittlement, Change in Dimension due to Void Swelling, Loss of Preload due to Stress Relaxation, or Loss of Material due to Wear

Loss of fracture toughness due to neutron irradiation embrittlement, change in dimension due to void swelling, loss of preload due to stress relaxation, or loss of material due to wear could occur in inaccessible locations for stainless steel and nickel-alloy Primary and Expansion PWR reactor vessel internal components. If aging effects are identified in accessible locations, the GALL Report recommends further evaluation of the aging effects in inaccessible locations on a plant-specific basis to ensure that this aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

Removed per LR-ISG-2011-04.

3.1.2.2.11 Cracking due to Primary Water Stress Corrosion Cracking (PWSCC).

1. *Foreign operating experience in steam generators with a similar design to that of Westinghouse Model 51 has identified extensive cracking due to primary water stress corrosion cracking (PWSCC) in steam generator (SG) divider plate assemblies fabricated of Alloy 600 and/or the associated Alloy 600 weld materials, even with proper primary water chemistry (EPRI TR-1014982). Cracks have been detected in the stub runner, adjacent to the tubesheet/stub runner weld and with depths of almost a third of the divider*

plate thickness. Therefore, the water chemistry program may not be effective in managing the aging effect of cracking due to PWSCC in SG divider plate assemblies. This is of particular concern for steam generators where the tube-tubesheet welds are considered structural welds and/or where the divider plate assembly contributes to the mechanical integrity of the tubesheet. Although these SG divider plate cracks may not have a significant safety impact in and of themselves, these cracks could impact adjacent items, such as the tubesheet and the channel head, if they propagate to the boundary with these items. For the tubesheet, PWSCC cracks in the divider plate could propagate to the tubesheet cladding with possible consequences to the integrity of the tube/tubesheet welds. For the channel head, the PWSCC cracks in the divider plate could propagate to the SG triple point and potentially affect the pressure boundary of the SG channel head. The existing program relies on control of reactor water chemistry to mitigate cracking due to PWSCC. The GALL Report recommends that a plant-specific AMP be evaluated, along with the primary water chemistry program, because the existing primary water chemistry program may not be capable of mitigating cracking due to PWSCC. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

2. *Cracking due to PWSCC could occur in steam generator nickel alloy tube-to-tubesheet welds exposed to reactor coolant. Unless the NRC has approved a redefinition of the pressure boundary in which the tube-to-tubesheet weld is no longer included, the effectiveness of the primary water chemistry program should be verified to ensure cracking is not occurring:*

   - *For plants with Alloy 600 steam generator tubes that have not been thermally treated and for which an alternate repair criteria such as C*, F* or W* has been permanently approved, the weld is no longer part of the pressure boundary and no plant specific aging management program is required;*

   - *For plants with Alloy 600 steam generator tubes that have not been thermally treated and for which there is no permanently approved alternate repair criteria such as C*, F* or W*, a plant-specific AMP is required;*

   - *For plants with Alloy 600TT steam generator tubes and for which an alternate repair criteria such as H* has been permanently approved, the weld is no longer part of the pressure boundary and no plant specific aging management program is required;*

   - *For plants with Alloy 600TT steam generator tubes and for which there is no alternate repair criteria such as H* permanently approved, a plant-specific AMP is required;*

- *For plants with Alloy 690TT steam generator tubes with Alloy 690 tubesheet cladding, the water chemistry is sufficient, and no further action or plant-specific aging management program is required;*
- *For plants with Alloy 690TT steam generator tubes and with Alloy 600 tubesheet cladding, either a plant-specific program or a rationale for why such a program is not needed is required.*

The existing program relies on control of reactor water chemistry to mitigate cracking due to PWSCC. The GALL Report recommends that a plant-specific AMP be evaluated, along with the primary water chemistry program, because the existing primary water chemistry program may not be capable of mitigating cracking due to PWSCC. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

These paragraphs in NUREG-1800 apply to PWRs only and is therefore not applicable to PNPP.

3.1.2.2.12 Cracking due to Fatigue

EPRI 1016596, Materials Reliability Program: Pressurized Water Reactor Internals Inspection and Evaluation Guidelines (MRP-227-Rev. 0) identifies cracking due to fatigue as an aging effect that can occur for the lower flange weld in the core support barrel assembly, fuel alignment plate in the upper internals assembly, and core support plate lower support structure in PWR internals designed by Combustion Engineering. The GALL Report recommends that inspection for cracking in this component be performed if acceptable fatigue life cannot be demonstrated by TLAA through the period of extended operation as defined in 10 CFR 54.3.

Removed per LR-ISG-2011-04.

3.1.2.2.13 Cracking due to Stress Corrosion Cracking and Fatigue

Cracking due to stress corrosion cracking and fatigue could occur in nickel alloy control rod guide tube assemblies, guide tube support pins exposed to reactor coolant, and neutron flux. The GALL Report, AMR Item IV.B2.RP-355, recommends further evaluation of a plant-specific AMP to ensure this aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

Removed per LR-ISG-2011-04.

3.1.2.2.14 Loss of Material due to Wear

Loss of material due to wear could occur in nickel alloy control rod guide tube assemblies, guide tube support pins and in Zircaloy-4 incore instrumentation lower thimble tubes exposed to reactor coolant, and neutron flux. The GALL Report, AMR Items IV.B2.RP-356 and IV.B3.RP- 357, recommends further evaluation of a plant-

specific AMP to ensure this aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

Removed per LR-ISG-2011-04.

3.1.2.2.15 Quality Assurance for Aging Management of Nonsafety-Related Components

Acceptance criteria are described in Branch Technical Position IQMB-1 (Appendix A.2 of this SRP-LR).

See Appendix B, Section B.1.3, for discussion of PNPP quality assurance procedures and administrative controls for aging management programs.

3.1.2.2.16 Ongoing Review of Operating Experience (Per LR-ISG-2011-05)

Ongoing review of operating experience is addressed in Appendix A, Section A.1 and Appendix B, Section B.1.4.

3.1.2.3 Time-Limited Aging Analyses

The time-limited aging analyses identified associated with the Reactor Vessel, Internals, and Reactor Coolant System components are addressed in Section 4. Table 4.1-2 provides TLAA results and identifies whether the TLAA remains valid for the PEO, will be managed during the PEO, and the LRA sections that address them.

3.1.3 Conclusion

The Reactor Vessel, Internals, and Reactor Coolant System piping fittings and components that are subject to aging management review have been identified in accordance with the requirements of 10 CFR 54.21. The aging management programs selected to manage aging effects for the Reactor Vessel, Internals, and Reactor Coolant System components are identified in the summaries in Section 3.1.2.1 above.

A description of these aging management programs is provided in Appendix B, along with the demonstration that the identified aging effects will be managed for the period of extended operation.

Therefore, based on the conclusions provided in Appendix B, the effects of aging associated with the Reactor Vessel, Internals and Reactor Coolant System components will be adequately managed so that there is reasonable assurance that the intended functions are maintained consistent with the current licensing basis during the period of extended operation.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-1	High strength, low-alloy steel top head closure stud assembly exposed to air with potential for reactor coolant leakage	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation (See SRP, Sec 4.3 “Metal Fatigue,” for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is evaluated as a TLAA. See further evaluation section 3.1.2.2.1.
3.1.1-2	PWR only				
3.1.1-3	Stainless steel or nickel alloy reactor vessel internal components exposed to reactor coolant and neutron flux	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation (See SRP, Sec 4.3 “Metal Fatigue,” for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is evaluated as a TLAA. See further evaluation section 3.1.2.2.1.
3.1.1-4	Steel pressure vessel support skirt and attachment welds	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation (See SRP, Sec 4.3 “Metal Fatigue,” for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is evaluated as a TLAA. See further evaluation section 3.1.2.2.1.
3.1.1-5	PWR only				

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-6	Steel (with or without nickel-alloy or stainless steel cladding), or stainless steel; or nickel-alloy reactor coolant pressure boundary components: piping, piping components, and piping elements exposed to reactor coolant	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation, and for Class 1 components environmental effects on fatigue are to be addressed. (See SRP, Sec 4.3 “Metal Fatigue,” for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is evaluated as a TLAA. See further evaluation section 3.1.2.2.1.
3.1.1-7	Steel (with or without nickel-alloy or stainless steel cladding), or stainless steel; or nickel alloy reactor vessel components: flanges; nozzles; penetrations; safe ends; thermal sleeves; vessel shells, heads and welds exposed to reactor coolant	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation, and for Class 1 components environmental effects on fatigue are to be addressed. (See SRP, Sec 4.3 “Metal Fatigue,” for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is evaluated as a TLAA. See further evaluation section 3.1.2.2.1.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801					
Item Number	**Component**	**Aging Effect/ Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1.1-8	PWR only				
3.1.1-9	PWR only				
3.1.1-10	PWR only				
3.1.1-11	Steel or stainless steel pump and valve closure bolting exposed to high temperatures and thermal cycles	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation; check ASME Code limits for allowable cycles (less than 7000 cycles) of thermal stress range. (SRP Sec 4.3 “Metal Fatigue,” for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See subsection 3.1.2.2.1)	Consistent with NUREG-1801. Fatigue is evaluated as a TLAA in LRA Section 4.3. See further evaluation section 3.1.2.2.1. Closure bolting in the Main and Reheat Steam, and the Main, Reheat, Extraction, and Miscellaneous Drains and the Auxiliary Steam systems are also aligned to this row. Additionally, hot (heat traced) stainless steel piping and valves in the Post-Accident Sampling system that are exposed to air are aligned to this row.
3.1.1-12	PWR only				

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-13	Steel (with or without stainless steel cladding) reactor vessel beltline shell, nozzles, and welds exposed to reactor coolant and neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement	TLAA is to be evaluated in accordance with Appendix G of 10 CFR Part 50 and RG 1.99. The applicant may choose to demonstrate that the materials of the nozzles are not controlling for the TLAA evaluations	Yes, TLAA (See subsection 3.1.2.2.3.1)	Consistent with NUREG-1801. Loss of fracture toughness is evaluated as a TLAA. See further evaluation section 3.1.2.2.3.1.
3.1.1-14	Steel (with or without cladding) reactor vessel beltline shell, nozzles, and welds; safety injection nozzles	Loss of fracture toughness due to neutron irradiation embrittlement	Chapter XI.M31, “Reactor Vessel Surveillance”	Yes, plant specific or integrated surveillance program (See subsection 3.1.2.2.3.2)	Consistent with NUREG-1801. Loss of fracture toughness is evaluated as a TLAA. See further evaluation section 3.1.2.2.3.2.
3.1.1-15	PWR only				

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-16	Stainless steel and nickel alloy top head enclosure vessel flange leak detection line	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking	A plant-specific aging management program is to be evaluated because existing programs may not be capable of mitigating or detecting crack initiation and growth due to SCC in the vessel flange leak detection line	Yes, plant-specific (See subsection 3.1.2.2.4.1)	Not applicable. There are no stainless steel or nickel alloy top head enclosure vessel flange leak detection piping components in the Reactor Vessel, Internals, and Reactor Coolant systems. The top head enclosure vessel flange leak detection line is carbon steel piping that is not susceptible to stress corrosion cracking (SCC) or intergranular stress corrosion cracking (IGSCC). See further evaluation section 3.1.2.2.4.1.
3.1.1-17	Stainless steel isolation condenser components exposed to reactor coolant	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components, and Chapter XI.M2, "Water Chemistry" for BWR water, and a plant-specific verification program	Yes, detection of aging effects is to be evaluated (See subsection 3.1.2.2.4.2)	Not applicable. PNPP does not have an isolation condenser. See further evaluation section 3.1.2.2.4.2.
3.1.1-18	PWR only				
3.1.1-19	PWR only				

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-20	PWR only				
3.1.1-21	Steel and stainless steel isolation condenser components exposed to reactor coolant	Cracking due to cyclic loading	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components The ISI program is to be augmented by a plant-specific verification program	Yes, detection of aging effects is to be evaluated (See subsection 3.1.2.2.7)	Not applicable. PNPP does not have an isolation condenser. See further evaluation subsection 3.1.2.2.7.
3.1.1-22	PWR only				
3.1.1-23	PWR only				
3.1.1-24	PWR only				
3.1.1-25	PWR only				
3.1.1-26	PWR only				
3.1.1-27	PWR only				
3.1.1-28	PWR only

Item Number	**Component**	**Aging Effect/ Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1.1-29	Nickel alloy core shroud and core plate access hole cover (welded covers) exposed to reactor coolant	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking, irradiation-assisted stress corrosion cracking	Chapter XI.M1, “ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD,” and Chapter XI.M2, “Water Chemistry,” and for BWRs with a crevice in the access hole covers, augmented inspection using UT or other acceptable techniques	No	Consistent with NUREG-1801 but is being managed by a different set of programs (BWR Vessel Internals and Water Chemistry) and with some program exceptions. The core shroud and access hole covers are stainless steel and nickel alloy. Cracking of this component is also addressed in item 3.1.1-103. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801					
Item Number	**Component**	**Aging Effect/ Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1.1-30	Stainless steel or nickel alloy penetration: drain line exposed to reactor coolant	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking, cyclic loading	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD," and Chapter XI.M2, "Water Chemistry"	No	Consistent with NUREG-1801 for different components and with some program exceptions. The ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD and Water Chemistry programs will manage cracking of steel with stainless steel cladding reactor vessel shell and bottom head components. PNPP does not have a stainless steel or nickel alloy drain line exposed to reactor coolant. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.1.1-31	Steel and stainless steel isolation condenser components exposed to reactor coolant	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD," and Chapter XI.M2, "Water Chemistry"	No	Not applicable. PNPP does not have an isolation condenser.
3.1.1-32	PWR only				
3.1.1-33	PWR only				

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-34	PWR only				
3.1.1-35	PWR only				
3.1.1-36	PWR only				
3.1.1-37	PWR only				
3.1.1-38	Cast austenitic stainless steel Class 1 pump casings, and valve bodies and bonnets exposed to reactor coolant >250 deg-C (>482 deg-F)	Loss of fracture toughness due to thermal aging embrittlement	Chapter XI.M1, “ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD” for Class 1 components. For pump casings and valve bodies, screening for susceptibility to thermal aging is not necessary.	No	Consistent with NUREG-1801. Loss of fracture toughness of pump casings and valve bodies is managed by the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD program.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801					
Item Number	**Component**	**Aging Effect/ Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1.1-39	Steel, stainless steel, or steel with stainless steel cladding Class 1 piping, fittings and branch connections < NPS 4 exposed to reactor coolant	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking (for stainless steel only), and thermal, mechanical, and vibratory loading	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components, Chapter XI.M2, "Water Chemistry," and XI.M35, "One-Time Inspection of ASME Code Class 1 Small-bore Piping"	No	Consistent with NUREG-1801 with some program exceptions. Cracking of Class 1 stainless steel valves and piping components < NPS 4 in the Reactor Coolant Pressure Boundary system is managed by the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD, Water Chemistry, and One-Time Inspection of ASME Code Class 1 Small Bore-Piping programs. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.1.1-40	PWR only				
3.1.1-40x	PWR only				

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-41	Nickel alloy core shroud and core plate access hole cover (mechanical covers) exposed to reactor coolant	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking, irradiation-assisted stress corrosion cracking	Chapter XI.M1, “ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD” for Class 1 components, and Chapter XI.M2, “Water Chemistry”	No	Not applicable. The core shroud support and access hole covers are stainless steel and contain nickel alloy. Cracking of these components is addressed in items 3.1.1-29 and 3.1.1-103.
3.1.1-42	PWR only				

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801					
Item Number	**Component**	**Aging Effect/ Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1.1-43	Stainless steel and nickel-alloy reactor vessel internals exposed to reactor coolant	Loss of material due to pitting and crevice corrosion	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components, and Chapter XI.M2, "Water Chemistry"	No	Consistent with NUREG-1801 for material, environment, and aging effect but with different programs credited and some program exceptions. Loss of material for stainless steel, and nickel alloy (including X-750) reactor vessel internals components is managed by the BWR Vessel Internals and Water Chemistry programs. This difference from the GALL recommendation is consistent with the purpose of the BWR Vessel Internals program. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Item Number	**Component**	**Aging Effect/ Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1.1-49	PWR only				
3.1.1-50	Cast austenitic stainless steel Class 1 piping, piping component, and piping elements and control rod drive pressure housings exposed to reactor coolant >250 deg-C (>482 deg-F)	Loss of fracture toughness due to thermal aging embrittlement	Chapter XI.M12, "Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)"	No	Not applicable. PNPP does not have cast austenitic stainless steel Class 1 piping, piping components, and piping elements or control rod drive pressure housings other than the pump casings and valve bodies addressed in item 3.1.1-38 that are exposed to reactor coolant >250 deg-C (>482 deg-F) subject to Loss of fracture toughness. The control rod drive housings are stainless steel and nickel alloy.

Item Number	**Component**	**Aging Effect/ Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1.1-59	PWR only				
3.1.1-60	Steel piping, piping components, and piping elements exposed to reactor coolant	Wall thinning due to flow-accelerated corrosion	Chapter XI.M17, “Flow-Accelerated Corrosion”	No	Consistent with NUREG-1801. The Flow- Accelerated Corrosion program will manage wall thinning (loss of material) due to flow accelerated corrosion of steel components exposed to reactor coolant (called "treated water" in the AMRs) in the Nuclear Boiler and Reactor Coolant Pressure Boundary systems.
3.1.1-61	PWR only				
3.1.1-62	PWR only				
3.1.1-63	Steel or stainless steel closure bolting exposed to air with reactor coolant leakage	Loss of material due to general (steel only), pitting, and crevice corrosion or wear	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. The Bolting Integrity program will manage loss of material for steel and high strength steel bolting exposed to air with reactor coolant leakage (other than the head closure stud assemblies that are addressed in Item 3.1.1-91).
3.1.1-64	PWR only				
3.1.1-65	PWR only				

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-66	PWR only				
3.1.1-67	Steel or stainless steel closure bolting exposed to air – indoor with potential for reactor coolant leakage	Loss of preload due to thermal effects, gasket creep, and self-loosening	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. The Bolting Integrity program will manage loss of preload for steel and high strength steel bolting exposed to air - indoor uncontrolled, and air with reactor coolant leakage in the Reactor Coolant Pressure Boundary, Reactor Vessel, Nuclear Boiler and Reactor Recirculation systems.
3.1.1-68	PWR only				
3.1.1-69	PWR only

3.1.1-78	PWR only				
3.1.1-79	Stainless steel; steel with nickel-alloy or stainless steel cladding; and nickel-alloy reactor coolant pressure boundary components exposed to reactor coolant	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801 for most components and with some program exceptions. The Water Chemistry program will manage loss of material of stainless steel, nickel alloy, and steel with stainless steel cladding components exposed to reactor coolant (called "Treated water" in the AMRs) in the Reactor Coolant Pressure Boundary, Nuclear Boiler and Reactor Recirculation systems. The One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. Loss of material due to erosion of the main steam line flow restrictor venturis is evaluated as a TLAA in LRA Section 4.6.2. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

3.1.1-83	PWR only				
3.1.1-84	Steel top head enclosure (without cladding) top head nozzles (vent, top head spray or RCIC, and spare) exposed to reactor coolant	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801 with some program exceptions. The Water Chemistry program will manage loss of material of steel top head components, nozzles and other Reactor Vessel components and welds exposed to reactor coolant. The One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

3.1.1-91	High-strength low alloy steel closure head stud assembly exposed to air with potential for reactor coolant leakage	Cracking due to stress corrosion cracking; loss of material due to general, pitting, and crevice corrosion, or wear (BWR)	Chapter XI.M3, “Reactor Head Closure Stud Bolting”	No	Consistent with NUREG-1801 with some program exceptions. The Reactor Head Closure Stud Bolting program will manage loss of material and cracking of high-strength steel Reactor Vessel closure head stud assemblies exposed to air with reactor coolant leakage. See Appendix B Section B.2.39 for Rx Head Closure Stud Bolting program exceptions to NUREG-1801.
3.1.1-92	PWR only				
3.1.1-93	PWR only				

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-94	Stainless steel and nickel alloy vessel shell attachment welds exposed to reactor coolant	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking	Chapter XI.M4, “BWR Vessel ID Attachment Welds,” and Chapter XI.M2, “Water Chemistry”	No	Consistent with NUREG-1801 with some program exceptions. The BWR Vessel ID Attachment Welds and Water Chemistry programs will manage cracking of stainless steel Reactor Vessel shell attachment welds exposed to reactor coolant. PNPP does not have nickel alloy vessel shell attachment welds exposed to reactor coolant in the Reactor Vessel, Internals, and Reactor Coolant systems. Nickel alloy nozzle and safe end welds are addressed by item 3.1.1-97. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801. See Appendix B Section B.2.13 for BWR Vessel ID Attachment Welds program exceptions to NUREG-1801.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-95	Steel (with or without stainless steel cladding) feedwater nozzles exposed to reactor coolant	Cracking due to cyclic loading	Chapter XI.M5, "BWR Feedwater Nozzle"	No	Consistent with NUREG-1801 with some program exceptions. The BWR Feedwater Nozzle program will manage cracking of the Reactor Vessel feedwater nozzle exposed to reactor coolant. See Appendix B Section B.2.10 for BWR Feedwater Nozzle program exceptions to NUREG-1801.
3.1.1-96	Steel (with or without stainless steel cladding) control rod drive return line nozzles exposed to reactor coolant	Cracking due to cyclic loading	Chapter XI.M6, "BWR Control Rod Drive Return Line Nozzle"	No	Consistent with NUREG-1801. The BWR Control Rod Drive Return Line Nozzle program will manage cracking of the (capped) Reactor Vessel control rod drive return nozzle exposed to reactor coolant.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-97	Stainless steel and nickel alloy piping, piping components, and piping elements greater than or equal to 4 NPS; nozzle safe ends and associated welds	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking	Chapter XI.M7, "BWR Stress Corrosion Cracking," and Chapter XI.M2, "Water Chemistry"	No	Consistent with NUREG-1801 with some program exceptions. The BWR Stress Corrosion Cracking and Water Chemistry programs will manage cracking of stainless steel, nickel alloy and steel with stainless steel cladding piping, piping components, and piping elements greater than or equal to NPS 4, nozzles, safe ends and associated welds in the Reactor Coolant Pressure Boundary and Reactor Vessel systems. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Item Number	**Component**	**Aging Effect/ Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1.1-98	Stainless steel or nickel alloy penetrations: instrumentation and standby liquid control exposed to reactor coolant	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking, cyclic loading	Chapter XI.M8, "BWR Penetrations," and Chapter XI.M2, "Water Chemistry"	No	Consistent with NUREG-1801 with the following clarification and with some program exceptions. The BWR Penetrations and Water Chemistry programs will manage cracking of stainless steel and nickel alloy control rod drive housings and incore housings that penetrate the Reactor Vessel and are exposed to reactor coolant. The Standby Liquid Control System does not connect to the Reactor Vessel directly, it connects to the High Pressure Core Spray supply line. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-99	Cast austenitic stainless steel; PH martensitic stainless steel; martensitic stainless steel; X-750 alloy reactor internal components exposed to reactor coolant and neutron flux	Loss of fracture toughness due to thermal aging and neutron irradiation embrittlement	Chapter XI.M9, "BWR Vessel Internals"	No	Consistent with NUREG-1801. The BWR Vessel Internals program will manage loss of fracture toughness of cast austenitic stainless steel and X-750 Reactor Vessel Internals components exposed to reactor coolant and neutron flux. PNPP does not have PH martensitic stainless steel or martensitic stainless steel Reactor Vessel Internal components.
3.1.1-100	Stainless steel reactor vessel internals components (jet pump wedge surface) exposed to reactor coolant	Loss of material due to wear	Chapter XI.M9, "BWR Vessel Internals"	No	Consistent with NUREG-1801. Loss of material for the jet pump restrainer bracket surface is aligned to this row to address wear. The Water Chemistry program is also credited for management of loss of material due to pitting and crevice corrosion, consistent with the discussion in 3.1.1-43.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-101	Stainless steel steam dryers exposed to reactor coolant	Cracking due to flow- induced vibration	Chapter XI.M9, "BWR Vessel Internals" for steam dryer	No	Consistent with NUREG-1801. The BWR Vessel Internals program will manage cracking of the stainless steel steam dryer.
3.1.1-102	Stainless steel fuel supports and control rod drive assemblies control rod drive housing exposed to reactor coolant	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking	Chapter XI.M9, “BWR Vessel Internals,” and Chapter XI.M2, “Water Chemistry”	No	Consistent with NUREG-1801 with some program exceptions. The BWR Vessel Internals and Water Chemistry programs will manage cracking of stainless steel fuel supports and control rod drive tube components exposed to reactor coolant. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-103	Stainless steel and nickel alloy reactor internal components exposed to reactor coolant and neutron flux	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking, irradiation-assisted stress corrosion cracking	Chapter XI.M9, "BWR Vessel Internals," and Chapter XI.M2, "Water Chemistry"	No	Consistent with NUREG-1801 for most components and with some program exceptions. The BWR Vessel Internals and Water Chemistry programs will manage cracking of stainless steel and nickel alloy reactor internals components exposed to reactor coolant and neutron flux that are not addressed by item 3.1.1-102. For the Incore dry tube assemblies, cracking is managed by the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD and Water Chemistry programs. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-104	X-750 alloy reactor vessel internal components exposed to reactor coolant and neutron flux	Cracking due to intergranular stress corrosion cracking	Chapter XI.M9, “BWR Vessel Internals” for core plate, and Chapter XI.M2, “Water Chemistry”	No	Consistent with NUREG-1801 with some program exceptions. The BWR Vessel Internals and Water Chemistry programs will manage cracking of X-750 vessel internals components exposed to reactor coolant and neutron flux. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.1.1-105	Steel piping, piping components and piping element exposed to concrete	None	None, provided 1) attributes of the concrete are consistent with ACI 318 or ACI 349 (low water-to-cement ratio, low permeability, and adequate air entrainment) as cited in NUREG-1557, and 2) plant OE indicates no degradation of the concrete	No, if conditions are met.	Not applicable. PNPP does not have steel piping, piping components or piping elements exposed to concrete in the Reactor Vessel, Internals or Reactor Coolant systems.

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-106	Nickel alloy piping, piping components and piping element exposed to air – indoor, uncontrolled, or air with borated water leakage	None	None	NA - No AEM or AMP	Consistent with NUREG-1801.
3.1.1-107	Stainless steel piping, piping components and piping element exposed to gas, concrete, air with borated water leakage, air – indoors, uncontrolled	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. In addition to the Reactor Vessel, Internals, and Reactor Coolant systems; stainless steel commodities in concrete in the Bulk Civil Commodities, Containment Structure, and Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures have been aligned with this item.
3.1.1-108	There is no Item Number 3.1.1-108 in NUREG-1800 Rev. 2 or subsequent ISGs.				
3.1.1-109	There is no Item Number 3.1.1-109 in NUREG-1800 Rev. 2 or subsequent ISGs.				

Table 3.1.1: Summary of Aging Management Evaluations for the Reactor Vessel, Internals, and Reactor Coolant System Components in Chapter IV of NUREG-1801

Item Number	Component	Aging Effect/ Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1.1-110 (LR-ISG-2012-01)	Any material, piping, piping components, and piping elements exposed to reactor coolant	Wall thinning due to erosion	Chapter XI.M17, "Flow-Accelerated Corrosion"	No	Not applicable. Steel piping, piping components and piping elements in the Reactor Vessel, Internals and Reactor Coolant systems that are susceptible to wall thinning due to flow-accelerated corrosion are managed by the Flow-Accelerated Corrosion program as described in item 3.1.1-60. There is no other piping, piping component, or piping element materials exposed to reactor coolant that have been identified as susceptible to wall thinning due to erosion in the Reactor Vessel, Internals or Reactor Coolant systems.

Notes for Table 3.1.2-1 through Table 3.1.2-6

Standard Notes

A. Consistent with NUREG-1801 item for component, material, environment and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment and aging effect, but a different aging management program is credited or NUREG-1801 identifies a plant-specific aging management program.

F. Material not in NUREG-1801 for this component.

G. Environment not in NUREG-1801 for this component and material.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

I. Aging effect in NUREG-1801 for this component, material and environment combination is not applicable.

J. Neither the component nor the material and environment combination are evaluated in NUREG-1801.

Plant-Specific Notes

101 Main steam line venturi material is A-351 grade CF8 (low molybdenum), with ferrite <20%. Based on the criteria set forth in the May 19, 2000, NRC (Grimes) letter, this material is not susceptible to thermal embrittlement.

102 High component surface temperature precludes moisture accumulation that could result in corrosion.

103 The internal environment of these components is Fyrquel™, a phosphate ester used as a hydraulic fluid. For the purposes of aging evaluation, this environment is compared to the GALL environment of "Lubricating oil."

104 See LRA section 4.6.2, Main Steam Line Flow Restrictors Erosion Analysis.

Plant-Specific Notes (Continued)

105 The Compressed Air Monitoring program provides assurance that the quality of the "Air - dry" environment supports the conclusion that no aging effects are expected.

106 Conservatively assumed as high strength steel. Per the CMTR for all the heats used to fabricate the studs the highest yield strength is 142,500 psi, which is < 150 psi. Hence, none of the bolts require treatment as high strength steel.

107 This component type represents high strength, low alloy steel flange bolts servicing the Reactor Head Spray flange (N8). High-strength steel and steel bolting in the environments of air with reactor coolant leakage, Air, and System temperature up to 288°C (550°F) are considered equivalent for the aging effects of Loss of Material, Loss of Preload, and Cumulative Fatigue Damage.

108 This component type represents the CRD housings that consists of stainless steel and nickel components with the nickel pipe welded to the reactor vessel head.

109 Loss of material for the jet pump restrainer bracket and cast austenitic stainless steel jet pump wedges surface is aligned to GALL line item to address wear.

110 These components are the stainless steel boundary valves in the Reactor Coolant Pressure Boundary System exposed to sodium pentaborate solution.

111 Per Table 4-1, EPRI Report 1010639, Non-Class 1 Mechanical Implementation Guideline and Mechanical Tool. Revision 4, Appendix D, Nickel-Base Alloy aging effects are treated same as stainless steel in a dried air environment. The Compressed Air Monitoring program provides assurance that the quality of the "Air - dry" environment supports the conclusion that no aging effects are expected.

3.2 AGING MANAGEMENT OF ENGINEERED SAFETY FEATURES

3.2.1 INTRODUCTION

This section provides the results of the aging management review for those components identified in Section 2.3.2, Engineered Safety Features, as being subject to aging management review. The systems, or portions of systems, which are addressed in this section are described in the indicated sections.

- Alternate Decay Heat Removal (Section 2.3.2.1)
- Annulus Exhaust Gas Treatment (Section 2.3.2.2)
- Containment Atmosphere Monitoring (Section 2.3.2.3)
- High Pressure Core Spray (Section 2.3.2.4)
- Low Pressure Core Spray (Section 2.3.2.5)
- Offgas (Section 2.3.2.6)
- Reactor Core Isolation Cooling (Section 2.3.2.7)
- Residual Heat Removal and Containment Spray (Section 2.3.2.8)
- Suppression Pool (Section 2.3.2.9)

3.2.2 RESULTS

The following tables summarize the results of the aging management review for the Engineered safety Features Systems.

- Table 3.2.2-1 Alternate Decay Heat Removal
- Table 3.2.2-2 Annulus Exhaust Gas Treatment
- Table 3.2.2-3 Containment Atmosphere Monitoring
- Table 3.2.2-4 High Pressure Core Spray
- Table 3.2.2-5 Low Pressure Core Spray
- Table 3.2.2-6 Offgas
- Table 3.2.2-7 Reactor Core Isolation Cooling
- Table 3.2.2-8 Residual Heat Removal and Containment Spray
- Table 3.2.2-9 Suppression Pool

3.2.2.1 Materials, Environment, Aging Effects Requiring Management and Aging Management Programs

The following sections list the materials, environments, aging effects requiring management, and aging management programs for the engineered safety features systems components subject to aging management review. Programs are described in Appendix B. Further details are provided in the system tables.

3.2.2.1.1 Alternate Decay Heat Removal

Materials

Alternate Decay Heat Removal system components are constructed of the following materials:

- CASS
- Stainless steel
- Steel

Environments

Alternate Decay Heat Removal system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Raw water
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Alternate Decay Heat Removal system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Alternate Decay Heat Removal system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- One-Time Inspection (B.2.35)
- Open-Cycle Cooling Water System (B.2.37)
- Water Chemistry (B.2.44)

3.2.2.1.2 Annulus Exhaust Gas Treatment

Materials

Annulus Exhaust Gas Treatment system components are constructed of the following materials:

- Aluminum
- Copper alloy <15% Zn
- Elastomers
- Stainless steel
- Steel

Environments

Annulus Exhaust Gas Treatment system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Annulus Exhaust Gas Treatment system require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Annulus Exhaust Gas Treatment system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.2.2.1.3 Containment Atmosphere Monitoring

Materials

Containment Atmosphere Monitoring system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Containment Atmosphere Monitoring system components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Containment Atmosphere Monitoring system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Containment Atmosphere Monitoring system components:

- Bolting Integrity (B.2.7)

3.2.2.1.4 High Pressure Core Spray

Materials

High Pressure Core Spray system components are constructed of the following materials:

- CASS
- Stainless steel
- Steel

Environments

High Pressure Core Spray system components are exposed to the following system environments: system

- Air – indoor, uncontrolled
- Lubricating oil
- Treated water
- Treated water >60°C (>140°F)

Aging Effects Requiring Management

The following aging effects associated with the High Pressure Core Spray system require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on High Pressure Core Spray system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.2.2.1.5 Low Pressure Core Spray

Materials

Low Pressure Core Spray system components are constructed of the following materials:

- CASS
- Stainless steel
- Steel

Environments

Low Pressure Core Spray system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Lubricating oil
- Treated water

- Treated water >60˚C (>140˚F)

Aging Effects Requiring Management

The following aging effects associated with the Low Pressure Core Spray system require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Low Pressure Core Spray system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.2.2.1.6 Offgas

Materials

Offgas system components are constructed of the following materials:

- CASS
- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Glass
- Gray cast iron
- Stainless steel
- Steel

Environments

Offgas system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Condensation
- Lubricating oil
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Offgas system require management:

- Cracking
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Offgas system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)
- Water Chemistry (B.2.44)

3.2.2.1.7 Reactor Core Isolation Cooling

Materials

Reactor Core Isolation Cooling system components are constructed of the following materials:

- CASS
- Glass
- Gray cast iron
- Stainless steel
- Steel

Environments

Reactor Core Isolation Cooling system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Lubricating oil
- Treated water
- Treated water >60°C (>140°F)

Aging Effects Requiring Management

The following aging effects associated with the Reactor Core Isolation Cooling system require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following aging management programs manage the effects of aging on Reactor Core Isolation Cooling system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.2.2.1.8 Residual Heat Removal and Containment Spray

Materials

Residual Heat Removal and Containment Spray system components are constructed of the following materials:

- CASS
- Stainless steel
- Steel
- Steel with stainless steel cladding

Environments

Residual Heat Removal and Containment Spray system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Lubricating oil
- Raw water
- Treated water
- Treated water >60°C (>140°F)

Aging Effects Requiring Management

The following aging effects associated with the Residual Heat Removal and Containment Spray system require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following aging management programs manage the effects of aging on Residual Heat Removal and Containment Spray system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Open-Cycle Cooling Water System (B.2.37)
- TLAA
- Water Chemistry (B.2.44)

3.2.2.1.9 Suppression Pool

Materials

Suppression Pool system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Suppression Pool system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Suppression Pool system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Suppression Pool system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.2.2.2 Further Evaluation of Aging Management as Recommended by NUREG-1800

NUREG-1800 indicates that further evaluation is necessary for certain aging effects and other issues discussed in Section 3.2.2.2 of NUREG-1800. The following sections are numbered in accordance with the discussions in NUREG-1800 and explain the PNPP approach to these areas requiring further evaluation. Programs are described in Appendix B.

Note - Italicized text at the beginning of each Further Evaluation subsection is taken directly from NUREG-1800 as supplemented by LR-ISG-2011-05 and LR-ISG-2012-02.

3.2.2.2.1 Cumulative Fatigue Damage

Fatigue is a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). This TLAA is addressed separately in Section 4.3, "Metal Fatigue Analysis," of this SRP-LR.

Fatigue is a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). The evaluation of metal fatigue as a TLAA for non-Class 1 components in the Residual Heat Removal and Containment Spray, High Pressure Core Spray, Low Pressure Core Spray, and Reactor Core Isolation Cooling systems is discussed in Section 4.3.2 either specifically or as part of the global evaluation. Likewise, in addition, Metal fatigue for non-Class 1 components in the Auxiliary systems (Control and Computer Rooms Humidification System) is also addressed in Section 4.3.2. See Section 4.3 for a complete evaluation of metal fatigue.

3.2.2.2.2 Loss of Material due to Cladding Breach

Loss of material due to cladding breach could occur for PWR steel pump casings with stainless steel cladding exposed to treated borated water. The GALL Report references NRC Information Notice 94-63, Boric Acid Corrosion of Charging Pump Casings Caused by Cladding Cracks, and recommends further evaluation of a plant-specific AMP to ensure that the aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

This paragraph in NUREG-1800 pertains to PWR steel charging pump casings with stainless steel cladding and is therefore not applicable to PNPP.

3.2.2.2.3 Loss of Material due to Pitting and Crevice Corrosion

1. *Loss of material due to pitting and crevice corrosion could occur in partially encased stainless steel tanks exposed to raw water due to cracking of the perimeter seal from weathering. The GALL Report recommends further evaluation to ensure that the aging effect is adequately managed. The GALL Report recommends that a plant-specific AMP be evaluated because moisture and water can egress under the tank if the perimeter seal is degraded. Acceptance criteria are described in Branch Technical Position RSLB-1 (Appendix A.1 of this SRP-LR).*

This paragraph in NUREG-1800 pertains to loss of material due to pitting and crevice corrosion in partially encased stainless steel tanks exposed to raw water due to cracking of the perimeter seal from weathering. Although this paragraph is referenced only by a PWR table line (V.D1.E-01) in NUREG-1801, it could also apply to BWR plants. However, the ESF systems at PNPP do not include partially encased stainless steel tanks requiring aging management that are exposed to this environment. Therefore, this paragraph is not applicable.

2. *Loss of material due to pitting and crevice corrosion could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air. The possibility of pitting and crevice corrosion also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Pitting and crevice corrosion is only known to occur in environments containing sufficient sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible.*

Loss of material due to pitting and crevice corrosion could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air, including air which has recently been introduced into buildings, such as near intake vents. At PNPP, there are no ESF system components requiring aging management review that are exposed to outdoor air. Therefore, this item was not used.

3.2.2.2.4 Loss of Material due to Erosion

Loss of material due to erosion could occur in the stainless steel high-pressure safety injection (HPSI) pump miniflow recirculation orifice exposed to treated borated water. The GALL Report recommends a plant-specific AMP be evaluated for erosion of the orifice due to extended use of the centrifugal HPSI pump for normal charging. The GALL Report references Licensee Event Report (LER) 50-275/94-023 for evidence of erosion. Further evaluation is recommended to ensure that the aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RSLB-1 (Appendix A.1 of this SRP-LR).

This paragraph in NUREG-1800 pertains to PWR high pressure safety injection (HPSI) pump miniflow recirculation orifice and is therefore not applicable to PNPP.

3.2.2.2.5 Loss of Material due to General Corrosion and Fouling that Leads to Corrosion

Loss of material due to general corrosion and fouling that leads to corrosion can occur for steel drywell and suppression chamber spray system nozzle and flow orifice internal surfaces exposed to air - indoor uncontrolled. This could result in plugging of the spray nozzles and flow orifices. This aging mechanism and effect will apply since the spray nozzles and flow orifices are occasionally wetted, even though the majority of the time this system is on standby. The wetting and drying of these components can accelerate corrosion and fouling. The GALL Report recommends further evaluation of a plant-specific AMP to ensure that the aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RSLB-1 (Appendix A.1 of this SRP-LR).

This item refers to loss of material due to general corrosion and fouling occurring for steel drywell and suppression chamber spray system nozzle and flow orifice internal surfaces exposed to indoor air. PNPP has stainless steel orifices and spray nozzles subject to aging management with an internal, air-indoor, uncontrolled environment. There are no steel spray system flow orifices or nozzles subject to aging management in an internal, uncontrolled indoor air environment in Engineered Safety Features systems at PNPP. Therefore, this item is not used.

3.2.2.2.6 Cracking due to Stress Corrosion Cracking

Cracking due to stress corrosion cracking could occur for stainless steel piping, piping components, piping elements and tanks exposed to outdoor air. The possibility of cracking also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Cracking is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible. Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those within 1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas subject to chloride contamination from other agricultural or industrial sources. This item is applicable for the environments described above. GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external chloride stress corrosion cracking is not expected. The GALL Report recommends further evaluation to determine whether an aging management program is needed to manage this aging effect based on the environmental conditions applicable to the plant and requirements applicable to the components.

Cracking due to stress corrosion cracking could occur for stainless steel piping, piping components, piping elements and tanks exposed to outdoor air, including air which has recently been introduced into buildings, such as near intake vents. At PNPP, there are no ESF system components in the scope of license renewal that are exposed to outdoor air. Therefore, this item is not applicable.

3.2.2.2.7 Quality Assurance for Aging Management of Nonsafety-Related Components

Acceptance criteria are described in Branch Technical Position IQMB-1 (Appendix A.2 of this SRP-LR.)

See Appendix B Section B.1.3 for discussion of PNPP quality assurance procedures and administrative controls for aging management programs.

3.2.2.2.8 Ongoing Review of Operating Experience (Per LR-ISG-2011-05)

Ongoing review of operating experience is addressed in Appendix A section A.1 and Appendix B Section B.1.4

3.2.2.2.9 Loss of Material due to Recurring Internal Corrosion

Recurring internal corrosion can result in the need to augment AMPs beyond the recommendations in the GALL Report. During the search of plant-specific OE conducted during the LRA development, recurring internal corrosion can be identified by the number of occurrences of aging effects and the extent of degradation at each localized corrosion site. This further evaluation item is applicable if the search of plant-specific OE reveals repetitive occurrences (e.g., one per refueling outage cycle that has occurred over: (a) three or more sequential or nonsequential cycles for a 10-year OE search, or (b) two or more sequential or nonsequential cycles for a 5-year OE search) of aging effects with the same aging mechanism in which the aging effect resulted in the component either not meeting plant-specific acceptance criteria or experiencing a reduction in wall thickness greater than 50 percent (regardless of the minimum wall thickness.

The GALL Report recommends that a plant-specific AMP, or a new or existing AMP, be evaluated for inclusion of augmented requirements to ensure the adequate management of any recurring aging effect(s). Potential augmented requirements include: alternative examination methods (e.g., volumetric versus external visual), augmented inspections (e.g., a greater number of locations, additional locations based on risk insights based on susceptibility to aging effect and consequences of failure, a greater frequency of inspections), and additional trending parameters and decision points where increased inspections would be implemented. Acceptance criteria are described in Appendix A.1, "Aging Management Review – Generic (Branch Technical Position RSLB-1)."

The applicant states: (a) why the program's examination methods will be sufficient to detect the recurring aging effect before affecting the ability of a component to perform its intended function, (b) the basis for the adequacy of augmented or lack of augmented inspections, (c) what parameters will be trended as well as the decision points where increased inspections would be implemented (e.g., the extent of degradation at individual corrosion sites, the rate of degradation change), (d) how inspections of components that are not easily accessed (i.e., buried, underground) will be conducted, and (e) how leaks in any involved buried or underground components will be identified.

Each plant-specific operating experience example should be evaluated to determine if the chosen AMP should be augmented even if the thresholds for significance of aging effect or frequency of occurrence of aging effect have not been exceeded. For example, during a 10-year search of plant specific operating experience, two instances of 360 degree 30 percent wall loss occurred at copper alloy to steel joints. Neither the significance of the aging effect nor the frequency of occurrence of aging effect threshold has been exceeded. Nevertheless, the operating experience should be evaluated to determine if the AMP that is proposed to manage the aging *effect is sufficient (e.g., method of inspection, frequency of inspection, number of inspections) to provide reasonable assurance that the CLB intended functions of the component will be met throughout the period of extended operation. Likewise, the GALL Report AMR items associated with the new FE items only cite raw water and waste water environments because OE indicates that these are the predominant environments associated with recurring internal corrosion; however, if the search of plant-specific OE reveals recurring internal corrosion in other water environments (e.g., treated water), the aging effect should be addressed in a similar manner.*

LR-ISG-2012-02 has been issued which addresses instances of recurring internal corrosion identified during review of plant-specific operating experience. The operating experience for PNPP has been reviewed and the Engineered Safety Features systems have not exhibited instances of recurring internal corrosion with a frequency that is consistent with the thresholds discussed in LR-ISG-2012-02.

3.2.2.3 Time-Limited Aging Analyses

The time-limited aging analyses identified associated with ESF System components are addressed in Section 4. Table 4.1-2 provides TLAA results and identifies whether the TLAA remains valid for the PEO, will be managed during the PEO, and the LRA sections that address them.

3.2.3 CONCLUSION

The Engineered Safety Features piping, fittings, and components that are subject to aging management review have been identified in accordance with the requirements of 10 CFR 54.21. The aging management programs selected to manage aging effects for the Engineered Safety Features components are identified in the summaries in Section 3.2.2.1 above.

A description of these aging management programs is provided in Appendix B, along with the demonstration that the identified aging effects will be managed for the period of extended operation.

Therefore, based on the conclusions provided in Appendix B, the effects of aging associated with the Engineered Safety Features components will be adequately managed so that there is reasonable assurance that the intended functions are maintained consistent with the current licensing basis during the period of extended operation.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-1	Stainless steel, Steel Piping, piping components, and piping elements exposed to Treated water (borated)	Cumulative fatigue damage due to fatigue	Fatigue is a time-limited aging analysis (TLAA) to be evaluated for the period of extended operation. See the SRP, Section 4.3 "Metal Fatigue," for acceptable methods for meeting the requirements of 10 CFR 54.21(c)(1).	Yes, TLAA (See subsection 3.2.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is evaluated as a TLAA. In addition to components in the Engineered Safety Features systems, components in the Control Room and Computer Room Steam Humidification system are also aligned to this row. See further evaluation section 3.2.2.2.1.
3.2.1-2	PWR only				
3.2.1-3	PWR only				
3.2.1-4	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See subsection 3.2.2.2.3)	Not applicable. At PNPP, there are no ESF system components subject to aging management that are exposed to air - outdoor. See further evaluation section 3.2.2.2.3.2.
3.2.1-5	PWR only				

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-6	Steel Drywell and suppression chamber spray system (internal surfaces): flow orifice; spray nozzles exposed to Air – indoor, uncontrolled (Internal)	Loss of material due to general corrosion; fouling that leads to corrosion	A plant-specific aging management program is to be evaluated	Yes, plant-specific (See subsection 3.2.2.2.5)	Not applicable. There are no steel spray system flow orifices or nozzles subject to aging management in the Engineered Safety Features systems that are in an uncontrolled indoor air environment. See further evaluation section 3.2.2.2.5.
3.2.1-7	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Cracking due to stress corrosion cracking	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See subsection 3.2.2.2.6)	Not applicable. At PNPP, there are no ESF system components subject to aging management that are exposed to air - outdoor. Those portions of the High Pressure Core Spray system and Reactor Core Isolation system suction piping from the Condensate Storage Tank are scoped under the Condensate Transfer System and addressed under 3.4.1-63. Also see further evaluation section 3.2.2.2.6.
3.2.1-8	PWR only				
3.2.1-9	PWR only				

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-10	Cast austenitic stainless steel Piping, piping components, and piping elements exposed to Treated water (borated) >250˚C (>482˚F), Treated water >250˚C (>482˚F)	Loss of fracture toughness due to thermal aging embrittlement	Chapter XI.M12, "Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)"	No	Not applicable. There are no cast austenitic stainless steel components subject to aging management review in the Engineered Safety Features systems that are exposed to treated water (borated) >250˚C (>482˚F) or treated water >250˚C (>482˚F).
3.2.1-11	Steel Piping, piping components, and piping elements exposed to Steam, Treated water	Wall thinning due to flow- accelerated corrosion	Chapter XI.M17, "Flow-Accelerated Corrosion"	No	Consistent with NUREG-1801. The Flow-Accelerated Corrosion program will manage wall thinning (loss of material) due to flow-accelerated corrosion in steel components exposed to treated water. The "Treated water" environment in this application includes both liquid and vapor phases.
3.2.1-12	Steel, high-strength Closure bolting exposed to Air with steam or water leakage	Cracking due to cyclic loading, stress corrosion cracking	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. The Bolting Integrity program will manage cracking of high-strength steel closure bolting in the Reactor Coolant Pressure Boundary and Reactor Vessel systems.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-13	Steel; stainless steel Bolting, Closure bolting exposed to Air – outdoor (External), Air – indoor, uncontrolled (External)	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. Loss of material of steel bolting exposed to air - indoor, uncontrolled environment will be managed by the Bolting Integrity program.
3.2.1-14	Steel Closure bolting exposed to Air with steam or water leakage	Loss of material due to general corrosion	Chapter XI.M18, "Bolting Integrity"	No	Not applicable. The "air with steam or water leakage" environment was not used in the Engineered Safety Features systems. Loss of material for bolting components in the Engineered Safety Features systems that are exposed to air environments is addressed in items 3.2.1-13 and 3.3.1-12

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-15	Copper alloy, Nickel alloy, Steel; stainless steel, Stainless steel, Steel; stainless steel Bolting, Closure bolting exposed to Any environment, Air – outdoor (External), Raw water, Treated borated water, Fuel oil, Treated water, Air – indoor, uncontrolled (External)	Loss of preload due to thermal effects, gasket creep, and self- loosening	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. The Bolting Integrity program will manage loss of preload for steel and stainless steel bolting in air - indoor uncontrolled and in treated water. Additionally, loss of preload for steel bolting in condensation environment is managed by the Bolting Integrity program and aligned to this row, because condensation is considered to be equivalent to Air - outdoor for evaluation of GALL consistency for Loss of preload for steel bolting.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-16	Steel Containment isolation piping and components (Internal surfaces), Piping, piping components, and piping elements exposed to Treated water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One- Time Inspection"	No	Consistent with NUREG-1801 with some program exceptions. The Water Chemistry program will manage loss of material for steel components exposed to treated water, and the One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. In addition to components in the Engineered Safety Features systems, some components in the Nuclear Boiler, Reactor Recirculation and Reactor Coolant Pressure Boundary systems are also aligned to this row. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-17	Aluminum, Stainless steel Piping, piping components, and piping elements exposed to Treated water	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One- Time Inspection”	No	Consistent with NUREG-1801 for most components, with a different program for submerged bolting, and some program exceptions. The Water Chemistry program will manage loss of material for stainless steel components exposed to treated water, and the One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. The Bolting Integrity program will manage loss of material for stainless steel suppression pool strainer bolting submerged in treated water. In addition to the Engineering Safety Features systems, the aluminum, upper containment pool gates in the Containment Structure and aluminum component and piping supports in the spent fuel pool (Bulk Civil Commodities) are also aligned with this item. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-18	Stainless steel Containment isolation piping and components (Internal surfaces) exposed to Treated water	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One- Time Inspection”	No	Not applicable. Management of loss of material for stainless steel components in the Engineered Safety Features systems that are exposed to treated water is aligned to items 3.2.1-16 and 3.2.1-17.
3.2.1-19 (LR-ISG-2011-01)	Stainless steel Heat exchanger tubes exposed to Treated water, Treated water (borated)	Reduction of heat transfer due to fouling	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One- Time Inspection”	No	Consistent with NUREG-1801 (as modified by LR-ISG-2011-01) with some program exceptions. The Water Chemistry program will manage reduction of heat transfer for stainless steel heat exchanger tubes and tube sheets exposed to treated water, and the One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.2.1-20 (LR-ISG-2011-01)	PWR only				
3.2.1-21 (LR-ISG-2011-01)	PWR only				

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-22 (LR-ISG-2011-01)	PWR only				
3.2.1-23	Steel Heat exchanger components, Containment isolation piping and components (Internal surfaces) exposed to Raw water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801. The Open-Cycle Cooling Water System program will manage loss of material for steel heat exchanger components exposed to raw water.
3.2.1-24	PWR only				
3.2.1-25	Stainless steel Heat exchanger components, Containment isolation piping and components (Internal surfaces) exposed to Raw water	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801. The Open-Cycle Cooling Water System program will manage loss of material for stainless steel heat exchanger components exposed to raw water.
3.2.1-26	Stainless steel Heat exchanger tubes exposed to Raw water	Reduction of heat transfer due to fouling	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801. The Open-Cycle Cooling Water System program will manage reduction of heat transfer for stainless steel heat exchanger tubes exposed to raw water.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-27	Stainless steel, Steel Heat exchanger tubes exposed to Raw water	Reduction of heat transfer due to fouling	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no steel heat exchanger tubes subject to aging management review in the Engineered Safety Features systems that are exposed to raw water. Management of reduction of heat transfer for stainless steel heat exchanger tubes exposed to raw water is addressed in item 3.2.1-26.
3.2.1-28	Stainless steel Piping, piping components, and piping elements exposed to Closed-cycle cooling water >60˚C (>140˚F)	Cracking due to stress corrosion cracking	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no stainless steel components subject to aging management review in the Engineered Safety Features systems that are exposed to closed-cycle cooling water >60˚C (>140˚F). Stainless steel piping components in ESF systems exposed to treated water >60˚C (>140˚F) are addressed under 3.4.1-11.
3.2.1-29	Steel Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no steel piping components subject to aging management review in the Engineered Safety Features systems that are exposed to closed-cycle cooling water.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-30	Steel Heat exchanger components exposed to Closed-cycle cooling water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with NUREG-1801. The Closed Treated Water Systems program will manage loss of material due to mechanisms other than selective leaching for gray cast iron heat exchanger components exposed to closed- cycle cooling water.
3.2.1-31	Stainless steel Heat exchanger components, Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to pitting and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with NUREG-1801. No components from the Engineered Safety Features systems are aligned to this row, but the Closed Treated Water Systems program will manage loss of material for the stainless steel Recirculation Pump seal coolers that are exposed to closed-cycle cooling water.
3.2.1-32	Copper alloy Heat exchanger components, Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no copper alloy Engineered Safety Features systems components subject to aging management review that are exposed to closed-cycle cooling water.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-33	Copper alloy, Stainless steel Heat exchanger tubes exposed to Closed-cycle cooling water	Reduction of heat transfer due to fouling	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no copper alloy or stainless steel Engineered Safety Features systems heat exchanger tubes subject to aging management review that are exposed to closed-cycle cooling water.
3.2.1-34	Copper alloy (>15% Zn or >8% Al) Piping, piping components, and piping elements, Heat exchanger components exposed to Closed-cycle cooling water	Loss of material due to selective leaching	Chapter XI.M33, “Selective Leaching”	No	Not applicable. There are no copper alloy (>15% Zn or >8% Al) Engineered Safety Features systems components subject to aging management review that are exposed to closed-cycle cooling water.
3.2.1-35	PWR only				
3.2.1-36	PWR only				
3.2.1-37	Gray cast iron Piping, piping components, and piping elements exposed to Soil	Loss of material due to selective leaching	Chapter XI.M33, “Selective Leaching”	No	Not applicable. There are no gray cast iron Engineered Safety Features systems components subject to aging management review that are exposed to soil.
3.2.1-38	Elastomers Elastomer seals and components exposed to Air – indoor, uncontrolled (External)	Hardening and loss of strength due to elastomer degradation	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801. The External Surfaces Monitoring of Mechanical Components program will manage hardening and loss of strength of elastomer flexible ventilation connections.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-39	Steel Containment isolation piping and components (External surfaces) exposed to Condensation (External)	Loss of material due to general corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. Steel piping components exposed to condensation in the Engineered Safety Features systems are addressed by item 3.2.1-69.
3.2.1-40	Steel Ducting, piping, and components (External surfaces), Ducting, closure bolting, Containment isolation piping and components (External surfaces) exposed to Air – indoor, uncontrolled (External)	Loss of material due to general corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801 for most components. The External Surfaces Monitoring of Mechanical Components program will manage loss of material for the Engineered Safety Features system steel piping, ducting and heat exchanger components exposed to an external environment of air - indoor, uncontrolled. The refueling bellows is aligned to this row, and is normally exposed to air-indoor, uncontrolled on both surfaces. The upper surface is exposed to treated water infrequently (during fuel movement) and is accessible when the upper pool is drained down. Because the lower surface is not exposed to fluid, the condition of the upper surface is expected to be representative of (or worse than) the lower surface.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
					Inspections of the upper surface will manage loss of material for both surfaces. In addition to the Engineering Safety Features systems, some steel components exposed to an air - indoor uncontrolled environment in the Nuclear Boiler and the Reactor Coolant Pressure Boundary systems are also aligned to this row. In addition, the reactor vessel support skirt in the Reactor Vessel system is aligned to this row with an aging evaluation that is consistent for material, environment and aging effect, but with a different program assignment. The ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD program will manage loss of material for the support skirt.
3.2.1-41	Steel External surfaces exposed to Air – outdoor (External)	Loss of material due to general corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no steel Engineered Safety Features systems components subject to aging management review that are exposed to an air - outdoor environment.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-42	Aluminum Piping, piping components, and piping elements exposed to Air - outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no aluminum Engineered Safety Features systems components subject to aging management review that are exposed to an air - outdoor environment.
3.2.1-43	Elastomers Elastomer seals and components exposed to Air – indoor, uncontrolled (Internal)	Hardening and loss of strength due to elastomer degradation	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. The Annulus Exhaust Gas Treatment system elastomer flexible ventilation connections have an internal environment of air - indoor, uncontrolled, but are aligned to item 3.3.1-76. There are no other elastomer Engineered Safety Features systems components subject to aging management review that are exposed to an air - indoor, uncontrolled internal environment.
3.2.1-44	Steel Piping and components (Internal surfaces), Ducting and components (Internal surfaces) exposed to Air – indoor, uncontrolled (Internal)	Loss of material due to general corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801 for most components. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components will manage loss of material for most steel components exposed to an internal environment of air – indoor, uncontrolled. In addition to components in the Engineered Safety Features systems,

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
					components from numerous other systems are also aligned to this row with management by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program. Some components are consistent for material, environment and aging effect, but a different program is used: the External Surfaces Monitoring of Mechanical Components program will manage internal surfaces of permanently drained components in the Emergency Closed Cooling Water system that perform a structural integrity function, but do not perform a pressure boundary or leakage boundary function. Externally observable aging effects for these components are expected to be representative of the internal conditions.
3.2.1-45	PWR only				

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-46	Steel Piping and components (Internal surfaces) exposed to Condensation (Internal)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no steel Engineered Safety Features systems piping components subject to aging management review that are exposed to an internal environment of condensation.
3.2.1-47	PWR only				
3.2.1-48	Stainless steel Piping, piping components, and piping elements (Internal surfaces); tanks exposed to Condensation (Internal)	Loss of material due to pitting and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. There are no stainless steel Engineered Safety Features systems components subject to aging management that are exposed to an internal environment of condensation. However, components from the Leakage Detection system are aligned to this row. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for these stainless steel components exposed to internal condensation.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-49	Steel Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801. The Lubricating Oil Analysis program will manage loss of material for steel components exposed to lubricating oil, and the One-Time Inspection program will be used to confirm the effectiveness of the Lubricating Oil Analysis program. The environment for some components in the Offgas system is 3M NOVEC™ 7100 refrigerant, a fluorinated hydrocarbon. This refrigerant is a liquid at room temperature and is compatible with metals. For the purpose of aging management comparison, this fluid is similar to lubricating oil. Materials susceptible to selective leaching subjected to water contaminated fuel oil and water-contaminated lube oil are managed under the Lubricating Oil Analysis and Fuel Oil Chemistry programs. These programs assure the exclusion of water. Furthermore, NUREG 2191 Selective Leaching AMP no longer includes water contaminated fuel oil and lube oil environments.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-50	Copper alloy, Stainless steel Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to pitting and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801. The Lubricating Oil Analysis program will manage loss of material for copper alloy components exposed to lubricating oil, and the One-Time Inspection program will be used to confirm the effectiveness of the Lubricating Oil Analysis program. The environment for some components in the Offgas system is 3M NOVEC™ 7100 refrigerant, a fluorinated hydrocarbon. This refrigerant is a liquid at room temperature and is compatible with metals. For the purpose of aging management comparison, this fluid is similar to lubricating oil. Loss of material for stainless steel in lubricating oil is addressed in items 3.3.1-100 and 3.4.1-44.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-51	Steel, Copper alloy, Stainless steel Heat exchanger tubes exposed to Lubricating oil	Reduction of heat transfer due to fouling	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801. The Lubricating Oil Analysis program will manage reduction of heat transfer for copper alloy and stainless steel heat exchanger tubes and tube sheets exposed to lubricating oil, and the One-Time Inspection program will be used to confirm the effectiveness of the Lubricating Oil Analysis program. In addition to components in the Engineered Safety Features systems, the Lubricating Oil Analysis program (with One-Time Inspection to confirm the effectiveness of the Lubricating Oil Analysis program) will manage reduction of heat transfer for copper alloy and stainless steel heat exchanger tubes from the following systems: Emergency Service Water, Control Complex Chilled Water, Combustible Gas Control, and Diesel Generator Cooling Water. There are no steel heat exchanger tubes subject to aging management review that are exposed to lubricating oil in the Engineered Safety Features systems.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-52	Steel (with coating or wrapping) Piping, piping components, and piping elements exposed to Soil or Concrete	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no steel components subject to aging management review in the Engineered Safety Features systems that are exposed to an environment of soil or concrete.
3.2.1-53 (LR-ISG-2011-03)	Stainless steel, nickel alloy piping, piping components, and piping elements exposed to soil or concrete	Loss of material due to pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no stainless steel or nickel alloy piping components subject to aging management in the Engineered Safety Features systems that are exposed to an environment of soil or concrete.
3.2.1-53x (LR-ISG-2011-03)	Steel, stainless steel, nickel alloy underground piping, piping components, and piping elements exposed to air-indoor uncontrolled or condensation (external)	Loss of material due to general (steel only), pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no underground piping components subject to aging management review for loss of material in the Engineered Safety Features systems that are exposed to an environment of air-indoor uncontrolled or condensation.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-54	Stainless steel Piping, piping components, and piping elements exposed to Treated water >60˚C (>140˚F)	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking	Chapter XI.M7, "BWR Stress Corrosion Cracking," and Chapter XI.M2, "Water Chemistry"	No	Not applicable. There are no stainless steel Engineered Safety Features systems piping components aligned to this row. Stainless steel piping components in the Engineering Safety Systems Components exposed to Treated water >60˚C (>140˚F) are age managed for Cracking due to stress corrosion cracking in item 3.4.1-11.
3.2.1-55	Steel Piping, piping components, and piping elements exposed to Concrete	None	None, provided 1) attributes of the concrete are consistent with ACI 318 or ACI 349 (low water-to-cement ratio, low permeability, and adequate air entrainment) as cited in NUREG-1557, and 2) plant OE indicates no degradation of the concrete	No, if conditions are met.	Not applicable. There are no steel piping components subject to aging management in the Engineered Safety Features systems that are exposed to an environment of concrete.
3.2.1-56	Aluminum Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (Internal/External)	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. Components in the Annulus Exhaust Gas Treatment system are aligned to this row.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-57	Copper alloy Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External), Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801 for copper alloy piping components in the Engineered Safety Features systems exposed to air - indoor, uncontrolled. There are no copper alloy piping components subject to aging management review in the Engineered Safety Features systems that are exposed to an environment of gas.
3.2.1-58	PWR only				
3.2.1-59	Galvanized steel Ducting, piping, and components exposed to Air – indoor, controlled (External)	None	None	NA - No AEM or AMP	Not applicable. There are no galvanized steel ducting, piping, and components subject to aging management review in the Engineered Safety Features systems exposed to Air - indoor controlled environment. Galvanized steel ducting, piping, and components subject to aging management review in the Engineered Safety Features systems were evaluated as steel in air - indoor, uncontrolled, and are addressed in item 3.2.1-40.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-60	Glass Piping elements exposed to Air – indoor, uncontrolled (External), Lubricating oil, Raw water, Treated water, Treated water (borated), Air with borated water leakage, Condensation (Internal/External), Gas, Closed- cycle cooling water, Air – outdoor	None	None	NA - No AEM or AMP	Consistent with NUREG-1801 for glass components in the Engineered Safety Features systems exposed to air - indoor uncontrolled, lubricating oil and condensation. The environment for some components in the Offgas system is 3M NOVEC™ 7100 refrigerant, a fluorinated hydrocarbon. For the purpose of aging management comparison, this fluid is similar to lubricating oil. Glass components subject to aging management review in the Engineered Safety Features systems are not exposed to other environments.
3.2.1-61	Nickel alloy Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External)	None	None	NA - No AEM or AMP	Not applicable. There are no nickel alloy piping components subject to aging management review in the Engineered Safety Features systems that are exposed to an environment of air - indoor, uncontrolled.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-62	Nickel alloy Piping, piping components, and piping elements exposed to Air with borated water leakage	None	None	NA - No AEM or AMP	Not applicable. There are no nickel alloy piping components subject to aging management review in the Engineered Safety Features systems that are exposed to an environment of air with borated water leakage.
3.2.1-63	Stainless steel Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External), Air with borated water leakage, Concrete, Gas, Air – indoor, uncontrolled (Internal)	None	None	NA - No AEM or AMP	Consistent with NUREG-1801 for stainless steel components exposed to air - indoor, uncontrolled (internal and external). Stainless steel components subject to aging management review in the Engineered Safety Features systems are not exposed to air with borated water leakage, concrete, or gas. Reactor vessel internal component type Dry Tube assembly is also aligned with this item. In addition to the Engineering Safety Features systems, the stainless steel, containment vessel electrical penetrations commodity in the Containment Structure is aligned with this item.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-64	Steel Piping, piping components, and piping elements exposed to Air – indoor, controlled (External), Gas	None	None	NA - No AEM or AMP	Not applicable. There are no steel piping components subject to aging management review in the Engineered Safety Features systems that are exposed to an environment of air - indoor, controlled or gas.
3.2.1-65 (LR-ISG-2012-01)	Any material, piping, piping components, and piping elements exposed to treated water, treated water (borated)	Wall thinning due to erosion	Chapter XI.M17, "Flow-Accelerated Corrosion"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-01). The Flow-Accelerated Corrosion program will manage wall thinning (loss of material) due to erosion for piping components in the Residual Heat Removal, Low Pressure Core Spray and High Pressure Core Spray systems for which OE indicates the potential for erosion.
3.2.1-66 (LR-ISG-2012-02)	Metallic piping, piping components, and tanks exposed to raw water or waste water	Loss of material due to recurring internal corrosion	A plant-specific aging management program is to be evaluated to address recurring internal corrosion	Yes, plant-specific (See Subsection 3.2.2.2.9)	Not applicable. Metallic piping components in Engineered Safety Features systems subject to aging management for loss of material and exposed to raw water or waste water are addressed in item 3.3.1-91. See subsection 3.2.2.2.9.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-67 (LR-ISG-2012-02)	Stainless steel or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to soil or concrete, or the following external environments air-outdoor, air-indoor uncontrolled, moist air, condensation	Cracking due to stress corrosion cracking	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not applicable. There are no stainless steel or aluminum tanks within the scope of the XI.M29 Aboveground Metallic Tanks program in the Engineered Safety Features systems.
3.2.1-68 (LR-ISG-2012-02)	Steel, stainless steel, or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to soil or concrete, or the following external environments air-outdoor, air-indoor uncontrolled, moist air, condensation	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not applicable. There are no steel, stainless steel or aluminum tanks within the scope of the XI.M29 Aboveground Metallic Tanks program in the Engineered Safety Features systems.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-69 (LR-ISG-2012-02)	Insulated steel, stainless steel, copper alloy, or aluminum, piping, piping components, and tanks exposed to condensation, air-outdoor	Loss of material due to general (steel, and copper alloy only), pitting, and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components" or Chapter XI.M29, “Aboveground Metallic Tanks,” (for tanks only)	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02). The External Surfaces Monitoring of Mechanical Components program will manage loss of material for insulated steel (including gray cast iron), stainless steel and copper alloy components exposed to condensation. There are no insulated steel, stainless steel or copper alloy components in the Engineered Safety Features systems that are exposed to air - outdoor. There are no tanks within the scope of the XI.M29 Aboveground Metallic Tanks program in the Engineered Safety Features systems.
3.2.1-70 (LR-ISG-2012-02)	Steel, stainless steel or aluminum tanks (within the scope of Chapter XI.M29, “Aboveground Metallic Tanks”) exposed to treated water, treated borated water	Loss of material due to general (steel only), pitting and crevice corrosion	Chapter XI.M29, “Aboveground Metallic Tanks”	No	Not applicable. There are no steel, stainless steel or aluminum tanks within the scope of the XI.M29 Aboveground Metallic Tanks program in the Engineered Safety Features systems.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2.1-71 (LR-ISG-2012-02)	Insulated stainless steel, aluminum, or copper alloy (> 15% Zn) piping, piping components, and tanks exposed to condensation, air-outdoor	Cracking due to stress corrosion cracking	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components" or Chapter XI.M29, "Aboveground Metallic Tanks," (for tanks only)	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02). The External Surfaces Monitoring of Mechanical Components program will manage cracking of insulated stainless steel components exposed to condensation. There are no tanks within the scope of the XI.M29 Aboveground Metallic Tanks program in the Engineered Safety Features systems. In addition to the Engineering Safety Features systems, the External Surfaces Monitoring of Mechanical Components program will manage cracking of aluminum insulation jacketing commodity exposed to air-outdoor in the Bulk Civil Commodities. However, Structures Monitoring program will manage cracking for aluminum components of metal siding, windows, conduits, damper and louver housings and fixed louvers1, and flood curbs exposed to air-outdoor in the Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures and Bulk Civil Commodities.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-72 (LR-ISG-2013-01)	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil	Loss of coating or lining integrity due to blistering, cracking, flaking, peeling, delamination, rusting, or physical damage, and spalling for cementitious coating/linings.	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Not applicable. There are no metallic components identified in the Engineered Safety Features systems with coatings or linings exposed to liquid environments.
3.2.1-73 (LR-ISG-2013-01)	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Not applicable. There are no metallic components identified in the Engineered Safety Features systems with coatings or linings exposed to liquid environments.

Table 3.2.1 Summary of Aging Management Evaluations for the Engineered Safety Features Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2.1-74 (LR-ISG-2013-01)	Gray cast iron piping component with internal coatings/linings exposed to closed-cycle cooling water, raw water, or treated water	Loss of material due to selective leaching	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Not applicable. There are no metallic components identified in the Engineered Safety Features systems with coatings or linings exposed to liquid environments.

Notes for Table 3.2.2-1 through Table 3.2.2-9

Standard Notes

A Consistent with NUREG-1801 item for component, material, environment and aging effect. AMP is consistent with NUREG-1801 AMP.
B Consistent with NUREG-1801 item for component, material, environment and aging effect. AMP takes some exceptions to NUREG-1801 AMP.
C Component is different, but consistent with NUREG-1801 item for material, environment and aging effect. AMP is consistent with NUREG-1801 AMP.
D Component is different, but consistent with NUREG-1801 item for material, environment and aging effect. AMP takes some exceptions to NUREG-1801 AMP.
E Consistent with NUREG-1801 item for material, environment and aging effect, but a different aging management program is credited or NUREG-1801 identifies a plant-specific aging management program.
F Material not in NUREG-1801 for this component.
G Environment not in NUREG-1801 for this component and material.
H Aging effect not in NUREG-1801 for this component, material, and environment combination.
I Aging effect in NUREG-1801 for this component, material and environment combination is not applicable.
J Neither the component nor the material and environment combination are evaluated in NUREG-1801.

Plant-Specific Notes

201 The internal environment of these components is Novec™ 7100, a fluorinated hydrocarbon used as a refrigerant. For the purposes of aging evaluation, this environment is compared to the GALL environment of "Lubricating oil."
202 The refueling bellows does not have an internal environment: Both sides are normally exposed to Air-indoor, uncontrolled. The upper surface is exposed to treated water only during refuelings and is accessible when drained down. External Surfaces Monitoring inspection of the upper surface of steel components is expected to provide leading indication of degradation.
203 Condensation environment is considered to be equivalent to Air - outdoor (external) for comparison of management of Loss of preload.
204 Per definitions in NUREG-1801, Section IX, Condensation is considered Raw Water.

Plant-Specific Notes (Continued)

205 External surface of elastomers in ventilation system duct and flexible connections is the same as the internal environment. So, monitoring the external surfaces will be indicative of internal surface. In addition to the Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components", additional testing, inspections, and reporting to be performed per Commitment L01090.

3.3 AGING MANAGEMENT OF AUXILIARY SYSTEMS

3.3.1 INTRODUCTION

This section provides the results of the aging management review for those components identified in Section 2.3.3, Auxiliary Systems, as being subject to aging management review. The systems, or portions of systems, which are addressed in this section are described in the indicated sections.

- Auxiliary Building Ventilation (Section 2.3.3.1)
- Breathable Air (Section 2.3.3.2)
- Building Heating (Section 2.3.3.3)
- Combustible Gas Control (Section 2.3.3.4)
- Computer Room HVAC (Section 2.3.3.5)
- Containment and Drywell Vacuum Relief (Section 2.3.3.6)
- Containment Integrated Leak Rate Test (Section 2.3.3.7)
- Containment Vessel and Drywell Purge (Section 2.3.3.8)
- Containment Vessel Chilled Water (Section 2.3.3.9)
- Control and Computer Room Humidification (Section 2.3.3.10)
- Control Complex Chilled Water (Section 2.3.3.11)
- Control Rod Drive (Section 2.3.3.12)
- Control Room HVAC and Emergency Recirculation (Section 2.3.3.13)
- Controlled Access and Miscellaneous Equipment Areas HVAC (Section 2.3.3.14)
- Diesel Generator and Auxiliaries (Section 2.3.3.15)
- Diesel Generator Building Ventilation (Section 2.3.3.16)
- ECCS Pump Room Cooling (Section 2.3.3.17)
- Emergency Closed Cooling (Section 2.3.3.18)
- Emergency Closed Cooling Pump Area HVAC (Section 2.3.3.19)
- Emergency Service Water (Section 2.3.3.20)
- Emergency Service Water Pump House Ventilation (Section 2.3.3.21)
- Emergency Service Water Screen Wash (Section 2.3.3.22)
- Feedwater Zinc Injection (Section 2.3.3.23)
- Fire Protection (Section 2.3.3.24)

- Floor and Equipment Drains (Section 2.3.3.25)
- Fuel Handling Area Ventilation (Section 2.3.3.26)
- Fuel Storage and Fuel Pool Cooling and Cleanup (Section 2.3.3.27)
- Hydrogen Water Chemistry (Section 2.3.3.28)
- Inclined Fuel Transfer System (Section 2.3.3.29)
- Industrial Waste Disposal (Section 2.3.3.30)
- Intermediate Building Ventilation (Section 2.3.3.31)
- Leak Detection (Section 2.3.3.32)
- Liquid Radwaste Disposal (Section 2.3.3.33)
- Liquid Radwaste Sumps (Section 2.3.3.34)
- MCC Switchgear and Miscellaneous Electrical Area HVAC, and Battery Room Exhaust (Section 2.3.3.35)
- Miscellaneous Area Ventilation (Section 2.3.3.36)
- Miscellaneous Electrical Areas Smoke Ventilation (Section 2.3.3.37)
- Miscellaneous Sump (Section 2.3.3.38)
- Nitrogen Supply (Section 2.3.3.39)
- Nuclear Closed Cooling (Section 2.3.3.40)
- Offgas Building Ventilation (Section 2.3.3.41)
- Penetration Electrical (Section 2.3.3.42)
- Penetration Pressurization (Section 2.3.3.43)
- Plant Foundation Underdrain (Section 2.3.3.44)
- Plant Radiation Monitoring and Process Monitoring, and Post Accident Radiation Monitoring (Section 2.3.3.45)
- Post Accident Sampling (Section 2.3.3.46)
- Potable Water Supply (Section 2.3.3.47)
- Rx Plant Sampling (Section 2.3.3.48)
- Radwaste Building Ventilation (Section 2.3.3.49)
- Reactor Vessel Servicing Equipment (Section 2.3.3.50)
- Reactor Water Clean Up and Reactor Water Clean Up Filter Demineralizer (Section 2.3.3.51)
- Safety Related Instrument Air (Section 2.3.3.52)
- Sanitary Drains and Sewer (Section 2.3.3.53)
- Service Air and Instrument Air (Section 2.3.3.54)

- Service Water (Section 2.3.3.55)
- Standby Liquid Control (Section 2.3.3.56)
- Steam Tunnel Cooling (Section 2.3.3.57)
- Storm Drain and Sewer (Section 2.3.3.58)
- Suppression Pool Drain and Clean Up (Section 2.3.3.59)
- Suppression Pool Makeup (Section 2.3.3.60)
- Turbine Building Chilled Water (Section 2.3.3.61)
- Turbine Building Closed Cooling (Section 2.3.3.62)
- Turbine Building Ventilation (Section 2.3.3.63)

Table 3.3.1, Summary of Aging Management Programs for Auxiliary Systems Evaluated in Chapter VII of NUREG-1801 provides the summary of the programs evaluated in NUREG-1801 for the auxiliary systems component group. This table uses the format described in the introduction to Section 3. Hyperlinks are provided to the program evaluations in Appendix B.

3.3.2 RESULTS

The following system tables summarize the results of aging management reviews and the NUREG-1801 comparison for the Auxiliary Systems.

Note that Table 3.3.2-42 Penetration Electrical, Table 3.3.2-50 Reactor Vessel Servicing Equipment, and Table 3.3.2-58 Storm Drain and Sewer systems do not have any mechanical components subject to aging management review and the corresponding AMR results tables contain no components.

3.3.2.1 Materials, Environment, Aging Effects Requiring Management and Aging Management Programs

The following sections list the materials, environments, aging effects requiring management, and aging management programs for the auxiliary systems components subject to aging management review. Aging management programs are described in Appendix B. Further details are provided in the system tables.

3.3.2.1.1 Auxiliary Building Ventilation

Materials

Auxiliary Building Ventilation system components are constructed of the following materials:

- Copper alloy <15% Zn
- Steel

Environments

Auxiliary Building Ventilation system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Raw water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Auxiliary Building Ventilation system components require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Auxiliary Building Ventilation system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.2 Breathable Air

Materials

Breathable Air system components are constructed of the following materials:

- Copper alloy >15% Zn
- Stainless steel
- Steel

Environments

Breathable Air system components are exposed to the following environments:

- Air – dry
- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Breathable Air system components require management:

- Loss of material

Aging Management Programs

The following aging management programs manage the effects of aging on Breathable Air system components:

- External Surfaces Monitoring of Mechanical Components (B.2.18)

3.3.2.1.3 Building Heating

Materials

Building Heating system components are constructed of the following materials:

- Copper alloy <15% Zn
- Stainless steel
- Steel

Environments

Building Heating system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Closed-cycle cooling water >60°C (>140°F)

Aging Effects Requiring Management

The following aging effects associated with the Building Heating system components require management:

- Cracking
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Building Heating system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)

- External Surfaces Monitoring of Mechanical Components (B.2.18)

3.3.2.1.4 Combustible Gas Control

Materials

Combustible Gas Control system components are constructed of the following materials:

- CASS
- Copper alloy <15% Zn
- Glass
- Gray cast iron
- Stainless steel
- Steel

Environments

Combustible Gas Control system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Gas
- Lubricating oil
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Combustible Gas Control system components require management:

- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following aging management programs manage the effects of aging on Combustible Gas Control system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)

- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.3.2.1.5 Computer Room HVAC

Materials

Computer Room HVAC components are constructed of the following materials:

- Steel

Environments

Computer Room HVAC components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Computer Room HVAC system require management:

- Loss of material

Aging Management Programs

The following aging management programs manage the effects of aging on Computer Room HVAC system components:

- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.6 Containment and Drywell Vacuum Relief

Materials

Containment and Drywell Vacuum Relief system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Containment and Drywell Vacuum Relief system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor

Aging Effects Requiring Management

The following aging effects associated with the Containment and Drywell Vacuum Relief system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Containment and Drywell Vacuum Relief system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.7 Containment Integrated Leak Rate Test

Materials

Containment Integrated Leak Rate Test system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Containment Integrated Leak Rate Test system components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Containment Integrated Leak Rate Test system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Containment Integrated Leak Rate Test components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.8 Containment Vessel and Drywell Purge

Materials

Containment Vessel and Drywell Purge system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Containment Vessel and Drywell Purge system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Containment Vessel and Drywell Purge system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Containment Vessel and Drywell Purge components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- One-Time Inspection (B.2.35)

- Water Chemistry (B.2.44)

3.3.2.1.9 Containment Vessel Chilled Water

Materials

Containment Vessel Chilled Water system components are constructed of the following materials:

- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Glass
- Gray cast iron
- Stainless steel
- Steel
- Steel with internal coating/lining

Environments

Containment Vessel Chilled Water system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Condensation
- Lubricating oil
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Containment Vessel Chilled Water system require management:

- Cracking
- Loss of coating or lining integrity
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Containment Vessel Chilled Water system components:

- Bolting Integrity (B.2.7)

- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)
- Water Chemistry (B.2.44)

3.3.2.1.10 Control and Computer Room Humidification

Materials

Control and Computer Room Humidification system components are constructed of the following materials:

- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Glass
- Stainless steel
- Steel

Environments

Control and Computer Room Humidification system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Condensation
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Control and Computer Room Humidification system require management:

- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Control and Computer Room Humidification system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)
- TLAA
- Water Chemistry (B.2.44)

3.3.2.1.11 Control Complex Chilled Water

Materials

Control Complex Chilled Water system components are constructed of the following materials:

- CASS
- Copper alloy <15% Zn
- Copper alloy >15% Zn, Solder Coated
- Copper alloy >15% Zn
- Glass
- Gray cast iron
- Stainless steel
- Steel
- Steel with internal coating/lining

Environments

Control Complex Chilled Water system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Condensation
- Gas
- Lubricating oil

- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Control Complex Chilled Water components require management:

- Cracking
- Loss of coating or lining integrity
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following aging management programs manage the effects of aging on Control Complex Chilled Water components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.3.2.1.12 Control Rod Drive

Materials

Control Rod Drive system components are constructed of the following materials:

- CASS
- Copper alloy >15% Zn
- Glass
- Gray cast iron
- Stainless steel
- Steel

Environments

Control Rod Drive system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Gas
- Lubricating oil
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Control Rod Drive components require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Control Rod Drive components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)
- TLAA
- Water Chemistry (B.2.44)

3.3.2.1.13 Control Room HVAC and Emergency Recirculation

Materials

Control Room HVAC and Emergency Recirculation system components are constructed of the following materials:

- Aluminum

- Copper alloy <15% Zn
- Elastomers
- Stainless Steel
- Steel

Environments

Control Room HVAC and Emergency Recirculation system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Condensation
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Control Room HVAC and Emergency Recirculation components require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Control Room HVAC and Emergency Recirculation components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.14 Controlled Access and Miscellaneous Equipment Areas HVAC

Materials

Controlled Access and Miscellaneous Equipment Areas HVAC system components are constructed of the following materials:

- Steel

Environments

Controlled Access and Miscellaneous Equipment Areas HVAC system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Controlled Access and Miscellaneous Equipment Areas HVAC system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Controlled Access and Miscellaneous Equipment Areas HVAC system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.15 Diesel Generator and Auxiliaries

3.3.2.1.15.1 Starting Air and Control Air

Materials

Starting Air and Control Air system components are constructed of the following materials:

- Aluminum
- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Glass
- Stainless steel
- Steel
- Zinc

Environments

Starting Air and Control Air system components are exposed to the following environments:

- Air – dry
- Air – indoor, uncontrolled
- Condensation
- Lubricating oil

Aging Effects Requiring Management

The following aging effects associated with the Starting Air and Control Air system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Starting Air and Control Air system components:

- Bolting Integrity (B.2.7)
- Compressed Air Monitoring (B.2.16)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)

3.3.2.1.15.2 Fuel Oil

Materials

Fuel Oil system components are constructed of the following materials:

- Aluminum
- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Gray cast iron
- Stainless steel
- Steel

- Steel with internal coating/lining

Environments

Fuel Oil system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Fuel oil
- Soil

Aging Effects Requiring Management

The following aging effects associated with the Fuel Oil system require management:

- Loss of coating or lining integrity
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Fuel Oil system components:

- Bolting Integrity (B.2.7)
- Buried and Underground Piping and Tanks (B.2.8)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Fuel Oil Chemistry (B.2.23)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)
- One-Time Inspection (B.2.35)

3.3.2.1.15.3 Cooling Water

Materials

Cooling Water system components are constructed of the following materials:

- Aluminum
- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Glass

- Gray cast iron
- Stainless steel
- Steel

Environments

Cooling Water system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Lubricating oil
- Raw water

Aging Effects Requiring Management

The following aging effects associated with the Cooling Water system require management:

- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following aging management programs manage the effects of aging on Cooling Water system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Open-Cycle Cooling Water System (B.2.37)
- Selective Leaching (B.2.42)

3.3.2.1.15.4 Lubricating Oil

Materials

Lubricating Oil system components are constructed of the following materials:

- Aluminum

- Copper alloy >15% Zn
- Glass
- Gray cast iron
- Stainless steel
- Steel

Environments

Lubricating Oil system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Lubricating oil

Aging Effects Requiring Management

The following aging effects associated with the Lubricating Oil system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Lubricating Oil system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)

3.3.2.1.15.5 Air Intake and Exhaust

Materials

Air Intake and Exhaust system components are constructed of the following materials:

- Aluminum
- Stainless steel
- Steel

Environments

Air Intake and Exhaust system components are exposed to the following environments:

- Air – indoor, uncontrolled

- Air – outdoor
- Closed-cycle cooling water
- Diesel exhaust
- Lubricating oil

Aging Effects Requiring Management

The following aging effects associated with the Air Intake and Exhaust system require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Air Intake and Exhaust system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- TLAA

3.3.2.1.16 Diesel Generator Building Ventilation

Materials

Diesel Generator Building Ventilation system components are constructed of the following materials:

- Elastomers
- Steel

Environments

Diesel Generator Building Ventilation system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor

Aging Effects Requiring Management

The following aging effects associated with the Diesel Generator Building Ventilation system require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Diesel Generator Building Ventilation system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.17 ECCS Pump Room Cooling

Materials

ECCS Pump Room Cooling system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

ECCS Pump Room Cooling system components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the ECCS Pump Room Cooling system require management:

- Loss of material

Aging Management Programs

The following aging management programs manage the effects of aging on ECCS Pump Room Cooling system components:

- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.18 Emergency Closed Cooling

Materials

Emergency Closed Cooling system components are constructed of the following materials:

- Copper alloy <15% Zn
- Glass
- Stainless steel
- Steel
- Steel with stainless steel cladding

Environments

Emergency Closed Cooling system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Raw water
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Emergency Closed Cooling system require management:

- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following aging management programs manage the effects of aging on Emergency Closed Cooling system components:

- Bolting Integrity (B.2.7)

- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- One-Time Inspection (B.2.35)
- Open-Cycle Cooling Water System (B.2.37)
- Water Chemistry (B.2.44)

3.3.2.1.19 Emergency Closed Cooling Pump Area HVAC

Materials

Emergency Closed Cooling Pump Area HVAC system components are constructed of the following materials:

- Elastomers
- Steel

Environments

Emergency Closed Cooling Pump Area HVAC system components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Emergency Closed Cooling Pump Area HVAC system require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Emergency Closed Cooling Pump Area HVAC system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.20 Emergency Service Water

Materials

Emergency Service Water system components are constructed of the following materials:

- CASS
- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Glass
- Stainless steel
- Steel

Environments

Emergency Service Water system components are exposed to the following environments:

- Air – dry
- Air – indoor, uncontrolled
- Condensation
- Lubricating oil
- Raw water
- Soil

Aging Effects Requiring Management

The following aging effects associated with the Emergency Service Water system require management:

- Cracking
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following aging management programs manage the effects of aging on Emergency Service Water system components:

- Bolting Integrity (B.2.7)
- Buried and Underground Piping and Tanks (B.2.8)
- External Surfaces Monitoring of Mechanical Components (B.2.18)

- Flow-Accelerated Corrosion (B.2.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Open-Cycle Cooling Water System (B.2.37)
- Selective Leaching (B.2.42)

3.3.2.1.21 Emergency Service Water Pump House Ventilation

Materials

Emergency Service Water Pump House Ventilation system components are constructed of the following materials:

- Steel

Environments

Emergency Service Water Pump House Ventilation system components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Emergency Service Water Pump House Ventilation system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Emergency Service Water Pump House Ventilation system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.22 Emergency Service Water Screen Wash

Materials

Emergency Service Water Screen Wash system components are constructed of the following materials:

- Gray cast iron
- Stainless steel
- Steel

Environments

Emergency Service Water Screen Wash system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Lubricating oil
- Raw water

Aging Effects Requiring Management

The following aging effects associated with the Emergency Service Water Screen Wash system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Emergency Service Water Screen Wash system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Open-Cycle Cooling Water System (B.2.37)
- Selective Leaching (B.2.42)

3.3.2.1.23 Feedwater Zinc Injection

Materials

Feedwater Zinc Injection system components are constructed of the following materials:

- Stainless steel

Environments

Feedwater Zinc Injection system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Feedwater Zinc Injection system require management:

- Loss of material

Aging Management Programs

The following aging management programs manage the effects of aging on Feedwater Zinc Injection system components:

- Closed Treated Water Systems (B.2.15)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.3.2.1.24 Fire Protection

Materials

Fire Protection system components are constructed of the following materials:

- Aluminum
- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Fiberglass
- Glass
- Gray cast iron
- Gray cast iron with internal coating/lining
- Polymers
- Stainless steel
- Steel

Environments

Fire Protection system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Closed-cycle cooling water
- Condensation
- Diesel exhaust
- Fuel oil
- Gas
- Lubricating oil
- Raw water
- Soil

Aging Effects Requiring Management

The following aging effects associated with the Fire Protection system require management:

- Change in mechanical properties, Blistering
- Cracking
- Cumulative fatigue damage
- Flow blockage
- Loss of coating or lining integrity
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following aging management programs manage the effects of aging on Fire Protection system components:

- Bolting Integrity (B.2.7)
- Buried and Underground Piping and Tanks (B.2.8)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Fire Protection (B.2.20)
- Fire Water System (B.2.21)
- Fuel Oil Chemistry (B.2.23)

- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)
- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)
- TLAA

3.3.2.1.25 Floor and Equipment Drains

Materials

Floor and Equipment Drains system components are constructed of the following materials:

- Copper alloy <15% Zn
- Gray cast iron
- Stainless steel
- Steel

Environments

Floor and Equipment Drains system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Concrete
- Soil
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Floor and Equipment Drains system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Floor and Equipment Drains system components:

- Bolting Integrity (B.2.7)

- Buried and Underground Piping and Tanks (B.2.8)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Selective Leaching (B.2.42)

3.3.2.1.26 Fuel Handling Area Ventilation

Materials

Fuel Handling Area Ventilation system components are constructed of the following materials:

- Aluminum
- Copper alloy <15% Zn
- Elastomers
- Stainless steel
- Steel

Environments

Fuel Handling Area Ventilation system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Fuel Handling Area Ventilation system require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Fuel Handling Area Ventilation system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)

- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.27 Fuel Storage and Fuel Pool Cooling and Cleanup

Materials

Fuel Storage and Fuel Pool Cooling and Cleanup system components are constructed of the following materials:

- Aluminum
- Boral
- CASS
- Glass
- Stainless steel
- Steel
- Steel with internal coating/lining

Environments

Fuel Storage and Fuel Pool Cooling and Cleanup system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Concrete
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Fuel Storage and Fuel Pool Cooling and Cleanup system require management:

- Change in dimension
- Loss of coating or lining integrity
- Loss of material
- Loss of preload
- Reduction of heat transfer
- Reduction of neutron absorption

Aging Management Programs

The following aging management programs manage the effects of aging on Fuel Storage and Fuel Pool Cooling and Cleanup system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)
- Monitoring of Neutron-Absorbing Materials Other Than Boraflex (B.2.30)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.3.2.1.28 Hydrogen Water Chemistry

Materials

The Hydrogen Water Chemistry system components are constructed of the following materials:

- Stainless steel

Environments

The Hydrogen Water Chemistry system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water >60˚C (>140˚F)

Aging Effects Requiring Management

The following aging effects associated with the Hydrogen Water Chemistry system require management:

- Cracking
- Cumulative fatigue damage
- Loss of material

Aging Management Programs

The following aging management programs manage the effects of aging on the Hydrogen Water Chemistry system components:

- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.3.2.1.29 Inclined Fuel Transfer Equipment

Materials

Inclined Fuel Transfer Equipment system components are constructed of the following materials:

- CASS
- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Glass
- Stainless steel
- Steel

Environments

Inclined Fuel Transfer Equipment system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Inclined Fuel Transfer Equipment system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Inclined Fuel Transfer Equipment system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)
- Water Chemistry (B.2.44)

3.3.2.1.30 Industrial Waste Disposal

Materials

Industrial Waste Disposal system components are constructed of the following materials:

- Steel

Environments

Industrial Waste Disposal system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Concrete
- Soil
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Industrial Waste Disposal system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Industrial Waste Disposal system components:

- Bolting Integrity (B.2.7)
- Buried and Underground Piping and Tanks (B.2.8)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.31 Intermediate Building Ventilation

Materials

Intermediate Building Ventilation system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Intermediate Building Ventilation system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Intermediate Building Ventilation system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Intermediate Building Ventilation system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.32 Leak Detection

Materials

Leak Detection system components are constructed of the following materials:

- Glass
- Stainless steel
- Steel

Environments

Leak Detection system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Condensation
- Treated water
- Treated water >60°C (>140°F)

Aging Effects Requiring Management

The following aging effects associated with the Leak Detection system require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Leak Detection system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.3.2.1.33 Liquid Radwaste Disposal

Materials

Liquid Radwaste Disposal system components are constructed of the following materials:

- CASS
- Stainless steel
- Steel
- Steel with internal coating/lining

Environments

Liquid Radwaste Disposal system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Concrete
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Liquid Radwaste Disposal system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Liquid Radwaste Disposal system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.3.2.1.34 Liquid Radwaste Sumps

Materials

Liquid Radwaste Sumps system components are constructed of the following materials:

- Gray cast iron
- Stainless steel
- Steel

Environments

Liquid Radwaste Sumps system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Liquid Radwaste Sumps system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Liquid Radwaste Sumps system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Selective Leaching (B.2.42)

3.3.2.1.35 MCC Switchgear and Miscellaneous Electrical Area HVAC and Battery Room Exhaust

Materials

MCC Switchgear and Miscellaneous Electrical Area HVAC and Battery Room Exhaust systems components are constructed of the following materials:

- Aluminum
- Elastomers
- Steel

Environments

MCC Switchgear and Miscellaneous Electrical Area HVAC and Battery Room Exhaust systems components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the MCC Switchgear and Miscellaneous Electrical Area HVAC and Battery Room Exhaust systems require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on MCC Switchgear and Miscellaneous Electrical Area HVAC and Battery Room Exhaust systems components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.36 Miscellaneous Area Ventilation

Materials

Miscellaneous Area Ventilation system components are constructed of the following materials:

- Elastomers
- Steel

Environments

Miscellaneous Area Ventilation c system omponents are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Miscellaneous Area Ventilation system require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Miscellaneous Area Ventilation system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.37 Miscellaneous Electrical Areas Smoke Ventilation

Materials

Miscellaneous Electrical Areas Smoke Ventilation system components are constructed of the following materials:

- Elastomers
- Steel

Environments

Miscellaneous Electrical Areas Smoke Ventilation system components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Miscellaneous Electrical Areas Smoke Ventilation system require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Miscellaneous Electrical Areas Smoke Ventilation system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.38 Miscellaneous Sump

Materials

Miscellaneous Sump system components are constructed of the following materials:

- Steel

Environments

Miscellaneous Sump system components are exposed to the following environments:

- Air – outdoor
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Miscellaneous Sump system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Miscellaneous Sump system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.39 Nitrogen Supply

Materials

Nitrogen Supply system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Nitrogen Supply system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Gas

Aging Effects Requiring Management

The following aging effects associated with the Nitrogen Supply system require management:

- Loss of material

Aging Management Programs

The following aging management programs manage the effects of aging on Nitrogen Supply system components:

- External Surfaces Monitoring of Mechanical Components (B.2.18)

3.3.2.1.40 Nuclear Closed Cooling

Materials

Nuclear Closed Cooling system components are constructed of the following materials:

- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Gray cast iron
- Stainless steel
- Steel
- Steel with internal coating/lining

Environments

Nuclear Closed Cooling system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Lubricating oil
- Raw water

Aging Effects Requiring Management

The following aging effects associated with the Nuclear Closed Cooling system require management:

- Loss of coating or lining integrity
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Nuclear Closed Cooling system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)

3.3.2.1.41 Offgas Building Ventilation

Materials

Offgas Building Ventilation system components are constructed of the following materials:

- Elastomers
- Steel

Environments

Offgas Building Ventilation system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Offgas Building Ventilation system require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Offgas Building Ventilation system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.42 Penetration Electrical

There are no mechanical components in the Electrical Penetration system subject to aging management review. The penetration components that support containment pressure boundary integrity are evaluated as structural components.

Materials

Penetration Electrical system components are constructed of the following materials:

- N/A

Environments

Penetration Electrical system components are exposed to the following environments:

- N/A

Aging Effects Requiring Management

The following aging effects associated with the Penetration Electrical system require management:

- None

Aging Management Programs

The following aging management programs manage the effects of aging on Penetration Electrical system components:

- None

3.3.2.1.43 Penetration Pressurization

Materials

Penetration Pressurization system components are constructed of the following materials:

- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Stainless steel
- Steel

Environments

Penetration Pressurization system components are exposed to the following environments:

- Air – dry
- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Penetration Pressurization system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Penetration Pressurization system components:

- Bolting Integrity (B.2.7)
- Compressed Air Monitoring (B.2.16)
- External Surfaces Monitoring of Mechanical Components (B.2.18)

3.3.2.1.44 Plant Foundation Underdrain

Materials

Plant Foundation Underdrain system components are constructed of the following materials:

- Steel

Environments

Plant Foundation Underdrain system components are exposed to the following environments:

- Raw water
- Soil

Aging Effects Requiring Management

The following aging effects associated with the Plant Foundation Underdrain system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Plant Foundation Underdrain system components:

- Bolting Integrity (B.2.7)
- Buried and Underground Piping and Tanks (B.2.8)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.45 Plant Radiation Monitoring and Process Monitoring and Post-Accident Radiation Monitoring

Materials

Plant Radiation Monitoring and Process Monitoring and Post Accident Radiation Monitoring systems components are constructed of the following materials:

- Copper alloy <15% Zn
- Stainless steel
- Steel

Environments

Plant Radiation Monitoring and Process Monitoring and Post Accident Radiation Monitoring systems components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Raw water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Plant Radiation Monitoring and Process Monitoring and Post Accident Radiation Monitoring systems require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Plant Radiation Monitoring and Process Monitoring and Post Accident Radiation Monitoring systems components:

- Bolting Integrity (B.2.7)

- Closed Treated Water Systems (B.2.15)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Open-Cycle Cooling Water System (B.2.37)

3.3.2.1.46 Post Accident Sampling

Materials

Post Accident Sampling system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Post Accident Sampling system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Post Accident Sampling system require management:

- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Post Accident Sampling system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- One-Time Inspection (B.2.35)
- TLAA

- Water Chemistry (B.2.44)

3.3.2.1.47 Potable Water Supply

Materials

Potable Water Supply system components are constructed of the following materials:

- Copper alloy <15% Zn
- Gray cast iron
- Stainless steel
- Steel
- Steel with internal coating/lining

Environments

Potable Water Supply system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Raw water

Aging Effects Requiring Management

The following aging effects associated with the Potable Water Supply system require management:

- Loss of coating or lining integrity
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Potable Water Supply system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)
- Selective Leaching (B.2.42)

3.3.2.1.48 Rx Plant Sampling

Materials

Rx Plant Sampling system components are constructed of the following materials:

- CASS
- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Glass
- Stainless steel
- Steel

Environments

Rx Plant Sampling system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Treated water
- Treated water >60°C (>140°F)

Aging Effects Requiring Management

The following aging effects associated with the Rx Plant Sampling system require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Process Sampling Rx Plant Sampling system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)
- TLAA

- Water Chemistry (B.2.44)

3.3.2.1.49 Radwaste Building Ventilation

Materials

Radwaste Building Ventilation system components are constructed of the following materials:

- Steel

Environments

Radwaste Building Ventilation system components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Radwaste Building Ventilation system require management:

- Loss of material

Aging Management Programs

The following aging management programs manage the effects of aging on Radwaste Building Ventilation system components:

- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.50 Reactor Vessel Servicing Equipment

Reactor Vessel Servicing Equipment have no mechanical system components subject to aging management.

Materials

Reactor Vessel Servicing Equipment components are constructed of the following materials:

- N/A

Environments

Reactor Vessel Servicing Equipment components are exposed to the following environments:

- N/A

Aging Effects Requiring Management

The following aging effects associated with the Reactor Vessel Servicing Equipment require management:

- N/A

Aging Management Programs

The following aging management programs manage the effects of aging on Reactor Vessel Servicing Equipment components:

- N/A

3.3.2.1.51 Reactor Water Clean Up and Reactor Water Clean Up Filter Demineralizer

Materials

Reactor Water Clean Up and Reactor Water Clean Up Filter Demineralizer systems components are constructed of the following materials:

- Copper alloy >15% Zn
- Glass
- Stainless steel
- Steel

Environments

Reactor Water Clean Up system and Reactor Water Clean Up Filter Demineralizer systems are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Treated water
- Treated water >60˚C (>140˚F)

Aging Effects Requiring Management

The following aging effects associated with the Reactor Water Clean Up and Reactor Water Clean Up Filter Demineralizer systems require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Reactor Water Clean Up and Reactor Water Clean Up Filter Demineralizer systems components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)
- TLAA
- Water Chemistry (B.2.44)

3.3.2.1.52 Safety Related Instrument Air

Materials

Safety Related Instrument Air system components are constructed of the following materials:

- Polymers
- Stainless steel
- Steel
- Steel with stainless steel cladding

Environments

Safety Related Instrument Air system components are exposed to the following environments:

- Air – dry
- Air – indoor, uncontrolled
- Condensation

Aging Effects Requiring Management

The following aging effects associated with the Safety Related Instrument Air system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Safety Related Instrument Air system components:

- Bolting Integrity (B.2.7)
- Compressed Air Monitoring (B.2.16)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.53 Sanitary Drains and Sewer

Materials

Sanitary Drains and Sewer system components are constructed of the following materials:

- Copper alloy >15% Zn
- Gray cast iron
- Steel

Environments

Sanitary Drains and Sewer system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Concrete
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Sanitary Drains and Sewer system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Sanitary Drains and Sewer system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)

- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Selective Leaching (B.2.42)

3.3.2.1.54 Service Air and Instrument Air

Materials

Service Air and Instrument Air system components are constructed of the following materials:

- Aluminum
- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Glass
- Stainless steel
- Steel

Environments

Service Air and Instrument Air system components are exposed to the following environments:

- Air – dry
- Air – indoor, uncontrolled
- Condensation
- Lubricating oil

Aging Effects Requiring Management

The following aging effects associated with the Service Air and Instrument Air system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Service Air and Instrument Air system components:

- Bolting Integrity (B.2.7)
- Compressed Air Monitoring (B.2.16)
- External Surfaces Monitoring of Mechanical Components (B.2.18)

- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)

3.3.2.1.55 Service Water

Materials

Service Water system components are constructed of the following materials:

- CASS
- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Gray cast iron
- Stainless steel
- Steel
- Steel with internal coating/lining

Environments

Service Water system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Condensation
- Raw water
- Soil

Aging Effects Requiring Management

The following aging effects associated with the Service Water system require management:

- Cracking
- Loss of coating or lining integrity
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Service Water system components:

- Bolting Integrity (B.2.7)

- Buried and Underground Piping and Tanks (B.2.8)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)

3.3.2.1.56 Standby Liquid Control

Materials

Standby Liquid Control system components are constructed of the following materials:

- CASS
- Stainless steel
- Steel

Environments

Standby Liquid Control system components are exposed to the following environments:

- Air – dry
- Air – indoor, uncontrolled
- Sodium pentaborate solution
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Standby Liquid Control system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Standby Liquid Control system components:

- Bolting Integrity (B.2.7)
- Compressed Air Monitoring (B.2.16)
- External Surfaces Monitoring of Mechanical Components (B.2.18)

- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.3.2.1.57 Steam Tunnel Cooling

Materials

Steam Tunnel Cooling system components are constructed of the following materials:

- Steel

Environments

Steam Tunnel Cooling system components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Steam Tunnel Cooling system require management:

- Loss of material

Aging Management Programs

The following aging management programs manage the effects of aging on Steam Tunnel Cooling system components:

- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.1.58 Storm Drain and Sewer

The Storm Drain and Sewer system has no mechanical system components subject to aging management. Storm Drain and Sewer system components are evaluated under Civil / Structural as water control structures. Building roof drain components are evaluated with Floor and Equipment Drains system.

Materials

The Storm Drain and Sewer system components are constructed of the following materials:

- N/A

Environment

Storm Drain and Sewer system components are exposed to the following environments:

- N/A

Aging Effects Requiring Management

The following aging effects associated with the Storm Drain and Sewer system require management:

- N/A

Aging Management Programs

The following aging management programs manage the effects of aging on Storm Drain and Sewer system components:

- N/A

3.3.2.1.59 Suppression Pool Drain and Clean Up

Materials

Suppression Pool Drain and Clean Up system components are constructed of the following materials:

- CASS
- Stainless steel
- Steel

Environments

Suppression Pool Drain and Clean Up system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Suppression Pool Drain and Clean Up system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Suppression Pool Drain and Clean Up system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.3.2.1.60 Suppression Pool Makeup

Materials

Suppression Pool Makeup system components are constructed of the following materials:

- CASS
- Stainless steel
- Steel

Environments

Suppression Pool Makeup system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Suppression Pool Makeup system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Suppression Pool Makeup system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- One-Time Inspection (B.2.35)

- Water Chemistry (B.2.44)

3.3.2.1.61 Turbine Building Chilled Water

Materials

Turbine Building Chilled Water system components are constructed of the following materials:

- Copper alloy <15% Zn
- Copper alloy >15% Zn
- Glass
- Gray cast iron
- Stainless steel
- Steel
- Steel with internal coating/lining

Environments

Turbine Building Chilled Water system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water
- Condensation
- Lubricating oil
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Turbine Building Chilled Water system require management:

- Cracking
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Turbine Building Chilled Water system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)

- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)
- Lubricating Oil Analysis (B.2.28)
- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)
- Water Chemistry (B.2.44)

3.3.2.1.62 Turbine Building Closed Cooling

Materials

Turbine Building Closed Cooling system components are constructed of the following materials:

- Gray cast iron
- Steel

Environments

Turbine Building Closed Cooling system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Closed-cycle cooling water

Aging Effects Requiring Management

The following aging effects associated with the Turbine Building Closed Cooling system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Turbine Building Closed Cooling system components:

- Bolting Integrity (B.2.7)
- Closed Treated Water Systems (B.2.15)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Selective Leaching (B.2.42)

3.3.2.1.63 Turbine Building Ventilation

Materials

Turbine Building Ventilation system components are constructed of the following materials:

- Steel

Environments

Turbine Building Ventilation system components are exposed to the following environments:

- Air – indoor, uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the Turbine Building Ventilation system require management:

- Loss of material

Aging Management Programs

The following aging management programs manage the effects of aging on Turbine Building Ventilation system components:

- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)

3.3.2.2 Further Evaluation of Aging Management as Recommended by NUREG-1800

NUREG-1800 indicates that further evaluation is necessary for certain aging effects and other issues discussed in Section 3.3.2.2 of NUREG-1800. The following sections are numbered in accordance with the discussions in NUREG-1800 and explain the PNPP approach to those areas requiring further evaluation. Programs are described in Appendix B.

Note - Italicized text at the beginning of each Further Evaluation subsection is taken directly from NUREG-1800 as supplemented by LR-ISG-2011-05 and LR-ISG-2012-02.

3.3.2.2.1 Cumulative Fatigue Damage

Fatigue is a TLAA as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). This TLAA is addressed separately in Section

4.3, "Metal Fatigue Analysis," or Section 4.7, "Other Plant-Specific Time-Limited Aging Analyses," of this SRP-LR.

Fatigue is a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are evaluated in accordance with 10 CFR 54.21(c). The evaluation of metal fatigue as a TLAA for non-Class 1 components in the Control and Computer Room Humidification, Control Rod Drive, Div.1&2 Standby Diesel Generator Exhaust, Intake and Crankcase, Hydrogen Water Chemistry, Leak Detection, Reactor Water Clean up, and Reactor Plant Sampling systems is discussed in Section 4.3.2 either specifically or as part of the global evaluation. Likewise, in addition, non-Class 1 components in the Emergency Safety Feature Systems (Residual Heat Removal and Containment Spray, High Pressure Core Spray, Low Pressure Core Spray, and Reactor Core Isolation Cooling systems) and Steam And Power Conversion Systems (Feedwater Control, Feedwater and Feedwater Leakage Control, and Main and Reheat Steam systems) is addressed in Section 4.3.2. See Section 4.3 for a complete evaluation of metal fatigue.

3.3.2.2.2 Cracking due to Stress Corrosion Cracking and Cyclic Loading

Cracking due to SCC and cyclic loading could occur in stainless steel PWR non-regenerative heat exchanger components exposed to treated borated water greater than 60°C (>140°F) in the chemical and volume control system. The existing aging management program on monitoring and control of primary water chemistry in PWRs manages the aging effects of cracking due to SCC. However, control of water chemistry does not preclude cracking due to SCC and cyclic loading. Therefore, the effectiveness of the water chemistry control program should be verified to ensure that cracking is not occurring. The GALL Report recommends that a plant-specific aging management program be evaluated to verify the absence of cracking due to SCC and cyclic loading to ensure that these aging effects are managed adequately. An acceptable verification program is to include temperature and radioactivity monitoring of the shell side water, and eddy current testing of tubes.

This paragraph in NUREG-1800 pertains to PWR non-regenerative heat exchanger components and is therefore not applicable to PNPP.

3.3.2.2.3 Cracking due to Stress Corrosion Cracking

Cracking due to stress corrosion cracking could occur for stainless steel piping, piping components, piping elements and tanks exposed to outdoor air. The possibility of cracking also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Cracking is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible. Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those within 1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas *subject to chloride contamination from other agricultural or industrial sources. This item is applicable for the environments described above.*

GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external chloride stress corrosion cracking is not expected. The GALL Report recommends further evaluation to determine whether an adequate aging management program is used to manage this aging effect based on the environmental conditions applicable to the plant and ASME Code Section XI requirements applicable to the components.

Cracking due to stress corrosion cracking could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air, including air which has recently been introduced into buildings, such as near intake vents. There are no stainless steel piping, piping components, piping elements, and tanks subject to aging management review that are exposed to Air – outdoor in the Auxiliary systems. Therefore, this item is not used.

3.3.2.2.4 Loss of Material due to Cladding Breach

Loss of material due to cladding breach could occur for PWR steel charging pump casings with stainless steel cladding exposed to treated borated water. The GALL Report references NRC Information Notice 94-63, "Boric Acid Corrosion of Charging Pump Casings Caused by Cladding Cracks," and recommends further evaluation of a plant-specific aging management program to ensure that the aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

This paragraph in NUREG-1800 pertains to PWR steel charging pump casings with stainless steel cladding exposed to treated borated water. PNPP is a BWR, and does not have steel charging pump casings with stainless steel cladding exposed to treated borated water. Therefore, this item is not applicable to PNPP.

3.3.2.2.5 Loss of Material due to Pitting and Crevice Corrosion

Loss of material due to pitting and crevice corrosion could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air. The possibility of pitting and crevice corrosion also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Pitting and crevice corrosion is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible. Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those within 1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas subject to chloride contamination *from other agricultural or industrial sources. This item is applicable for the environments described above.*

GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external pitting or crevice corrosion is not expected. The GALL Report recommends further evaluation to determine whether an adequate aging management program is used to manage this aging effect based on the environmental conditions applicable to the plant and ASME Code Section XI requirements Quality Assurance for Aging Management of Nonsafety-Related Components.

Loss of material due to pitting and crevice corrosion could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air, including air which has recently been introduced into buildings, such as near intake vents. There are no stainless steel piping, piping components, piping elements, and tanks subject to aging management review that are exposed to outdoor air in the Auxiliary systems. Therefore, this item is not used.

3.3.2.2.6 Quality Assurance for Aging Management of Nonsafety-Related Components

Acceptance criteria are described in Branch Technical Position IQMB-1 (Appendix A.2, of this SRP-LR.)

See Appendix B Section B.1.3 for discussion of PNPP quality assurance procedures and administrative controls for aging management programs.

3.3.2.2.7 Ongoing Review of Operating Experience (Per LR-ISG-2011-05)

Ongoing review of operating experience is addressed in Appendix A, Section A.1 and Appendix B, Section B.1.4.

3.3.2.2.8 Loss of Material due to Recurring Internal Corrosion

Recurring internal corrosion can result in the need to augment AMPs beyond the recommendations in the GALL Report. During the search of plant-specific OE conducted during the LRA development, recurring internal corrosion can be identified by the number of occurrences of aging effects and the extent of degradation at each localized corrosion site. This further evaluation item is applicable if the search of plant-specific OE reveals repetitive occurrences (e.g., one per refueling outage cycle that has occurred over: (a) three or more sequential or nonsequential cycles for a 10-year OE search, or (b) two or more sequential or nonsequential cycles for a 5-year OE search) of aging effects with the same aging mechanism in which the aging effect resulted in the component either not meeting plant-specific acceptance criteria or experiencing a reduction in wall thickness greater than 50 percent (regardless of the minimum wall thickness.

The GALL Report recommends that a plant-specific AMP, or a new or existing AMP, be evaluated for inclusion of augmented requirements to ensure the adequate management of any recurring aging effect(s). Potential augmented requirements include: alternative examination methods (e.g., volumetric versus external visual), augmented inspections (e.g., a greater number of locations, additional locations based on risk insights based on susceptibility to aging effect and consequences of failure, a greater frequency of inspections), and additional trending parameters and decision points where increased inspections would be implemented. Acceptance criteria are described in Appendix A.1, "Aging Management Review – Generic (Branch Technical Position RSLB-1)."

The applicant states: (a) why the program's examination methods will be sufficient to detect the recurring aging effect before affecting the ability of a component to perform its intended function, (b) the basis for the adequacy of augmented or lack of augmented inspections, (c) what parameters will be trended as well as the decision points where increased inspections would be implemented (e.g., the extent of degradation at individual corrosion sites, the rate of degradation change), (d) how inspections of components that are not easily accessed (i.e., buried, underground) will be conducted, and (e) how leaks in any involved buried or underground components will be identified.

Each plant-specific operating experience example should be evaluated to determine if the chosen AMP should be augmented even if the thresholds for significance of aging effect or frequency of occurrence of aging effect have not been exceeded. For example, during a 10-year search of plant specific operating experience, two instances of 360 degree 30 percent wall loss occurred at copper alloy to steel joints. Neither the significance of the aging effect nor the frequency of occurrence of aging effect threshold has been exceeded. Nevertheless, the operating experience should be evaluated to determine if the AMP that is proposed to manage the aging effect is sufficient (e.g., method of inspection, frequency of inspection, number of inspections) to provide reasonable assurance that the CLB intended functions of the component will be met throughout the period of extended operation. Likewise, the GALL Report AMR items associated with the new FE items only cite raw water and waste water environments because OE indicates that these are the predominant environments associated with recurring internal corrosion; however, if the search of plant-specific OE reveals recurring internal corrosion in other water environments (e.g., treated water), the aging effect should be addressed in a similar manner.

LR-ISG-2012-02 has been issued which addresses instances of recurring internal corrosion identified during review of plant-specific operating experience. The operating experience for PNPP has been reviewed and instances of internal corrosion in the Emergency Service Water and Fire Water Systems has been identified with a frequency that is consistent with the thresholds discussed in LR-ISG-2012-02.

As provided in the Open-Cycle Cooling Water Program (LRA Section B.2.37), loss of material due to recurring internal corrosion and erosion for the Emergency Service Water System is managed by augmented inspections utilizing the Flow Accelerated Corrosion

Program (LRA Section B.2.22). These inspections consist of volumetric wall thickness examinations. Locations that have experienced loss of material are monitored for wall thickness and a loss rate is determined. The next inspection or component repair/replacement occurs prior to exceeding minimum wall acceptance criteria.

As provided in the Fire Water System Program (LRA Section B.2.21), loss of material due to recurring internal corrosion for the Fire Water System is managed by augmented inspections. The program will be enhanced to require that when visual inspections are used to detect loss of material, the inspection technique is capable of detecting surface irregularities that could indicate wall loss to below nominal pipe wall thickness due to corrosion and corrosion product deposition. Where such irregularities are detected, follow-up volumetric wall thickness examinations will be performed. For the buried piping, visual inspections of the piping interior surfaces will be performed whenever the piping internal surface is made accessible due to maintenance and repair activities. In addition, a portion of the aboveground inspection locations will be selected with process conditions similar to those in the buried piping to use as an indicator of the condition of the buried piping.

3.3.2.3 Time-Limited Aging Analysis

The time-limited aging analyses identified associated with Auxiliary System components and Structural components (e.g., Cranes) are addressed in Section 4. Table 4.1-2 provides TLAA results and identifies whether the TLAA remains valid for the PEO, will be managed during the PEO, and the LRA sections that address them.

3.3.3 Conclusion

The Auxiliary Systems piping, fittings, and components that are subject to aging management review have been identified in accordance with the requirements of 10 CFR 54.21. The aging management programs selected to manage aging effects for the Auxiliary Systems components are identified in the summaries in Section 3.3.2.1 above.

A description of these aging management programs is provided in Appendix B, along with the demonstration that the identified aging effects will be managed for the period of extended operation.

Therefore, based on the conclusions provided in Appendix B, the effects of aging associated with the Auxiliary Systems components will be adequately managed so that there is reasonable assurance that the intended functions are maintained consistent with the current licensing basis during the period of extended operation.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-1	Steel Cranes: structural girders exposed to Air – indoor, uncontrolled (External)	Cumulative fatigue damage due to fatigue	Fatigue is a time-limited aging analysis (TLAA) to be evaluated for the period of extended operation for structural girders of cranes that fall within the scope of 10 CFR 54 (Standard Review Plan, Section 4.7, "Other Plant- Specific Time-Limited Aging Analyses," for generic guidance for meeting the requirements of 10 CFR 54.21(c)(1))	Yes, TLAA (See subsection 3.3.2.2.1)	Consistent with NUREG-1801. This item is not used by Auxiliary systems. Steel cranes in the Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures, Containment Structure and Water Control Structures are evaluated as structural components and are aligned with this item. Cumulative fatigue damage is a TLAA. Also, see further evaluation section 3.3.2.2.1.
3.3.1-2	Stainless steel, Steel Heat exchanger components and tubes, Piping, piping components, and piping elements exposed to Treated borated water, Air - indoor, uncontrolled, Treated water	Cumulative fatigue damage due to fatigue	Fatigue is a time-limited aging analysis (TLAA) to be evaluated for the period of extended operation. See the SRP, Section 4.3 "Metal Fatigue," for acceptable methods for meeting the requirements of 10 CFR 54.21(c)(1).	Yes, TLAA (See subsection 3.3.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is a TLAA. See further evaluation section 3.3.2.2.1. In addition to Auxiliary Systems components, TLAA will also manage fatigue of Feedwater, Main Steam, Residual Heat Removal, High Pressure Core Spray, Low Pressure Core Spray and Reactor Core Isolation Cooling components.
3.3.1-3	PWR only				

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-4	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Cracking due to stress corrosion cracking	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See subsection 3.3.2.2.3)	Not applicable. There are no Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor in the Auxiliary systems. See further evaluation section 3.3.2.2.3.
3.3.1-5	PWR only				
3.3.1-6	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See subsection 3.3.2.2.5)	Not applicable. There are no Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor in the Auxiliary systems. See further evaluation 3.3.2.2.5.
3.3.1-7	PWR only				
3.3.1-8	PWR only				
3.3.1-9	PWR only				
3.3.1-10	Steel, high-strength Closure bolting exposed to Air with steam or water leakage	Cracking due to stress corrosion cracking; cyclic loading	Chapter XI.M18, "Bolting Integrity"	No	Not applicable. There is no steel, high strength closure bolting subject to aging management review in the Auxiliary systems that is exposed to air with steam or water leakage.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-11	Steel, high-strength High-pressure pump, closure bolting exposed to Air with steam or water leakage	Cracking due to stress corrosion cracking; cyclic loading	Chapter XI.M18, "Bolting Integrity"	No	Not applicable. There is no steel, high strength, high pressure pump closure bolting subject to aging management review in the Auxiliary systems that is exposed to air with steam or water leakage.
3.3.1-12	Steel; stainless steel Closure bolting, Bolting exposed to Condensation, Air – indoor, uncontrolled (External), Air – outdoor (External)	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. The Bolting Integrity program will manage loss of material for steel bolting exposed to air - indoor, uncontrolled, air - outdoor, and condensation. In addition to bolting in the Auxiliary systems, the Bolting Integrity program will manage loss of material for steel bolting in the Offgas system exposed to condensation.
3.3.1-13	Steel Closure bolting exposed to Air with steam or water leakage	Loss of material due to general corrosion	Chapter XI.M18, "Bolting Integrity"	No	Not applicable. There is no steel closure bolting subject to aging management review in the Auxiliary systems that is exposed to air with steam or water leakage.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-14	Steel, Stainless Steel Bolting exposed to Soil	Loss of preload	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. The Bolting Integrity program will manage loss of preload for steel bolting exposed to soil. There is no stainless steel bolting subject to aging management review in the Auxiliary systems that is exposed to soil.
3.3.1-15	Steel; stainless steel, Copper alloy, Nickel alloy, Stainless steel Closure bolting, Bolting exposed to Air – indoor, uncontrolled (External), Any environment, Air – outdoor (External), Raw water, Treated borated water, Fuel oil, Treated water	Loss of preload due to thermal effects, gasket creep, and self- loosening	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. The Bolting Integrity program will manage loss of preload of stainless steel bolting in air - indoor uncontrolled and treated water and steel bolting in Air - indoor uncontrolled, Air-outdoor, Condensation, and Raw water. Additionally, for the purpose of aging management comparison of loss of preload for steel bolting, the condensation environment is considered equivalent to Air - outdoor. There is no copper alloy or nickel alloy bolting subject to aging management review in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-16	Stainless steel Piping, piping components, and piping elements exposed to Treated water >60˚C (>140˚F)	Cracking due to stress corrosion cracking, intergranular stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M25, "BWR Reactor Water Cleanup System"	No	Consistent with NUREG 1801 with some program exceptions. Alignment contains the CRD Hydraulic Lines connected to the CRDMs under the Reactor Vessel. Reactor water cleanup system piping downstream of the second containment isolation valve, 4 inch NPS or greater that is exposed to treated water >60˚C (>140˚F), is carbon steel, and is not subject to NRC Generic Letter (GL) 88-01 requirements. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

3.3.1-17 (LR-ISG-2011-01)	Stainless steel Heat exchanger tubes exposed to Treated water, Treated borated water	Reduction of heat transfer due to fouling	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2011-01) with some program exceptions. The Water Chemistry program will manage reduction of heat transfer for stainless steel heat exchanger tubes exposed to treated water. The One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. There are no stainless steel heat exchanger tubes subject to aging management review in the Auxiliary systems that are exposed to treated borated water. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-18	Stainless steel High- pressure pump, casing, Piping, piping components, and piping elements exposed to Treated borated water >60˚C (>140˚F), Sodium pentaborate solution >60˚C (>140˚F)	Cracking due to stress corrosion cracking	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One-Time Inspection”	No	Not applicable. There are no stainless steel high pressure pump or piping components subject to aging management review in the Auxiliary systems that are exposed to treated borated water >60˚C (>140˚F) or sodium pentaborate solution >60˚C (>140˚F).
3.3.1-19	Stainless steel Regenerative heat exchanger components exposed to Treated water >60˚C (>140˚F)	Cracking due to stress corrosion cracking	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One-Time Inspection”	No	Not applicable. The regenerative heat exchanger components subject to aging management review in the Auxiliary Systems are made of steel and cracking is not one of its aging effects.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-20	Stainless steel, Stainless steel; steel with stainless steel cladding Heat exchanger components exposed to Treated borated water >60˚C (>140˚F), Treated water >60˚C (>140˚F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801 with some program exceptions. The Water Chemistry program will manage cracking of stainless steel piping and valves exposed to treated water >60˚C (>140˚F). In addition to components in the Auxiliary systems, the Water Chemistry program will manage cracking of Residual Heat Removal heat exchanger tubes and Reactor Recirculation pump seal coolers exposed to treated water >60˚C (>140˚F). The One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. There are no stainless steel or steel with stainless steel cladding heat exchanger components subject to aging management review in the Auxiliary systems that are exposed to treated water >60˚C (>140˚F). See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.3.1-21	Steel Piping, piping components, and piping elements	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801 with the following clarifications and with some program exceptions. The Water Chemistry program will manage loss of material for steel

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
	exposed to Treated water				components exposed to treated water, and the One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. In addition, loss of material for steel components in the Standby Liquid Control system exposed to sodium pentaborate solution are also aligned to this item but managed with a different program. Sodium pentaborate is a subset of treated water that results in similar aging effects for steel components. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components will manage loss of material for these steel lines, which are test lines, system drains or tank overflow lines exposed to this environment but typically are drained. They are conservatively modeled as containing sodium pentaborate. Loss of material in Flex piping and piping components in storage for the Standby Liquid Control system and subjected to unmonitored treated water is aligned with this item but managed with a different program, the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting

					Components. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.3.1-22	Copper alloy Piping, piping components, and piping elements exposed to Treated water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801 with some program exceptions. The Water Chemistry program will manage loss of material for copper alloy components exposed to treated water, and the One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.3.1-23	Aluminum Piping, piping components, and piping elements exposed to Treated water	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Not applicable. Loss of material for aluminum components exposed to treated water in the Auxiliary Systems is addressed in item 3.3.1-25.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-24	Aluminum Piping, piping components, and piping elements exposed to Treated water	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One-Time Inspection”	No	Consistent with NUREG-1801 with the following clarifications and with some program exceptions. This item is not used in the Auxiliary systems. Loss of material for aluminum components subject to aging management review in the Auxiliary systems exposed to treated water is addressed in item 3.3.1-25. The Water Chemistry program will manage cracking and loss of material for Aluminum fuel pool liner plates and gates subject to aging management review in the Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures. The One-Time Inspection program will confirm the effectiveness of the chemistry program. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-30	Concrete; cementitious material Piping, piping components, and piping elements exposed to Raw Water	Changes in material properties due to aggressive chemical attack	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no concrete or cementitious piping components subject to aging management review in the Auxiliary systems that are exposed to raw water. Cement-lined piping in the Fire Protection system is addressed in items 3.3.1-138 and 3.3.1-139.
3.3.1-30x	Fiberglass, HDPE Piping, piping components, and piping elements exposed to Raw water (internal)	Cracking, blistering, change in color due to water absorption	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801 for material, environment and aging effect with a different program assignment. The Fire Water System program will manage change in material properties and blistering of ASTM D-2996 fiberglass reinforced epoxy piping in the Fire Protection system.
3.3.1-31	Concrete; cementitious material Piping, piping components, and piping elements exposed to Raw Water	Cracking due to settling	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no concrete or cementitious piping components subject to aging management review in the Auxiliary systems that are exposed to raw water. Cement-lined piping in the Fire Protection system is addressed in items 3.3.1-138 and 3.3.1-139.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-32	Reinforced concrete, asbestos cement Piping, piping components, and piping elements exposed to Raw water	Cracking due to aggressive chemical attack and leaching; Changes in material properties due to aggressive chemical attack	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no reinforced concrete or asbestos piping components subject to aging management review in the Auxiliary systems that are exposed to raw water.
3.3.1-32x	Elastomer seals and components exposed to raw water	Hardening and loss of strength due to elastomer degradation; loss of material due to erosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no elastomer components subject to aging management review in the Auxiliary systems that are exposed to raw water.
3.3.1-33	Concrete; cementitious material Piping, piping components, and piping elements exposed to Raw Water	Loss of material due to abrasion, cavitation, aggressive chemical attack, and leaching	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no concrete or cementitious piping components subject to aging management review in the Auxiliary systems that are exposed to raw water. Cement-lined piping in the Fire Protection system is addressed in items 3.3.1-138 and 3.3.1-139.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-34	Nickel alloy, Copper alloy Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no nickel alloy components subject to aging management review in the Auxiliary systems that are exposed to raw water. Loss of material for copper alloy piping components exposed to raw water, managed by the Open-Cycle Cooling Water System is addressed in items 3.3.1-36.
3.3.1-35	Copper alloy Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. Loss of material for copper alloy piping components exposed to raw water in the Auxiliary systems and managed by the Open-Cycle Cooling Water System is addressed in item 3.3.1-36.
3.3.1-36	Copper alloy Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801. The Open-Cycle Cooling Water System will manage loss of material of copper alloy piping components exposed to raw water in the Emergency Service Water and Plant Radiation Monitoring and Process Monitoring systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-37 (LR-ISG-2013-01)	Steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2013-01). The Open-Cycle Cooling Water System program will manage loss of material for steel piping components exposed to raw water.
3.3.1-38	Copper alloy, Steel Heat exchanger components exposed to Raw water	Loss of material due to general, pitting, crevice, galvanic, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801 for most components, but with a different program for submerged bolting. The Open-Cycle Cooling Water program will manage loss of material for steel and copper alloy heat exchanger components exposed to raw water whose source is the Emergency Service Water system. The Bolting Integrity program will manage loss of material for steel pump casing bolting submerged in raw water.
3.3.1-39	Stainless steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting and crevice corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. Loss of material for stainless steel components in raw water, managed by the Open-Cycle Cooling Water System program is addressed in item 3.3.1-40.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-40	Stainless steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting and crevice corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801. The Open-Cycle Cooling Water System will manage loss of material for stainless steel components exposed to raw water in the Emergency Closed Cooling, Emergency Service Water, Emergency Service Water Screen Wash, and Plant Radiation Monitoring and Process Monitoring systems. Heat Exchanger tubes and tubesheets in the Emergency Closed Cooling Water system are also aligned to this row.
3.3.1-41	Stainless steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. Loss of material for stainless steel components in raw water, managed by the Open-Cycle Cooling Water System program is addressed in item 3.3.1-40.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-42	Copper alloy, Titanium, Stainless steel Heat exchanger tubes exposed to Raw water	Reduction of heat transfer due to fouling	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801 for most components in the Emergency Closed Cooling and Emergency Service Water systems, and consistent for material, environment and aging effect with a different program assigned for components in the Fire Protection system. The Open-Cycle Cooling Water System program will manage reduction of heat transfer for copper alloy and stainless steel heat exchanger tubes exposed to raw water in in the Emergency Closed Cooling and Emergency Service Water systems. In the Fire Protection system, the Fire Water System program will manage reduction of heat transfer for the copper alloy diesel-driven fire pump jacket water heat exchanger tubes exposed to raw water. There are no titanium heat exchanger tubes subject to aging management and exposed to raw water in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-43	Stainless steel Piping, piping components, and piping elements exposed to Closed- cycle cooling water >60˚C (>140˚F)	Cracking due to stress corrosion cracking	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with NUREG-1801.The Closed Treated Water Systems program will manage cracking of stainless steel piping components exposed to closed-cycle cooling water >60˚C (>140˚F) in the Building Heating system.
3.3.1-44	Stainless steel; steel with stainless steel cladding Heat exchanger components exposed to Closed-cycle cooling water >60˚C (>140˚F)	Cracking due to stress corrosion cracking	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no stainless steel or steel with stainless steel heat exchanger components subject to aging management that are exposed to closed-cycle cooling water >60˚C (>140˚F) in the Auxiliary systems.
3.3.1-45	Steel Piping, piping components, and piping elements; tanks exposed to Closed- cycle cooling water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with NUREG-1801.The Closed Treated Water Systems program will manage loss of material for steel piping components and tanks exposed to closed-cycle cooling water.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-46	Steel, Copper alloy Heat exchanger components, Piping, piping components, and piping elements exposed to Closed- cycle cooling water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with NUREG-1801. The Closed Treated Water Systems program will manage loss of material for steel and copper alloy heat exchanger and piping components exposed to closed-cycle cooling water.
3.3.1-47	Stainless steel; steel with stainless steel cladding Heat exchanger components exposed to Closed-cycle cooling water	Loss of material due to microbiologically-influenced corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with NUREG-1801. The Closed Treated Water Systems program will manage loss of material for stainless steel and steel with stainless steel cladding heat exchanger components exposed to closed-cycle cooling water.
3.3.1-48	Aluminum Piping, piping components, and piping elements exposed to Closed- cycle cooling water	Loss of material due to pitting and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no aluminum piping components subject to aging management review in the Auxiliary systems that are exposed to closed-cycle cooling water.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-49	Stainless steel Piping, piping components, and piping elements exposed to Closed- cycle cooling water	Loss of material due to pitting and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with NUREG-1801. The Closed Treated Water Systems program will manage loss of material for stainless steel components exposed to closed-cycle cooling water. In addition, heat exchanger components in the Fuel Pool Cooling and Cleanup system and the Control Complex Chilled Water system are also aligned to this row for managing loss of material.
3.3.1-50	Stainless steel, Copper Alloy, Steel Heat exchanger tubes exposed to Closed- cycle cooling water	Reduction of heat transfer due to fouling	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with NUREG-1801. The Closed Treated Water Systems program will manage reduction of heat transfer of stainless steel and copper alloy heat exchanger tubes exposed to closed-cycle cooling water. There are no steel heat exchanger tubes subject to aging management review in the Auxiliary systems that are exposed to closed-cycle cooling water.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-51	Boraflex Spent fuel storage racks: neutron-absorbing sheets (PWR), Spent fuel storage racks: neutron-absorbing sheets (BWR) exposed to Treated borated water, Treated water	Reduction of neutron-absorbing capacity due to Boraflex degradation	Chapter XI.M22, “Boraflex Monitoring”	No	Not applicable. There are no Boraflex neutron-absorbers subject to aging management review at PNPP. Aging management of Boral neutron absorbers is described in item 3.3.1-102.
3.3.1-52	Steel Cranes: rails and structural girders exposed to Air – indoor, uncontrolled (External)	Loss of material due to general corrosion	Chapter XI.M23, “Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems”	No	Consistent with NUREG-1801. This item is not used in the Auxiliary systems. The Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems Program will manage loss of material for steel crane rails and structural girders subject to aging management in the Containment Structure, Water Control Structures, and the Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures and exposed to air-indoor, uncontrolled.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-53	Steel Cranes - rails exposed to Air – indoor, uncontrolled (External)	Loss of material due to wear	Chapter XI.M23, "Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems"	No	Not applicable. This line item was not used for the Auxiliary systems. Steel crane rails subject to aging management exposed to air-indoor, uncontrolled environment are addressed under items 3.3.1-52, 3.5.1-77 and 3.5.1-92.
3.3.1-54	Copper alloy Piping, piping components, and piping elements exposed to Condensation	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M24, "Compressed Air Monitoring"	No	Not applicable. Components exposed to compressed air downstream of air dryers are assigned the Air - dry environment. Aging evaluations for these components were compared to NUREG-1801 rows for dry air that recommended no aging management program, but were assigned the Compressed Air Monitoring program to ensure that a dried air environment is maintained. See item 3.3.1-114. Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components manages loss of material in copper alloy piping, piping components and piping elements subject to aging management and exposed to internal condensation in the Service Air and Instrument Air systems, see item 3.3.1-89.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-55	Steel Piping, piping components, and piping elements: compressed air system exposed to Condensation (Internal)	Loss of material due to general and pitting corrosion	Chapter XI.M24, "Compressed Air Monitoring"	No	Not applicable. Components exposed to compressed air downstream of air dryers are assigned the Air - dry environment. Aging evaluations for these components were compared to NUREG-1801 rows for dry air that recommended no aging management program, but were assigned the Compressed Air Monitoring program to ensure that a dried air environment is maintained. See item 3.3.1-121. Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components manages loss of material in steel piping, piping components and piping elements subject to aging management and exposed to internal condensation in the Service Air, Instrument Air and Safety Related Instrument Air systems, see item 3.3.1-95.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-56	Stainless steel Piping, piping components, and piping elements exposed to Condensation (Internal)	Loss of material due to pitting and crevice corrosion	Chapter XI.M24, "Compressed Air Monitoring"	No	Not applicable. Components exposed to compressed air downstream of air dryers are assigned the Air - dry environment. Aging evaluations for these components were compared to NUREG-1801 rows for dry air that recommended no aging management program, but were assigned the Compressed Air Monitoring program to ensure that a dried air environment is maintained. See item 3.3.1-120. Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components manages loss of material in stainless steel piping, piping components and piping elements subject to aging management and exposed to internal condensation in the Service Air, Instrument Air and Safety Related Instrument Air systems, see item 3.3.1-95.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-57	Elastomers Fire barrier penetration seals exposed to Air - indoor, uncontrolled, Air – outdoor	Increased hardness; shrinkage; loss of strength due to weathering	Chapter XI.M26, "Fire Protection"	No	Consistent with NUREG-1801 with the following clarifications: This item is not used by the Auxiliary Systems. The Fire Protection Program will manage change in material properties and cracking of elastomer fire barrier penetration sealant, seismic isolation Joint, and fire stop commodities subject to aging management and exposed to air - indoor in the Bulk Civil Commodities. Other elastomer fire penetration seals exposed to air are addressed under items 3.5.1-33 and 3.5.1-72.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-58	Steel Halon/carbon dioxide fire suppression system piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M26, "Fire Protection"	No	Consistent with NUREG-1801. The Fire Protection program will manage loss of material for steel carbon dioxide system piping components exposed to air - indoor, uncontrolled. There are no Halon system components subject to aging management in the Auxiliary systems. In addition to the Auxiliary systems, the Fire Protection Program will manage loss of material for steel Containment Isolation Dampers for U2 Containment Isolation (2M14), Fire Damper Housing, Fire Damper Housing 2M15, Flood curbs, and Louver and Damper housings including 2M49 Fire Dampers in the Bulk Civil Commodities and steel Drywell mechanical penetrations and Fuel Transfer tube penetration in the Containment Structure, Unit 1, subject to aging management and exposed to air - indoor.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-59	Steel Fire rated doors exposed to Air - indoor, uncontrolled, Air – outdoor	Loss of material due to wear	Chapter XI.M26, "Fire Protection"	No	Consistent with NUREG-1801 with the following clarifications: This line item was not used for the Auxiliary systems. The Fire Protection Program will manage loss of material for steel Damper and louver housings and fixed louvers2, and Fire door and barriers, Tornado Doors in the Bulk Civil Commodities and Drywell electrical penetrations in the Containment Structure, Unit 1, subject to aging management and exposed to air - indoor. Steel fire doors and barriers exposed to air are addressed under item 3.5.1-92.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-60	Reinforced concrete Structural fire barriers: walls, ceilings and floors exposed to Air - indoor, uncontrolled	Concrete cracking and spalling due to aggressive chemical attack, and reaction with aggregates	Chapter XI.M26, "Fire Protection," and Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. This item is not used in the Auxiliary systems. The Fire Protection and Structures Monitoring programs will manage cracking of concrete fire barriers exposed to Air - indoor, uncontrolled environment including beams, columns, floor and roof slabs and interior walls, and ceiling of DDFP Room, manway, hatches, manhole and hatch covers drywell, shield building cylinder wall and dome subject to aging management in the Bulk Civil Commodities, Water Control Structures, and the Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures and Containment Structure, Unit 1.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-61	Reinforced concrete Structural fire barriers: walls, ceilings and floors exposed to Air – outdoor	Cracking, loss of material due to freeze- thaw, aggressive chemical attack, and reaction with aggregates	Chapter XI.M26, “Fire Protection,” and Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801 with the following clarifications: This line item was not used for the Auxiliary systems. The Fire Protection program will manage change in material properties and cracking for concrete fire barriers exposed to air-outdoor in the Bulk Civil Commodities. Reinforced concrete exposed to air-outdoor environment other than structural fire barriers are addressed under item 3.5.1-66.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-62	Reinforced concrete Structural fire barriers: walls, ceilings and floors exposed to Air - indoor, uncontrolled, Air – outdoor	Loss of material due to corrosion of embedded steel	Chapter XI.M26, “Fire Protection,” and Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801 with the following clarifications: This line item was not used for the Auxiliary systems. The Fire Protection program will manage loss of material and including corrosion of embedded steel reinforcing for concrete fire barriers exposed to air-outdoor in the Bulk Civil Commodities. Concrete barriers other than reinforced concrete Structural fire barriers exposed to air environments subject to aging management for loss of material and including corrosion of embedded steel are addressed under item 3.5.1-66.
3.3.1-63	Steel Fire Hydrants exposed to Air – outdoor	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M27, "Fire Water System"	No	Consistent with NUREG-1801. The Fire Water System program will manage loss of material for gray cast iron fire hydrants exposed to an air - outdoor environment.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-64 (LR-ISG-2012-02)	Steel, Copper alloy Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion; flow blockage due to fouling	Chapter XI.M27, "Fire Water System"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02). The Fire Water System program will manage loss of material and flow blockage in steel and copper alloy components exposed to raw water in the Fire Protection system. Steel is used here in the broad category of carbon steel, alloy steel, cast iron, gray cast iron, malleable iron, and high-strength low-alloy, steel. All are vulnerable to loss of material due to the various aging mechanisms cited under this table 1 item number. In addition, fire pump steel bolting in the Fire Protection system that is submerged in raw water is aligned to this row but will be managed for loss of material under the Bolting Integrity program.
3.3.1-65 (LR-ISG-2012-02)	Aluminum Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting and crevice corrosion, fouling that leads to corrosion; flow blockage due to fouling	Chapter XI.M27, "Fire Water System"	No	Not applicable. There are no aluminum components subject to aging management review in the Fire Protection system that are exposed to raw water.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-66 (LR-ISG-2012-02)	Stainless steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting and crevice corrosion; fouling that leads to corrosion; flow blockage due to fouling	Chapter XI.M27, "Fire Water System"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02). The Fire Water System program will manage loss of material of stainless steel piping components exposed to raw water in the Fire Protection system.
3.3.1-67 (LR-ISG-2012-02)	Steel Tanks exposed to Air – outdoor (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not applicable. There are no steel tanks subject to aging management review in the Auxiliary systems that are exposed to air - outdoor.
3.3.1-68	Steel Piping, piping components, and piping elements exposed to Fuel oil	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M30, "Fuel Oil Chemistry", and Chapter XI.M32, "One-Time Inspection"	No	Not applicable. Loss of material for steel components in fuel oil are aligned to item 3.3.1-70.
3.3.1-69	Copper alloy Piping, piping components, and piping elements exposed to Fuel oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M30, "Fuel Oil Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801. The Fuel Oil Chemistry program will manage loss of material for copper alloy piping components exposed to fuel oil, and the One-Time Inspection program will be used to confirm the effectiveness of the Fuel Oil Chemistry program.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-70	Steel Piping, piping components, and piping elements; tanks exposed to Fuel oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M30, "Fuel Oil Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801 for most components. The Fuel Oil Chemistry program will manage loss of material for steel piping components and tanks exposed to fuel oil, and the One-Time Inspection program will be used to confirm the effectiveness of the Fuel Oil Chemistry program. Materials susceptible to selective leaching subjected to water contaminated fuel oil are managed under the Fuel Oil Chemistry and One-Time Inspection programs. These programs assure the exclusion of water. Furthermore, NUREG 2191 Selective Leaching AMP no longer includes water contaminated fuel oil environments. Also, steel floor and equipment drain pans and funnels in the Floor and Equipment Drain system exposed to fuel oil are aligned to this row but are managed for loss of material under the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-71	Stainless steel, Aluminum Piping, piping components, and piping elements exposed to Fuel oil	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M30, "Fuel Oil Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801 for most components. The Fuel Oil Chemistry program will manage loss of material for stainless steel piping components exposed to fuel oil, and the One-Time Inspection program will be used to confirm the effectiveness of the Fuel Oil Chemistry program. There are no tanks (stainless steel or aluminum) nor aluminum piping components subject to aging management review in the Auxiliary systems that are exposed to fuel oil. Also, stainless steel floor and equipment drain pans and funnels in the Floor and Equipment Drain system exposed to fuel oil are aligned to this row but are managed for loss of material under the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-72 (LR-ISG-2012-02)	Gray cast iron, Copper alloy (>15% Zn or >8% Al) Piping, piping components, and piping elements, Heat exchanger components exposed to Treated water, Closed-cycle cooling water, Soil, Raw water, Waste water	Loss of material due to selective leaching	Chapter XI.M33, “Selective Leaching”	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02) and with some program exceptions. The Selective Leaching program will manage loss of material due to selective leaching for gray cast iron and copper alloy (>15% Zn) components exposed to treated water, closed-cycle cooling water, soil, raw water, waste water. In addition, to the Auxiliary systems, gray cast iron heat exchanger components exposed to Closed-cycle cooling water in the Off Gas system are also aligned to this row. See Appendix B Section B.2.42 for Selective Leaching program exceptions to NUREG-1801.
3.3.1-73	Concrete; cementitious material Piping, piping components, and piping elements exposed to Air - outdoor	Changes in material properties due to aggressive chemical attack	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no concrete or cementitious material piping components subject to aging management review in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-74	Concrete; cementitious material Piping, piping components, and piping elements exposed to Air - outdoor	Cracking due to settling	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no concrete or cementitious material piping components subject to aging management review in the Auxiliary systems.
3.3.1-75	Reinforced concrete, asbestos cement Piping, piping components, and piping elements exposed to Air – outdoor	Cracking due to aggressive chemical attack and leaching; Changes in material properties due to aggressive chemical attack	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no reinforced concrete or asbestos cement piping components subject to aging management review in the Auxiliary systems.
3.3.1-76	Elastomers Elastomer: seals and components exposed to Air – indoor, uncontrolled (Internal/External)	Hardening and loss of strength due to elastomer degradation	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801 for most components. The External Surfaces Monitoring of Mechanical Components program manages degradation of internal and external surfaces of ventilation flexible connections made of asbestos-polyester cloth reinforced with Dow Nordel™ (EPDM) that are exposed to air - indoor, uncontrolled on both internal and external surfaces. In addition to the Auxiliary systems, External Surfaces Monitoring of Mechanical

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
					Components will manage hardening and loss of strength in elastomer flexible connections subject to aging management in the Annulus Exhaust Gas Treatment system exposed to Air-indoor, uncontrolled (internal) and are aligned to this row with exposure to Air-indoor, uncontrolled (external) aligned to row item 3.2.1-38. ESF Ventilation ductwork silicone sealant will continue to be age managed under Commitment L01090. The Structures Monitoring program will manage change in material properties and cracking for elastomer, Tefzel Ties commodities subject to aging management in the Bulk Civil Commodities and exposed to air-indoor, uncontrolled. The External Surfaces of Mechanical Components will manage the same aging effect for elastomer insulation commodities subject to aging management in the Bulk Civil Commodities and exposed to air-indoor, uncontrolled.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-77	Concrete; cementitious material Piping, piping components, and piping elements exposed to Air - outdoor	Loss of material due to abrasion, cavitation, aggressive chemical attack, and leaching	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no concrete or cementitious material piping components subject to aging management review in the Auxiliary systems.
3.3.1-78	Steel Piping and components (External surfaces), Ducting and components (External surfaces), Ducting; closure bolting exposed to Air – indoor, uncontrolled (External), Air – indoor, uncontrolled (External), Air – outdoor (External), Condensation (External)	Loss of material due to general corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801 for most components. The External Surfaces Monitoring of Mechanical Components program will manage loss of material for most steel components exposed to air - indoor, uncontrolled, air - outdoor, and condensation environments. In addition to components in the Auxiliary systems, the External Surfaces Monitoring of Mechanical Components program will manage loss of material for steel components in the Reactor Recirculation system. The Fire Protection program will manage loss of material for steel CO2 fire protection piping in air - outdoor.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-79	Copper alloy Piping, piping components, and piping elements exposed to Condensation (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801. The External Surfaces Monitoring of Mechanical Components program will manage loss of material for copper alloy components exposed to condensation.
3.3.1-80	Steel Heat exchanger components, Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External), Air – outdoor (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801. The External Surfaces Monitoring of Mechanical Components program will manage loss of material for steel components exposed to air - indoor, uncontrolled and air - outdoor. In addition to external surfaces, this program is used to manage aging effects on the internal surfaces of components exposed to air-outdoor when the external surface is the same or more severe environment. So monitoring the external surfaces will be indicative of internal surface.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-81	Copper alloy, Aluminum Piping, piping components, and piping elements exposed to Air – outdoor (External), Air - outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801 for most components. The External Surfaces Monitoring of Mechanical Components program will manage loss of material for copper alloy and aluminum components in the Auxiliary systems exposed to air - outdoor. The Fire Water System program will manage loss of material for copper alloy spray nozzles in the Fire Protection system exposed to air-outdoor. In addition to the Auxiliary systems, aluminum insulation jacketing commodity subject to aging management in the Bulk Civil Commodities is aligned with this item.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-82	Elastomers Elastomer: seals and components exposed to Air – indoor, uncontrolled (External)	Loss of material due to wear	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801. The External Surfaces Monitoring of Mechanical Components program will manage the aging effects of elastomers exposed to Air-indoor uncontrolled. Aging effects for the ventilation flexible connections made of asbestos-polyester cloth reinforced with Dow Nordel™ (EPDM) are also addressed in item 3.3.1-76. In addition to the Auxiliary systems, External Surfaces Monitoring of Mechanical Components will manage loss of material in elastomer flexible connections subject to aging management in the Annulus Exhaust Gas Treatment system exposed to Air-indoor, uncontrolled. Aging effects for ESF ductwork sealant will continue to be managed under Commitment L01090, which monitors silicone sealant samples in an Auxiliary system (Miscellaneous Area Ventilation system). There are no other elastomer components subject to aging management review in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-83	Stainless steel Diesel engine exhaust piping, piping components, and piping elements exposed to Diesel exhaust	Cracking due to stress corrosion cracking	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage cracking of stainless steel components exposed to diesel exhaust. In addition to the Auxiliary systems, the Structures Monitoring program will manage cracking of stainless steel, Diesel Exhaust hallway insulation bolting1 subject to aging management review in the Bulk Civil Commodities.
3.3.1-84	There is no NUREG-1800 item 3.3.1-84				
3.3.1-85	Elastomers Elastomer seals and components exposed to Closed- cycle cooling water	Hardening and loss of strength due to elastomer degradation	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no elastomer components subject to aging management review in the Auxiliary systems that are exposed to closed-cycle cooling water.
3.3.1-86	Elastomers Elastomers, linings, Elastomer: seals and components exposed to Treated borated	Hardening and loss of strength due to elastomer degradation	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no elastomer components subject to aging management review in the Auxiliary systems that are exposed to treated borated water, treated water or raw water.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
	water, Treated water, Raw water				
3.3.1-87	There is no NUREG-1800 item 3.3.1-87				
3.3.1-88	Steel; stainless steel Piping, piping components, and piping elements, Piping, piping components, and piping elements, diesel engine exhaust exposed to Raw water (potable), Diesel exhaust	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for steel and stainless steel components exposed to diesel exhaust in the Fire Protection and Diesel Generator Air Intake and Exhaust systems and to raw water in the Potable Water Supply system. In addition to the Auxiliary systems, the Structures Monitoring program will manage loss of material for stainless steel, Diesel Exhaust hallway insulation bolting1 subject to aging management review in the Bulk Civil Commodities.
3.3.1-89 (LR-ISG-2012-02)	Steel, Copper alloy Piping, piping components, and piping elements exposed to Moist air or condensation (Internal)	Loss of material due to general, pitting, and crevice corrosion	For fire water system components: Chapter XI.M27, "Fire Water System," or for other components: Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02) for most components. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for steel and copper alloy piping components exposed to air - indoor,

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
			and Ducting Components"		uncontrolled, air - outdoor, and condensation. The External Surfaces Monitoring of Mechanical Components program will manage loss of material for steel roof drain strainer bodies exposed to outdoor air in the Floor and Equipment Drains system. Moist air or condensation (Internal) is considered equivalent to Outdoor air. The external surface of copper alloy heat exchanger tubes and components within ventilation units are also aligned to this item, as they are internal to the ventilation units. The internal surfaces of steel heat exchanger shells exposed to Air – indoor, uncontrolled environment in the Diesel Generator Jacket water system are also aligned to this item. PNPP does not have any fire water system steel or copper alloy components subject to aging management exposed to internal moist air or condensation (internal) environments.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-90	Steel Ducting and components (Internal surfaces) exposed to Condensation (Internal)	Loss of material due to general, pitting, crevice, and (for drip pans and drain lines) microbiologically-influenced corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for steel components exposed to condensation (internal).
3.3.1-91	Steel Piping, piping components, and piping elements; tanks exposed to Waste Water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for steel components exposed to waste water. In addition to components in the Auxiliary systems, the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for components in the Respirator Cleaning system and Annulus Exhaust Gas Treatment system.
3.3.1-92	Aluminum Piping, piping components, and piping elements exposed to Condensation (Internal)	Loss of material due to pitting and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for aluminum components that are exposed to condensation in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-93	Copper alloy Piping, piping components, and piping elements exposed to Raw water (potable)	Loss of material due to pitting and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for copper alloy components exposed to raw water in the Potable Water Supply system.
3.3.1-94	Stainless steel Ducting and components exposed to Condensation	Loss of material due to pitting and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no stainless steel ducting components subject to aging management review in the Auxiliary systems that are exposed to condensation. Loss of material for other stainless steel components in the Auxiliary systems exposed to condensation (internal) is addressed in item 3.3.1-95.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-95	Copper alloy, Stainless steel, Nickel alloy, Steel Piping, piping components, and piping elements, Heat exchanger components, Piping, piping components, and piping elements; tanks exposed to Waste water, Condensation (Internal)	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for copper alloy, stainless steel and steel components exposed to waste water or condensation (internal). In addition to Auxiliary systems components, the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for stainless steel components in the Respirator Cleaning system, and will manage loss of material for stainless steel, sump liners and penetrations commodities subject to aging management and exposed to waste water in the Containment Structure and Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-96	Elastomers Elastomer: seals and components exposed to Air – indoor, uncontrolled (Internal)	Loss of material due to wear	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801 with the following clarifications: The External Surfaces Monitoring of Mechanical Components program will manage the loss of material due to wear of elastomers exposed to the same internal and external environments. The Aging effects for the ventilation flexible connections made of asbestos-polyester cloth reinforced with Dow Nordel™ (EPDM) are also addressed in item 3.3.1-76. In addition to the Auxiliary systems, elastomer flexible connections subject to aging management in the Annulus Exhaust Gas Treatment system exposed to Air-indoor, uncontrolled are aligned to this row. Aging effects for ESF ductwork sealant will continue to be managed under Commitment L01090, which monitors silicone sealant samples in an Auxiliary system (Miscellaneous Area Ventilation system). There are no other elastomer components subject to aging management review in the Auxiliary systems.

3.3.1-97	Steel Piping, piping components, and piping elements, Reactor coolant pump oil collection system: tanks, Reactor coolant pump oil collection system: piping, tubing, valve bodies exposed to Lubricating oil	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801 for most components. The Lubricating Oil Analysis program will manage loss of material for steel components exposed to lubricating oil. In addition to Auxiliary systems components, the Lubricating Oil Analysis program will manage loss of material for steel components in the Reactor Recirculation system exposed to Fyrquel hydraulic fluid. The One-Time Inspection program will be used to confirm the effectiveness of the Lubricating Oil Analysis program. Materials susceptible to selective leaching subjected to water contaminated lube oil are managed under the Lubricating Oil Analysis and One-Time Inspection programs. These programs assure the exclusion of water. Furthermore, NUREG 2191 Selective Leaching AMP no longer includes water contaminated lube oil environments. Also, steel floor and equipment drain pans and funnels in the Floor and Equipment Drain system exposed to lube oil are aligned to this row but are managed for loss of material under the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program.
3.3.1-98	Steel Heat exchanger	Loss of material due to general, pitting,	Chapter XI.M39, "Lubricating Oil	No	Consistent with NUREG-1801. The Lubricating Oil Analysis program

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
	components exposed to Lubricating oil	crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Analysis," and Chapter XI.M32, "One-Time Inspection"		will manage loss of material for steel heat exchanger components exposed to lubricating oil. In addition to Auxiliary systems components, the Lubricating Oil Analysis program will manage loss of material for steel components in the Reactor Recirculation system exposed to Fyrquel hydraulic fluid. The One-Time Inspection program will be used to confirm the effectiveness of the Lubricating Oil Analysis program.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-99	Copper alloy, Aluminum Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to pitting and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Consistent with NUREG-1801 for most components. The Lubricating Oil Analysis program will manage loss of material for copper alloy and aluminum piping components exposed to lubricating oil. Heat exchanger components in various Auxiliary systems with the same material, environment, and aging effect are also aligned to this row item. In addition to Auxiliary systems components, the Lubricating Oil Analysis program will manage loss of material for copper alloy and aluminum components in the Reactor Recirculation system exposed to Fyrquel hydraulic fluid. The One-Time Inspection program will be used to confirm the effectiveness of the Lubricating Oil Analysis program.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-100	Stainless steel Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801 for most components. The Lubricating Oil Analysis program will manage loss of material for stainless steel piping components exposed to lubricating oil. Heat exchanger components in various Auxiliary systems with the same material, environment, and aging effect are also aligned to this row item. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material of stainless steel drains exposed to lubricating oil in the Floor and Equipment Drains system. In addition to Auxiliary systems components, the Lubricating Oil Analysis program will manage loss of material for stainless steel components in the Reactor Recirculation system exposed to Fyrquel hydraulic fluid. The One-Time Inspection program will be used to confirm the effectiveness of the Lubricating Oil Analysis program.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-101	Aluminum Heat exchanger tubes exposed to Lubricating oil	Reduction of heat transfer due to fouling	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801: The Lubricating Oil Analysis will manage reduction of heat transfer for aluminum heat exchanger tube fins exposed to lubricating oil.
3.3.1-102	Boral®; boron steel, and other materials (excluding Boraflex) Spent fuel storage racks: neutron-absorbing sheets (PWR), Spent fuel storage racks: neutron-absorbing sheets (BWR) exposed to Treated borated water, Treated water	Reduction of neutron-absorbing capacity; change in dimensions and loss of material due to effects of SFP environment	Chapter XI.M40, "Monitoring of Neutron-Absorbing Materials other than Boraflex"	No	Consistent with NUREG-1801. The Monitoring of Neutron-Absorbing Materials other than Boraflex program will manage change in dimension, loss of material and reduction of neutron absorption for Boral neutron absorbers exposed to treated water.
3.3.1-103	Reinforced concrete, asbestos cement Piping, piping components, and piping elements exposed to Soil or concrete	Cracking due to aggressive chemical attack and leaching; Changes in material properties due to aggressive chemical attack	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no reinforced concrete or asbestos cement piping components subject to aging management review in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-104	HDPE, Fiberglass Piping, piping components, and piping elements exposed to Soil or concrete	Cracking, blistering, change in color due to water absorption	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Consistent with NUREG-1801. The Buried and Underground Piping and Tanks program will manage change in material properties and blistering (these aging effects are considered to be equivalent to cracking, blistering and change in color) for fiberglass piping exposed to soil in the Fire Protection program. There is no HDPE piping subject to aging management review in the Auxiliary systems.
3.3.1-105	Concrete cylinder piping, Asbestos cement pipe Piping, piping components, and piping elements exposed to Soil or concrete	Cracking, spalling, corrosion of rebar due to exposure of rebar	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no concrete cylinder or asbestos cement piping components subject to aging management review in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-106	Steel (with coating or wrapping) Piping, piping components, and piping elements exposed to Soil or concrete	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Consistent with NUREG-1801. The Buried and Underground Piping and Tanks program will manage loss of material for steel components exposed to soil. Effectiveness of special coatings or wrappings on buried components is not credited for completely mitigating aging effects throughout the period of extended operation. Steel piping components subject to aging management in the Auxiliary systems that are exposed to concrete are addressed in 3.3.1-112.
3.3.1-107 (LR-ISG-2011-03)	Stainless steel, nickel alloy piping, piping components, and piping elements exposed to Soil or concrete	Loss of material due to pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Consistent with NUREG-1801, as modified by LR-ISG-2011-03. The Buried and Underground Piping and Tanks program will manage loss of material for stainless steel piping components exposed to soil. There are no nickel alloy components subject to aging management in the Auxiliary systems that are exposed to soil.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-108 (LR-ISG-2011-03)	Titanium, super austenitic, aluminum, copper alloy, stainless steel, nickel alloy piping, piping components, and piping elements, bolting exposed to soil or concrete	Loss of material due to pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. Loss of material for stainless steel components in the Auxiliary systems exposed to soil is addressed in item 3.3.1-107. There are no titanium, super austenitic, aluminum, copper alloy, or nickel alloy piping components subject to aging management in the Auxiliary systems that are exposed to soil or concrete.
3.3.1-109	Steel Bolting exposed to Soil or concrete	Loss of material due to general, pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Consistent with NUREG-1801. The Buried and Underground Piping and Tanks program will manage loss of material for steel bolting exposed to soil. There is no steel bolting subject to aging management review in the Auxiliary systems that is exposed to concrete.
3.3.1-109x (LR-ISG-2011-03)	Underground aluminum, copper alloy, stainless steel, nickel alloy steel piping, piping components, and piping elements	Loss of material due to general (steel only), pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no underground (in vaults or tunnels outside of buildings) aluminum, copper alloy, stainless steel or nickel alloy piping components subject to aging management in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-110	Stainless steel Piping, piping components, and piping elements exposed to Treated water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M7, "BWR Stress Corrosion Cracking," and Chapter XI.M2, "Water Chemistry"	No	Not applicable. There are no stainless steel Auxiliary systems piping components aligned to this item. Components in the Reactor Coolant Pressure Boundary and Reactor Vessel systems within the scope of the BWR Stress Corrosion Cracking program are addressed in item 3.1.1-97. The Water Chemistry program will manage Cracking due to stress corrosion cracking of Stainless Steel Piping, piping components and piping elements in the Auxiliary systems and the One-Time Inspection program will be used to confirm its effectiveness. - See items 3.3.1-20 and 3.4.1-11.
3.3.1-111	Steel Structural steel exposed to Air – indoor, uncontrolled (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. This item is not used by Auxiliary systems. The Structures Monitoring program will manage loss of material for steel commodities comprising the Fuel Handling and Refueling Platforms in the Bulk Civil Commodities exposed to Air-indoor, uncontrolled.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-112	Steel Piping, piping components, and piping elements exposed to Concrete	None	None, provided 1) attributes of the concrete are consistent with ACI 318 or ACI 349 (low water-to-cement ratio, low permeability, and adequate air entrainment) as cited in NUREG-1557, and 2) plant OE indicates no degradation of the concrete	No, if conditions are met.	Consistent with NUREG-1801. Embedded steel components are in concrete that meets the guidelines of ACI-301 and ACI-318. [USAR 3.8.4.2] Concrete around embedded piping is not exposed to aggressive environments as cited in NUREG-1557, and a plant OE search has not identified degradation of concrete around embedded piping. Cast Iron roof drain external surfaces embedded in concrete is aligned with this GALL Item
3.3.1-113	Aluminum Piping, piping components, and piping elements exposed to Air – dry (Internal/External), Air – indoor, uncontrolled (Internal/External), Air – indoor, controlled (External), Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801 with the following clarifications: In addition to Auxiliary systems components, components in the Nuclear Boiler and Reactor Recirculation systems are also aligned to this item. For aluminum components exposed to air - dry in the Nuclear Boiler, Service Air, and Standby Diesel Generator systems, the Compressed Air Monitoring program is assigned to ensure that the air remains dry and free of contaminants supporting the conclusion that no aging effects are expected.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-114	Copper alloy Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (Internal/External), Air – dry, Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801 for most components with the following clarifications: Copper alloy heat exchanger components in various Auxiliary systems exposed to Air-indoor, uncontrolled environments are aligned to this item. Item 3.3.1-130 addresses management of flow blockage for copper alloy sprinkler heads exposed to air-indoor, uncontrolled. In addition to Auxiliary systems components, copper piping and valve bodies in the Annulus Exhaust Gas Treatment system and valve bodies in the Reactor Recirculation system are also aligned to this item. For copper components in an air – dry environment, the Compressed Air Monitoring program will ensure that the air remains dry and free of contaminants supporting the conclusion that no aging effects are expected.
3.3.1-115	PWR only				
3.3.1-116	Galvanized steel Piping, piping components, and piping elements	None	None	NA - No AEM or AMP	Consistent with NUREG-1801 with the following clarifications. Zinc valve bodies in the Diesel Generator Control Air and Start Air

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
	exposed to Air - indoor, uncontrolled				system are aligined with galvanized steel in this item. The Compressed Air Monitoring program is assigned to the internal environment to provide assurance that the quality of the "Air - dry" environment supports the conclusion that no aging effects are expected. In addition to the Auxiliary systems, this item is aligned with external surfaces of different components, namely the Reactor Vessel steel components near rated operating temperature. Applicable aging effects associated with high temperature, fatigue evaluations, and radiation effects are assigned to the internal surfaces subjected to reactor coolant and are not duplicated here. For the purposes of an aging assessment, galvanized steel components are evaluated as steel and these steel surfaces are exposed to drywell air. These components consist of various nozzles, safe ends, nozzle and safe end welds, vessel shell, top and bottom heads and vessel closure flange and welds. In general, if

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
					present zinc coating would not credited for corrosion protection.
3.3.1-117	Glass Piping elements exposed to Air – indoor, uncontrolled (External), Lubricating oil, Closed-cycle cooling water, Air – outdoor, Fuel oil, Raw water, Treated water, Treated borated water, Air with borated water leakage, Condensation (Internal/External) Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801 with the following clarifications: Glass components in the Auxiliary systems in various environments are addressed in item 3.3.1-117. There are no nickel alloy components subject to aging management review in the Auxiliary systems.
3.3.1-118	Nickel alloy Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External)	None	None	NA - No AEM or AMP	Not applicable. There are no nickel alloy components subject to aging management review in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-119	Nickel alloy, PVC, Glass Piping, piping components, and piping elements exposed to Air with borated water leakage, Air – indoor, uncontrolled, Condensation (Internal), Waste Water	None	None	NA - No AEM or AMP	Consistent with NUREG-1801 with the following clarifications: The sight glass in the Fire Water System is not PVC, but is a transparent polymer. Glass components in the Auxiliary systems in various environments are addressed in item 3.3.1-117. There are no nickel alloy components subject to aging management review in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-120	Stainless steel Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (Internal/External), Air – indoor, uncontrolled (External), Air with borated water leakage, Concrete, Air – dry, Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801 for most components. For components exposed to dried air downstream of air dryers, the Compressed Air Monitoring program is assigned to ensure that the environment will remain dry and free of contaminants supporting the conclusion that no aging effects are expected. In addition to the Auxiliary systems, components exposed to internal environments of air-dry and air-indoor, uncontrolled in the Nuclear Boiler system and Reactor Recirculation system are also aligned to this row. In addition to the Auxiliary systems, stainless steel Base Plates1 exposed to concrete in the Bulk Civil Commodities are also aligned with this item. Also see Item 3.4.1-58 for stainless steel piping components in the Auxiliary systems exposed to Air-indoor, uncontrolled.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-121	Steel Piping, piping components, and piping elements exposed to Air – indoor, controlled (External), Air – dry, Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801 for most components. There are no components in air-indoor, controlled aligned with this item. In addition to Auxiliary systems components, gas accumulators in the Reactor Recirculation system are also aligned to this item. For components in an air - dry environment downstream of air dryers, the Compressed Air Monitoring program is assigned to ensure that the environment will remain dry and free of contaminants supporting the conclusion that no aging effects are expected. Gas filled containment vessel electrical penetrations in the Containment Structure are also aligned with this item. Steel storage tanks with internal stainless steel cladding in the Safety Related Instrument Air system exposed to air-dry (internal) are addressed in 3.3.1-120.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-122	Titanium Heat exchanger components, Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled or Air – outdoor	None	None	NA - No AEM or AMP	Not applicable. There are no titanium components subject to aging management review in the Auxiliary systems.
3.3.1-123	Titanium (ASTM Grades 1,2, 7, 11, or 12 that contains > 5% aluminum or more than 0.20% oxygen or any amount of tin) Heat exchanger components other than tubes, Piping, piping components, and piping elements exposed to Raw water	None	None	NA - No AEM or AMP	Not applicable. There are no titanium components subject to aging management review in the Auxiliary systems.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-124 (LR-ISG-2011-01)	Stainless steel, Steel (with stainless steel or nickel-alloy cladding) Spent fuel storage racks (BWR), Spent fuel storage racks (PWR), Piping, piping components, and piping elements; exposed to Treated water >60˚C (>140˚F), Treated borated water >60˚C (>140˚F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Not applicable. There are no stainless steel or steel (with stainless steel or nickel-alloy cladding) spent fuel storage racks subject to aging management review in the Auxiliary systems that are exposed to Treated water >60˚C (>140˚F) or Treated borated water >60˚C (>140). Station procedures maintain pool temperature <130˚F. There are no steel (with stainless steel or nickel-alloy cladding) Piping, piping components, and piping elements subject to aging management review in the Auxiliary systems that are exposed to Treated water >60˚C (>140˚F) or Treated borated water >60˚C (>140). In the Auxiliary systems, Water Chemistry and One-Time Inspection program will manage cracking of stainless steel Piping, piping components, and piping elements subject to aging management exposed to Treated water >60˚C (>140˚F). See items 3.3.1-20 and 3.4.1-11.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-125 (LR-ISG-2011-01)	Steel (with stainless steel cladding); stainless steel Spent fuel storage racks (BWR), Spent fuel storage racks (PWR), Piping, piping components, and piping elements exposed to Treated water, Treated borated water	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection	No	Not applicable. There are no steel (with stainless steel cladding) or stainless steel spent fuel storage racks subject to aging management review in the Auxiliary systems. PNPP fuel storage racks are made of aluminum. Aluminum storage racks and stainless steel Piping components, and piping elements subject to aging management in the Auxiliary systems exposed to treated water are addressed in item 3.3.1-25.
3.3.1-126 (LR-ISG-2012-01)	Any material, piping, piping components, and piping elements exposed to treated water, treated water (borated), raw water	Wall thinning due to erosion	Chapter XI.M17, "Flow-Accelerated Corrosion"	No	Consistent with NUREG-1801 (as modified by ISG-2012-01). The Flow-Accelerated Corrosion program manages wall thinning (loss of material) where operating experience indicates the potential for erosion in treated water and raw water. Piping components in the Emergency Closed Cooling system exposed to closed-cycle cooling water are also aligned to this row, as closed-cooling water is a subset of treated water. There is no component exposed to borated treated water aligned to this item.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-127 (LR-ISG-2012-02)	Metallic piping, piping components, and tanks exposed to raw water or waste water	Loss of material due to recurring internal corrosion	A plant-specific aging management program is to be evaluated to address recurring internal corrosion	Yes, plant-specific (See Subsection 3.3.2.2.8)	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02). The Open Cycle Cooling Water and Fire Water System programs are augmented to address loss of material due to recurrent internal corrosion for steel piping and piping components in the Auxiliary systems as described in Further Evaluation section 3.3.2.2.8. There are no components exposed to waste water and tanks that aligned with this item.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-128 (LR-ISG-2012-02)	Steel, stainless steel, or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to soil or concrete, or the following external environments air-outdoor, air-indoor uncontrolled, moist air, condensation	Loss of material due to general (steel only), pitting, or crevice corrosion; cracking due to stress corrosion cracking (stainless steel and aluminum only)	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02) for the material, environment and aging effect with the following explanation. There are no steel, stainless steel or aluminum tanks subject to aging management review in the Auxiliary systems that are within the scope of the Aboveground Metallic Tanks program. However, cracking of buried, stainless steel Piping within the Fire Protection System is aligned with this item with the difference of a piping component and the exception that the aging effect is being managed with the Buried and Underground Piping and Tanks Program.
3.3.1-129 (LR-ISG-2012-02)	Steel tanks exposed to soil or concrete; air-indoor uncontrolled, raw water, treated water, waste water, condensation	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not applicable. There are no steel tanks subject to aging management review in the Auxiliary systems that are within the scope of the Aboveground Metallic Tanks program.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-130 (LR-ISG-2012-02)	Metallic sprinklers exposed to air-indoor controlled, air-indoor uncontrolled, air-outdoor, moist air, condensation, raw water, treated water	Loss of material due to general (where applicable), pitting, crevice, and microbiologically-influenced corrosion, fouling that leads to corrosion; flow blockage due to fouling	Chapter XI.M27, "Fire Water System"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02). The Fire Water System program will manage loss of material and flow blockage for metallic sprinkler heads with internal environments of raw water and air – indoor, uncontrolled. The sprinkler heads subject to aging management in the Fire Protection System under the Auxiliary Systems are not exposed to other environments.
3.3.1-131 (LR-ISG-2012-02)	Steel, stainless steel, copper alloy, or aluminum fire water system piping, piping components and piping elements exposed to air-indoor uncontrolled (internal), air-outdoor (internal), or condensation (internal)	Loss of material due to general (steel, and copper alloy only), pitting, crevice, and microbiologically influenced corrosion, fouling that leads to corrosion; flow blockage due to fouling	Chapter XI.M27, "Fire Water System"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02). The Fire Water System program will manage loss of material and flow blockage for steel and copper alloy fire water piping and piping components with internal environments of air – indoor, uncontrolled and air-outdoor. There is no internal condensation environment in the fire water system components. The dry pipe, outdoor deluge piping is also conservatively evaluated using an internal environment of raw water. The resulting aging effects are the same as this line item (3.3.1-131) and are managed by the same program – the Fire Water System

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
					Program. The conservative evaluation subsumes this line item within two other Table 3 line items, 3.3.1-64 and 3.3.1-66. Aluminum piping or piping components (flame arrestors) that are subject to aging management in the Fire Protection system exposed to air-indoor uncontrolled (internal) are addressed in 3.3.1-113 and those exposed to air-outdoor (internal) are addressed in 3.3.1-81. Copper alloy sprinkler heads in the Fire Water System program potentially experiencing internal flow blockage and exposed to air-indoor, uncontrolled are addressed in item 3.3.1-130.
3.3.1-132 (LR-ISG-2012-02)	Insulated steel, stainless steel, copper alloy, aluminum, or copper alloy (> 15% Zn) piping, piping components, and tanks exposed to condensation, air-outdoor	Loss of material due to general (steel, and copper alloy only), pitting, and crevice corrosion; cracking due to stress corrosion cracking (aluminum, stainless steel and copper alloy (>15% Zn) only)	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components" or Chapter XI.M29, “Aboveground Metallic Tanks” (for tanks only)	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02) with the following clarifications. The External Surfaces Monitoring of Mechanical Components program will manage loss of material for the external surfaces of insulated steel, stainless steel and copper alloy piping, piping components, tanks and steel heat exchanger chilled water channels in the Auxiliary systems exposed to condensation and will manage cracking for the

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
					external surfaces of insulated stainless steel components exposed to condensation. There are no components in the Auxiliary systems exposed to air-outdoor and there are no aluminum or copper alloy components exposed to condensation that are addressed by this item. The External Surfaces Monitoring of Mechanical Components program will manage loss of material for steel piping and piping components (insulated or uninsulated) in the Auxiliary systems exposed to air - outdoor as addressed in items 3.3.1-78, 3.3.1-80 and 3.3.1-89. There are no tanks subject to aging management review that are within the scope of the Aboveground Metallic Tanks program in the Auxiliary systems. In addition to the Auxility systems, the Fire Protection program will manage cracking and loss of material for Aluminum Damper and louver housings and fixed louvers1 in the Bulk Civil Commodities exposed to Air-outdoor.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-133 (LR-ISG-2012-02)	Underground HDPE piping, piping components, and piping elements in an air-indoor uncontrolled or condensation (external) environment	Cracking, blistering, change in color due to water absorption	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no underground HDPE components subject to aging management review in the Auxiliary systems.
3.3.1-134 (LR-ISG-2012-02)	Steel, stainless steel, or copper alloy piping, piping components, and piping elements, and heat exchanger components exposed to a raw water environment (for nonsafety-related components not covered by NRC GL 89-13)	Loss of material due to general (steel and copper alloy only), pitting, crevice, and microbiologically influenced corrosion, fouling that leads to corrosion	Chapter XI.MI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02). The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program will manage loss of material for steel, stainless steel and copper alloy piping, piping components, and piping elements in the Auxiliary systems exposed to raw water.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-135 (LR-ISG-2012-02)	Steel or stainless steel pump casings submerged in a waste water (internal and external) environment	Loss of material due to general (steel only), pitting, crevice, and microbiologically influenced corrosion	Chapter XI.MI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. Loss of material of stainless steel pump casings subject to aging management review in the Auxiliary systems that are submerged in a waste water (internal and external) environment are addressed in items 3.3.1-91 and 3.3.1-95 with the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program and in item 3.3.1-72 for gray cast iron with the Selective Leaching program.
3.3.1-136 (LR-ISG-2012-02)	Steel, stainless steel or aluminum fire water storage tanks exposed to air-indoor uncontrolled, air-outdoor, condensation, moist air, raw water, treated water	Loss of material due to general (steel only), pitting, crevice, and microbiologically influenced corrosion, fouling that leads to corrosion; cracking due to stress corrosion cracking (stainless steel and aluminum only)	Chapter XI.M27, "Fire Water System"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02) with a different component and program. This item is not used in the Auxiliary systems. PNPP does not have a fire water storage tank. The Water Chemistry and One Time Inspection programs will manage loss of material and cracking for aluminum, component and piping supports in the Bulk Civil Commodities exposed to treated water.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3.1-137 (LR-ISG-2012-02)	Steel, stainless steel or aluminum tanks (within the scope of Chapter XI.M29, “Aboveground Metallic Tanks”) exposed to treated water, treated borated water	Loss of material due to general (steel only) pitting and crevice corrosion	Chapter XI.M29, “Aboveground Metallic Tanks”	No	Not applicable. There are no steel, stainless steel or aluminum tanks subject to aging management review in the Auxiliary systems that are within the scope of the Aboveground Metallic Tanks program.
3.3.1-138 (LR-ISG-2013-01)	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, lubricating oil, or fuel oil	Loss of coating or lining integrity due to blistering, cracking, flaking, peeling, delamination, rusting, or physical damage, and spalling for cementitious coating/linings.	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2013-01). The Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks program will manage loss of coating or lining integrity for metallic components in the Auxiliary systems with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, or fuel oil. There are no metallic piping, piping components, heat exchangers, tanks with internal coatings/linings subject to aging management exposed to treated borated water or lubricating oil.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-139 (LR-ISG-2013-01)	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leasds to corrosion	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2013-01). The Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks program will manage loss of material for metallic components with internal coatings/linings in the Auxiliary systems exposed to closed-cycle cooling water, raw water, or treated water. LR-ISG-2013-01 did not add NUREG-1801 rows for loss of material in fuel oil. However, the XI.M42 program includes management of loss of material in fuel oil. There are no metallic piping, piping components, heat exchangers, tanks with internal coatings/linings subject to aging management exposed to treated borated water or lubricating oil.

Table 3.3.1 Summary of Aging Management Evaluations for the Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3.1-140 (LR-ISG-2013-01)	Gray cast iron piping component with internal coatings/linings exposed to closed-cycle cooling water, raw water, or treated water	Loss of material due to selective leaching	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2013-01). The Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks will manage loss of material due to selective leaching for components with internal coatings/linings exposed to raw water. No coatings are identified for gray cast iron components in other environments.

Notes for Table 3.3.2-1 through Table 3.3.2-63

Standard Notes

A	Consistent with NUREG-1801 item for component, material, environment and aging effect. AMP is consistent with NUREG-1801 AMP.
B	Consistent with NUREG-1801 item for component, material, environment and aging effect. AMP takes some exceptions to NUREG-1801 AMP.
C	Component is different, but consistent with NUREG-1801 item for material, environment and aging effect. AMP is consistent with NUREG-1801 AMP.
D	Component is different, but consistent with NUREG-1801 item for material, environment and aging effect. AMP takes some exceptions to NUREG-1801 AMP.
E	Consistent with NUREG-1801 item for material, environment and aging effect, but a different aging management program is credited or NUREG-1801 identifies a plant-specific aging management program.
F	Material not in NUREG-1801 for this component.
G	Environment not in NUREG-1801 for this component and material.
H	Aging effect not in NUREG-1801 for this component, material, and environment combination.
I	Aging effect in NUREG-1801 for this component, material and environment combination is not applicable.
J	Neither the component nor the material and environment combination are evaluated in NUREG-1801.

Plant-Specific Notes

301	Sodium pentaborate solution is a subset of treated water that results in similar aging effects for steel components. Steel piping exposed to sodium pentaborate when system is tested, drained, or are tank overflow lines. Lines are typically drained.
302	LR-ISG-2013-01 did not add NUREG-1801 rows for loss of material in fuel oil. However, the XI.M42 program includes acceptance criteria which supports management of loss of material in the metallic substrate in closed-cycle cooling water, raw water, treated water, treated borated water, waste water, fuel oil, and lubricating oil. This loss of material of the metallic substrate exposed to fuel oil is also managed under the Fuel Oil Chemistry and the One-Time Inspection programs.
303	Aging evaluation of glass with an internal environment of air is equivalent to the aging evaluation of glass with an external environment of indoor air.
304	Aging of the diesel fire pump jacket water HX is managed by the Fire Water System program.

Plant-Specific Notes (Continued)

305 The Service Water supply to the Alternate Decay Heat Removal system is normally drained and blown dry. Internal and external environments are air.

306 Closed-cycle cooling water is considered a subset of Treated water for this GALL comparison. Erosion identified by site OE in this system is managed by the Flow-Accelerated Corrosion program.

307 Components provide only structural support, and are isolated, with internal environment of air. Internal aging effects are expected to be similar to those visible externally.

308 Condensation environment is considered to be equivalent to Air - outdoor (external) for Loss of preload aging management comparison.

309 The Compressed Air Monitoring program provides assurance that the quality of the "Air - dry" environment supports the conclusion that no aging effects are expected.

310 Based on plant operating experience, there are no aging effects requiring management for the polymer Fire Protection water sight glasses, or Safety-Related Instrument Air condensate tank. Polymers are not expected to experience aging effects unless exposed to elevated temperatures or radiation levels capable of attacking the specific chemical composition. The sight glass is not PVC, but is a transparent polymer. These components are exposed to indoor air externally, and to condensation or fire water internally. These environments do not include elevated temperatures or radiation levels.

311 Internal Environment of the exhaust side CS - Relief Valve body parts is Air-Uncontrolled. External surface is the same or more severe environment. So monitoring the external surfaces will be indicative of internal CS parts.

312 Galvanic Corrosion mechanism results since susceptibility assumes a more cathodic metal is connected to the piping system.

313 Only small portion of Potable water system has an internal lining. A part of this pipe section is in the Control Complex is treated as a separate component.

314 This piping section of pipe is connected to discharge flapper valve (0P64F0511) and encased in concrete. Internal surface of the valve is representative of the piping condition.

315 Visual inspection of bolts securing discharge flapper valve (0P64F0511) is needed since leakage is not expected in a normally depressurized pipe. This valve prevents backflow into Diesel Generator Buildings in the event of flooding.

Plant-Specific Notes (Continued)

316 The 2 inch vent pipes on top of the Oil Interceptor Tank 0P64A0001 are exposed to soil and are included with piping in this AMP line item.

317 This component is PY-0P64F0511 and the attached piping up to the concrete Sludge Holding Sump.

318 External surface of vent pipes or intake filter housing is the same or more severe environment. So, monitoring the external surfaces will be indicative of internal surface.

319 Thermocouples in Reactor Recirculation System are installed in Nuclear Closed Cooling System piping.

320 Spray Header is normally below water level in the upper pools. When pools are drained down for refueling they are exposed to air indoors.

321 Liquid Radwaste is a waste water system and it has no downstream components in the scope of License Renewal. The program selected will manage loss of material due to corrosion.

322 Roof Drains are gray cast iron body in outdoor air and is treated as steel and managed by external surfaces program. Selective leaching is not expected in an outdoor air environment. Moist air or condensation (Internal) is considered equivalent to Outdoor air.

323 In addition to the Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components", additional testing, inspections, and reporting to be performed per Commitment L01090.

324 Bolting Integrity Program is enhanced to perform visual inspection of submerged bolting for ESW/ESW Screenwash pumps, diesel/motor fire pumps, Suppression Pool Suction Strainer, and Spent Fuel Rack Grid Structure for loss of material and loss of preload.

325 Although buried piping and tanks have special coatings or wrappings, no credit for mitigating aging effects are taken, and in this case, the material of steel is considered equivalent for comparison to NUREG-1801 table 2 Items.

326 The component is located within HVAC ducting and components, and the external surfaces of this component are subject to the internal HVAC environment during normal operation. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program performs visual inspections which are capable of identifying aging mechanisms which cause reduction of heat transfer.

327 Represents miscellaneous floor drains, equipment drain pans, and funnels with leakage boundary intended function highlighted on system boundary drawings.

Plant-Specific Notes (Continued)

328	In this section of stainless steel piping, the vast majority is below the threshold temperature for cracking due to SSC/IGSCC. The smaller amount up to the automatic vent valves are greater than the threshold temperatures.
329	Emergency Closed Cooling Pump Area fans do not normally operate, and chilled water does not bypass the coils. Chilled water in NSR area coolers and SR plenums may bypass the coils based upon exit temperature, but are conservatively assumed to experience condensation. Reduction in heat transfer is assumed due to fouling from debris or corrosion, which can be detected by visual inspection.
330	This bolting attaches the external, fire pump inlet strainer elements to the suction bowls. Loss of preload is not applicable aging effect since this is not a joint and would not fail its intended function.
331	Ductile Iron is considered the same as Gray Cast Iron for assignment of aging effects and AMPs which is consistent with NUREG-2191 (GALL-SLR).
332	External surface of elastomers in ventilation system duct and flexible connections is the same as the internal environment. So, monitoring the external surfaces will be indicative of internal surface. In addition to the Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components", additional testing, inspections, and reporting to be performed per Commitment L01090.
333	Per definitions in NUREG-1801, Section IX, Condensation is considered Raw Water.
334	Surfaces are not exposed to prolonged wetting other than humidity. Per EPRI Report 1010639, Non-Class 1 Mechanical Implementation Guideline and Mechanical Tools, Revision 4, Appendix E, Section 3.5, "Zinc is used (as a coating) because of its corrosion resistance in an external environment and because it provides galvanic protection of the base metal where discontinuities or damage of the coating has occurred." In this case, the valve body base material is zinc and not steel. In an air-dry and air-indoor, uncontrolled environments, Zinc is resistant to corrosion and similar to galvanized steel.
335	Aging effect is per EPRI Report 1010639, Non-Class 1 Mechanical Implementation Guideline and Mechanical Tools, Revision 4, Appendix G, Table 6-7. The assigned program is capable of detecting the aging effect.
336	Aging effect is per EPRI Report 1010639, Non-Class 1 Mechanical Implementation Guideline and Mechanical Tools, Revision 4, Appendix C, Table 4-2 with potential for water pooling assumed. The assigned inspection program is capable of detecting the aging effect and fuel oil chemistry program is preventative by ensuring water is removed.
337	Fatigue is a TLAA. See LRA Section 3.3.2.3 for further evaluation.

Plant-Specific Notes (Continued)

338 Surfaces are not exposed to prolonged wetting other than humidity. Per EPRI Report 1010639, Non-Class 1 Mechanical Implementation Guideline and Mechanical Tools, Revision 4, Appendix E, Section 3.5, "Zinc is used (as a coating) because of its corrosion resistance in an external environment and because it provides galvanic protection of the base metal where discontinuities or damage of the coating has occurred." In this case, the valve body base material is zinc and not steel. In an air-dry and air-indoor, uncontrolled environments, Zinc is resistant to corrosion and similar to galvanized steel in either environment. The Compressed Air Monitoring program provides assurance that the quality of the "Air - dry" environment supports the conclusion that no aging effects are expected.

3.4 AGING MANAGEMENT OF STEAM AND POWER CONVERSION SYSTEMS

3.4.1 INTRODUCTION

This section provides the results of the aging management review for those components identified in Section 2.3.4, Steam and Power Conversion System, as being subject to aging management review. The systems, or portions of systems, which are addressed in this section are described in the indicated sections.

- Auxiliary Steam and Drains (Section 2.3.4.1)
- Condensate (Section 2.3.4.2)
- Condensate Transfer and Storage (Section 2.3.4.3)
- Control Rod Drive Rebuild Equipment (Section 2.3.4.4)
- Extraction Steam (Section 2.3.4.5)
- Feed Water Control, Feedwater and Feedwater Leakage Control (Section 2.3.4.6)
- Main Condenser (including the main turbine shell) (Section 2.3.4.7)
- Main and Reheat Steam (Section 2.3.4.8)
- Main, Reheat, Extraction, and Miscellaneous Drain (Section 2.3.4.9)
- Respirator Cleaning (Section 2.3.4.10)
- Service Water and Emergency Service Water Chlorination (Section 2.3.4.11)
- Two Bed Demineralizer and Distribution, and Mixed Bed Demineralizer and Distribution (Section 2.3.4.12)

3.4.2 RESULTS

The following tables summarize the results of the aging management review for Steam and Power Conversion System.

- Table 3.4.2-1 Auxiliary Steam and Drains
- Table 3.4.2-2 Condensate
- Table 3.4.2-3 Condensate Transfer and Storage
- Table 3.4.2-4 Control Rod Drive Rebuild Equipment
- Table 3.4.2-5 Extraction Steam
- Table 3.4.2-6 Feed Water Control, Feedwater and Feedwater Leakage Control
- Table 3.4.2-7 Main Condenser (including the main turbine shell)
- Table 3.4.2-8 Main and Reheat Steam
- Table 3.4.2-9 Main, Reheat, Extraction, and Miscellaneous Drain

- Table 3.4.2-10 Respirator Cleaning
- Table 3.4.2-11 Service Water and Emergency Service Water Chlorination
- Table 3.4.2-12 Two Bed Demineralizer and Distribution, and Mixed Bed Demineralizer and Distribution

Note that the Extraction Steam system does not have any mechanical components subject to aging management review and the corresponding AMR results table contains no components.

3.4.2.1 Materials, Environment, Aging Effects Requiring Management and Aging Management Programs

The following sections list the materials, environments, aging effects requiring management, and aging management programs for the steam and power conversion systems components subject to aging management review. Aging management programs are described in Appendix B. Further details are provided in the system tables.

3.4.2.1.1 Auxiliary Steam and Drains

Materials

Auxiliary Steam and Drains system components are constructed of the following materials:

- Steel

Environments

Auxiliary Steam and Drains system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Auxiliary Steam and Drains system require management:

- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Auxiliary Steam and Drains system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.4.2.1.2 Condensate

Materials

Condensate system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Condensate system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Condensate system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Condensate system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.4.2.1.3 Condensate Transfer and Storage

Materials

Condensate Transfer and Storage system components are constructed of the following materials:

- Stainless steel
- Steel
- Steel with internal coating/lining

Environments

Condensate Transfer and Storage system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Soil
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Condensate Transfer and Storage system require management:

- Cracking
- Loss of coating or lining integrity
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Condensate Transfer and Storage system components:

- Aboveground Metallic Tanks (B.2.2)
- Bolting Integrity (B.2.7)
- Buried and Underground Piping and Tanks (B.2.8)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.27)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.4.2.1.4 Control Rod Drive Rebuild Equipment

Materials

Control Rod Drive Rebuild Equipment system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Control Rod Drive Rebuild Equipment system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Control Rod Drive Rebuild Equipment system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Control Rod Drive Rebuild Equipment system components:

- Bolting Integrity (B.2.7)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.4.2.1.5 Extraction Steam

The N36 Extraction Steam system does not contain any mechanical components that are safety-related, or that are credited for regulated events. The N36 system does contain mechanical components that are non-safety related whose failure could result in failure of a safety related function. However, all of those components are active and are not subject to aging management review. No N36 system components perform a pressure boundary or leakage boundary intended function. The Extraction Steam system components are not subject to aging management.

Materials

Extraction Steam system components are constructed of the following materials:

- N/A

Environments

Extraction Steam system components are exposed to the following environments:

- N/A

Aging Effects Requiring Management

The following aging effects associated with the Extraction Steam system require management:

- N/A

Aging Management Programs

The following aging management programs manage the effects of aging on Extraction Steam system components:

- N/A

3.4.2.1.6 Feed Water Control, Feedwater and Feedwater Leakage Control

Materials

Feed Water Control, Feedwater and Feedwater Leakage Control systems components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Feed Water Control, Feedwater and Feedwater Leakage Control systems components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water
- Treated water >60°C (>140°F)

Aging Effects Requiring Management

The following aging effects associated with the Feed Water Control, Feedwater and Feedwater Leakage Control systems require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Feed Water Control, Feedwater and Feedwater Leakage Control systems components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.4.2.1.7 Main Condenser (including the main turbine shell)

Materials

Main Condenser system components are constructed of the following materials:

- Aluminum
- Stainless steel
- Steel

Environments

Main Condenser system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Raw water
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Main Condenser system components require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Main a Condenser system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)

- One-Time Inspection (B.2.35)
- Open-Cycle Cooling Water System (B.2.37)
- Water Chemistry (B.2.44)

3.4.2.1.8 Main and Reheat Steam

Materials

Main and Reheat Steam system components are constructed of the following materials:

- Stainless steel
- Steel

Environments

Main and Reheat Steam system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water
- Treated water >60°C (>140°F)

Aging Effects Requiring Management

The following aging effects associated with the Main and Reheat Steam system require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Main and Reheat Steam system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.4.2.1.9 Main, Reheat, Extraction, and Miscellaneous Drain

Materials

Main, Reheat, Extraction, and Miscellaneous Drain system components are constructed of the following materials:

- Steel

Environments

Main, Reheat, Extraction, and Miscellaneous Drain system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Main, Reheat, Extraction, and Miscellaneous Drain system require management:

- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Main, Reheat, Extraction, and Miscellaneous Drain system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Flow-Accelerated Corrosion (B.2.22)
- One-Time Inspection (B.2.35)
- TLAA
- Water Chemistry (B.2.44)

3.4.2.1.10 Respirator Cleaning

Materials

Respirator Cleaning system components are constructed of the following materials:

- Copper alloy >15% Zn
- Stainless steel
- Steel

Environments

Respirator Cleaning system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Respirator Cleaning system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Respirator Cleaning system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- One-Time Inspection (B.2.35)
- Selective Leaching (B.2.42)
- Water Chemistry (B.2.44)

3.4.2.1.11 Service Water and Emergency Service Water Chlorination

Materials

Service Water and Emergency Service Water Chlorination components are constructed of the following materials:

- Glass
- Polymers
- Steel

Environments

Service Water and Emergency Service Water Chlorination components are exposed to the following environments:

- Air – indoor, uncontrolled

- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Service Water and Emergency Service Water Chlorination components require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Service Water and Emergency Service Water Chlorination components:

- Bolting Integrity (B.2.7)

3.4.2.1.12 Two Bed Demineralizer and Distribution and Mixed Bed Demineralizer and Distribution

Materials

Two Bed Demineralizer and Distribution and Mixed Bed Demineralizer and Distribution system components are constructed of the following materials:

- Copper alloy <15% Zn
- Stainless steel
- Steel

Environments

Two Bed Demineralizer and Distribution and Mixed Bed Demineralizer and Distribution system components are exposed to the following environments:

- Air – indoor, uncontrolled
- Concrete
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Two Bed Demineralizer and Distribution and Mixed Bed Demineralizer and Distribution system require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following aging management programs manage the effects of aging on Two Bed Demineralizer and Distribution and Mixed Bed Demineralizer and Distribution system components:

- Bolting Integrity (B.2.7)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- One-Time Inspection (B.2.35)
- Water Chemistry (B.2.44)

3.4.2.2 Further Evaluation of Aging Management as Recommended by NUREG-1800

NUREG-1800 indicates that further evaluation is necessary for certain aging effects and other issues discussed in Section 3.4.2.2 of NUREG-1800. The following sections are numbered in accordance with the discussions in NUREG-1800 and explain the PNPP approach to these areas requiring further evaluation. Programs are described in Appendix B.

Note - Italicized text at the beginning of each Further Evaluation subsection is taken directly from NUREG-1800 as supplemented by LR-ISG-2011-05 and LR-ISG-2012-02.

3.4.2.2.1 Cumulative Fatigue Damage

Fatigue is a TLAA as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). This TLAA is addressed separately in Section 4.3, "Metal Fatigue Analysis," of this SRP-LR. The related GALL Report items invoked by the subsection are VIII.D1.S-11, VIII.D2.S-11, VIII.G.S-11, VIII.B1.S-08, VIII.B2.S-08.

Fatigue is a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are evaluated in accordance with 10 CFR 54.21(c). The evaluation of metal fatigue as a TLAA for non-Class 1 components in the: Main and Reheat Steam, Main, Reheat, Extraction, and Miscellaneous Drains; Feedwater Control, Feedwater and Feedwater Leakage Control; and Auxiliary Steam and Drains systems is addressed in Section 4.3.2 either specifically or as part of the global evaluation. Likewise, in addition, the evaluation of metal fatigue as a TLAA for non-Class 1 components in the Auxiliary Systems (Reactor Water Clean Up system) is discussed in Section 4.3.2. See Section 4.3 for a complete evaluation of metal fatigue.

3.4.2.2.2 Cracking due to Stress Corrosion Cracking (SCC)

Cracking due to stress corrosion cracking could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air. The possibility of cracking also extends to components exposed to air which has recently *been introduced into buildings, i.e., components near intake vents. Cracking is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible. Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those within 1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas subject to chloride contamination from other agricultural or industrial sources. This item is applicable for the environments described above.*

GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external chloride stress corrosion cracking is not expected. The GALL Report recommends further evaluation to determine whether an adequate aging management program is used to manage this aging effect based on the environmental conditions applicable to the plant and ASME Code Section XI requirements applicable to the components.

Cracking due to stress corrosion cracking could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air, including air which has recently been introduced into buildings, such as near intake vents. This item is not applicable. Stainless steel components in the Steam and Power Conversion systems exposed to outdoor air are insulated. Cracking of these components is managed by the External Surfaces Monitoring of Mechanical Components program as addressed in Table 3.4.1 item 63. The External Surfaces Monitoring of Mechanical Components program is consistent with the recommendations of NUREG-1801, XI.M36 as modified by LR-ISG-2012-02.

3.4.2.2.3 Loss of Material Due to Pitting and Crevice Corrosion

Loss of material due to pitting and crevice corrosion could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air. The possibility of pitting and crevice corrosion also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Pitting and crevice corrosion is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible. Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those within 1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas subject to chloride contamination from other agricultural or industrial sources. This item is applicable for the environments described above.

GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external pitting or crevice corrosion is not expected. The GALL Report recommends further evaluation to determine whether an adequate aging management program is used to manage this aging effect based on the environmental conditions applicable to the plant and ASME Code Section XI requirements Quality Assurance for Aging Management of Nonsafety-Related Components.

Loss of material could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air, including air which has recently been introduced into buildings, such as near intake vents. This item is not applicable. Stainless steel components in the Steam and Power Conversion systems exposed to outdoor air are insulated. Loss of material for these components is managed by the External Surfaces Monitoring of Mechanical Components program as addressed in Table 3.4.1 item 63. The External Surfaces Monitoring of Mechanical Components program is consistent with the recommendations of NUREG-1801, XI.M36 as modified by LR-ISG-2012-02.

3.4.2.2.4 Quality Assurance for Aging Management of Nonsafety-Related Components

Acceptance criteria are described in Branch Technical Position IQMB-1 (Appendix A.2, of this SRP-LR).

See Appendix B Section B.1.3 for discussion of PNPP quality assurance procedures and administrative controls for aging management programs.

3.4.2.2.5 Ongoing Review of Operating Experience (Per LR-ISG-2011-05)

Ongoing review of operating experience is addressed in Appendix A, Section A.1 and Appendix B, Section B.1.4.

3.4.2.2.6 Loss of Material due to Recurring Internal Corrosion

Recurring internal corrosion can result in the need to augment AMPs beyond the recommendations in the GALL Report. During the search of plant-specific OE conducted during the LRA development, recurring internal corrosion can be identified by the number of occurrences of aging effects and the extent of degradation at each localized corrosion site. This further evaluation item is applicable if the search of plant-specific OE reveals repetitive occurrences (e.g., one per refueling outage cycle that has occurred over: (a) three or more sequential or nonsequential cycles for a 10-year OE search, or (b) two or more sequential or nonsequential cycles for a 5-year OE search) of aging effects with the same aging mechanism in which the aging effect resulted in the component either not meeting plant-specific acceptance criteria or experiencing a reduction in wall thickness greater than 50 percent (regardless of the minimum wall thickness.

The GALL Report recommends that a plant-specific AMP, or a new or existing AMP, be evaluated for inclusion of augmented requirements to ensure the adequate management of any recurring aging effect(s). Potential augmented requirements include: alternative examination methods (e.g., volumetric versus external visual), augmented inspections (e.g., a greater number of locations, additional locations based on risk insights based on susceptibility to aging effect and consequences of failure, a greater frequency of inspections), and additional trending parameters and decision points where increased inspections would be implemented. Acceptance criteria are described in Appendix A.1, "Aging Management Review – Generic (Branch Technical Position RSLB-1)."

The applicant states: (a) why the program's examination methods will be sufficient to detect the recurring aging effect before affecting the ability of a component to perform its intended function, (b) the basis for the adequacy of augmented or lack of augmented inspections, (c) what parameters will be trended as well as the decision points where increased inspections would be implemented (e.g., the extent of degradation at individual corrosion sites, the rate of degradation change), (d) how inspections of components that are not easily accessed (i.e., buried, underground) will be conducted, and (e) how leaks in any involved buried or underground components will be identified.

Each plant-specific operating experience example should be evaluated to determine if the chosen AMP should be augmented even if the thresholds for significance of aging effect or frequency of occurrence of aging effect have not been exceeded. For example, during a 10-year search of plant specific operating experience, two instances of 360 degree 30 percent wall loss occurred at copper alloy to steel joints. Neither the significance of the aging effect nor the frequency of occurrence of aging effect threshold has been exceeded. Nevertheless, the operating experience should be evaluated to determine if the AMP that is proposed to manage the aging effect is sufficient (e.g., method of inspection, frequency of inspection, number of inspections) to provide reasonable assurance that the CLB intended functions of the component will be met throughout the period of extended operation. Likewise, the GALL Report AMR items associated with the new FE items only cite raw water and waste water environments because OE indicates that these are the predominant environments associated with recurring internal corrosion; however, if the search of plant-specific OE reveals recurring internal corrosion in other water environments (e.g., treated water), the aging effect should be addressed in a similar manner.

LR-ISG-2012-02 has been issued which addresses instances of recurring internal corrosion identified during review of plant-specific operating experience. The operating experience for PNPP has been reviewed and instances of internal corrosion in the Steam and Power Conversion Systems have not been identified with a frequency that is consistent with the thresholds discussed in LR-ISG-2012-02.

3.4.2.3 Time-Limited Aging Analysis

The time-limited aging analyses identified associated with Steam and Power Conversion system components are addressed in Section 4. Table 4.1-2 provides TLAA results and identifies whether the TLAA remains valid for the PEO, will be managed during the PEO and the LRA sections that address them.

3.4.3 CONCLUSION

The Steam and Power Conversion System piping, fittings, and components that are subject to aging management review have been identified in accordance with the requirements of 10 CFR 54.21. The aging management programs selected to manage aging effects for the Steam and Power Conversion Systems components are identified in the summaries in Section 3.4.2.1 above.

A description of these aging management programs is provided in Appendix B, along with the demonstration that the identified aging effects will be managed for the period of extended operation.

Therefore, based on the conclusions provided in Appendix B, the effects of aging associated with the Steam and Power Conversion System components will be adequately managed so that there is reasonable assurance that the intended functions are maintained consistent with the current licensing basis during the period of extended operation.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4.1-1	Steel Piping, piping components, and piping elements exposed to Steam or Treated water	Cumulative fatigue damage due to fatigue	Fatigue is a time- limited aging analysis (TLAA) to be evaluated for the period of extended operation. See the SRP, Section 4.3 "Metal Fatigue," for acceptable methods for meeting the requirements of 10 CFR 54.21(c)(1).	Yes, TLAA (See subsection 3.4.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is evaluated as a TLAA. In addition to Steam and Power Conversion system components, components in the Reactor Water Clean-Up system are also aligned to this row. See further evaluation section 3.4.2.2.1.
3.4.1-2	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Cracking due to stress corrosion cracking	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See subsection 3.4.2.2.2)	Not applicable. Cracking of stainless steel components in the Steam and Power Conversion systems exposed to air - outdoor are addressed in item 3.4.1-63. See further evaluation section 3.4.2.2.2.
3.4.1-3	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See subsection 3.4.2.2.3)	Not applicable. Loss of material of stainless steel components in the Steam and Power Conversion systems exposed to air - outdoor are addressed in item 3.4.1-63. See further evaluation section 3.4.2.2.3.
3.4.1-4	PWR only				

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4.1-5	Steel Piping, piping components, and piping elements exposed to Steam, Treated water	Wall thinning due to flow-accelerated corrosion	Chapter XI.M17, "Flow-Accelerated Corrosion"	No	Consistent with NUREG-1801. The Flow-Accelerated Corrosion program will manage wall thinning (loss of material) due to flow-accelerated corrosion of steel piping components exposed to treated water. The Main Condenser pressure boundary and internal structural components are also aligned with this item. In addition to Steam and Power Conversion system components, components in the Reactor Water Clean-Up system are aligned to this row. The environment name "Treated water" is used in this application to address both liquid and vapor phases.
3.4.1-6	Steel, Stainless Steel Bolting exposed to Soil	Loss of preload	Chapter XI.M18, "Bolting Integrity "	No	Consistent with NUREG-1801. The Bolting Integrity program will manage loss of preload for steel bolting exposed to soil.
3.4.1-7	High-strength steel Closure bolting exposed to Air with steam or water leakage	Cracking due to cyclic loading, stress corrosion cracking	Chapter XI.M18, "Bolting Integrity"	No	Not applicable. There is no high-strength steel closure bolting exposed to air with steam or water leakage in the Steam and Power Conversion systems.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4.1-8	Steel; stainless steel Bolting, Closure bolting exposed to Air – outdoor (External), Air – indoor, uncontrolled (External)	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801 for steel bolting, with a difference identified for stainless steel bolting. The Bolting Integrity program will manage loss of material for steel bolting exposed to air – outdoor and air – indoor, uncontrolled. Loss of material for stainless steel bolting in air - indoor, uncontrolled was not identified as an applicable aging effect. EPRI 1010639 Appendix F (Bolted Closures) does not identify loss of material as an aging effect requiring management for stainless steel fasteners in indoor air. EPRI 1010639 Appendix E (External Surfaces) indicates that stainless steel may be susceptible to pitting and crevice corrosion in indoor air if: 1. Temperature <212˚F, and 2a. Surface is buried or subjected to a concentration of contaminants, or 2b. Surface is exposed to an aggressive environment in outdoor locations. The only stainless steel bolting subject to aging management review in the Steam and Power Conversion systems is

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
					closure bolting for the Main Steam Line Shutoff valves, which are normally well above the threshold temperature for this aging effect in stainless steel, which precludes the presence of liquid water. Loss of preload for this bolting is managed by the Bolting Integrity program as addressed in item 3.4.1-10. Cumulative fatigue damage for this bolting is managed by TLAA, as addressed in item 3.1.1-11.
3.4.1-9	Steel Closure bolting exposed to Air with steam or water leakage	Loss of material due to general corrosion	Chapter XI.M18, "Bolting Integrity"	No	Not applicable. The environment name "Air with steam or water leakage" was not used to describe bolting environments. The Bolting Integrity program will manage loss of material for steel bolting exposed to an indoor air environment as addressed in item 3.4.1-8.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-10	Copper alloy, Nickel alloy, Steel; stainless steel, Steel; stainless steel Bolting, Closure bolting exposed to Any environment, Air – outdoor (External), Air – indoor, uncontrolled (External)	Loss of preload due to thermal effects, gasket creep, and self- loosening	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. The Bolting Integrity program will manage loss of preload for steel and stainless steel bolting exposed to air - indoor, uncontrolled and air - outdoor. There is no copper alloy or nickel alloy closure bolting subject to aging management review in the Steam and Power Conversion systems. Loss of preload in steel bolting subject to aging management in the Steam and Power Conversion systems and exposed to soil is addressed in Item 3.4.1-6.
3.4.1-11	Stainless steel Piping, piping components, and piping elements, Tanks, Heat exchanger components exposed to Steam, Treated water >60˚C (>140˚F)	Cracking due to stress corrosion cracking	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One- Time Inspection”	No	Consistent with NUREG-1801 with some program exceptions. The Water Chemistry program will manage cracking of stainless steel components exposed to treated water >60˚C (>140˚F), and the One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry Program. In addition to components in the Power Conversion Systems, components in the Nuclear Boiler, Reactor Recirculation, Residual Heat Removal, High Pressure Core

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
					Spray, Low Pressure Core Spray, Reactor Core Isolation Cooling, Hydrogen Water Chemistry, Leakage Detection, Reactor Coolant Pressure Boundary and Reactor Water Clean-Up systems are also aligned to this row. Also, aligned are piping, piping components and piping elements and the High Pressure heater components in the Feedwater System. The Reactor Coolant Pressure Boundary system components are the main steam flow venturi inserts that are not pressure boundary components and a full bore RCIC flow element. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-12	Steel; stainless steel Tanks exposed to Treated water	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One- Time Inspection"	No	Consistent with NUREG-1801 with some program exceptions. The Water Chemistry program will manage loss of material for steel and stainless steel tanks subject to aging management in the Steam and Power Conversion systems exposed to treated water. The One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.4.1-13	PWR only

3.4.1-14	Steel Piping, piping components, and piping elements, PWR heat exchanger components exposed to Steam, Treated water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One- Time Inspection”	No	Consistent with NUREG-1801 with some program exceptions. The Water Chemistry program will manage loss of material for steel Piping, piping components, and piping elements subject to aging management in the Steam and Power Conversion systems exposed to treated water, steam. The One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. The Main Condenser pressure boundary and internal structural components are aligned with this item. There are no PWR heat exchanger components as PNPP is a BWR. Also see Item 3.4.1-15. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-15	Steel Heat exchanger components exposed to Treated water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One- Time Inspection"	No	Consistent with NUREG-1801 with some program exceptions. The Water Chemistry program will manage loss of material for steel, heat exchanger components subject to aging management in the Steam and Power Conversion systems exposed to treated water. The One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. These components include steel HP Feedwater Heater components and the Main Condenser tubesheet. Also see item 3.4.1-14. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4.1-16	Copper alloy, Stainless steel, Nickel alloy, Aluminum Piping, piping components, and piping elements, Heat exchanger components and tubes, PWR heat exchanger components exposed to Treated water, Steam	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One- Time Inspection"	No	Consistent with NUREG-1801 with some program exceptions. The Water Chemistry program will manage loss of material of copper alloy, aluminum, and stainless steel components exposed to treated water. The One-Time Inspection program will be used to confirm the effectiveness of the Water Chemistry program. In addition to components in the Steam and Power Conversion systems, copper alloy components in the Offgas system are also aligned to this row. Also, stainless steel, civil commodities for component and piping supports, Fuel Handling and Refueling Platforms, Fuel Prep Machine, and general purpose grapple1 in the Bulk Civil Commodities are aligned to this item. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.4.1-17	PWR only				

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-18	Copper alloy, Stainless steel Heat exchanger tubes exposed to Treated water	Reduction of heat transfer due to fouling	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One- Time Inspection”	No	Not applicable. There are no copper alloy heat exchanger tubes subject to aging management review in the Steam and Power Conversion systems that are exposed to treated water. There are no stainless steel heat exchanger tubes exposed to Treated water with an intended function of heat transfer in the Steam and Power Conversion systems. Other aging effects of the Number 6 feedwater heater tubes are addressed in table items 3.3.1-2, 3.4.1-11 and 3.4.1-16.
3.4.1-19	Stainless steel, Steel Heat exchanger components exposed to Raw Water	Loss of material due to general, pitting, crevice, galvanic, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801 for material, environment, aging effect and AMP. The waterbox and tubesheet in the Main Condenser is aligned with this item. There are no stainless steel or other steel components subject to aging management in the Steam and Power Conversion systems exposed to raw water.

3.4.1-23	Stainless steel Piping, piping components, and piping elements exposed to Closed-cycle cooling water >60˚C (>140˚F)	Cracking due to stress corrosion cracking	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no components subject to aging management review in the Steam and Power Conversion systems that are exposed to closed - cycle cooling water >60˚C (>140˚F).
3.4.1-24	Steel Heat exchanger components exposed to Closed-cycle cooling water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no components subject to aging management review in the Steam and Power Conversion systems that are exposed to closed-cycle cooling water.
3.4.1-25	Steel Heat exchanger components exposed to Closed-cycle cooling water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no components subject to aging management review in the Steam and Power Conversion systems that are exposed to closed-cycle cooling water.
3.4.1-26	Stainless steel Heat exchanger components, Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to pitting and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no components subject to aging management review in the Steam and Power Conversion systems that are exposed to closed - cycle cooling water.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4.1-27	Copper alloy Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no components subject to aging management review in the Steam and Power Conversion systems that are exposed to closed-cycle cooling water.
3.4.1-28	Steel, Stainless steel, Copper alloy Heat exchanger components and tubes, Heat exchanger tubes exposed to Closed-cycle cooling water	Reduction of heat transfer due to fouling	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no heat exchanger components subject to aging management review in the Steam and Power Conversion systems that are exposed to closed-cycle cooling water.
3.4.1-29	Steel Tanks exposed to Air – outdoor (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Consistent with NUREG-1801. The Aboveground Metallic Tanks program will manage loss of material for the steel Condensate Storage Tan exposed to air-outdoor. No other tanks are within the scope of the Aboveground Metallic Tanks program.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-30 (LR-ISG-2012-02)	Steel, Stainless Steel, Aluminum Tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to Soil or Concrete, or the following external environments air-outdoor, air-indoor uncontrolled, moist air, condensation	Loss of material due to general (steel only), pitting, and crevice corrosion; cracking due to stress corrosion cracking (stainless steel and aluminum only)	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02). The Aboveground Metallic Tanks program will manage loss of material for the external bottom surface of the steel Condensate Storage Tank that is exposed to soil. No other tanks are within the scope of the Aboveground Metallic Tanks program and no stainless steel or aluminum materials comprising the Condensate Storage Tank that is exposed to soil or concrete or the following external environments air-outdoor, air-indoor uncontrolled, moist air, condensation. For steel components comprising the Condensate Storage Tank and exposed to air-outdoor, see item 3.4.1-29.

Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-34	Steel External surfaces exposed to Air – indoor, uncontrolled (External), Air – outdoor (External), Condensation (External)	Loss of material due to general corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801. The External Surfaces Monitoring of Mechanical Components program will manage loss of material for steel components in the Steam and Power Conversion systems exposed to air - indoor, uncontrolled. Steel components exposed to air - outdoor are addressed in Items 3.4.1-8, 3.4.1-29 and 3.4.1-63. There are no steel components subject to aging management review in the Steam and Power Conversion systems that are exposed to condensation.
3.4.1-35	Aluminum Piping, piping components, and piping elements exposed to Air - outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no aluminum components subject to aging management review in the Steam and Power Conversion systems that are exposed to air - outdoor.
3.4.1-36	PWR only				
3.4.1-37	Steel Piping, piping components, and piping elements exposed to Condensation (Internal)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no steel components subject to aging management review in the Steam and Power Conversion systems that are exposed to an internal environment of condensation.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-38	PWR only				
3.4.1-39	Stainless steel Piping, piping components, and piping elements exposed to Condensation (Internal)	Loss of material due to pitting and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no stainless steel components subject to aging management review in the Steam and Power Conversion systems that are exposed to an internal environment of condensation.
3.4.1-40	Steel Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Not applicable. There are no steel components subject to aging management review in the Steam and Power Conversion systems that are exposed to lubricating oil.
3.4.1-41	PWR only				
3.4.1-42	PWR only				
3.4.1-43	Copper alloy Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to pitting and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Not applicable. There are no copper alloy components subject to aging management review in the Steam and Power Conversion systems that are exposed to lubricating oil.
3.4.1-44	Stainless steel Piping, piping components, and piping elements, Heat exchanger components exposed to Lubricating oil	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Consistent with NUREG-1801. There are no stainless steel components subject to aging management review exposed to lubricating oil in the Steam and Power Conversion systems, but

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
					the Lubricating Oil Analysis program will manage loss of material for stainless steel motor oil components in the Residual Heat Removal, High Pressure Core Spray, and Low Pressure Core Spray systems, as well as stainless steel Reactor Core Isolation Cooling and Offgas systems lubricating oil components. Additionally, the specific environment for components in the Offgas system aligned to this item is NOVEC™ 7100 refrigerant, a fluorinated hydrocarbon which is similar to lubricating oil for aging management comparison. The One-Time Inspection program will be used to confirm the effectiveness of the Lubricating Oil Analysis program. Stainless steel heat exchanger and piping, piping components and piping elements subject to aging management exposed to lubricating oil are also addressed in Items 3.2.1-51 and 3.3.1-100.
3.4.1-45	PWR only				
3.4.1-46	PWR only				

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-47 (LR-ISG-2011-03)	Steel (with coating or wrapping), stainless steel, nickel-alloy piping, piping components, and piping elements; tanks exposed to Soil or Concrete	Loss of material due to general (steel only), pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Consistent with NUREG-1801. The Buried and Underground Piping and Tanks program will manage loss of material for piping, piping components and piping elements subject to aging management in the Steam and Power Conversion systems exposed to soil. Loss of material for the steel Condensate Storage Tank exposed to soil is addressed in item 3.4.1-30 and bolting exposed to soil is addressed in 3.4.1-50. There are no other steel (with coating or wrapping), stainless steel or nickel alloy piping, piping components, and piping elements or tanks subject to aging management review in the Steam and Power Conversion systems that are exposed to soil or concrete (buried).
3.4.1-48 (LR-ISG-2011-03)	Stainless steel, nickel alloy bolting exposed to soil	Loss of material due to pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There is no stainless steel bolting subject to aging management review in the Steam and Power Conversion systems that is exposed to soil.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4.1-49 (LR-ISG-2011-03)	Stainless steel, nickel alloy piping, piping components, and piping elements exposed to soil or concrete	Loss of material due to pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not Applicable. There are no nickel alloy components subject to aging management exposed to soil or concrete. See items 3.3.1-107, 3.3.1-128 and 3.4.1-47 for management of stainless steel components subject to aging management review and exposed to soil. Stainless steel piping subject to aging management review that are embedded in concrete and in the Steam and Power Conversion systems are within structures. They are not buried and have no aging effects. See item 3.4.1-58.
3.4.1-50	Steel Bolting exposed to Soil	Loss of material due to general, pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Consistent with NUREG-1801. The Buried and Underground Piping and Tanks program will manage loss of material for steel bolting subject to aging management in the Steam and Power Conversion systems exposed to soil.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4.1-50x (LR-ISG-2011-03)	Underground stainless steel, nickel alloy, steel piping, piping components, and piping elements	Loss of material due to general (steel only), pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no underground stainless steel, nickel alloy or steel piping, piping components, and piping elements subject to aging management review in the Steam and Power Conversion systems.
3.4.1-51	Steel Piping, piping components, and piping elements exposed to Concrete	None	None, provided 1) attributes of the concrete are consistent with ACI 318 or ACI 349 (low water-to-cement ratio, low permeability, and adequate air entrainment) as cited in NUREG-1557, and 2) plant OE indicates no degradation of the concrete	No, if conditions are met.	Not applicable. There are no steel components subject to aging management review in the Steam and Power Conversion systems that are exposed to concrete.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-52	Aluminum Piping, piping components, and piping elements exposed to Gas, Air – indoor, uncontrolled (Internal/External)	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. There are no aluminum components subject to aging management review in the Steam and Power Conversion systems that are exposed to gas. The turbine rupture discs are aluminum and installed in the Low Pressure Turbine exhaust hood and exposed to an air – indoor, uncontrolled environment (External). No credit is taken for its external elastomer cover and there are no other aluminum components subject to aging management in the Steam and Power Conversion systems exposed to an air -indoor uncontrolled environment.
3.4.1-53	PWR only				

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4.1-54	Copper alloy Piping, piping components, and piping elements exposed to Gas, Air – indoor, uncontrolled (External)	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. Copper alloy components subject to aging management in the Steam and Power Conversion System exposed to air-indoor, uncontrolled are aligned with this item. There are no Copper alloy components subject to aging management in the Steam and Power Conversion System exposed to gas.
3.4.1-55	Glass Piping elements exposed to Lubricating oil, Air – outdoor, Condensation (Internal/External), Raw water, Treated water, Air with borated water leakage, Gas, Closed-cycle cooling water, Air – indoor, uncontrolled (External)	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. Glass piping elements are only exposed to air-indoor, uncontrolled and treated water in the Steam and Power Conversion systems and are aligned to this item. In addition to the Steam and Power Conversion systems, civil commodities exposed to air-indoor, uncontrolled in the Bulk Civil Commodities, Containment Structure, and Turbine Bldgs and Associated Structures, Process Facilities, and Yard Structures are aligned to this item.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-56	Nickel alloy Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External)	None	None	NA - No AEM or AMP	Not applicable. There are no nickel alloy components subject to aging management review in the Steam and Power Conversion systems that are exposed to air – indoor, uncontrolled.
3.4.1-57	Nickel alloy, PVC Piping, piping components, and piping elements exposed to Air with borated water leakage, Air – indoor, uncontrolled, Condensation (Internal)	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. Polyvinylidene fluoride (PVDF) is considered an equivalent material for this comparison for components in the Emergency Service Water Chlorination system. PVC piping, piping components and piping elements in the Steam and Power Conversion systems subject to aging management exposed to an external air-indoor, uncontrolled environment is aligned to this item. There are no PVC components subject to aging management in the Steam and Power Conversion systems with an internal condensation environment and there are no Nickel alloy components subject to aging management in the Steam and Power Conversion systems.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-58	Stainless steel Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External), Concrete, Gas, Air – indoor, uncontrolled (Internal)	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. Stainless steel piping, piping components and piping elements and a Tank subject to aging management in the Steam and Power Conversion systems exposed to air-indoor, uncontrolled and concrete are aligned with this item. There are no stainless steel piping, piping components and piping elements subject to aging management exposed gas or air-indoor, uncontrolled (internal) in the Steam and Power Conversion systems. In addition to the Steam and Power Conversion systems, Stainless steel piping, piping components and piping elements subject to aging management in the Div. 1 & 2 Standby Diesel Generator Exhaust, Intake and Crankcase system and exposed to air-indoor, uncontrolled are aligned with this item.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-59	Steel Piping, piping components, and piping elements exposed to Air – indoor controlled (External), Gas	None	None	NA - No AEM or AMP	Not applicable. There are no steel components subject to aging management review in the Steam and Power Conversion systems that are exposed to air – indoor, controlled or gas.
3.4.1-60 (LR-ISG-2012-01)	Any material, piping, piping components, and piping elements exposed to treated water	Wall thinning due to erosion	Chapter XI.M17, "Flow-Accelerated Corrosion"	No	Not applicable. Loss of material due to flow-accelerated corrosion is addressed in items 3.4.1-5, 3.4.1-14 and 3.4.1-15. Erosion has not been identified by plant OE review in the Steam and Power Conversion systems.
3.4.1-61 (LR-ISG-2012-02)	Metallic piping, piping components, and tanks exposed to raw water or waste water	Loss of material due to recurring internal corrosion	A plant-specific aging management program is to be evaluated to address recurring internal corrosion	Yes, plant-specific (See subsection 3.4.2.2.6)	Not applicable. For metallic components subject to aging management review exposed to waste water in the Steam and Power Conversion systems see items 3.3.1-91 and 3.3.1-95, and for the condenser tubesheet exposed to raw water, see item 3.4.1-19. See further evaluation topic 3.4.2.2.6.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-62 (LR-ISG-2012-02)	Steel, stainless steel or aluminum tanks (within the scope of Chapter XI.M29, “Aboveground Metallic Tanks”) exposed to treated Water	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M29, “Aboveground Metallic Tanks”	No	Not applicable. The only tank within the scope of the Aboveground Metallic Tanks program is the Condensate Storage Tank. Loss of material for this internally-coated steel tank exposed to Treated water is addressed in item 3.4.1-67.
3.4.1-63 (LR-ISG-2012-02)	Insulated steel, stainless steel, copper alloy, aluminum, or copper alloy (> 15% Zn) piping, piping components, and tanks exposed to condensation, air-outdoor	Loss of material due to general (steel, and copper alloy), pitting, or crevice corrosion, and cracking due to stress corrosion cracking (aluminum, stainless steel and copper alloy (>15% Zn) only)	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components" or Chapter XI.M29, “Aboveground Metallic Tanks” (for tanks only)	No	Consistent with NUREG-1801 (as modified by LR-ISG-2012-02). The External Surfaces Monitoring of Mechanical Components program will manage loss of material for insulated steel and stainless steel piping components exposed to air - outdoor, and will manage cracking of insulated stainless steel piping components exposed to air - outdoor. The Aboveground Metallic Tanks program will manage loss of material of the insulated steel Condensate Storage Tank exposed to air - outdoor. No other piping components subject to aging management review in the Steam and Power Conversion systems are exposed to an external environment of air - outdoor or condensation.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-64 (LR-ISG-2012-02)	Jacketed calcium silicate or fiberglass insulation in an air-indoor uncontrolled or air-outdoor environment	Reduced thermal insulation resistance due to moisture intrusion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not Applicable. This item is not used in the Steam and Power Conversion Systems. There are no Jacketed calcium silicate or fiberglass insulation subject to aging management with an intended function of thermal insulation in the Bulk Civil Commodities.
3.4.1-65 (LR-ISG-2012-02)	Jacketed foamglas ® (glass dust) insulation in an air-indoor uncontrolled or air-outdoor environment	Reduced thermal insulation resistance due to moisture intrusion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. This item is not used in the Steam and Power Conversion Systems. There are no foamglas® insulation components with an intended function of thermal insulation in the Steam and Power Conversion systems.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4.1-66 (LR-ISG-2013-01)	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil	Loss of coating or lining integrity due to blistering, cracking, flaking, peeling, delamination, rusting, or physidcal damage, and spalling for cementitious coating/linings.	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2013-01). The Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks program will manage loss of coating or lining integrity for the Condensate Storage Tank exposed to treated water. No other internally coated or lined metallic piping, piping components, heat exchangers, or tanks subject to aging management review are in the Steam and Power Conversion systems.

Table 3.4.1 Summary of Aging Management Evaluations for the Steam and Power Conversion Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4.1-67 (LR-ISG-2013-01)	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leasds to corrosion	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Consistent with NUREG-1801 (as modified by LR-ISG-2013-01). The Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks program will manage loss of material for the Condensate Storage Tank exposed to treated water. No other internally coated or lined metallic piping, piping components, heat exchangers, or tanks subject to aging management review are in the Steam and Power Conversion systems.
3.4.1-68 (LR-ISG-2013-01)	Gray cast iron piping component with internal coatings/linings exposed to closed-cycle cooling water, raw water, or treated water	Loss of material due to selective leaching	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Not applicable. No internally coated or lined gray cast iron components subject to aging management review have been identified in the Steam and Power Conversion systems.

Notes for Table 3.4.2-1 through Table 3.4.2-12

Standard Notes

A Consistent with NUREG-1801 item for component, material, environment and aging effect. AMP is consistent with NUREG-1801 AMP.

B Consistent with NUREG-1801 item for component, material, environment and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C Component is different, but consistent with NUREG-1801 item for material, environment and aging effect. AMP is consistent with NUREG-1801 AMP.

D Component is different, but consistent with NUREG-1801 item for material, environment and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E Consistent with NUREG-1801 item for material, environment and aging effect, but a different aging management program is credited or NUREG-1801 identifies a plant-specific aging management program.

F Material not in NUREG-1801 for this component.

G Environment not in NUREG-1801 for this component and material.

H Aging effect not in NUREG-1801 for this component, material, and environment combination.

I Aging effect in NUREG-1801 for this component, material and environment combination is not applicable.

J Neither the component nor the material and environment combination are evaluated in NUREG-1801.

Plant-Specific Notes

401 The PNPP "Treated water" environment includes the steam phase.

402 Based on plant operating experience, there are no aging effects requiring management for the Service Water and Emergency Service Water Chlorination system polymer components in a treated water or air – indoor uncontrolled environment. The materials are polyvinylidene fluoride (PVDF) and polyvinyl chloride (PVC), and the treated water environment is sodium hypochlorite at a concentration of 12% to 15%. This material is not expected to experience aging effects unless exposed to elevated temperatures or radiation levels capable of attacking the specific chemical composition. The material in these environments is not expected to experience significant aging effects due to elevated temperatures or radiation levels.

403 The Main Condenser pressure boundary and internal structural components are also aligned with this item.

404 The component is the Main Condenser tubesheet serving a structural support intended function.

405 The FW Heaters 6A and 6B tubes are aligned with this item to support the Pressure boundary Intended function.

Plant-Specific Notes (Continued)

406 Rupture disc is positioned on the exhaust hood in a location not subject to high velocity low temperature steam and subject to condenser pressure.

3.5 AGING MANAGEMENT OF CONTAINMENTS, STRUCTURES, AND COMPONENT SUPPORTS

3.5.1 INTRODUCTION

This section provides the results of the aging management review for those structural components identified in Section 2.4.1, Structures and Component Supports, as being subject to aging management review. The following structures and commodity groups are addressed in this section, and are described in the indicated sections.

- Containment Structure, Unit 1 (includes reactor building and containment vessel) (Section 2.4.1)
- Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures (Section 2.4.2)
- Water Control Structures (Section 2.4.3)
- Structural Bulk Commodities (Section 2.4.4)

3.5.2 RESULTS

The following tables summarize the results of the aging management review for Structures.

- Table 3.5.2-1 Containment Structure, Unit 1 (includes the reactor building and containment vessel)
- Table 3.5.2-2 Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures
- Table 3.5.2-3 Water Control Structures
- Table 3.5.2-4 Bulk Commodities

3.5.2.1 Materials, Environment, Aging Effects Requiring Management and Aging Management programs

The following sections list the materials, environments, aging effects requiring management, and aging management programs for structures and component supports subject to aging management review. Programs are described in Appendix B. Further details are provided in the structures and commodities tables.

3.5.2.1.1 Containment Structure, Unit 1 (includes the reactor building and containment vessel)

Materials

The Containment Structure components are constructed of the following materials:

- Aluminum
- Coatings
- Concrete
- Copper alloy <15% Zn
- Elastomer
- Fiberglass
- Fiberglass fabric
- Glass
- Porous concrete
- Stainless steel
- Steel
- Steel with stainless steel cladding

Environments

The Containment Structure components are exposed to the following environments:

- Air - dry
- Air – indoor, uncontrolled
- Air – outdoor
- Concrete
- Gas
- Raw water
- Soil
- Treated water

- Waste water

Aging effects Requiring Management

The following aging effects associated with the Containment Structure require management:

- Change in material properties
- Cracking
- Cumulative fatigue damage
- Loss of coating integrity
- Loss of material
- Loss of material (Corrosion of embedded steel reinforcing)
- Loss of preload
- Loss of sealing

Aging Management Programs

The following aging management programs manage the effects of aging on the Containment Structure components:

- 10 CFR 50, Appendix J (B.2.1)
- ASME Section XI, Subsection IWE (B.2.4)
- ASME Section XI, Subsection IWF (B.2.5)
- ASME Section XI, Subsection IWL (B.2.6)
- Fire Protection (B.2.20)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B.2.26)
- One-Time Inspection (B.2.35)
- Protective Coating Monitoring and Maintenance (B.2.38)
- Structures Monitoring (B.2.43)
- TLAA
- Water Chemistry (B.2.44)

3.5.2.1.2 Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures

Materials

The Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures components are constructed of the following materials:

- Aluminum
- Concrete
- Concrete Block
- Galvanized steel
- Glass
- Porous concrete
- Stainless steel
- Steel

Environments

The Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Concrete
- Raw water
- Soil
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures require management:

- Change in material properties
- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of material (Corrosion of embedded steel reinforcing)

Aging Management Programs

The following aging management programs manage the effects of aging on the Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures components:

- Fire Protection (B.2.20)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.25)
- Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B.2.26)
- One-Time Inspection (B.2.35)
- Structures Monitoring (B.2.43)
- TLAA
- Water Chemistry (B.2.44)

3.5.2.1.3 Water Control Structures

Materials

The Water Control Structures components are constructed of the following materials:

- Concrete
- Elastomer
- Galvanized steel
- Porous concrete
- Rock/Stone/Soil
- Stainless Steel
- Steel

Environments

The Water Control Structures components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Raw water
- Soil

Aging Effects Requiring Management

The following aging effects associated with the Water Control Structures require management:

- Change in material properties
- Cracking
- Cumulative fatigue damage
- Flow blockage
- Loss of form
- Loss of material
- Loss of material (Corrosion of embedded steel reinforcing)
- Loss of sealing

Aging Management Programs

The following aging management programs manage the effects of aging on the Water Control Structures components:

- Fire Protection (B.2.20)
- RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.41)
- Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B.2.26)
- Structures Monitoring (B.2.43)
- TLAA

3.5.2.1.4 Bulk Commodities

Materials

The Bulk Commodities components are constructed of the following materials:

- 3M Interam®
- Aluminum
- Concrete
- Elastomer
- Fiberglass/ Alumina silicate/ Calcium silicate/ Ceramic fiber
- Fiberglass Fabric
- Galvanized steel
- Glass

- High strength steel
- Lubrite®/ Fluorogold®
- Polymer
- Porcelain
- Pyrocrete
- Stainless steel
- Steel
- Wood

Environments

The Bulk Commodities components are exposed to the following environments:

- Air – indoor, uncontrolled
- Air – outdoor
- Concrete
- Diesel Exhaust
- Raw water
- Soil
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Bulk Commodities require management:

- Change in material properties
- Cracking
- Delamination
- Flow Blockage
- Loss of material
- Loss of material (Corrosion of embedded steel reinforcing)
- Loss of mechanical function
- Loss of preload
- Loss of sealing
- Loss of Strength

Aging Management Programs

The following aging management programs manage the effects of aging on the Bulk Commodities components:

- ASME Section XI, Subsection IWF (B.2.5)
- External Surfaces Monitoring of Mechanical Components (B.2.18)
- Fire Protection (B.2.20)
- One-Time Inspection (B.2.35)
- RG 1.127 – Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.41)
- Structures Monitoring (B.2.43)
- Water Chemistry (B.2.44)

3.5.2.2 Further Evaluation of Aging Management as Recommended by NUREG-1800

NUREG-1800 indicates that further evaluation is necessary for certain aging effects and other issues discussed in Section 3.5.2.2 of NUREG-1800. The following sections are numbered in accordance with the discussions in NUREG-1800 and explain the PNPP approach to these areas requiring further evaluation. Programs are described in Appendix B.

Note - Italicized text at the beginning of each Further Evaluation subsection is taken directly from NUREG-1800 as supplemented by LR-ISG-2011-04 and LR-ISG-2011-05.

3.5.2.2.1 PWR and BWR Containments

3.5.2.2.1.1 Cracking and Distortion due to Increased Stress Levels from Settlement; Reduction of Foundation Strength, and Cracking due to Differential Settlement and Erosion of Porous Concrete Subfoundations.

Cracking and distortion due to increased stress levels from settlement could occur in PWR and BWR concrete and steel containments. The existing program relies on ASME Section XI, Subsection IWL to manage these aging effects. Also, reduction of foundation strength and cracking, due to differential settlement and erosion of porous concrete sub foundations could occur in all types of PWR and BWR containments. The existing program relies on the structures monitoring program to manage these aging effects. However, some plants may rely on a dewatering system to lower the site ground water level. If the plant's current licensing basis (CLB) credits a de-watering system to control settlement, the GALL Report recommends further evaluation to verify the continued functionality of the de-watering system during the period of extended operation.

PNPP does not rely on a dewatering system for control of settlement. But plant substructures were designed with porous concrete and a permanent underdrain system to reduce hydrostatic pressure. The Reactor Building is founded on Chagrin shale. Chagrin shale is bedrock with a maximum total expected settlement between 1/3 and ½ inch. Differential settlement between safety-related and nonsafety-related structures can affect safety-related structures. However, the nonsafety-related structures adjacent to safety-related structures are also founded on bedrock. The Structures Monitoring Program includes monitoring the settlement and rebound of structures. Measured settlement has been minimal. The PNPP below-grade environment is not aggressive (pH > 5.5, chlorides < 500 ppm, and sulfates < 1,500 ppm). Reviews of PNPP OE have not identified any aging effects that resulted from an aggressive below-grade environment. As a result, cracking and distortion due to increased stress level from settlement; reduction of foundation strength, and cracking due to differential settlement and erosion of the porous concrete subfoundation are not aging effects requiring management for the PNPP concrete containment basemat. The absence of concrete aging effects is confirmed under the Containment Inservice Inspection – IWL program.

3.5.2.2.1.2 Reduction of Strength and Modulus due to Elevated Temperature

Reduction of strength and modulus of concrete due to elevated temperatures could occur in PWR and BWR concrete and steel containments. The implementation of 10 CFR 50.55a and ASME Section XI, Subsection IWL would not be able to identify the reduction of strength and modulus of concrete due to elevated temperature. Subsection CC-3440 of ASME Section III, Division 2, specifies the concrete temperature limits for normal operation or any other long-term period. The GALL Report recommends further evaluation of a plant-specific aging management program if any portion of the concrete containment components exceeds specified temperature limits, i.e., general area temperature greater than 66°C (150°F) and local area temperature greater than 93°C (200°F). Higher temperatures may be allowed if tests and/or calculations are provided to evaluate the reduction in strength and modulus of elasticity and these reductions are applied to the design calculations. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

During normal operation, areas within containment are maintained at or below an average temperature of 95°F. For Mark III steel containments, this GALL item applies to the containment basemat and the concrete fill-in annulus. Since those components are in the lower elevations of the containment structure, they will be below the average temperature. Therefore, change in material properties due to elevated temperature is not an aging effect requiring management for containment concrete. Concrete aging is managed by the ASME Section XI, Subsection IWL and Structures Monitoring programs as described in other Table 3.5.1 items.

3.5.2.2.1.3 Loss of Material due to General, Pitting and Crevice Corrosion

1. *Loss of material due to general, pitting, and crevice corrosion could occur in steel elements of inaccessible areas for all types of PWR and BWR containments. The existing program relies on ASME Section XI, Subsection*

IWE, and 10 CFR Part 50, Appendix J, to manage this aging effect. The GALL Report recommends further evaluation of plant-specific programs to manage this aging effect if corrosion is indicated from the IWE examinations. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR). Loss of material due to general, pitting, and crevice corrosion could occur in steel elements of inaccessible areas for all types of PWR and BWR containments.

PNPP has a Mark III containment structure constructed with a reinforced concrete shield building enclosing a free standing steel containment vessel and does not have a drywell shell, embedded shell or region shielded by diaphragm floors. To prevent corrosion of the inaccessible areas of the lower portion (basemat area) of the containment liner plate, the interior and exterior surfaces are protected from contact with the atmosphere by complete concrete encasement. It is not credible for ground water to reach this portion of the liner plate, assuming a crack in the concrete, since the basemat concrete at this location is greater than five feet thick and poured in multiple horizontal planes. Additionally a waterproof membrane and work-slab is constructed below this area. Therefore, corrosion of the liner plate is not expected. Interior concrete is monitored for cracks under the Structures Monitoring program. The steel containment vessel and areas where the steel vessel becomes embedded in the concrete floor are inspected in accordance with the ASME Section XI, Subsection IWE and Structures Monitoring programs. Therefore, no additional plant specific activities are warranted.

2. *Loss of material due to general, pitting, and crevice corrosion could occur in steel torus shell of Mark I containments. The existing program relies on ASME Section XI, Subsection IWE, and 10 CFR Part 50, Appendix J, to manage this aging effect. The GALL Report recommends further evaluation of plant-specific programs to manage this aging effect if corrosion is significant. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

PNPP has a Mark III steel containment, enclosed by a reinforced concrete cylinder. Therefore, loss of material due to general, pitting, and crevice corrosion which may occur in the steel torus shell of Mark I containments does not apply.

3. *Loss of material due to general, pitting, and crevice corrosion could occur in steel torus ring girders and downcomers of Mark I containments, downcomers of Mark II containments, and interior surface of suppression chamber shell of Mark III containments. The existing program relies on ASME Section XI, Subsection IWE to manage this aging effect. The GALL Report recommends further evaluation of plant specific programs to manage this aging effect if corrosion is significant. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRPLR).*

PNPP is a Mark III steel containment, enclosed by a reinforced concrete cylinder. PNPP is a BWR Mark Ill with a free-standing steel containment vessel (SCV) with a suppression pool chamber whose floor and outer wall are integral to the SCV. The portion of the SCV outer wall exposed to the suppression pool is clad with stainless steel. Therefore, the carbon steel SCV is not exposed to the suppression pool water environment. The interior surfaces of the suppression chamber that is integral to the SCV, including the stainless steel cladding, are inspected in accordance with the requirements of Subsection IWE of the ASME Code Section XI.

Therefore, loss of material due to general, pitting, and crevice corrosion to the carbon steel surface of the suppression chamber is not an aging effect requiring management for the interior surfaces of the suppression pool that is integral to the SCV, because it is lined with stainless steel. However, the Containment lnservice Inspection - IWE Program manages loss of material due to general, pitting, and crevice corrosion for the stainless steel clad portion of the interior surfaces of suppression chamber that is integral to the SCV.

3.5.2.2.1.4 Loss of Prestress due to Relaxation, Shrinkage, Creep, and Elevated Temperature

Loss of prestress forces due to relaxation, shrinkage, creep, and elevated temperature for PWR prestressed concrete containments and BWR Mark II prestressed concrete containments is a Time-Limited Aging Analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). The evaluation of this TLAA is addressed separately in Section 4.5, "Concrete Containment Tendon Prestress Analysis," of this SRP-LR.

The PNPP containment is a steel vessel enclosed by a reinforced concrete cylindrical structure (not prestressed). Therefore, loss of prestress due to relaxation, shrinkage, creep, and elevated temperature does not apply.

3.5.2.2.1.5 Cumulative Fatigue Damage

If included in the current licensing basis, fatigue analyses of suppression pool steel shells (including welded joints) and penetrations (including penetration sleeves, dissimilar metal welds, and penetration bellows) for all types of PWR and BWR containments and BWR vent header, vent line bellows, and downcomers are TLAAs as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). The evaluation of this TLAA is addressed separately in Section 4.6, "Containment Liner Plates, Metal Containments, and Penetrations Fatigue Analysis," of this SRP-LR.

TLAAs are evaluated in accordance with 10 CFR 54.21(c) as documented in Section 4. Fatigue TLAAs for the PNPP Mark III containment vessel, bellows and welds and associated penetrations are evaluated as documented in Section 4.5. The NUREG-1801 BWR components (e.g., torus, suppression pool shell, vent line bellows, and unbraced downcomers) related to Mark I and II containments are not applicable to the PNPP Mark III containment.

3.5.2.2.1.6 Cracking due to Stress Corrosion Cracking

Cracking due to stress corrosion cracking of stainless steel penetration bellows and dissimilar metal welds could occur in all types of PWR and BWR containments. The existing program relies on ASME Section XI, Subsection IWE and10 CFR Part 50,

Appendix J, to manage this aging effect. The GALL Report recommends further evaluation of additional appropriate examinations/evaluations implemented to detect these aging effects for stainless steel penetration bellows and dissimilar metal welds.

NUREG-1801 recommends further evaluation of inspection methods to detect cracking due to stress corrosion cracking (SCC) since visual VT-3 examinations may be unable to detect this aging effect. Potentially susceptible components at PNPP are penetration sleeves and bellows and associated welds. SCC is an aging mechanism that requires the simultaneous action of an aggressive chemical environment, sustained tensile stress, and a susceptible material. Elimination of any one of these elements will eliminate susceptibility to SCC. Stainless steel elements of containment, including dissimilar welds, are not susceptible to SCC, because, these elements are not subject to an aggressive chemical environment. A review of plant operating experience did not identify cracking of these components, and containment pressure boundary functions have not been identified as a concern. Although an aggressive chemical environment doesn't exist, the potential for SCC is assumed for these components, and the aging effect is managed by the ASME Section XI, Subsection IWE and 10 CFR 50, Appendix J programs for containment penetrations, and by the ASME Section XI, Subsection IWE and Structures Monitoring programs for drywell mechanical penetrations.

3.5.2.2.1.7 Loss of Material (Scaling, Spalling) and Cracking due to Freeze-Thaw

Loss of material (scaling, spalling) and cracking due to freeze-thaw could occur in inaccessible areas of PWR and BWR concrete containments. The GALL Report recommends further evaluation of this aging effect for plants located in moderate to severe weathering conditions.

PNPP inaccessible and accessible concrete areas are designed in accordance with American Concrete Institute (ACI) specification ACI 318, Building Code Requirements for Reinforced Concrete, which results in low permeability and resistance to aggressive chemical solutions. Concrete quality was determined by following guidance as specified in ACI 318 Subsection 4.2.5 and Table 4.2.5. PNPP concrete also meets requirements of guidance provided in ASTM International (ASTM) standards for selection, application and testing of concrete and concrete aggregate. Inaccessible areas are generally those below grade, where temperatures are not expected to support freeze/thaw. Therefore, loss of material (scaling, spalling) and cracking due to freeze thaw is not applicable for concrete in inaccessible areas. The absence of concrete aging effects is confirmed by the ASME Section XI, Subsection IWL and Structures Monitoring programs.

3.5.2.2.1.8 Cracking due to Expansion from Reaction with Aggregate

Cracking due to expansion from reaction with aggregates could occur in inaccessible areas of concrete elements of PWR and BWR concrete and steel containments. The GALL Report recommends further evaluation to determine if a plant-specific aging management program is required to manage this aging effect. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

PNPP containment concrete (basemat and concrete fill in annulus) is designed in accordance with specification ACI 318, Building Code Requirements for Reinforced Concrete and concrete specification requires that the potential reactivity of aggregates be tested in accordance with ASTM C 289 and ASTM C 227. Also ASTM C 295 was used to identify elements in the aggregate which may be unfavorably reactive with alkalis in cement. Concrete structures are not exposed to flowing water and the concrete used was constructed in accordance with the recommendations in ACI 318 Subsection 4.2.5 for concrete quality. Thus, cracking due to reaction with aggregates has not been observed on PNPP concrete structures, including Containment Structures. Nevertheless, the ASME Section XI, Subsection IWL program and the Structures Monitoring program will continue to inspect and monitor the concrete Containment Structures for cracking due to any mechanism. PNPP will also examine exposed portions of below-grade concrete, when excavated for any reason, in accordance with the Structures Monitoring program. Accessible concrete surfaces of the containment fill in annulus are monitored for cracking due to expansion from reaction with aggregates by the ASME Section XI, Subsection IWL program and are addressed under Item Number 3.5.1-19. The ASME Section XI, Subsection IWL program requires evaluation of the acceptability of inaccessible areas when conditions exist in accessible areas that could indicated the presence of, or result in, degradation of such inaccessible areas. In addition, other accessible containment structure concrete is monitored for cracking due to expansion from reaction with aggregates by the Structures Monitoring program and addressed under Item Number 3.5.1-54. The Structures Monitoring program also requires evaluation of the acceptability of inaccessible areas when conditions exist in accessible areas that could indicate the presence of, or result in, degradation in such inaccessible areas. The condition of accessible and above-grade concrete is used as an indicator of the condition of the inaccessible and below-grade structural components and provides reasonable assurance that degradation of inaccessible structural components will be detected before a loss of an intended function.

PNPP structural concrete was constructed as recommended to preclude cracking due to this mechanism; therefore, no plant-specific aging management program is required. The ASME Section XI, Subsection IWL program and the Structures Monitoring program are described in Appendix B.

3.5.2.2.1.9 Increase in Porosity and Permeability due to Leaching of Calcium Hydroxide and Carbonation

Increase in porosity and permeability due to leaching of calcium hydroxide and carbonation could occur in inaccessible areas of concrete elements of PWR and BWR concrete and steel containments. The GALL Report recommends further evaluation if leaching is observed in accessible areas that impact intended functions. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

The PNPP below-grade environment is not aggressive (pH > 5.5, chlorides < 500 ppm, and sulfates < 1,500 ppm). Concrete was provided with at least the minimum required air content and a low water/cement ratio as specified in ACI 318. The potential for an increase in porosity and permeability due to leaching of calcium hydroxide and carbonation has been previously evaluated. Engineering evaluations performed for the OE discussed in the Aging Management Program "Structures Monitoring" concluded that the interior of the porous concrete layer (under the plant buildings) is fairly stagnant and leaching of calcium is localized in the peripheral portions of the porous concrete pad, and not uniformly throughout the pad. Therefore, this aging effect will not fail the intended function of the porous concrete, if it occurs.

3.5.2.2.2 Safety-Related and Other Structures and Component Supports

Structure groups and component support groups as used in the following discussions are defined in NUREG-1800, Section 3.5.1.

3.5.2.2.2.1 Aging Management of Inaccessible Areas

1. *Loss of material (spalling, scaling) and cracking due to freeze-thaw could occur in below grade inaccessible concrete areas of Groups 1-3, 5 and 7-9 structures. The GALL Report recommends further evaluation of this aging effect for inaccessible areas of these Groups of structures for plants located in moderate to severe weathering conditions.*

Aggregates used during construction were in accordance with specifications and materials conforming to ACI and ASTM standards. PNPP structures are constructed of a dense, durable mixture of sound coarse aggregate, fine aggregate, cement, water, and admixture. Water/cement ratios and air entrainment percentages are within the limits provided in ACI 318. Therefore, loss of material (spalling, scaling) and cracking due to freeze thaw are not aging effects requiring management for PNPP Groups 1–3, 5, 7–9 structures. The absence of concrete aging effects is confirmed by the ASME Section XI, Subsection IWL and Structures Monitoring programs.

2. *Cracking due to expansion and reaction with aggregates could occur in below-grade inaccessible concrete areas for Groups 1-5 and 7-9 structures. The GALL Report recommends further evaluation of inaccessible areas of these Groups of structures if concrete was not constructed in accordance with the recommendations in the GALL Report.*

Aggregates were selected locally and were in accordance with specifications and materials conforming to ACI and ASTM standards at the time of construction. PNPP structures are constructed of a dense, durable mixture of sound coarse aggregate, fine aggregate, cement, water, and admixture. Water/ cement ratios and air entrainment percentages were within the limits provided in ACI 318. Therefore, cracking due to expansion and reaction with aggregates for Groups 1– 5, 7–9 structures is not expected; however, this potential aging effect is managed, regardless of the mechanism that may cause the aging effect.

Cracking associated with expansion due to reaction with aggregates has not been observed in PNPP structures. Nevertheless, the Structures Monitoring program continues to inspect and monitor concrete structures for cracking due to any mechanism. Accessible concrete is monitored for cracking due to expansion from reaction with aggregates by the Structures Monitoring program that is addressed under Item Number

3.5-54. The Structures Monitoring program requires evaluation of the acceptability of inaccessible areas when conditions exist in accessible areas that could indicate the presence of, or result in, degradation of such inaccessible areas. PNPP will also examine exposed portions of below-grade concrete when excavated for any reason, in accordance with the Structures Monitoring program. The condition of accessible and above-grade concrete is used as an indicator of the condition of the inaccessible and below-grade structural components and provides reasonable assurance that degradation of inaccessible structural components will be detected before loss of an intended function. The PNPP structural concrete was constructed as recommended to preclude cracking due to this mechanism; therefore, no plant-specific aging management program or further evaluation of inaccessible below-grade concrete for this mechanism is required. The Structures Monitoring program is described in Appendix B.

Additionally, in 2014, PNPP performed petrographic examination of concrete cores from Unit 2 Auxiliary Building per ASTM C856. The concrete cores for testing were extracted horizontally from the walls. The purpose of the examination was to evaluate the overall condition of concrete, as well as to evaluate the concrete for the presence of alkali-aggregate reaction, and if present, its extent throughout the concrete. The examination indicated no evidence of alkali-aggregate reaction (either alkali-silica reaction or alkali-carbonate reaction) in the three concrete cores. No alkali-silica gel, cracks, microcracks, or aggregate reaction rims were observed. No evidence of other deleterious mechanisms (such as freeze-thaw deterioration or delayed ettringite formation) was observed in the three concrete cores.

3. *Cracking and distortion due to increased stress levels from settlement could occur in below-grade inaccessible concrete areas of structures for all Groups, and reduction in foundation strength, and cracking due to differential settlement and erosion of porous concrete subfoundations could occur in below-grade inaccessible concrete areas of Groups 1-3, 5 -9 structures. The existing program relies on structure monitoring programs to manage these aging effects. Some plants may rely on a de-watering system to lower the site ground water level. If the plant's CLB credits a de-watering system, the GALL Report recommends verification of the continued functionality of the de-watering system during the period of extended operation. The GALL Report recommends no further evaluation if this activity is included in the scope of the applicant's structures monitoring program.*

For Groups 1–3, 5–9, support for most Seismic Category I structures is founded either on Chagrin shale or on Class A fill over lower till. Chagrin shale is bedrock with a maximum total expected settlement between 1/3 and ½ inch. Lower till is exceedingly dense with a safety factor greater than 13 against bearing capacity. Class A fill is well-consolidated fill. When the Maintenance Rule program was initiated the results of periodic settlement and rebound monitoring became part of the Maintenance Rule evaluation of plant structures. Settlement and rebound monitoring began during construction and has continued to the present. More than twenty years of settlement and rebound monitoring has revealed minimal settlement. PNPP groundwater is not aggressive. Potential total and differential settlements is addressed in the design of foundations at the site. The results of the monitoring program have demonstrated that cracks and distortion due to increased stress levels from settlement for below grade inaccessible concrete areas of structures for all groups and reduction in foundation strength, and cracking, due to differential settlement and erosion of porous concrete subfoundation in below grade inaccessible concrete areas for Groups 1–3, 5–9 structures is not an aging effect requiring management for PNPP concrete. Nonetheless, accessible concrete components will be monitored by the ASME Section XI, Subsection IWL and Structures Monitoring programs to confirm the absence of aging effects. The Structures Monitoring Program will continue to evaluate settlement and rebound measurement results.

4. *Increase in porosity and permeability, and loss of strength due to leaching of calcium hydroxide and carbonation could occur in below-grade inaccessible concrete areas of Groups 1-5 and 7-9 structures. The GALL Report recommends further evaluation if leaching is observed in accessible areas that impact intended functions.*

Aggregates were selected locally and were in accordance with specifications and materials conforming to ACI and ASTM standards at the time of construction to ensure concrete durability. PNPP structures are constructed of a dense, durable mixture of sound coarse aggregate, fine aggregate, cement, water, and admixture. These groups of structures at PNPP use a dense low permeable concrete with an acceptable water-to-cement ratio, which provides an acceptable degree of protection against aggressive chemical attack.

The PNPP below-grade environment is not aggressive. Therefore, increase in porosity and permeability, and loss of strength due to leaching of calcium hydroxide and carbonation of below grade inaccessible concrete areas are not aging effects requiring management for PNPP Groups 1–5 and 7–9 concrete structures. The absence of concrete aging effects is confirmed by the ASME Section XI, Subsection IWL and Structures Monitoring programs.

3.5.2.2.2.2 Reduction of Strength and Modulus of Concrete Structures due to Elevated Temperature

Reduction of strength and modulus of concrete due to elevated temperatures could occur in PWR and BWR Group 1-5 concrete structures. For any concrete elements that exceed specified temperature limits, further evaluations are recommended. Appendix A of ACI 349-85 specifies the concrete temperature limits for normal operation or any other long-term period. The temperatures shall not exceed 66°C (150°F) except for local areas, which are allowed to have increased temperatures not to exceed 93°C (200°F). The GALL Report recommends further evaluation of a plant-specific program if any portion of the safety-related and other concrete structures exceeds specified temperature limits, i.e., general area temperature greater than 66°C (150°F) and local area temperature greater than 93°C (200°F). Higher temperatures may be allowed if tests and/or calculations are provided to evaluate the reduction in strength and modulus of elasticity and these reductions are applied to the design calculations. The acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

ACI 349 specifies concrete temperature limits for normal operations or any other long term period. The temperatures shall not exceed 150°F except for local areas, which are allowed to have increased temperatures not to exceed 200°F. During normal operation, primary containment average temperature is maintained at or below 95°F. Also, drywell average temperature is maintained at or below 145°F. Piping penetrations carrying hot fluid (pipe temperature > 200 degrees F) through the reactor building concrete cylinder wall use piping that is insulated as required to maintain the concrete temperature adjoining the embedded sleeve at or below 200 degrees F."

Structures outside of containment do not expose concrete to temperatures in excess of 150°F for normal operations or any other long-term period. PNPP concrete elements do not exceed the temperature limits associated with aging degradation due to elevated temperature. Therefore, reduction of strength and modulus of concrete due to elevated temperatures is not an aging effect requiring management.

3.5.2.2.2.3 Aging Management of Inaccessible Areas for Group 6 Structures

For inaccessible areas of certain Group 6 structures, aging effects are covered by inspections in accordance with the Structures Monitoring program.

1. *Loss of material (spalling, scaling) and cracking due to freeze-thaw could occur in below grade inaccessible concrete areas of Group 6 structures. The GALL Report recommends further evaluation of this aging effect for inaccessible areas for plants located in moderate to severe weathering conditions.*

The below grade inaccessible concrete areas of PNPP Group 6 structures were constructed in a manner that minimizes the potential for any freeze-thaw aging effects. Therefore, loss of material (spalling, scaling) and cracking due to freeze-thaw are not aging effects requiring management for PNPP Groups 6 structures. The absence of concrete aging effects is confirmed by the Structures Monitoring and RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants programs.

2. *Cracking due to expansion and reaction with aggregates could occur in below-grade inaccessible reinforced concrete areas of Group 6 structures. The GALL Report recommends further evaluation to determine if a plant-specific aging management program is required to manage this aging effect. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

Aggregates were selected locally and were in accordance with specifications and materials conforming to ACI and ASTM standards at the time of construction. PNPP structures are constructed of a dense, durable mixture of sound coarse aggregate, fine aggregate, cement, water, and admixture. Water/ cement ratios, and air entrainment percentages are within the limits provided in ACI 318-63. The PNPP below-grade environment is not aggressive (pH > 5.5, chlorides < 500 ppm, and sulfates < 1,500 ppm). Therefore, cracking due to expansion and reaction with aggregates in below grade inaccessible concrete areas of Group 6 Structures is not expected; however, this potential aging effect is managed regardless of the mechanism that caused the aging effect.

Cracking associated with expansion due to reaction with aggregates has not been observed in PNPP Group 6 structures. Nevertheless, the Regulatory Guide (RG) 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants program continues to inspect and monitor Group 6 concrete structures for cracking due to any mechanism. Accessible Group 6 concrete is monitored for cracking due to expansion from reaction with aggregates by the RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants program and is addressed under Item Number 3.5.1-54. The RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants program requires evaluation of the acceptability of inaccessible areas when conditions exist in accessible areas that could indicate the presence of, or result in, degradation in such inaccessible areas. The condition of accessible and above-ground concrete is used as an indicator of the condition of the inaccessible and below-grade structural components and provides reasonable assurance that degradation of inaccessible structural components will be detected before a loss of an intended function. PNPP will also examine exposed portions of the below-grade concrete when excavated for any reason, in accordance with the Structures Monitoring program. PNPP structural concrete was constructed as recommended to preclude cracking due to this mechanism. Therefore, no plant-specific aging management program is required for inaccessible, below-grade, Group 6 structures for this mechanism. The RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants program, and the Structures Monitoring program are described in Appendix B.

3. *Increase in porosity and permeability and loss of strength due to leaching of calcium hydroxide and carbonation could occur in inaccessible areas of concrete elements of Group 6 structures. The GALL Report recommends further evaluation if leaching is observed in accessible areas that impact intended functions. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

Below-grade exterior reinforced concrete at PNPP is not exposed to an aggressive environment (pH less than 5.5), or to chloride or sulfate solutions beyond defined limits (greater than 500 ppm chloride, or greater than 1500 ppm sulfate). Therefore, increase in porosity and permeability, and loss of strength due to leaching of calcium hydroxide and carbonation in inaccessible areas of concrete elements are not aging effects requiring management for below-grade inaccessible concrete areas of PNPP Group 6 structures. The absence of concrete aging effects is confirmed under the Structures Monitoring program.

3.5.2.2.2.4 Cracking due to Stress Corrosion Cracking and Loss of Material due to Pitting and Crevice Corrosion

Cracking due to stress corrosion cracking and loss of material due to pitting and crevice corrosion could occur for Group 7 and 8 stainless steel tank liners exposed to standing water. The GALL Report recommends further evaluation of plant-specific programs to manage these aging effects. The acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

NUREG-1800 Section 3.5.2.2.2.4 applies to stainless steel liners for concrete or steel tanks. No tanks with stainless steel liners are included in the scope of license renewal. Pool and sump liners are normally below the threshold temperature for stress corrosion cracking. Loss of material for sump liners will be managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program as addressed in item 3.3.1-95. Loss of material for liners in treated water pools are managed by the Water Chemistry program as addressed in items 3.3.1-25 and 3.5.1-78. The One-Time Inspection program will confirm the effectiveness of the Water Chemistry program for pools in containment as addressed in item 3.3.1-25.

3.5.2.2.2.5 Cumulative Fatigue Damage due to Fatigue

Fatigue of component support members, anchor bolts, and welds for Groups B1.1, B1.2, and B1.3 component supports is a TLAA as defined in 10 CFR 54.3 only if a CLB fatigue analysis exists. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). The evaluation of this TLAA is addressed separately in Section 4.3, "Metal Fatigue Analysis," of this SRP-LR.

TLAA are evaluated in accordance with 10 CFR 54.21(c) as documented in Section 4 of this application. During the process of identifying TLAAs in the PNPP current licensing basis, no fatigue analyses were identified for component support members, component support welds, and support anchorages to building structure for Groups B1.1, B1.2, and B1.3.

3.5.2.2.3 Quality Assurance for Aging Management of Nonsafety-Related Components

Acceptance criteria are described in Branch Technical Position IQMB-1 (Appendix A.2 of this SRP-LR).

See Appendix B Section B.1.3 for discussion of PNPP quality assurance procedures and administrative controls for aging management programs.

3.5.2.2.4 Ongoing Review of Operating Experience (per LR-ISG-2011-05)

Ongoing review of operating experience is addressed in Appendix A, Section A.1 and Appendix B, Section B.1.4.

3.5.2.3 Time-Limited Aging Analysis

Potential TLAA identified for structural components and commodities include fatigue analyses for the containment vessel plate, cranes, and penetrations, and associated bellows. These topics are discussed in Section 4.6.

3.5.3 CONCLUSION

The structural components and commodities subject to aging management review have been identified in accordance with the criteria of 10 CFR 54.21. The aging management programs selected to manage the effects of aging on structural components and commodities are identified in Section 3.5.2.1 and the following tables. A description of the aging management programs is provided in Appendix B of this application, along with the demonstration that the identified aging effects will be managed for the period of extended operation.

Therefore, based on the demonstrations provided in Appendix B, the effects of aging associated with the structural components and commodities will be managed such that there is reasonable assurance that the intended functions will be maintained consistent with the current licensing basis during the period of extended operation.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.5.1-1	Concrete: dome; wall; basemat; ring girders; buttresses, Concrete elements, all	Cracking and distortion due to increased stress levels from settlement	Chapter XI.S2, "ASME Section XI, Subsection IWL" or Chapter XI.S6, "Structure Monitoring" If a de-watering system is relied upon for control of settlement, then the licensee is to ensure proper functioning of the de-watering system through the period of extended operation.	Yes, if a de-watering system is relied upon to control settlement (See subsection 3.5.2.2.1.1)	PNPP does not rely on a dewatering system for control of settlement. Perry has a free standing steel containment vessel with its base foundation founded on the reactor building's foundation mat. For further evaluation refer to section 3.5.2.2.1.1.
3.5.1-2	Concrete: foundation; subfoundation	Reduction of foundation strength and cracking due to differential settlement and erosion of porous concrete subfoundation	Chapter XI.S6, "Structures Monitoring" If a de-watering system is relied upon for control of erosion, then the licensee is to ensure proper functioning of the de- watering system through the period of extended operation.	Yes, if a de-watering system is relied upon to control settlement (See subsection 3.5.2.2.1.1)	A layer of porous concrete supports the PNPP reactor building foundation. However, PNPP does not rely on a dewatering system for control of settlement. For further evaluation refer to section 3.5.2.2.1.1.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.5.1-3	Concrete: dome; wall; basemat; ring girders; buttresses, Concrete: containment; wall; basemat, Concrete: basemat, concrete fill-in annulus	Reduction of strength and modulus due to elevated temperature (>150˚F general; >200˚F local)	A plant-specific aging management program is to be evaluated.	Yes, if temperature limits are exceeded (See subsection 3.5.2.2.1.2)	Perry's containment is a free-standing steel containment vessel. The concrete foundation of the containment is not exposed to general and local temperatures that exceed the thresholds. For further evaluation, see Section 3.5.2.2.1.2.
3.5.1-4	Steel elements (inaccessible areas): drywell shell; drywell head; and drywell shell	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, "ASME Section XI, Subsection IWE," and Chapter XI.S4, "10 CFR Part 50, Appendix J"	Yes, if corrosion is indicated from the IWE examinations (See subsection 3.5.2.2.1.3.1)	The PNPP Mark III containment design includes a drywell head and drywell wall. The upper drywell wall extends up to the drywell top slab. Above the drywell vent region, the inside face of the drywell is formed with a steel plate. The surface of the upper drywell wall and drywell head are considered to be accessible. For further discussion see Section 3.5.2.2.1.3 Item 1.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-5	Steel elements (inaccessible areas): liner; liner anchors; integral attachments, Steel elements (inaccessible areas): suppression chamber; drywell; drywell head; embedded shell; region shielded by diaphragm floor (as applicable)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, "ASME Section XI, Subsection IWE" and Chapter XI.S4, "10 CFR Part 50, Appendix J"	Yes, if corrosion is indicated from the IWE examinations (See subsection 3.5.2.2.1.3.1)	Consistent with NUREG-1801. PNPP is a BWR Mark III with a free-standing SCV. The Containment Inservice Inspection IWE and the Containment Leak Rate Programs manage the loss of material of steel elements in this listing. For further evaluation, see Section 3.5.2.2.1.3 Item 1.
3.5.1-6	Steel elements: torus shell	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, "ASME Section XI, Subsection IWE" and Chapter XI.S4, "10 CFR Part 50, Appendix J"	Yes, if corrosion is significant Recoating of the torus is recommended. (See subsection 3.5.2.2.1.3.2)	PNPP is a BWR Mark III with a free-standing SCV. PNPP containment does not have the listed steel element. For further discussion, see Section 3.5.2.2.1.3 Item 2.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.5.1-7	Steel elements: torus ring girders; downcomers;, Steel elements: suppression chamber shell (interior surface)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, "ASME Section XI, Subsection IWE"	Yes, if corrosion is significant (See subsection 3.5.2.2.1.3.3)	PNPP is a BWR Mark III with a free-standing SCV. The PNPP BWR containment does not have a torus ring girder or downcomers. PNPP does have a suppression chamber for the suppression pool. The suppression chamber inner surface is integral to the SCV, clad with stainless steel. Therefore, loss of material due to general, pitting and crevice corrosion related to carbon steel for this listing is not an aging effect requiring management for the SCV suppression pool. For further discussion, see Section 3.5.2.2.1.3 Item 2.
3.5.1-8	Prestressing system: tendons	Loss of prestress due to relaxation; shrinkage; creep; elevated temperature	Yes, TLAA	Yes, TLAA (See subsection 3.5.2.2.1.4)	NUREG- 1801 items referencing this item are associated with concrete containments. This is applicable only to PWR and BWR prestressed concrete containments. PNPP containment is a BWR Mark III steel containment and does not incorporate a prestressing system. For further evaluation, see Section 3.5.2.2.1.4.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.5.1-9	Penetration sleeves; penetration bellows, Steel elements: torus; vent line; vent header; vent line bellows; downcomers, Suppression pool shell; unbraced downcomers, Steel elements: vent header; downcomers	Cumulative fatigue damage due to fatigue (Only if CLB fatigue analysis exists)	Yes, TLAA	Yes, TLAA (See subsection 3.5.2.2.1.5)	Consistent with NUREG-1801. Fatigue of containment penetrations is a TLAA. See sections 3.5.2.2.1.5 and 4.6.2.
3.5.1-10	Penetration sleeves; penetration bellows	Cracking due to stress corrosion cracking	Chapter XI.S1, “ASME Section XI, Subsection IWE,” and Chapter XI.S4, “10 CFR Part 50, Appendix J”	Yes, detection of aging effects is to be evaluated (See subsection 3.5.2.2.1.6)	Not applicable - This table row applies to PWRs.
3.5.1-11	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (inaccessible areas): basemat, Concrete (inaccessible areas): dome; wall; basemat	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Further evaluation is needed for plants that are located in moderate to severe weathering conditions (weathering index >100 day-inch/yr) (NUREG-1557).	Yes, for plants located in moderate to severe weathering conditions (See subsection 3.5.2.2.1.7)	PNPP containment is a free-standing SCV, completely enclosed by a reinforced concrete shield building. The concrete foundation mat (basemat) of the PNPP primary containment is protected from the external environments by the reactor building's base foundation. Therefore, the concrete elements of the SCV foundation (basemat) are not subject to the listed aging effects due to freeze-thaw. For further evaluation, see Section 3.5.2.2.1.7.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-12	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (inaccessible areas): basemat, Concrete (inaccessible areas): containment; wall; basemat, Concrete (inaccessible areas): basemat, concrete fill-in annulus	Cracking due to expansion from reaction with aggregates	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if concrete is not constructed as stated function (See subsection 3.5.2.2.1.8)	PNPP containment is a free-standing SCV completely enclosed by a reinforced concrete shield building. The SCV does not contain the listed concrete components except for its foundation, which is integral to the reactor building basemat. For further evaluation, see Section 3.5.2.2.1.8.
3.5.1-13	Concrete (inaccessible areas): basemat, Concrete (inaccessible areas): dome; wall; basemat	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if leaching is observed in accessible areas that impact intended function (See subsection 3.5.2.2.1.9)	Consistent with NUREG-1801. Change in material properties is inclusive of Increase in porosity and permeability. For loss of strength due to leaching of calcium hydroxide and carbonation See further evaluation, Section 3.5.2.2.1.9.
3.5.1-14	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (inaccessible areas): containment; wall; basemat	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if leaching is observed in accessible areas that impact intended function (See subsection 3.5.2.2.1.9)	NUREG- 1801 items referencing this item number are associated with BWR concrete containment structures, and PNPP is an SCV. For further evaluation, see Section 3.5.2.2.1.9.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-15	Concrete (accessible areas): basemat	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Chapter XI.S2, "ASME Section XI, Subsection IWL"	No	PNPP containment is a free-standing SCV, and its concrete foundation is integral to the reactor building basemat and does not contain a basemat with accessible areas.
3.5.1-16	Concrete (accessible areas): basemat, Concrete: containment; wall; basemat	Increase in porosity and permeability; cracking; loss of material (spalling, scaling) due to aggressive chemical attack	Chapter XI.S2, "ASME Section XI, Subsection IWL," or Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. Aging of the porous concrete foundation will be maanged by the Structures Monitoring program.
3.5.1-17	Concrete (accessible areas): dome; wall; basemat; ring girders; buttresses	Increase in porosity and permeability; cracking; loss of material (spalling, scaling) due to aggressive chemical attack	Chapter XI.S2, "ASME Section XI, Subsection IWL"	No	The GALL components associated with this item refer to concrete containments. Perry's design is a BWR Mark III Steel containment, such that the PNPP design does not contain the listed concrete components.
3.5.1-18	Concrete (accessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (accessible areas): basemat	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Chapter XI.S2, "ASME Section XI, Subsection IWL"	No	PNPP containment is a free-standing SCV, and its concrete foundation is integral to the reactor building basemat. The reactor building basemat is not considered to be accessible.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-19	Concrete (accessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (accessible areas): basemat, Concrete (accessible areas): containment; wall; basemat, Concrete (accessible areas): basemat, concrete fill-in annulus	Cracking due to expansion from reaction with aggregates	Chapter XI.S2, “ASME Section XI, Subsection IWL”	No	PNPP containment is a free-standing SCV, and its concrete foundation is integral to the reactor building basemat. The reactor building basemat is not considered to be accessible. The top surface of the annulus concrete is accessible. Aging of annulus concrete will be managed by the ASME Section XI, Subsection IWL.
3.5.1-20	Concrete (accessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (accessible areas): containment; wall; basemat	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Chapter XI.S2, “ASME Section XI, Subsection IWL”	No	The GALL components associated with this item refer to concrete containments. Perry's design is a BWR Mark III Steel containment, such that the PNPP design does not contain the listed concrete components.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-21	Concrete (accessible areas): dome; wall; basemat; ring girders; buttresses; reinforcing steel, Concrete (accessible areas): basemat; reinforcing steel, Concrete (accessible areas): dome; wall; basemat; reinforcing steel	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S2, "ASME Section XI, Subsection IWL"	No	Consistent with NUREG-1801 with the following clarifications. The ASME Section XI, Subsection IWL program will manage cracking of the annulus concrete in Containment within the scope of the ASME program. Loss of bond and loss of material are not applicable aging effects for the annulus concrete exposed to Air-indoor, uncontrolled. The Structures Monitoring program manages cracking in concrete beams, columns, floors and interior walls in Containment that are not in the scope of ASME Section XI, Subsection IWL. See Item 3.5.1-24.
3.5.1-22	Concrete (inaccessible areas): basemat; reinforcing steel	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S6, "Structures Monitoring"	No	The GALL components associated with this item refer to BWR Mark I and II concrete containments. Perry's design is a BWR Mark III Steel containment, such that the PNPP design does not contain the listed concrete components.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.5.1-23	Concrete (inaccessible areas): basemat; reinforcing steel, Concrete (inaccessible areas): dome; wall; basemat; reinforcing steel	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S2, "ASME Section XI, Subsection IWL," or Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring program will manage applicable aging effects of the concrete basemat and Shield building cylinder wall and dome in the Containment Structure exposed to its environment. Loss of bond is not an applicable aging effect for these environments.
3.5.1-24	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (inaccessible areas): basemat, Concrete (accessible areas): dome; wall; basemat	Increase in porosity and permeability; cracking; loss of material (spalling, scaling) due to aggressive chemical attack	Chapter XI.S2, "ASME Section XI, Subsection IWL," or Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801 with the following clarifications. The Structures Monitoring program will manage aging of cracking of Containment concrete elements exposed to Air-indoor, uncontrolled and Air-outdoor not within the scope of ASME Section XI, Subsection IWL. Increase in porosity and permeability and loss of material (spalling, scaling) due to aggressive chemical attack are not an applicable aging effect for these Component types in Air-indoor, uncontrolled and Air-outdoor. Loss of material is associated with aggressive chemical attack of containment structure concrete shield building cylinder wall and dome exposed to an Air-outdoor environment.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
					See Item 3.5.1-21 for concrete elements within the scope of ASME Section XI, Subsection IWL. There are no concrete elements with aging effects of increase in porosity and permeability aligned with this item. For accessible and inaccessible concrete and porous concrete elements susceptible to an increase in porosity and permeability see items 3.5.1-13, 3.5.1-61 and 3.5.1-67.
3.5.1-25	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses; reinforcing steel	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S2, "ASME Section XI, Subsection IWL," or Chapter XI.S6, "Structures Monitoring"	No	Assigned to PWRs only
3.5.1-26	Moisture barriers (caulking, flashing, and other sealants)	Loss of sealing due to wear, damage, erosion, tear, surface cracks, or other defects	Chapter XI.S1, "ASME Section XI, Subsection IWE"	No	The ISI (IWE) program is not used to manage moisture barriers. However, loss of sealing is a consequence of the aging effects cracking and change in material properties, and the Structures Monitoring Program manages the listed aging effect for similar elastomer commodities.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-27	penetration sleeves; penetration bellows, Steel elements: torus; vent line; vent header; vent line bellows; downcomers, Suppression pool shell	Cracking due to cyclic loading (CLB fatigue analysis does not exist)	Chapter XI.S1, “ASME Section XI, Subsection IWE,” and Chapter XI.S4, “10 CFR Part 50, Appendix J”	No	PNPP has a CLB fatigue analysis associated with penetration sleeves and suppression pool liner at the containment wall, and therefore this aging effect is addressed under line Item 3.5.1-9. PNPP is a BWR Mark III which does not have a torus, vent lines or downcomers.
3.5.1-28	Personnel airlock, equipment hatch, CRD hatch	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, “ASME Section XI, Subsection IWE,” and Chapter XI.S4, “10 CFR Part 50, Appendix J”	No	Consistent with NUREG-1801. Loss of material for the personnel airlocks and equipment hatch will be managed by the ASME Section XI, Subsection IWE and 10 CFR 50, Appendix J programs.
3.5.1-29	Personnel airlock, equipment hatch, CRD hatch: locks, hinges, and closure mechanisms	Loss of leak tightness due to mechanical wear of locks, hinges and closure mechanisms	Chapter XI.S1, “ASME Section XI, Subsection IWE,” and Chapter XI.S4, “10 CFR Part 50, Appendix J”	No	Consistent with NUREG-1801. The Containment Inservice Inspection-IWE and Containment Leak Rate Programs manage the listed aging effect.
3.5.1-30	Pressure-retaining bolting	Loss of preload due to self-loosening	Chapter XI.S1, “ASME Section XI, Subsection IWE,” and Chapter XI.S4, "10 CFR Part 50, Appendix J"	No	Consistent with NUREG-1801 for component and aging effect. Additionally, the Condensation environment is considered equivalent to Air - outdoor for evaluation of GALL consistency for Loss of preload for steel bolting.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-31	Pressure-retaining bolting, Steel elements: downcomer pipes	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, “ASME Section XI, Subsection IWE”	No	Consistent with NUREG-1801. Loss of material for pressure retaining structural bolting will be managed by the ASME Section XI, Subsection IWE program.
3.5.1-32	Prestressing system: tendons; anchorage components	Loss of material due to corrosion	Chapter XI.S2, “ASME Section XI, Subsection IWL”	No	NUREG- 1801 items referencing this item are associated with concrete containments and are applicable to PWR and BWR prestressed concrete containments. PNPP is a BWR with a free-standing SCV. There are no prestressed tendons associated with PNPP containment design.
3.5.1-33	Seals and gaskets	Loss of sealing due to wear, damage, erosion, tear, surface cracks, or other defects	Chapter XI.S4, “10 CFR Part 50, Appendix J "	No	Consistent with NUREG-1801, with a different program assigned for some components and with the following clarifications. Aging of elastomer seals will be managed by the 10 CFR 50, Appendix J program. Aging effects for elastomer seals susceptible to change in material properties and cracking are aligned with the aging effect loss of sealing. The Structures Monitoring program will manage aging of elastomer upper containment pool gate seals which are not within the scope of the 10 CFR 50, Appendix J

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
					program although located within the Containment Structure. Fire Protection Program will manage the loss of sealing in the Shield Building electrical penetration seals and sealants having a fire barrier (FB) intended function. Change in material properties and cracking is aligned with the aging effect loss of sealing. The External surfaces Monitoring of Mechanical Components will manage change in material properties and cracking of elastomer penetration sealant and door, manway, and hatch seals and gaskets exposed to Air-indoor, uncontrolled in Bulk Civil Commodities. Other elastomer seals and gaskets and fire penetration seals exposed to air are addressed under items 3.3.1-57 and 3.5.1-72.
3.5.1-34 (LR-ISG-2013-01)	Service Level I coatings	Loss of coating integrity due to blistering, cracking, flaking, peeling, delamination, rusting, or physical damage	Chapter XI.S8, "Protective Coating Monitoring and Maintenance"	No	Consistent with NUREG-1801. Loss of coating integrity of service level I coatings will be managed by the Protective Coating Monitoring and Maintenance program.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-35	Steel elements (accessible areas): liner; liner anchors; integral attachments, Penetration sleeves, Steel elements (accessible areas): drywell shell; drywell head; drywell shell in sand pocket regions;, Steel elements (accessible areas): suppression chamber, drywell; drywell head; embedded shell; region shielded by diaphragm floor (as applicable), Steel elements (accessible areas): drywell shell; drywell head	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, "ASME Section XI, Subsection IWE," and Chapter XI.S4, "10 CFR Part 50, Appendix J"	No	Consistent with NUREG-1801. The ASME Section XI, Subsection IWE and 10 CFR 50, Appendix J programs will manage loss of material of steel elements associated with the containment pressure boundary.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-36	Steel elements: drywell head; downcomers	Fretting or lockup due to mechanical wear	Chapter XI.S1, "ASME Section XI, Subsection IWE"	No	NUREG- 1801 items referencing this item are associated with Mark I and II BWR steel containment vessels. Perry's design is a BWR Mark III Steel containment, such that the PNPP design does not contain downcomers. The ASME Section XI, Subsection IWE program will be used to manage fretting or lockup of the carbon steel, steel elements: drywell head exposed to air - indoor uncontrolled in the Primary Containment.
3.5.1-37	Steel elements: suppression chamber (torus) liner (interior surface)	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.S1, "ASME Section XI, Subsection IWE," and Chapter XI.S4, "10 CFR Part 50, Appendix J"	No	NUREG- 1801 items referencing this item are associated with Mark I and II BWR concrete containments. Perry's steel containment is a BWR Mark III design and does not include a torus. Loss of material of the stainless steel clad containment vessel exposed to the suppression pool water will be managed by the ASME Section XI, Subsection IWE and 10 CFR 50, Appendix J programs.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-38	Steel elements: suppression chamber shell (interior surface)	Cracking due to stress corrosion cracking	Chapter XI.S1, "ASME Section XI, Subsection IWE," and Chapter XI.S4, "10 CFR Part 50, Appendix J"	No	Three factors are necessary to initiate and propagate cracking due to stress corrosion cracking (SCC). These factors are susceptible or sensitized material (resulting from manufacturing or installation process), a high tensile stress (residual or applied), and corrosive environment (high temperatures, moist or wetted environment or an environment contaminated with chlorides, fluorides, or sulfates). Elimination or reduction of any of these factors will decrease the likelihood of SCC. SCC of PNPP stainless suppression chamber liner is not considered credible because the corrosive environment (concentration of chloride or sulfate contaminants and temperatures greater than 140°F) does not exist for the suppression chamber shell. Therefore, SCC of PNPP stainless suppression chamber liner is not expected.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-39	Steel elements: vent line bellows	Cracking due to stress corrosion cracking	Chapter XI.S1, "ASME Section XI, Subsection IWE," and Chapter XI.S4, "10 CFR Part 50, Appendix J"	No	NUREG- 1801 items referencing this item are associated with Mark I steel containments. Perry's design is a BWR Mark III Steel containment, such that the PNPP design does not contain components associated with vent line bellows.
3.5.1-40	Unbraced downcomers, Steel elements: vent header; downcomers	Cracking due to cyclic loading (CLB fatigue analysis does not exist)	Chapter XI.S1, "ASME Section XI, Subsection IWE"	No	NUREG- 1801 items referencing this item are associated with Mark II concrete and steel containments. Perry's design is a BWR Mark III Steel containment, such that the PNPP design does not contain components associated with unbraced downcomers and vent header; downcomers.
3.5.1-41	Steel elements: drywell support skirt, Steel elements (inaccessible areas): support skirt	None	None	NA - No AEM or AMP	NUREG- 1801 items referencing this item are associated with Mark I and II concrete and steel containments. Perry's design is a BWR Mark III Steel containment, such that the PNPP design does not contain components associated with a drywell support skirt.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-42	Groups 1-3, 5, 7-9:Concrete (inaccessible areas): foundation	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Further evaluation is required for plants that are located in moderate to severe weathering conditions (weathering index >100 day-inch/yr) (NUREG-1557)	Yes, for plants located in moderate to severe weathering conditions (See subsection 3.5.2.2.2.1.1)	Consistent with NUREG-1801. The loss of material (spalling, scaling) and cracking due to freeze thaw are not aging effects requiring management for PNPP Groups 1–3, 5, 7–9 structures. The absence of concrete aging effects is confirmed by the ASME Section XI, Subsection IWL and Structures Monitoring programs. For further evaluation, see Section 3.5.2.2.2.1 Item 1.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-43	All Groups except Group 6:Concrete (inaccessible areas): all	Cracking due to expansion from reaction with aggregates	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if concrete is not constructed as stated (See subsection 3.5.2.2.2.1.2)	Cracking due to expansion and reaction with aggregates for Groups 1– 5, 7–9 structures is not expected; however, this potential aging effect is managed, regardless of the mechanism that may cause the aging effect. Structures Monitoring program continues to inspect and monitor concrete structures for cracking due to any mechanism. Accessible concrete is monitored for cracking due to expansion from reaction with aggregates by the Structures Monitoring program that is addressed under Item Number 3.5-54. For further evaluation, see Section 3.5.2.2.2.1 item 2.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-44	All Groups: concrete: all	Cracking and distortion due to increased stress levels from settlement	Chapter XI.S6, "Structures Monitoring" If a de-watering system is relied upon for control of settlement, then the licensee is to ensure proper functioning of the de-watering system through the period of extended operation.	Yes, if a de-watering system is relied upon to control settlement (See subsection 3.5.2.2.2.1.3)	Consistent with NUREG-1801. The Structures Monitoring Program manages the listed aging effect. PNPP has adequate settlement monitoring procedure in place. The program provides for periodic monitoring of settlement or rebound of safety class buildings by determining the elevation of permanent settlement markers. For further evaluation, see Section 3.5.2.2.2.1 Item 3.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-45	Groups 1-3, 5-9: concrete: foundation; subfoundation	Reduction in foundation strength, cracking due to differential settlement,erosion of porous concrete subfoundation	Chapter XI.S6, “Structures Monitoring” If a de-watering system is relied upon for control of settlement, then the licensee is to ensure proper functioning of the de-watering system through the period of extended operation.	Yes, if a de-watering system is relied upon to control settlement (See subsection 3.5.2.2.2.1.3)	Consistent with NUREG-1801. PNPP does not rely on a dewatering system for control of settlement. The Structures Monitoring Program manages the listed aging effect. PNPP has adequate settlement monitoring procedure in place. The results of the monitoring program have demonstrated that cracks and distortion due to increased stress levels from settlement for below grade inaccessible concrete areas of structures for all groups and reduction in foundation strength, and cracking, due to differential settlement and erosion of porous concrete subfoundation in below grade inaccessible concrete areas for Groups 1–3, 5–9 structures is not an aging effect requiring management for PNPP concrete. For further evaluation, see Section 3.5.2.2.2.1 Item 3.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-46	Groups 1-3, 5-9: concrete: foundation; subfoundation	Reduction of foundation strength and cracking due to differential settlement and erosion of porous concrete subfoundation	Chapter XI.S6, "Structures Monitoring" If a de-watering system is relied upon for control of settlement, then the licensee is to ensure proper functioning of the de-watering system through the period of extended operation.	Yes, if a de-watering system is relied upon to control settlement (See subsection 3.5.2.2.2.1.3)	Consistent with NUREG-1801. PNPP does not rely on a dewatering system for control of settlement. The Structures Monitoring program conservatively manages loss of material, which would result in reduction of foundation strength and cracking due to differential settlement from erosion of porous concrete foundation, if it occurs. These aging effects are not expected to occur. The Structures Monitoring program will confirm it is not occurring. See Section 3.5.2.2.2.1 Item 3.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-47	Groups 1-5, 7-9: concrete (inaccessible areas): exterior above- and below-grade; foundation	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if leaching is observed in accessible areas that impact intended function (See subsection 3.5.2.2.2.1.4)	The PNPP below-grade environment is not aggressive. Therefore, increase in porosity and permeability, and loss of strength due to leaching of calcium hydroxide and carbonation of below grade inaccessible concrete areas are not aging effects requiring management for PNPP Groups 1–5 and 7–9 concrete structures. The absence of concrete aging effects is confirmed by the ASME Section XI, Subsection IWL and Structures Monitoring programs. For further evaluation, see Section 3.5.2.2.2.1 Item 4.
3.5.1-48	Groups 1-5: concrete: all	Reduction of strength and modulus due to elevated temperature (>150˚F general; >200˚F local)	A plant-specific aging management program is to be evaluated.	Yes, if temperature limits are exceeded (See subsection 3.5.2.2.2.2)	The reduction of strength and modulus of concrete due to elevated temperatures is not an aging effect requiring management for PNPP. For further evaluation, see Section 3.5.2.2.2.2.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.5.1-49	Groups 6 - concrete (inaccessible areas): exterior above- and below-grade; foundation; interior slab	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Further evaluation is required for plants that are located in moderate to severe weathering conditions (weathering index >100 day-inch/yr) (NUREG-1557)	Yes, for plants located in moderate to severe weathering conditions (See subsection 3.5.2.2.2.3.1)	The below grade inaccessible concrete areas of PNPP Group 6 structures were constructed in a manner that minimizes the potential for any freeze-thaw aging effects. Therefore, loss of material (spalling, scaling) and cracking due to freeze-thaw are not aging effects requiring management for PNPP Groups 6 structures. For further evaluation, see Section 3.5.2.2.2.3 Item 1.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-50	Groups 6: concrete (inaccessible areas): all	Cracking due to expansion from reaction with aggregates	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if concrete is not constructed as stated See subsection 3.5.2.2.2.3.2)	Consistent with NUREG-1801. Cracking due to expansion and reaction with aggregates in below grade inaccessible concrete areas of Group 6 Structures is not expected; however, this potential aging effect is managed regardless of the mechanism that caused the aging effect. Cracking associated with expansion due to reaction with aggregates has not been observed in PNPP Group 6 structures. Nevertheless, the Regulatory Guide (RG) 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants program continues to inspect and monitor Group 6 concrete structures for cracking due to any mechanism. Accessible Group 6 concrete is monitored for cracking due to expansion from reaction with aggregates by the RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants program and is addressed under Item Number 3.5.1-54. For further evaluation, see Section 3.5.2.2.2.3 Item 2.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-51	Groups 6: concrete (inaccessible areas): exterior above- and below-grade; foundation; interior slab	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if leaching is observed in accessible areas that impact intended function (See subsection 3.5.2.2.2.3.3)	Consistent with NUREG-1801. Below-grade exterior reinforced concrete at PNPP is not exposed to an aggressive environment (pH less than 5.5), or to chloride or sulfate solutions beyond defined limits (greater than 500 ppm chloride, or greater than 1500 ppm sulfate). Therefore, increase in porosity and permeability, and loss of strength due to leaching of calcium hydroxide and carbonation in inaccessible areas of concrete elements are not aging effects requiring management for below-grade inaccessible concrete areas of PNPP Group 6 structures. The absence of concrete aging effects is confirmed under the Structures Monitoring program. For further evaluation, see Section 3.5.2.2.2.3 Item 3.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-52	Groups 7, 8 - steel components: tank liner	Cracking due to stress corrosion cracking; Loss of material due to pitting and crevice corrosion	A plant-specific aging management program is to be evaluated.	Yes, plant-specific (See subsection 3.5.2.2.2.4)	Consistent with NUREG-1801. NUREG-1800 Section 3.5.2.2.2.4 applies to stainless steel liners for concrete or steel tanks. At PNPP, no tanks with stainless steel liners are included in the scope of license renewal. Pool and sump liners are normally below the threshold temperature for stress corrosion cracking. Loss of material for sump liners will be managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components program as addressed in item 3.3.1-95. Loss of material for liners in treated water pools are managed by the Water Chemistry program as addressed in items 3.3.1-25 and 3.5.1-78. The One-Time Inspection program will confirm the effectiveness of the Water Chemistry program for pools in containment as addressed in item 3.3.1-25. For further evaluation, see Section 3.5.2.2.2.4.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.5.1-53	Support members; welds; bolted connections; support anchorage to building structure	Cumulative fatigue damage due to fatigue (Only if CLB fatigue analysis exists)	Yes, TLAA	Yes, TLAA (See subsection 3.5.2.2.2.5)	No CLB fatigue analysis exists for component supports members, welds, and support anchorage to building structure. For further evaluation, see Section 3.5.2.2.2.5.
3.5.1-54	All groups except 6: concrete (accessible areas): all	Cracking due to expansion from reaction with aggregates	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. The Structures Monitoring program will manage cracking of concrete in Containment.
3.5.1-55	Building concrete at locations of expansion and grouted anchors; grout pads for support base plates	Reduction in concrete anchor capacity due to local concrete degradation/ service-induced cracking or other concrete aging mechanisms	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. The Structures Monitoring Program manages the listed aging effect.
3.5.1-56	Concrete: exterior above- and below-grade; foundation; interior slab	Loss of material due to abrasion; cavitation	Chapter XI.S7, “Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants” or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. The Regulatory Guide 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants Program manages the listed aging effect.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.5.1-57	Constant and variable load spring hangers; guides; stops	Loss of mechanical function due to corrosion, distortion, dirt, overload, fatigue due to vibratory and cyclic thermal loads	Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Consistent with NUREG-1801. The ASME Section XI, Subsection IWF program will manage aging of ASME Class 1, 2 and 3 supports.
3.5.1-58	Earthen water-control structures: dams; embankments; reservoirs; channels; canals and ponds	Loss of material; loss of form due to erosion, settlement, sedimentation, frost action, waves, currents, surface runoff, seepage	Chapter XI.S7, "Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants" or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. The Regulatory Guide 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants program will manage loss of material and loss of form for steel, galvanized steel, rock, stone and soil materials in intake and discharge structures, swales, streams (major, diversion and remnant minor, berms and culvert) comprising the Water Control Structures. Other aging effects for these component types are addressed in 3.5.1-59, 3.5.1-60 and 3.5.1-61.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-59	Group 6: concrete (accessible areas): all	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S7, "Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants" or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. The Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants program will manage aging of concrete components in water control structures. Loss of bond is inclusive with change in material properties. See also 3.5.1-58 for loss of material in concrete.
3.5.1-60	Group 6: concrete (accessible areas): exterior above- and below-grade; foundation	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Chapter XI.S7, "Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants" or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. The RG 1.127, Inspection of Water-Control Structures associated with Nuclear Power Plants program will be used to manage loss of material (spalling, scaling) and cracking of the concrete due to freeze-thaw (accessible areas).

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-61	Group 6: concrete (accessible areas): exterior above- and below-grade; foundation; interior slab	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Chapter XI.S7, "Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants" or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. The Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants program will manage change in material properties of concrete components exposed to raw water. Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation are inclusive of change in material properties. See also 3.5.1-13, 3.51-24 and 3.5.1-67 that address increase in porosity and permeability and 3.5.1-13 for loss of strength due to leaching of calcium hydroxide and carbonation for the other component types in structures and Bulk Civil Commodities.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-62	Group 6: Wooden Piles; sheeting	Loss of material; change in material properties due to weathering, chemical degradation, and insect infestation repeated wetting and drying, fungal decay	Chapter XI.S7, “Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants” or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	PNPP does not have the listed components associated with water control structures.
3.5.1-63	Groups 1-3, 5, 7-9: concrete (accessible areas): exterior above- and below-grade; foundation	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring Program manages the listed aging effect.
3.5.1-64	Groups 1-3, 5, 7-9: concrete (accessible areas): exterior above- and below-grade; foundation	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Chapter XI.S6, “Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring program will be used to manage loss of material (spalling, scaling) and cracking of the concrete due to freeze-thaw (accessible areas).

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-65	Groups 1-3, 5, 7-9: concrete (inaccessible areas): below-grade exterior; foundation, Groups 1-3, 5, 7-9: concrete (accessible areas): below-grade exterior; foundation, Groups 6: concrete (inaccessible areas): all	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring program will manage aging of concrete exposed to raw water and soil. Loss of bond is inclusive in change of material properties.
3.5.1-66	Groups 1-5, 7, 9: concrete (accessible areas): interior and above-grade exterior	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. The Structures Monitoring program will manage aging of concrete exposed to air - indoor, uncontrolled and air - outdoor. Loss of bond is inclusive in change of material properties.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-67	Groups 1-5, 7, 9: Concrete: interior; above-grade exterior, Groups 1-3, 5, 7-9 - concrete (inaccessible areas): below-grade exterior; foundation, Group 6: concrete (inaccessible areas): all	Increase in porosity and permeability; cracking; loss of material (spalling, scaling) due to aggressive chemical attack	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring program will manage aging of concrete exposed to Air-outdoor, Raw water and Soil. Change in material properties is inclusive of increase in porosity and permeability for these component types. See also 3.5.1-13, 3.5.1-24 and 3.5.1-61 for where increase in porosity and permeability is addressed for the other structures and Bulk Civil Commodities subject to aging management review.
3.5.1-68	High-strength structural bolting	Cracking due to stress corrosion cracking	Chapter XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-1801. The ASME Section XI, Subsection IWF program will manage cracking of high strength structural bolting.
3.5.1-69	High-strength structural bolting	Cracking due to stress corrosion cracking	Chapter XI.S6, "Structures Monitoring“ Note: ASTM A 325, F 1852, and ASTM A 490 bolts used in civil structures have not shown to be prone to SCC. SCC potential need not be evaluated for these bolts.	No	Consistent with NUREG-1801. The Structures Monitoring program will manage cracking of high-strength structural bolting.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-70	Masonry walls: all	Cracking due to restraint shrinkage, creep, and aggressive environment	Chapter XI.S5, "Masonry Walls"	No	Consistent with NUREG-1801. The masonry walls that are within the scope of license renewal at PNPP are limited to isolated non-safety related, non-seismic Category I structures not meeting the criteria of I.E Bulletin 80-11. The Masonry Walls program manages aging of PNPP masonry block walls.
3.5.1-71	Masonry walls: all	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Chapter XI.S5, "Masonry Walls"	No	Consistent with NUREG-1801. The masonry walls that are within the scope of license renewal at PNPP are limited to isolated non-safety related, non-seismic Category I structures not meeting the criteria of I.E Bulletin 80-11. The Masonry Walls program manages aging of PNPP masonry block walls.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-72	Seals; gasket; moisture barriers (caulking, flashing, and other sealants)	Loss of sealing due to deterioration of seals, gaskets, and moisture barriers (caulking, flashing, and other sealants)	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801 with the following clarifications and a different program for some components. The Structures Monitoring program will manage aging of elastomer seals and barriers subject to aging management in the containment structure and bulk civil commodities exposed to air - indoor, uncontrolled, air - outdoor and treated water. Aging effects for elastomer seals susceptible to change in material properties and cracking are aligned with the aging effect loss of sealing. Fire Protection program will monitor the loss of sealing when acting as a fire barrier. Other elastomer seals and gaskets and fire penetration seals exposed to air are addressed under items 3.3.1-57 and 3.5.1-33.
3.5.1-73 (LR-ISG-2013-01)	Service Level I coatings	Loss of coating integrity due to blistering, cracking, flaking, peeling, delamination, rusting, or physical damage	Chapter XI.S8, "Protective Coating Monitoring and Maintenance"	No	Consistent with NUREG-1801. The Protective Coating Monitoring and Maintenance Program manage the listed aging effect.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-74	Sliding support bearings; sliding support surfaces	Loss of mechanical function due to corrosion, distortion, dirt, debris, overload, wear	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. The Structures Monitoring program will be used to manage loss of mechanical distortion, dirt, debris, function of lubrite sliding support surfaces overload, wear exposed to air-indoor uncontrolled in Structures and Component Supports.
3.5.1-75	Sliding surfaces	Loss of mechanical function due to corrosion, distortion, dirt, debris, overload, wear	Chapter XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-1801. The ASME Section XI, Subsection IWF program will be used to manage loss of distortion, dirt, debris, mechanical function of lubrite sliding surfaces exposed to air-indoor uncontrolled in Structures and Component Supports.
3.5.1-76	Sliding surfaces: radial beam seats in BWR drywell	Loss of mechanical function due to corrosion, distortion, dirt, overload, wear	Chapter XI.S6, “Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring program will manage loss of mechanical function of sliding surfaces.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-77	Steel components: all structural steel	Loss of material due to corrosion	Chapter XI.S6, "Structures Monitoring" If protective coatings are relied upon to manage the effects of aging, the structures monitoring program is to include provisions to address protective coating monitoring and maintenance.	No	Consistent with NUREG-1801. The Structures Monitoring program will manage loss of material for for structural steel components exposed to Air-indoor, uncontrolled and Air-outdoor. Protective coatings are not relied upon to manage the effects of aging. Long term scaffolds are aligned to this item. Lifting lugs aging mechanism is aligned with this item. Also see Item 3.5.1-92.
3.5.1-78	Steel components: fuel pool liner	Cracking due to stress corrosion cracking; Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Monitoring of the spent fuel pool water level in accordance with technical specifications and leakage from the leak chase channels.	No, unless leakages have been detected through the SFP liner that cannot be accounted for from the leak chase channels	Consistent with NUREG-1801 for management of loss of material of the liner with some clarifications and program exceptions. The Water Chemistry program will manage loss of material for stainless steel fuel pool liner components. Spent fuel pool level is monitored in accordance with the Operational Requirements Manual. Leak chase channels are monitored periodically. For component types where leakage would not be relevant for detection of loss of material or cracking, the One-Time Inspection program will confirm the effectiveness of the Water Chemistry program. Loss of

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
					material of stainless steel anchor bolts and embedments will be managed by the Structures Monitoring program. Cracking is not an aging effect for stainless steel exposed to treated water in the spent fuel pool, because normal temperature of the water is below the threshold for cracking of stainless steel (140F). See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.5.1-79	Steel components: piles	Loss of material due to corrosion	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801 with the following clarifications. PNPP does not have the steel piles. Structures Monitoring program will manage loss of material in steel component types exposed to raw water in Bulk Civil Commodities, Water Control Structures, and Turbine Buildings and Associated Structures, Process Facilities, and Yard Structures.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-80	Structural bolting	Loss of material due to general, pitting and crevice corrosion	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring program will manage loss of material for structural bolting. High strength steel is aligned with steel for loss of material. For high strength steel structural bolting exposed to Air-indoor subject to loss of material and within the scope of ASME Section XI, Subsection IWF, See Items 3.5.1-81. For other Anchor and Structural bolting in Air-outdoor subject to loss of material see Item 3.5.1-82.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-81	Structural bolting	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Consistent with NUREG-1801. The ASME Section XI, Subsection IWF program will manage loss of material for steel and high strength steel ASME Class 1, 2, 3 and MC Supports bolting exposed to Air-indoor, uncontrolled associated with ASME supports. High strength steel is aligned with steel for loss of material. For high strength steel structural bolting exposed to Air-indoor and Air-outdoor subject to loss of material and not within the scope of ASME Section XI, Subsection IWF, See Items 3.5.1-80 and 3.5.1-82. For steel ASME Class 1, 2, 3 and MC Supports bolting exposed to Air-outdoor see Item 3.5.1-86.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-82	Structural bolting	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring program will manage loss of material for structural bolting. High strength steel is aligned with steel for loss of material. For high strength steel structural bolting exposed to Air-indoor subject to loss of material and within the scope of ASME Section XI, Subsection IWF, See Items 3.5.1-81. For other Anchor and Structural bolting in Air-indoor, uncontrolled subject to loss of material see Item 3.5.1-80.
3.5.1-83	Structural bolting	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S7, "Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants" or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. In addition to managing structural bolting for water control structures, the Regulatory Guide 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants program will manage aging of structural steel in water control structures.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-84	Structural bolting	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Consistent with NUREG-1801 with some program exceptions and with a different program credited. The Structures Monitoring and Water Chemistry programs will manage loss of material of the submerged drywell head and associated bolting. The bolting and head are removed during each refueling outage. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.5.1-85	Structural bolting	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," for BWR water, and Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Consistent with NUREG-1 801 with some program exceptions. The ASME Section XI, Subsection IWF, and Water Chemistry programs will be used to manage loss of material of the stainless steel bolting and supports for ASME Class 2 and 3 piping and components exposed to the treated water environment. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-86	Structural bolting	Loss of material due to pitting and crevice corrosion	Chapter XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-1801. The ASME Section XI, Subsection IWF program will manage loss of material of structural bolting exposed to Air-outdoor associated with ASME supports. For structural bolting within the scope of ASME Section XI, Subsection IWF also see Item 3.5.1-81.
3.5.1-87	Structural bolting	Loss of preload due to self-loosening	Chapter XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with NUREG-1801. The ASME Section XI, Subsection IWF program will manage loss of preload of structural bolting associated with ASME supports.
3.5.1-88	Structural bolting	Loss of preload due to self-loosening	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. The Structures Monitoring program will manage loss of preload for structural bolting.
3.5.1-89	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to boric acid corrosion	Chapter XI.M10, “Boric Acid Corrosion”	No	N/A - PWR Only

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-90	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M2, "Water Chemistry," for BWR water, and Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Consistent with NUREG-1801 with some program exceptions. Loss of material for stainless steel support members in treated water will be managed by the Water Chemistry and ASME Section XI, Subsection IWF programs. See Appendix B Section B.2.44 for Water Chemistry program exceptions to NUREG-1801.
3.5.1-91	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to general and pitting corrosion	Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Consistent with NUREG-1801. The Inservice Inspection-IWF Program manage the listed aging effect.
3.5.1-92	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to general and pitting corrosion	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring program will manage Loss of material of steel supports and anchorages and other steel commodities exposed to Air-indoor, uncontrolled and Air-outdoor. Also see Item 3.5.1-77.
3.5.1-93	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to pitting and crevice corrosion	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Fire Protection program will manage loss of material for structural aluminum, stainless steel and galvanized steel components.

Table 3.5.1 Summary of Aging Management Evaluations for Containments, Structures and Component Supports					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.5.1-94	Vibration isolation elements	Reduction or loss of isolation function due to radiation hardening, temperature, humidity, sustained vibratory loading	Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	PNPP does not have any vibration isolation elements. If any installed in future, Structures Monitoring Program will be used to manage the listed aging effects.
3.5.1-95	Aluminum, galvanized steel and stainless steel Support members; welds; bolted connections; support anchorage to building structure exposed to Air – indoor, uncontrolled	None	None	NA - No AEM or AMP	Consistent with NUREG-1801.
